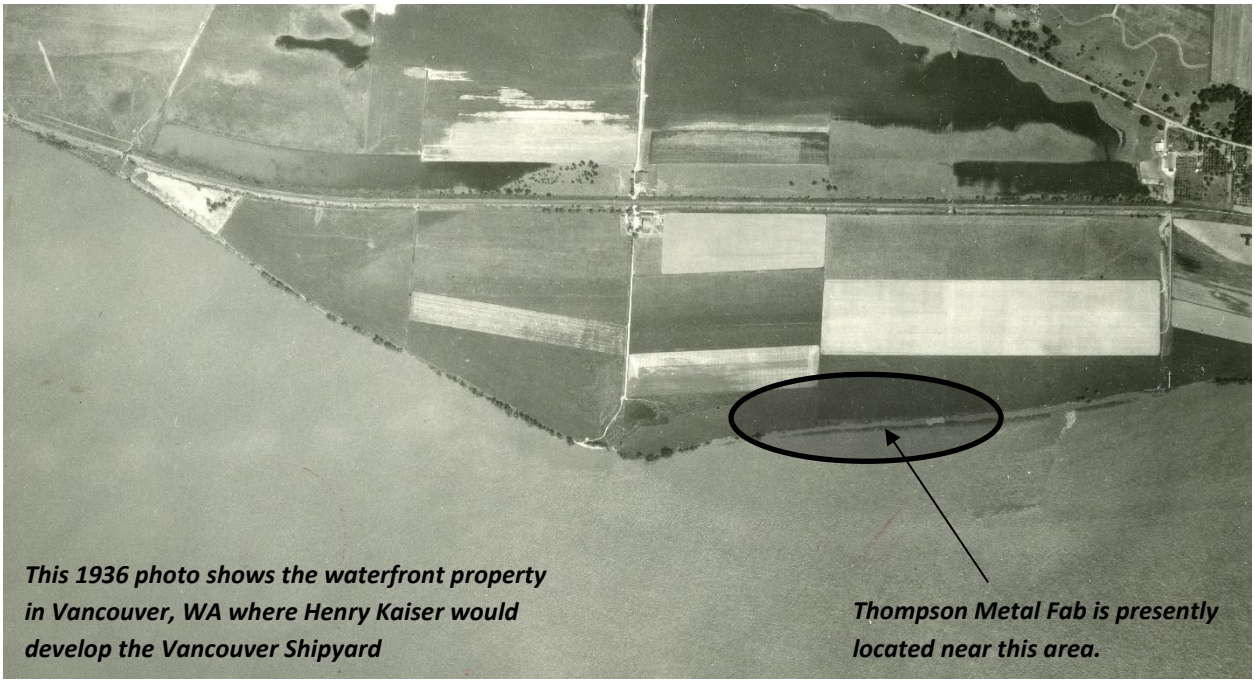
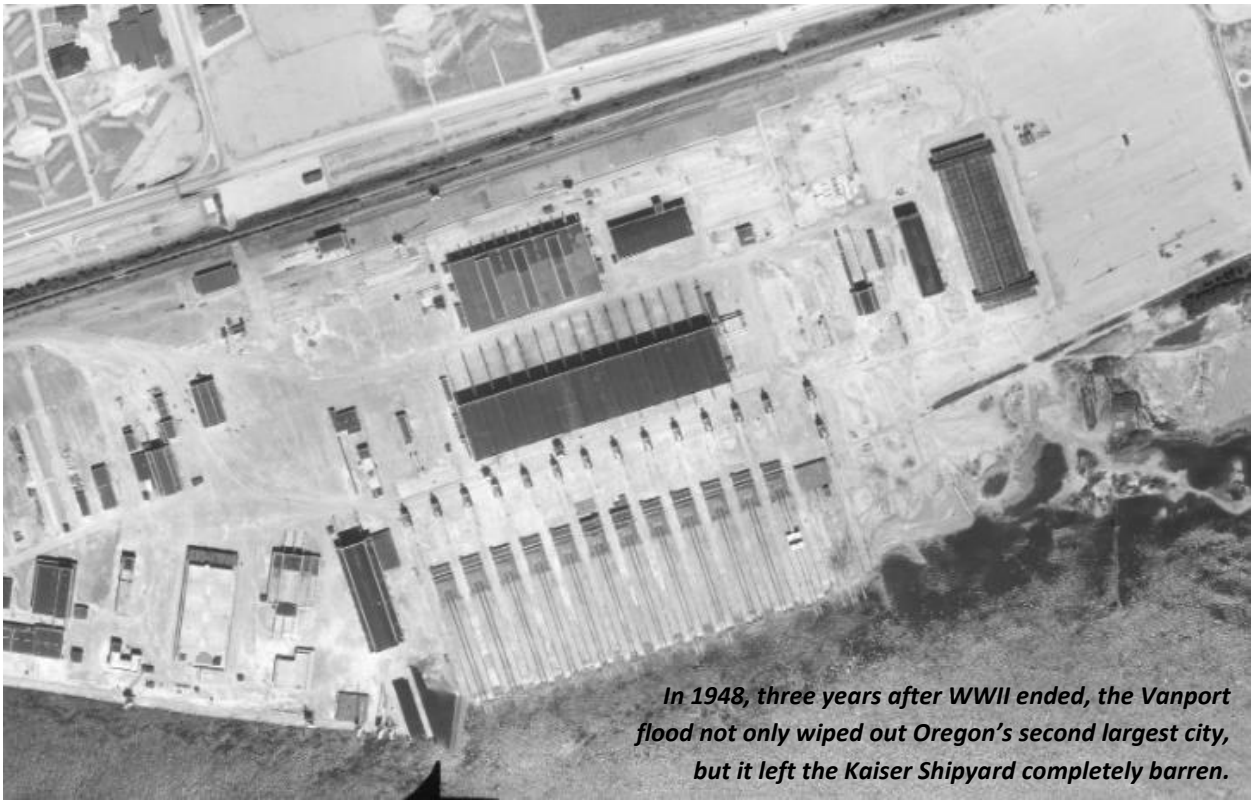
Bridge to be opened at Captain's discretion for loads under 72' high.



This 1936 photo shows the waterfront property in Vancouver, WA where Henry Kaiser would develop the Vancouver Shipyard

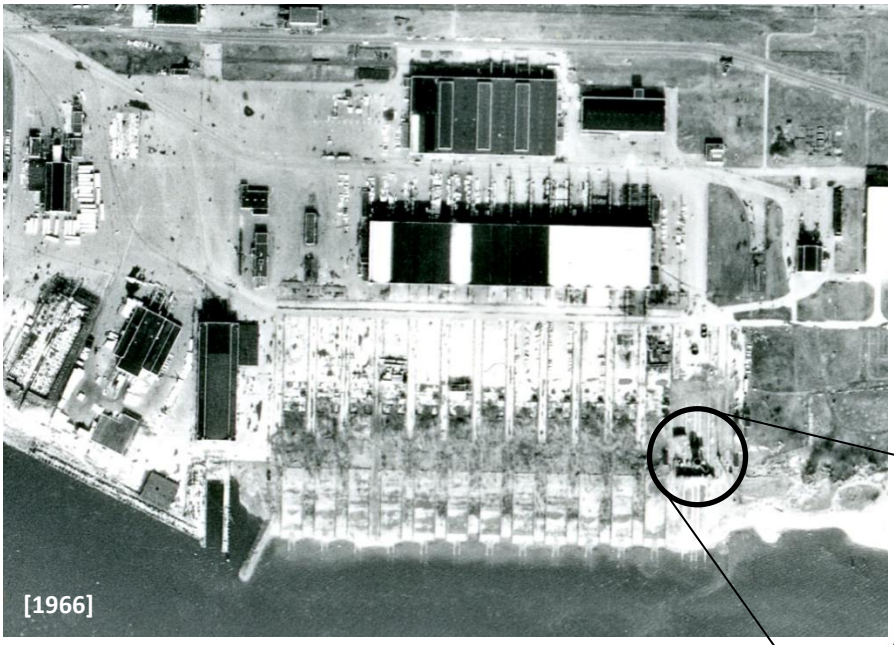
Thompson Metal Fab is presently located near this area.

In just a few years nearly 200-acres was redeveloped, providing Vancouver a major industrial waterfront facility. An active Kaiser Shipyard is shown here in 1943



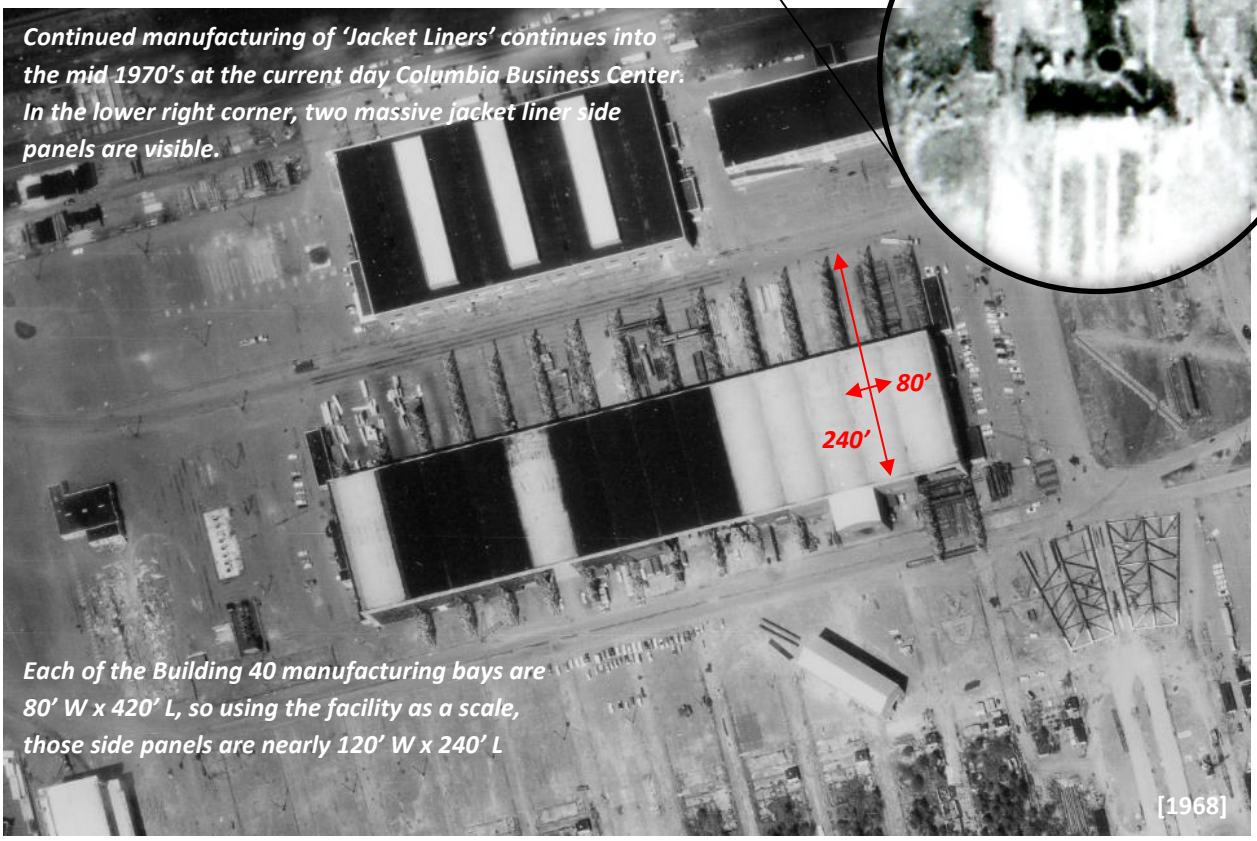
In 1948, three years after WWII ended, the Vanport flood not only wiped out Oregon's second largest city, but it left the Kaiser Shipyard completely barren.

By 1956, the facilities at the current Columbia Business Center are in full operation once more, leveraging the capacity to support the industrial needs of the time.



[1966]

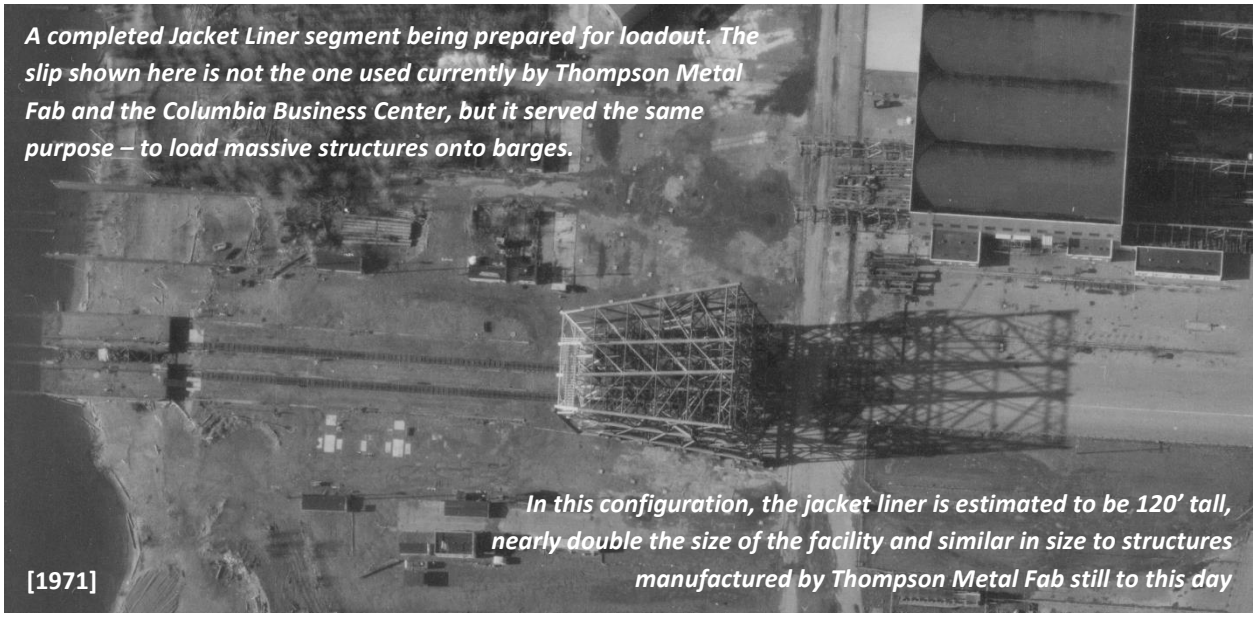
The development of offshore oil in California required the fabrication of massive infrastructure. Typically, offshore oil fabrication is done in the Gulf states, but with major oil production now on the West Coast those Gulf state areas could not lend support and a West Coast facility was required.



Continued manufacturing of 'Jacket Liners' continues into the mid 1970's at the current day Columbia Business Center. In the lower right corner, two massive jacket liner side panels are visible.

Each of the Building 40 manufacturing bays are 80' W x 420' L, so using the facility as a scale, those side panels are nearly 120' W x 240' L

[1968]



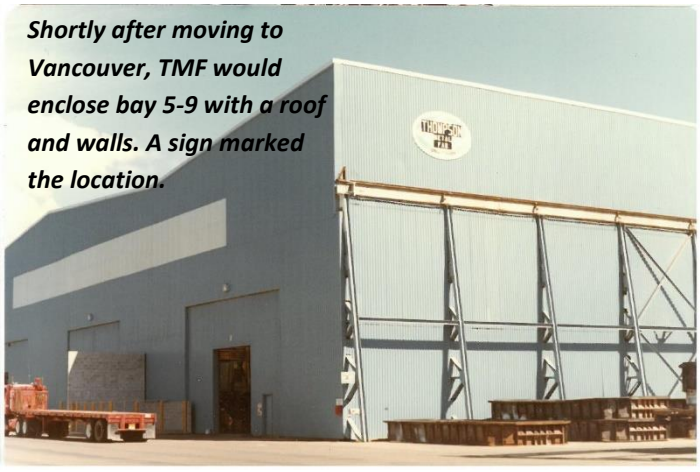
A completed Jacket Liner segment being prepared for loadout. The slip shown here is not the one used currently by Thompson Metal Fab and the Columbia Business Center, but it served the same purpose – to load massive structures onto barges.

In this configuration, the jacket liner is estimated to be 120' tall, nearly double the size of the facility and similar in size to structures manufactured by Thompson Metal Fab still to this day

[1971]

Roofing being extended to Building 40, Bay 10-12 (current Thompson Metal Fab).

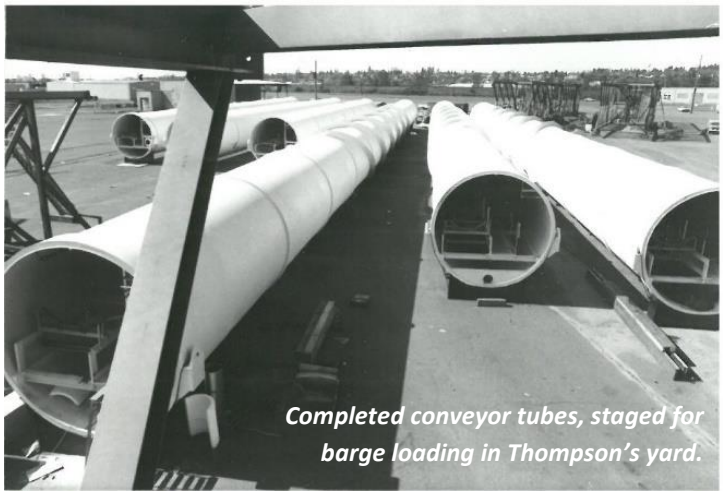
TMF Project Managers, early 1970's



Shortly after moving to Vancouver, TMF would enclose bay 5-9 with a roof and walls. A sign marked the location.

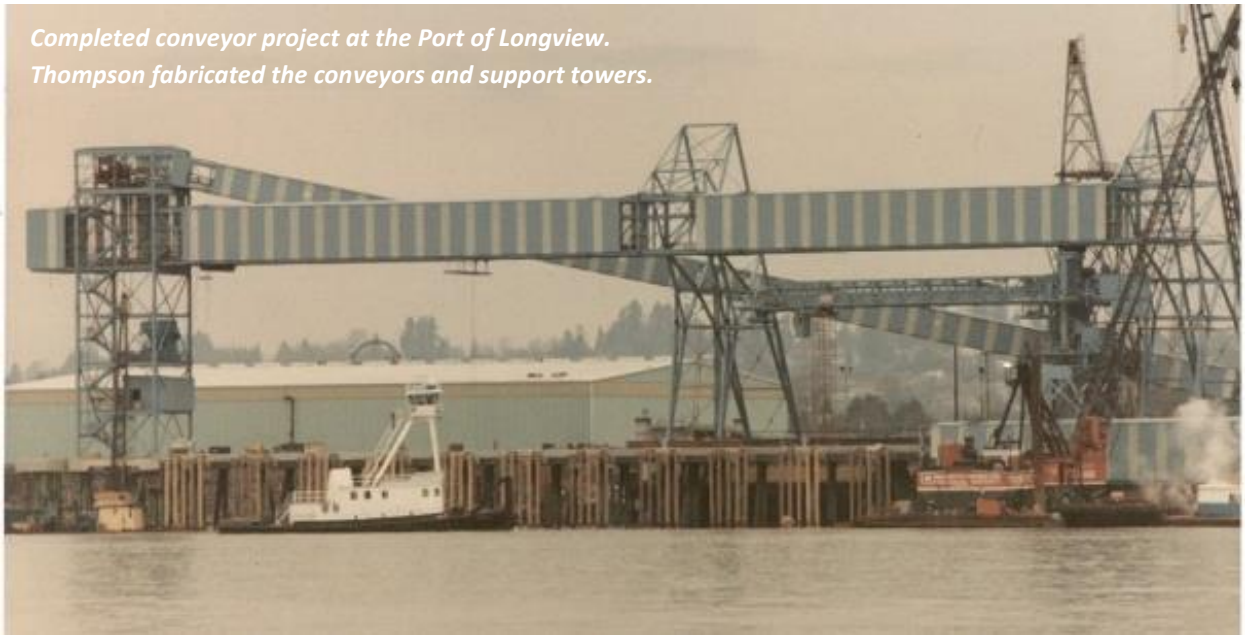
At 300' long, this conveyor nearly takes up the entire length of a bay at TMF

A barge is being loaded with conveyors for delivery to Bay Area, CA

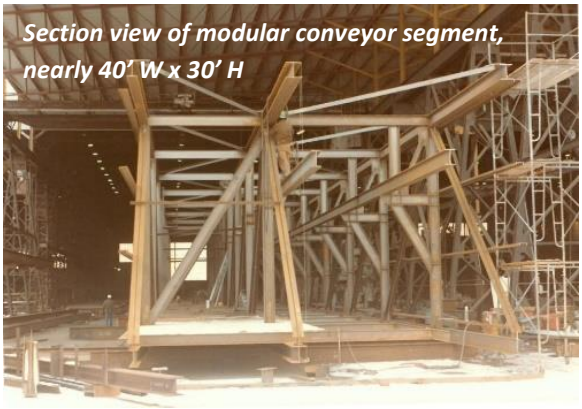


Completed conveyor tubes, staged for barge loading in Thompson's yard.

Conveyor systems and support towers were a major part of Thompson's first few decades at the Columbia Business Center. TMF's barge slip allowed for massive, modular deliveries to Ports, pulp & paper factories, and other industrial areas.



Completed conveyor project at the Port of Longview. Thompson fabricated the conveyors and support towers.



Section view of modular conveyor segment, nearly 40' W x 30' H

Conveyor being loaded on barge at Thompson Metal Fab.

There are numerous Ports on the Columbia River with large, developed properties and robust industrial activity. These Ports are critical to our region and are the hub for most incoming goods.

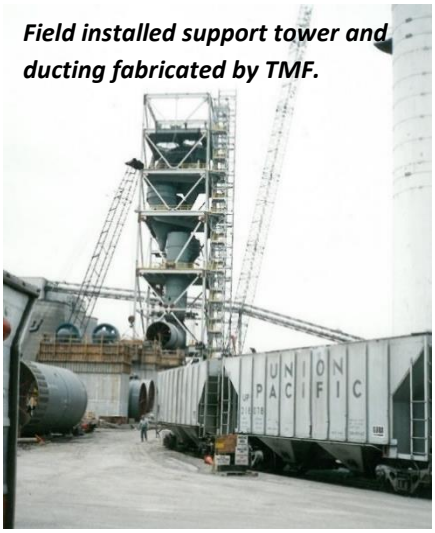
Conveyor systems are often used at Ports to quickly handle and transfer bulk materials. Thompson Metal Fab manufactured and delivered the massive conveyor system and support towers shown here and delivered to the Port of Longview.

Modular structures were loaded on a barge and erected in the field. Delivering modular units allows for quicker assembly in the field and easier integration of all mechanical components.

Conveyors come in many shapes and sizes, depending on the intended use. Shipping the structures pre-assembled saves on time and money in the long-run and is a value-add for Owners and other stakeholders. Shown here are additional examples of projects that were manufactured by Thompson and delivered all over the West Coast, from Toledo, OR to Sacramento, CA.

Heavy ducting for baghouses requires a facility like Thompson's. They can accommodate the size of the infrastructure in their shop and ship over the water by barge. The large duct section shown here is nearly 30' high and over 100' long.

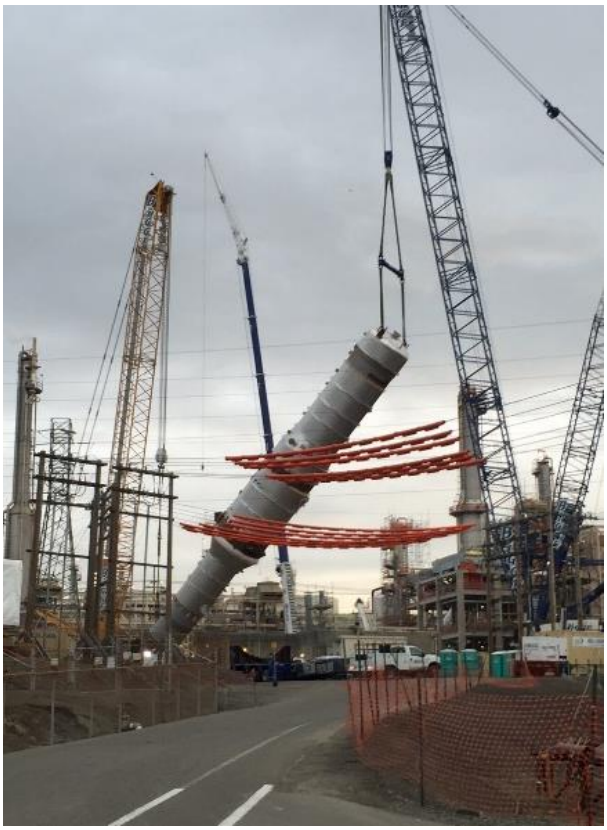
Structural tower inside Thompson's shop being outfitted with piping and ducting systems. This tower is well over 30' high.



Field installed support tower and ducting fabricated by TMF.

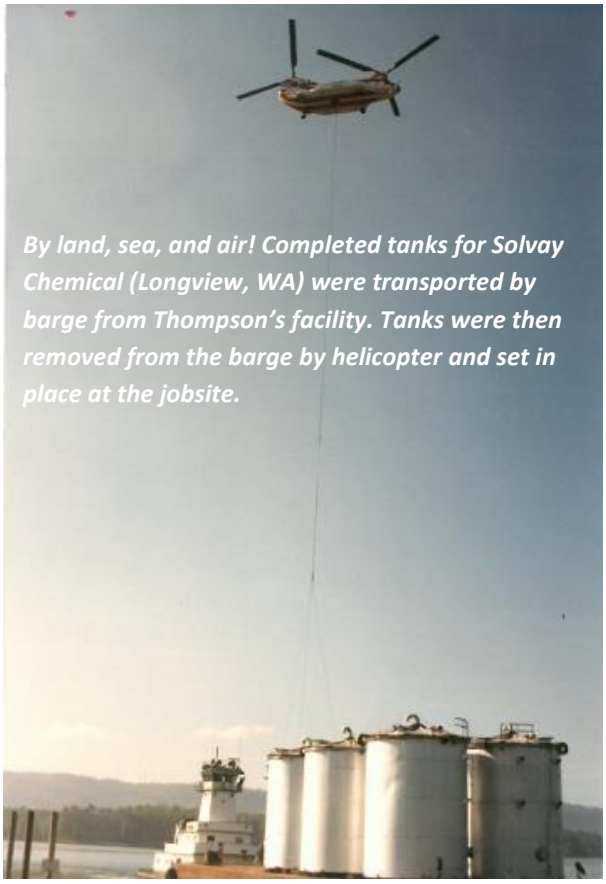
Baghouse components being loaded on a barge from Thompson Metal Fab's facility

Nearly touching the rafters, this giant structural building will soon be outfitted with mechanical items prior to load out on the barge. The size of Thompson's facility provides value to project owners who seek out modular, turn-key solutions for their infrastructure needs.



Refineries on the West Coast are typically located on coastal properties or are otherwise accessible by deep water ports. In addition to capacity expansion and improvements, these facilities have processing vessels and other equipment that wear out over time and need to be replaced.

Shown here at the Phillips 66 facility in Rodeo, CA, Thompson Metal Fab fabricated a "prefractioner" tower which was 17' diameter x 126' L. Too large and heavy to ship over the road, this vessel was delivered by barge and direct to the jobsite.

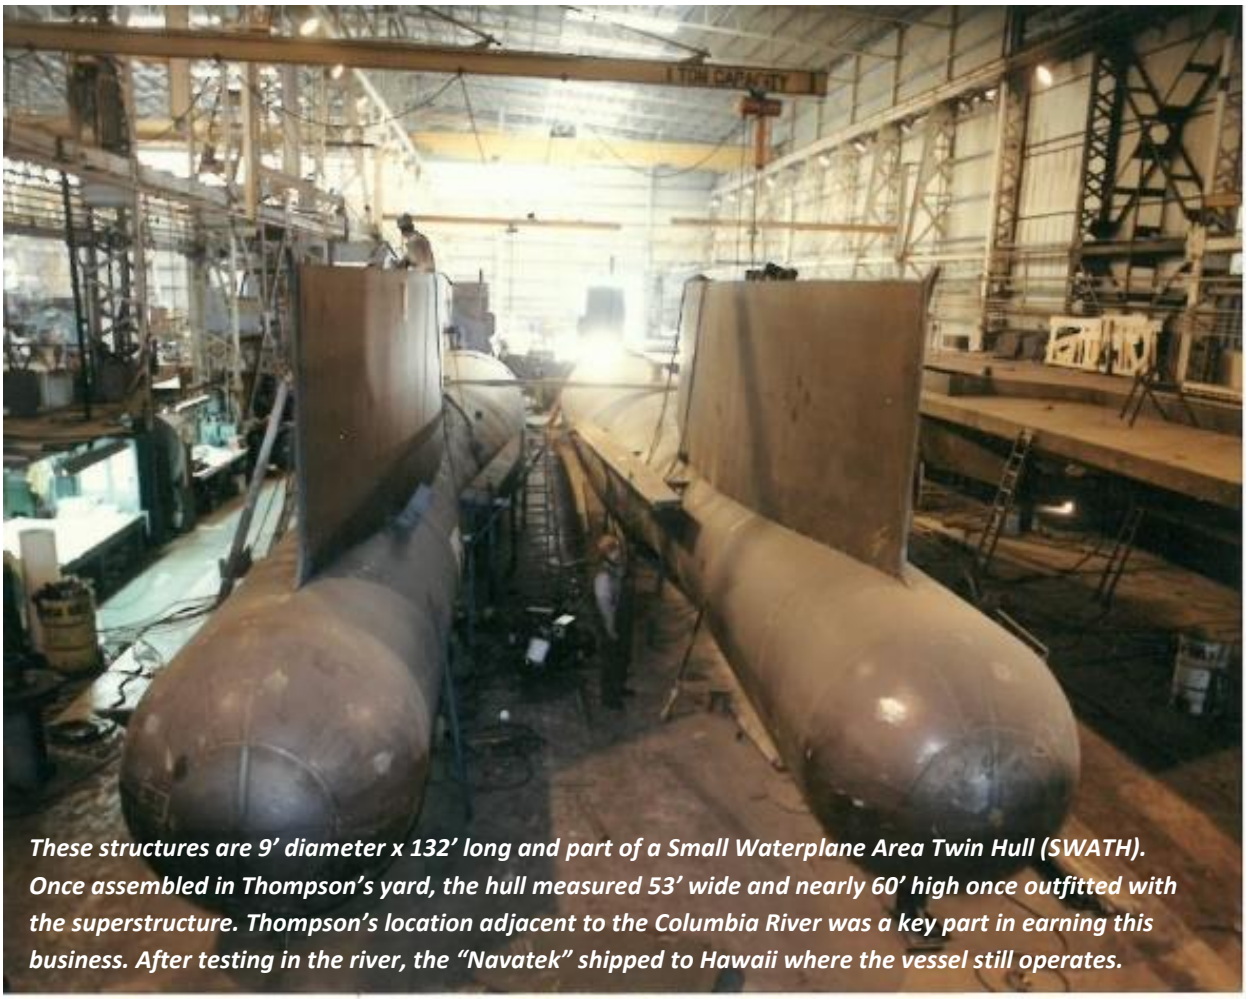


By land, sea, and air! Completed tanks for Solvay Chemical (Longview, WA) were transported by barge from Thompson's facility. Tanks were then removed from the barge by helicopter and set in place at the jobsite.

Process vessels and skids are being loaded on a barge from Thompson Metal Fab's facility. This load will be delivered to Alaska and used on the North Slope. These units are well over 20' and 40' long.

Large tanks for Amalgamated Sugar in Portland, OR. The tanks are used as part of their manufacturing process. Due to the size of the tanks, they were shipped by barge and then transloaded to a truck for final delivery.

Trunnions for the Interstate Bridge shown above in Thompson's shop. Their proximity to the bridge made TMF an ideal location when repairs were needed. Shown below are two Seattle area bridge projects that were completed at the Columbia Business Center, painted by TMF, and delivered to the jobsite by barge.



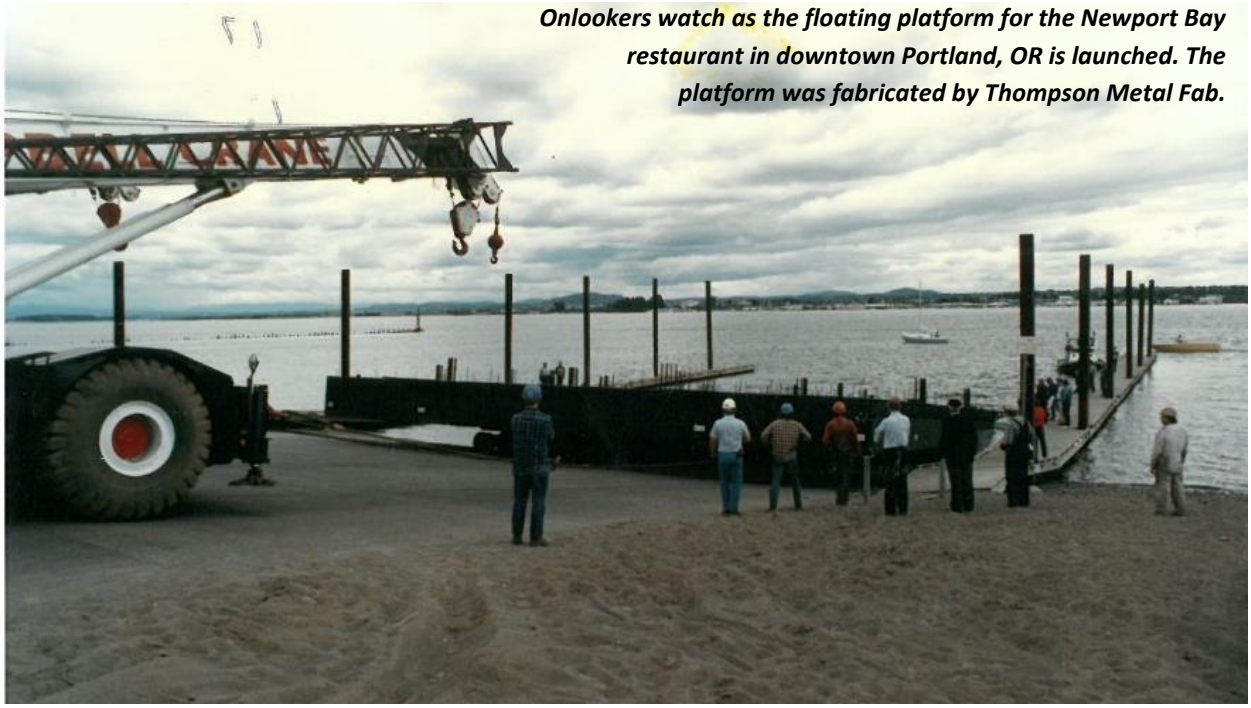
These structures are 9’ diameter x 132’ long and part of a Small Waterplane Area Twin Hull (SWATH). Once assembled in Thompson’s yard, the hull measured 53’ wide and nearly 60’ high once outfitted with the superstructure. Thompson’s location adjacent to the Columbia River was a key part in earning this business. After testing in the river, the “Navatek” shipped to Hawaii where the vessel still operates.

Barge load approaching the Interstate Bridge after leaving Thompson Metal Fab. TMF's massive facility is seen in the background.

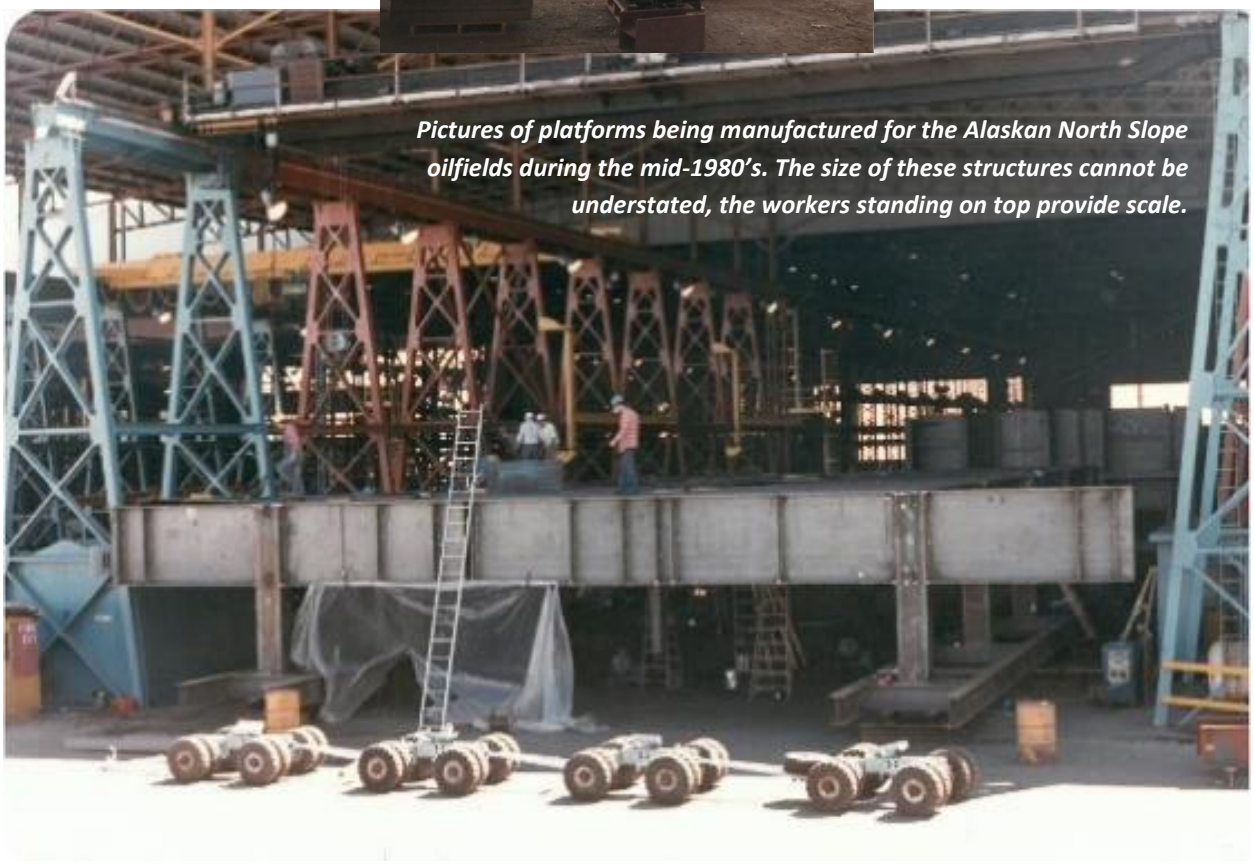
Shown above and below is a modular segment of the Power Barge fabricated by TMF. Segments were pre-fabricated in the shop before being assembled in Thompson's yard. The final assembly was 105' W x 30' H x 284' L

At left, large platform is being flipped inside Thompson Metal Fab's shop.

Thompson Metal Fab has a legacy of fabricating unique, complex, and often massive structures which require delivery by water.



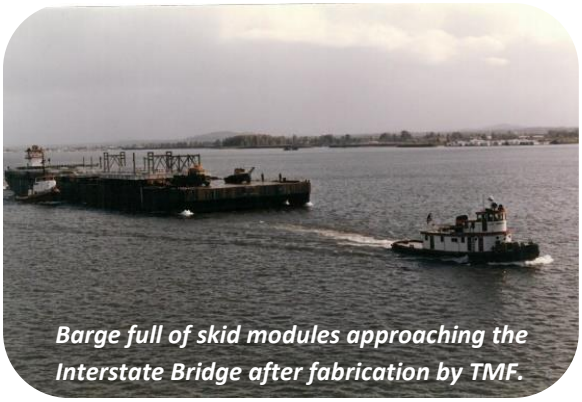
Onlookers watch as the floating platform for the Newport Bay restaurant in downtown Portland, OR is launched. The platform was fabricated by Thompson Metal Fab.



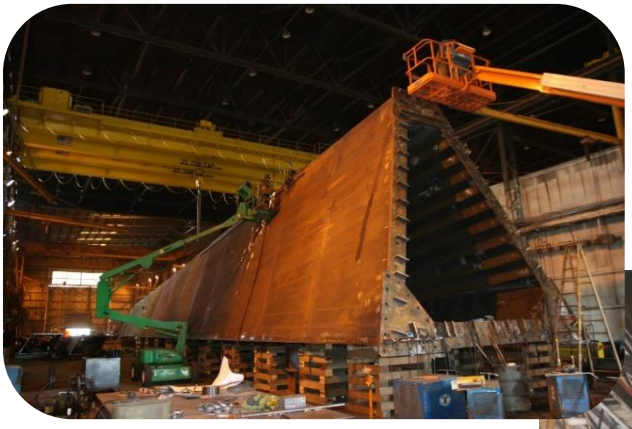
Pictures of platforms being manufactured for the Alaskan North Slope oilfields during the mid-1980's. The size of these structures cannot be understated, the workers standing on top provide scale.

Shown below, load out of the cradle base that would carry PGE's Trojan nuclear reactor. TMF fabricated the base and the shielding enclosures.

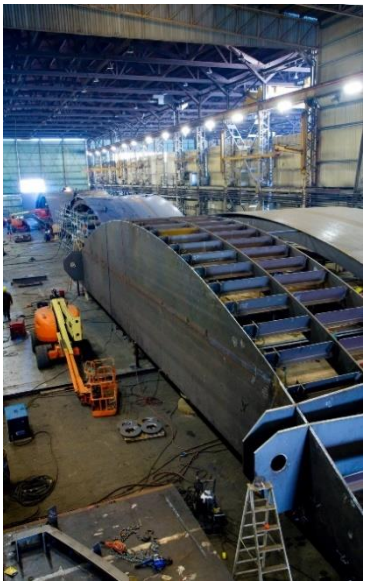
Support towers nearing the Interstate Bridge. This load is headed for the Port of Sacramento upon completion at Thompson Metal Fab



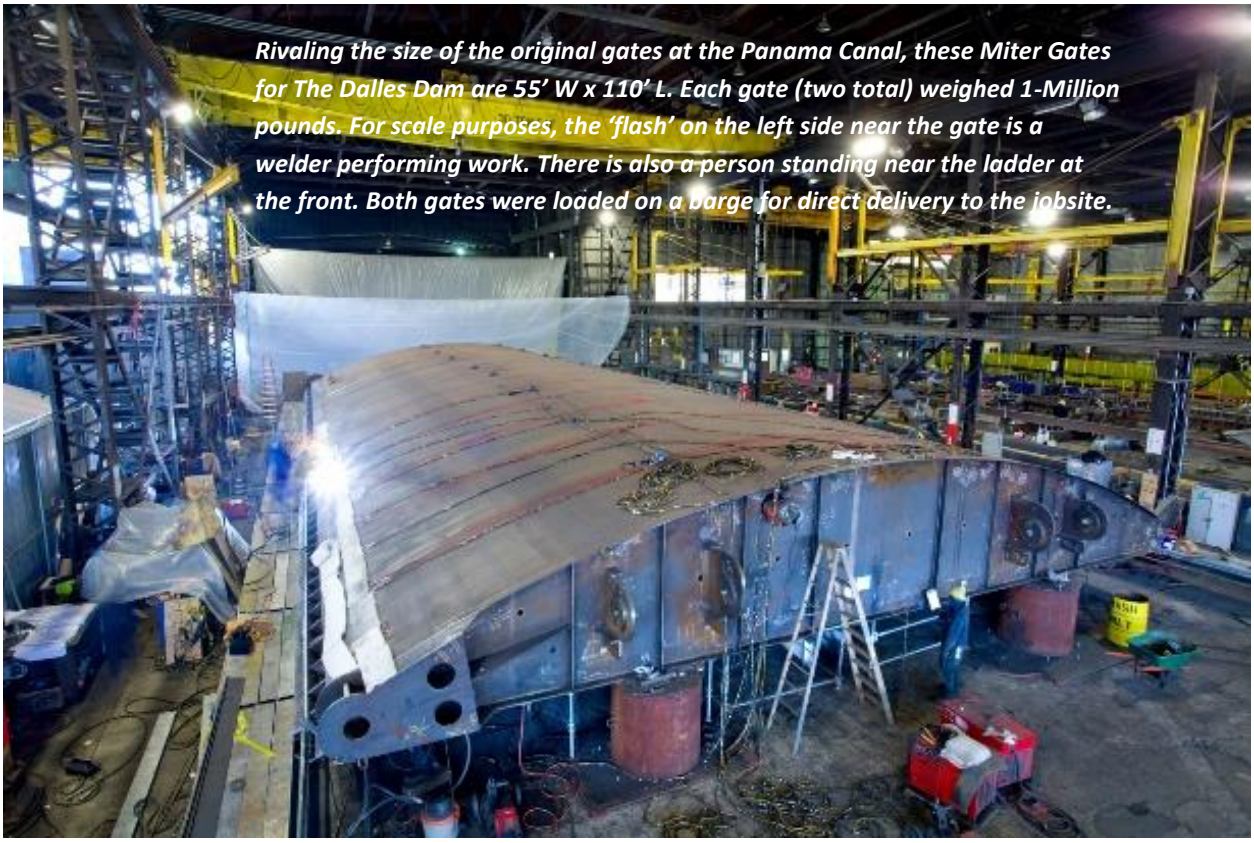
Barge full of skid modules approaching the Interstate Bridge after fabrication by TMF.



The lower segment of the iconic Portland Aerial Tram's tower is shown inside Thompson Metal Fab's shop. Including the bunking underneath, the tower is nearly 40' high and 30' wide. The completed tower can be seen at OHSU, spanning over I-405.



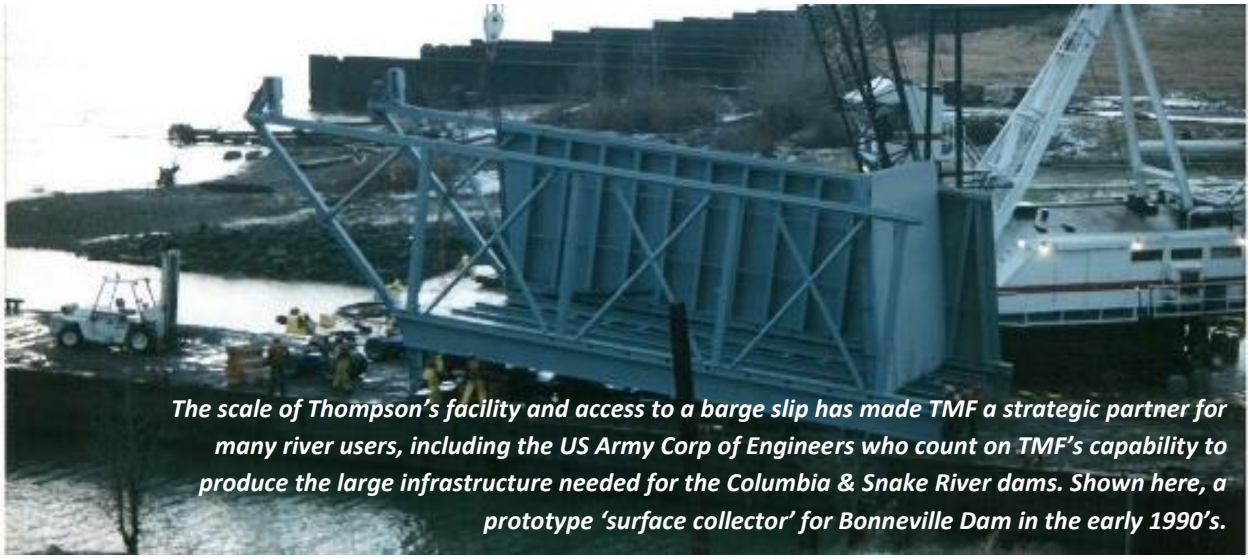
Fabrication of the Lower Monumental Dam Lift Gate is shown at left inside Thompson's shop. Due to its size (nearly 1.5-Million pounds) the gate was fabricated in three segments, loaded on a barge, and finished in the field by the General Contractor. The picture here shows the three segments be aligned for fit verification at TMF's yard. Final dimensions are 88' W x 84' H



Rivaling the size of the original gates at the Panama Canal, these Miter Gates for The Dalles Dam are 55' W x 110' L. Each gate (two total) weighed 1-Million pounds. For scale purposes, the 'flash' on the left side near the gate is a welder performing work. There is also a person standing near the ladder at the front. Both gates were loaded on a barge for direct delivery to the jobsite.

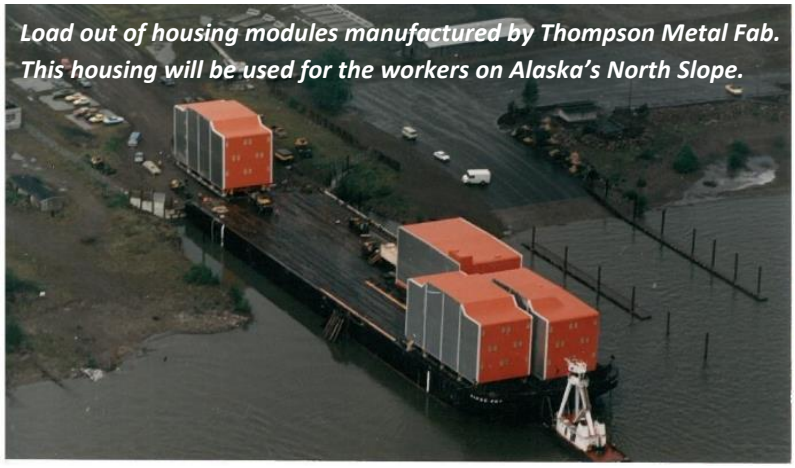
Many of the structures fabricated by TMF require the use of specialty moving systems for handling around the shop and for loading barges. Shown here, an SPMT (Self Propelled Modular Transporter) is used to move one of the Ward Cove Rection Dolphins from TMF's Bay 8 and out to the barge slip for loading. Each reaction dolphin is 30' x 30' x 12' H

Barge load out for the Ward Cove Ferry Terminal Expansion project. All structures were fabricated at the Columbia Business Center, including the Transfer Span and Reaction Dolphins which were completed by Thompson. The Transfer Span, shown near the back of the barge is 14' H x 140' L. These structures were delivered direct to the jobsite in Ketchikan, AK.



The scale of Thompson's facility and access to a barge slip has made TMF a strategic partner for many river users, including the US Army Corp of Engineers who count on TMF's capability to produce the large infrastructure needed for the Columbia & Snake River dams. Shown here, a prototype 'surface collector' for Bonneville Dam in the early 1990's.

Shown above and below are multiple barge loadings for a massive project at Lower Granite Dam in the mid-1990's. All structures were fabricated by Thompson Metal Fab and loaded out at the Columbia Business Center.



Load out of housing modules manufactured by Thompson Metal Fab. This housing will be used for the workers on Alaska's North Slope.

Enclosed modules to be used for a drilling rig, shown inside TMF's shop

Modular fabrication has long been a part of Thompson's history and success. The size of their facility at the Columbia Business Center allows TMF to offer large, turn-key, fully-operational modular systems which get used for housing, data centers, oil production/drilling, crude oil processing, technology, electrification, water treatment, chemical processing, fuel storage, pipe handling, and conveyor systems – among other uses. Remote jobsite locations and size of many of these structure require use of the barge slip, adjacent to Thompson's facility.

Example of processing modules being manufactured inside Thompson Metal Fab

Walls, roof, and equipment being installed on 44' x 97' skid shown below

Thompson's extensive experience with turn-key modular systems made it a valuable partner as a new market emerged for these products. Increase demand for technology pushed groups, like Intel, to expand their facilities. 'Cloud based' data storage requires facilities on the ground that can house servers. Increased online shopping (i.e. Amazon) requires warehouses and data centers. As the world becomes dependent on technology the demand for these custom, modular buildings has significantly increased.

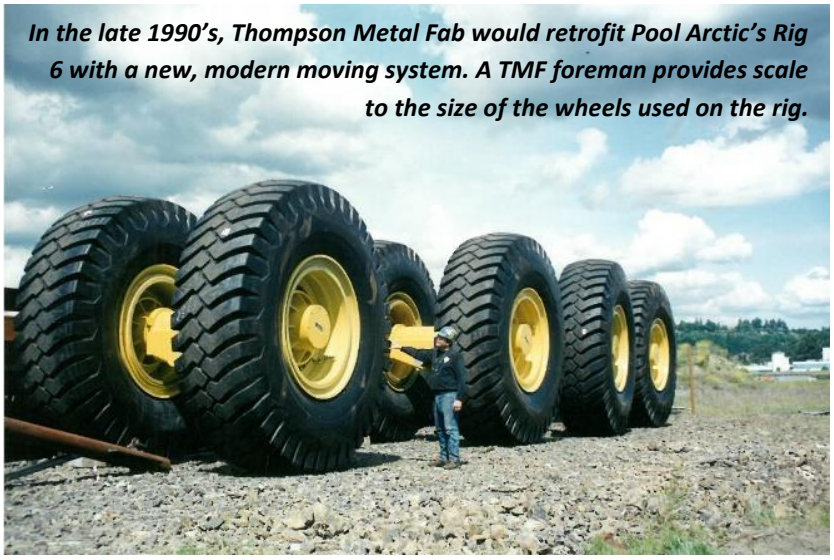
Shown below in late 2019, this skid represents the largest non-oil related module manufactured by TMF. At 44' W x 97' L, this module is too large to ship over the road, and too big to be handled in the field.

To accommodate field conditions, a shipping 'split' was engineered in the middle of the floor (shown) and in the roof trusses. The 44-ft mega module would ship via barge, and completely outfitted in two segments.

Two 44' x 97' modules were manufactured by TMF, each with a shipping split described above. Shown in the middle of this picture are two of the four total segments prior to barge loading.

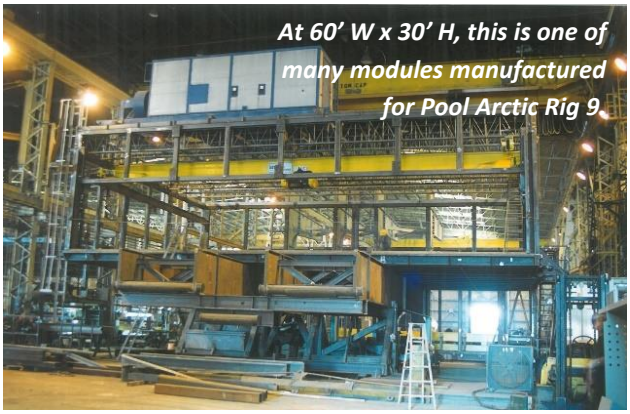
Also shown is the BNSF Wind River Bridge. This was manufactured at the Columbia Business Center and would ship via barge completely assembled and installed in one-piece.

Pool Arctic Rig 3 Retrofit, performed by TMF



In the late 1990's, Thompson Metal Fab would retrofit Pool Arctic's Rig 6 with a new, modern moving system. A TMF foreman provides scale to the size of the wheels used on the rig.

Manufacturing Pool Arctic's Rig 9 inside TMF.

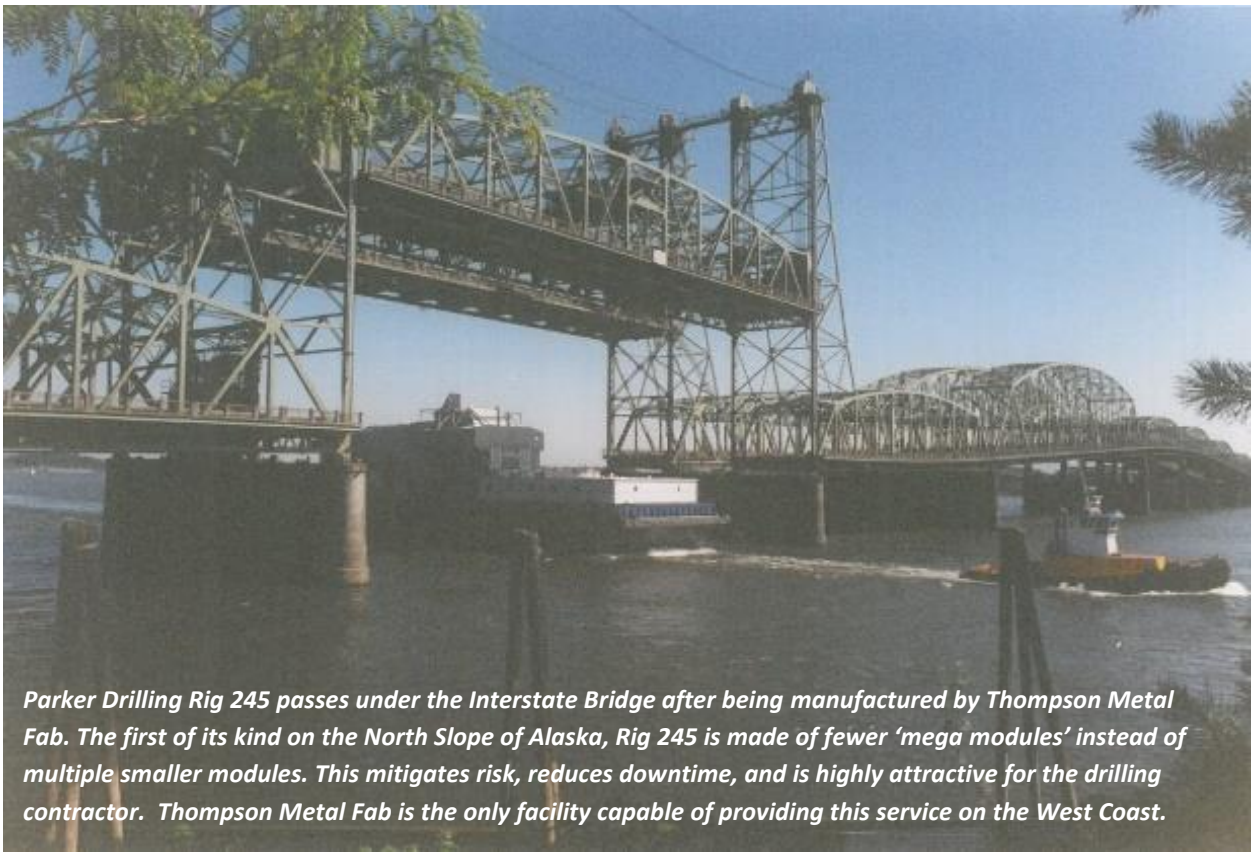


At 60' W x 30' H, this is one of many modules manufactured for Pool Arctic Rig 9.

Following some of its recent predecessors (i.e. Rig 245), Rig 9 would use the 'mega module' concept to reduce downtime on the North Slope

Over the last 30-years, 15 rig projects have been awarded to Thompson Metal Fab. Nearly 1/3rd of the rigs in Alaska have some connection to TMF.

Shown at right, Nordic-Calista's Rig 3 being 'rigged up' in Thompson's yard in 1997. This workover rig is used to restore production on exiting wells.



Parker Drilling Rig 245 passes under the Interstate Bridge after being manufactured by Thompson Metal Fab. The first of its kind on the North Slope of Alaska, Rig 245 is made of fewer 'mega modules' instead of multiple smaller modules. This mitigates risk, reduces downtime, and is highly attractive for the drilling contractor. Thompson Metal Fab is the only facility capable of providing this service on the West Coast.

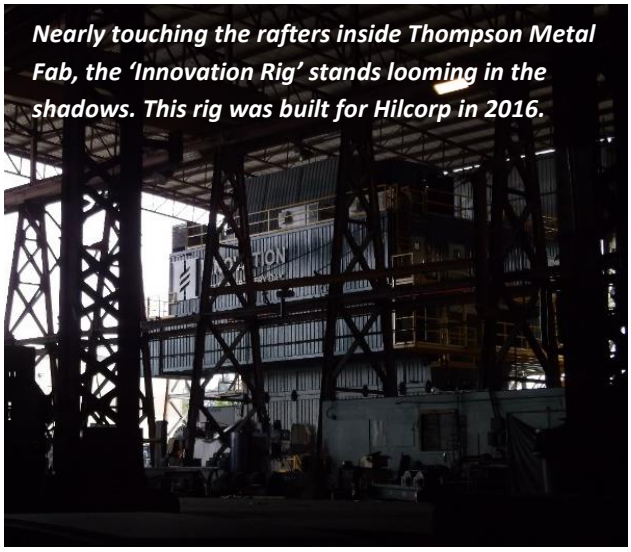
No, the picture to the right is not the inside of a 'big box' store, but it is the size of one! This is the inside of the Liberty Rig's Pipe Module (see above) and is where all production drill pipe is stored.

At the time it was manufactured, the Liberty Rig was the world's largest land-based drilling rig. Everything about this rig was supersized, including the mast shown here inside Thompson Metal Fab. Drill structures, like the one shown here, require special certification for manufacturing, and TMF is the only facility on the West Coast who holds that certification while also boasting a facility/yard of its size, in addition to roll-on/roll-off barge capabilities.

For new rig builds, drilling contractors traditionally manage the design and hire their own sub-contractors (structural, electrical, mechanical, etc.) For Doyon Drilling's Rig 25, TMF was hired as the General Contractor and managed all rig-build efforts on behalf of Doyon. As a result, Rig 25 becomes the rig built by Thompson as General Contractor.

Rig 25 is a sought after work-horse on Alaska's North Slope and is a dependable rig in Doyon's fleet. This picture shows a very proud Thompson team at the end of the project.

Shown above is the part of the substructure base for Rig 272. Its twin (Rig 273) was manufactured at the same time at TMF. Picture below shows the yard assembly of Rig 272, Rig 273, and Rig 25.



Nearly touching the rafters inside Thompson Metal Fab, the 'Innovation Rig' stands looming in the shadows. This rig was built for Hilcorp in 2016.

The Interstate Bridge looks on in the distance as Thompson Metal Fab manufactures three rig projects from their Columbia Business Center facility. Shipping clearance on Rig 272 & 273 (blue) would be nearly 160'.

Marine Industries and Fabricators

Company: Vigor

Company provided the following information to the IBR Program.

Vigor Works, LLC. is a Heavy Industrial Fabrication Company that serves the Marine, Hydro-Electric, Nuclear, Oil & Gas and Steel Bridge Industries. The wide variety of products produced by Vigor Works support private industry as well as Government Agencies (local, state, federal). Past and present projects completed from the Columbia Industrial Park include fully assembled final products: Bridges, Oil Field Modules/Platforms, Marine Vessels and other extremely large infrastructure type goods which have limited areas for fabrication due to water loadout/shipping and air draft restrictions.

Vigor Works (in and adjacent to the Columbia Industrial Park) are uniquely qualified and situated to support strategic and industrial needs, particularly our national infrastructure of dams, locks and bridges and marine vessels. The living wage trade jobs created by this work are critical to the health of the Vancouver/Portland area. Vigor currently supports ~1500 trade related jobs in the Portland Metro area which includes three separate locations in and around the Columbia Industrial Park.

Heavy investment in capital and people has occurred in all three Vancouver locations upriver of the I-5 bridge. By maintaining flexibility to pursue and provide ultra large product for customers, we can continue to pursue this type of work to support the jobs and economy of Vancouver. Our sites are unique due to their access to a large metro area with truck, rail and marine access.

The current bridge height has been important for commerce and shipments along the Columbia River for nearly a century and even more critically important since the war effort in the 1940s. In the late sixties and early seventies, offshore drilling rigs were constructed at this location and had to transit under the bridge. These offshore platforms required the bridge to be raised to its full height of 174 feet to allow them to pass under the raised span. More recently we have watched drilling equipment destined for Alaska being assembled in the Columbia Industrial Park that required 150 feet of clearance to be shipped down the river. Vigor consistently evaluates opportunities for product up to 110 feet in height. The additional height of blocking, transport barge freeboard and clearance margin, easily results in an air draft requirement of 130’ for these projects. Ideally, we recommend a height of 150 feet air draft.

Our other Portland facility located on Swan Island (Portland Shipyard) also engages in large fabrications and we have in the past, barged components to/from the Vancouver facilities. Our Marine Fabrication work has also resulted in portions of vessels being shipped via barge to Ketchikan and we are currently evaluating shipping product components to our Seattle Shipyard- the exact size of those products have not yet been determined. In the future, we would expect to ship product both upriver and down river.

The lower height of the bridge will limit Vigor Works’ ability to compete on some projects. The ability and direct access to shipping on the Pacific Ocean and subsequent trade routes to Alaska or the gulf coast and Mississippi River system (via the Panama Canal) is critical for our full and sustained operation. One recent project was delivered to New Jersey.

.

In summary:

The Bridge Height is now is 174 feet; this height has been needed as follows:

- 1960 to 1975 Drilling Platforms for the California Offshore Field.
- 1980 to 1995 Various loads from the Industrial Park to locations in Alaska and elsewhere.

- 2000 to 2012 Drilling Equipment for Parker Drilling assembled in the Park and shipped to Alaska.

Current:

- We are evaluating Vancouver for long term production related to partial or all construction for upcoming work. The final bridge height could impact the amount of work completed in Vancouver.
- We anticipate there will be some opportunity for future module or drill platform work associated with Alaska as equipment requires replacement.
- We expect, although do not know what the development of offshore wind will need for industrial shore side support.

Conclusion:

This Marine Highway is used by a multitude of users with traffic going both upstream and down. We ship goods from the industrial park upstream of the bridge to Swan Island Ship Yard and from the Swan Island Ship Yard to the industrial park. The I-205 Bridge upstream of the bridge has a clearance of 144 feet and downstream of the bridge we have clearance limited only at Astoria and that is 196 feet with the Lewis and Clark (Longview) bridge over 200 feet. We believe it is critical to our business and the viability of the river system used for commerce to keep the height of this bridge at least 150 feet.

Marine Industries and Fabricators

Company: Schnitzer Steel

Company provided the following information to the IBR Program.

From: Tony Belot
To: Brian Carrico
Cc: Nicole McDermott
Subject: RE: Interstate Bridge Program - Vessels
Date: Thursday, August 5, 2021 10:59:03 AM
Attachments: image001.png
image002.png
image003.png
image004.pn

Brian,

Thank you for your patience, Brian. Here is our updated information you requested:

Schnitzer Steel owns two vessels—MAX 111 (flat deck barge with bin walls) and CHIPPY 002 (flat deck barge with bin walls)—and uses a third—B5 (flat deck barge with bin walls)—which is owned by Bernert Barge Lines. Schnitzer Steel uses Bernert Barge Lines as its tug company. The information provided by Bernert Barge Lines for air draft and air gap would apply to Schnitzer Steel since none of the Schnitzer Steel vessels is taller than the tugs. The vessels average two trips in March and four to six trips per month during all other months of the year.

From: Brian Carrico <Brian.Carrico@interstatebridge.org>

Cc: Nicole McDermott <Nicole.McDermott@interstatebridge.org>
Subject: [EXTERNAL] Interstate Bridge Program - Vessels

Tony - Thanks for looking into this. Attached is the data previously provided by Schnitzer in 2012. We are looking to confirm or update this information. This is how it was described in our report.

Schnitzer Steel owns two vessels—MAX 111 (flat deck barge with bin walls) and CHIPPY 002 (flat deck barge with bin walls)—and uses a third—Inland Conveyor (flat deck self-unloading barge with bin walls)—which is owned by Cemex and chartered to Bernert Barge Lines. Schnitzer Steel uses Bernert Barge Lines as its tug company. The information provided by Bernert Barge Lines for air draft and air gap would apply to Schnitzer Steel since none of the Schnitzer Steel vessels is taller than the tugs. The vessels average two trips in March and four trips per month during all other months of the year.

Information on the project can be found at the website below.

Regards,

Brian

To: Brian Carrico <Brian.Carrico@interstatebridge.org>
Subject: FW: Dredge Oregon and North Portland Harbor

As requested Brian – updated data for Dredge Oregon, and vessel call numbers for T-6, below. For berths 603-605, moving forward: those numbers will increase significantly. We've just added a second weekly container service, and have 2 charter operations that extend for at least a year.

Subject: RE: Dredge Oregon and North Portland Harbor

Fred,
Here's the vessel calls by berth for the last five years. I wouldn't call this entirely accurate, but it's pretty close. Needed to use three different data sets to assemble this, with all three having slightly different numbers due to some duplicate entries, and lay berth vessel calls. Data sources included my own, marine security logs, and the Columbia River Pilots. If Brian needs fully accurate numbers, this will take more time, but the counts below are likely fairly close to accurate. In short, 601 and 605 are the busiest berths, while 603 and 604 are rarely used. Berth 607 is in a state of transition currently with Hondas departure so uncertain what level of vessel call forecast to apply to 607

looking forward.

		Year				
		2016	2017	2018	2019	2020
Berth	601	64	60	57	68	66
	603	0	2	1	3	1
	604	0	1	5	4	0
	605	0	5	23	10	49
	607	71	45	71	39	12

Let me know if you have any questions.
Thanks,
Randy

EXTERNAL EMAIL:

Fred - I don't think I followed up with you after our call a couple weeks ago. As discussed, I am looking to confirm vessel specifics for Dredge Oregon and information on vessel use of Port berths on the Columbia River.

In regard to the dredge, attached is the information provided for the CRC effort. If you could review this information and confirm that it is accurate or provide updates, we can make sure our information is up to date.

For vessel use I am looking for is the number of calls per year for Berths 601, 603, 604, 605 and 607. It would be good to provide data for the last 5 years. You can provide the data in whatever format is easiest.

Thanks, and let me know if you have any questions. I would appreciate information by the end of August.

    s. Do you have a Business Plan? No plans currently. Defer to USACE.
    t. Other Miscellaneous:
        i. The Dredge utilizes ‘spuds’ to hold itself on position and navigate within the channel. When in the stowed position for transit, the spuds are the highest point on the dredge at approximately 75’ above the waterline. If the Dredge were required to transit upriver from the I-5 bridge, based on the frequency of historical requirements, it would be reasonable to hire a derrick barge and crane to remove the spuds at the Port’s facility in the Swan Island harbor and place them on a barge, and then re-install the spuds after the Dredge has been towed upriver from the I-5 bridge. The air draft of the spuds stowed for transit should not govern the height of the CRC.

GENERAL NOTES:

The present drawing constitutes a General Lay-Out drawing. Its purpose is to evidence the location of the main items related to the installation of the IHC Spud Lifting System. Consequently the information contained is generaly not to be used for fabrication purposes. However, Details 1, 2 & 3 as described in this drawing may be considered valid for fabrication subject to the following note:
All structural elements shown, and relevant information, are based on IHC standards and should be verified as required, against:
- U.S. standards;
- ABS rules (steel grade selection, strength calculations etc);

NOTES ON STRUCTURAL INDICATIONS:

- All dimensions are based on metric units converted to imperial units (inches, unless otherwise indicated). These should be checked and confirmed with imperial units during engineering;
- Mild Steel unless otherwise specified;
- Cylinder and cylinder tub support details to be further developed based on adjacent structures;
- Materials (e.g. steel grade vs. plate thickness) to be in accordance with ABS rules and U.S. standards;
- Tapering of plates to be in accordance with ABS rules.

NOTES ON LOADS ACTING ON THE VESSEL:

- The loads on the Spud base and on the Spud Gates have been determined for a dredging depth of 55', based on the bending capacity of the Original Spuds of the Oregon [Ref.2]. Therefore, it must be ensured that the actual force on the Spud, as resulting from actual operation of the Vessel (thus based on dredging force, swing winch force, current, wind etc.), always remains below 295 kN.
- The load associated to the Cylinder operation (798kN) is calculated based on the standard configuration of the Cylinder for use on the IHC B65.
- The load associated to the HPU (40kn) corresponds to the supply as descibed in [Ref.4] and is to be considered as approximate.

NOTES ON IHC SPUD LIFTING SYSTEM COMPONENTS:

- The Spud Gates and Spud keeps shown in the present drawing, deviate from the standard IHC design for B65 [Ref.3], as follows:
  - Both have been modified in height in order to fit the Oregon deck height;
  - A radious has been introduced on top and bottom gates for a smoother load introduction;
  - Longitudinal plating of Spud gates have been slightly adjusted in order to fit Oregon's transversal spacing;
  - For a detailed description of the Spud Well Gate see Ref. 5
- The HPU as per [Ref.4] has an estimated envelope size of 2500x1200x2500mm (LxWxH) and will be mounted on a painted carbon steel skid frame, they lay-out of which is unknown at the moment. The HPU will need to be hosted in a Technical Space. The latter has been drawn, for reference, on main deck but should be treated as preliminary since pending exact arrangement.

Attachments: IBRP_Vessel Data Sheets_Puget Sound Naval Shipyard_2021.pdf

Hello Brian,

Attached are the updated vessel data sheets.

Please note that the YP 701 and YTT 10 previously listed in 2012 are no longer expected.

Thank you for giving us the opportunity to provide input on the I-5 Bridge replacement.

Hi Rachel, it has been a little while since I sent this. I wanted to check in to see if you have been able to review and confirm this information or if you need anything else from us to complete the effort.

Let me know if I can be of further assistance.

Brian

Thanks for getting back to me so quickly. Attached are a few things. The PDF files are the actual data used in the 2012 effort. We translated this into a new Word document (also

attached) that you could use to update information. Alternatively, you could access our online survey to input the information (at the link in the prior email).

Hello Brian,

Thank you for contacting us about navigation needs for our shipments on the Columbia River. Please send me the prior information you need reviewed and verified, and myself or someone from my office will get back to you.

Thank you.

Subject: [Non-DoD Source] Interstate Bridge Replacement Project - PSNS Vessel Use Columbia River

Rachel,

I am part of the team working on the Interstate Bridge (IBR) Program for ODOT and WSDOT (https://www.interstatebridge.org/rivernavigation/). I am reaching to you as part of the projects efforts to complete a Navigation impact Report as part of the USCG permitting process for the new bridge. We are collecting information on vessel use of the Columbia River and you provided information for PSNS for the prior Columbia River Crossing Project. We are seeking to validate and update the previously provided information. Are you the correct person to do this? If so can I send you the prior information to review and confirm? Thanks in advance for your time and feel free to reach out if you have any questions specific to this

request or the program in general.

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

Company/Owner Name: Puget Sound Naval Shipyard

Vessel Name:
Barge 40

Vessel Type:
Freight Barge

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:No

Vessel Category: National Defense

USCG Document Number:
1035597

Primary Mooring Location *(waterway milepoint, if known)*:
Bremerton, WA

Type and quantity of cargo, if applicable:
1 Package

Length (overall; ft):
250

Beam (width; ft):
68

VESSEL DATA SHEET, CONT.

Draft (ft) - *depth of hull below waterline, fully laden*:
14.75, worst case

Air Draft (ft) - *height of highest fixed point above waterline, unladen*:
50 (combined barge and package above waterline)

Air Gap (ft) - *desired clearance from highest fixed point to lowest part of bridge*:
15

Safety Margin (ft) *horizontal clearance required by vessel to navigate through the bridge*:
100

Transit speed under Interstate Bridge and Load Configuration:
10 knots
Full Load Displacement: 3302 long tons

Time of Year of Passage:
Shipments typically occur during mid-March to mid-April and September through October.
Shipment time and frequency can vary but averages two per year.

Tug Assistance Required:Yes

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Tongue Point Job Corps
   b. Name of contact: Captain James VanWormer
   c. Phone number (Office): 503.338.4977 (Cell): 206.715.8174
   d. Email: vanwormer.james@jobcorps.org
   e. Address: 37573 Old Hwy 30 City: Astoria
      State: OR Zip code: 97146
2. Vessel
   a. ID: b. Name: M/V Ironwood
   c. Type: ex USCG Buoy tender d. USCG Document Number: WLB297
3. Vessel Configuration
   a. Identify vessel configuration:
   - Is a vessel specification sheet available? No
   - Configuration shown on the sheet: not shown, photo only
   - What is the lowest height configuration for transport? 77' (74' without antenna)

   b. What is the gantry configuration? N/A Estimated gantry height: N/A

   c. Does the barge have spuds? N/A
   - Height above waterline for travel? N/A
   - Can the spuds be removed for travel? N/A
   - Work and cost involved in removing spuds? N/A
4. Vessel Location
   a. Where is the vessel currently located? Tongue Point, Columbia River
   b. Is it working on a job? N/A Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Priot to end of July, Just need a few days advance notice.

Brian,

I did just get a response on the upcoming planned activities from our Operating Project Managers.

The Yaquina looks to be the tallest USACE vessel that we expect to transit through the area. Annual O&M dredging's in water work window is 1 August to 30 September but we need to have the ability to address shoals at any time of year. I believe that's how we landed on the river level + Yaq height clearance in our formal letter to the CRC.

As far as future work goes, our contractors often move equipment and materials via barge to construction projects. For example recent gate replacements, JD AWS electrical building, etc along with the large cranes mobilized to handle these. The largest crane I've heard coming up river was "The General" which I think Kiewit now owns.

I am trying to verify the dimensions of "the General" as well as the largest items we've moved under contract (likely The Dalles or John Day Gates). Otherwise there is nothing planned that would be impacted by the bridge height.

Thanks, Jeff

Hey Brian,

Sorry for the slow response. I would be the correct contact to validate this information. I am working with our Navigation team to answer this question but as far as I'm tracking it was just the Yaquina. Hoping I can get you a formal response by tomorrow.

Thanks, Jeff

Subject: [Non-DoD Source] Interstate Bridge Replacement Project - USACE vessels/Navigation needs

Jeff,

I am part of the team working on the Interstate Bridge (IBR) Program addressing the USCG permit. We are collecting information on vessel use of the Columbia River and are validating and updating the data provided by the USACE for the prior Columbia River Crossing Project.

The information at that time was provided by Marci Johnson. Would you be the best contact for validating the information? Specifically, I am looking to confirm information on the Yaquina, whether any other USACE vessels would be expected to transit through the area (either North Portland Harbor or the main channel) and whether there are any planned activities at upstream dams would require specific shipments under the bridge in the future.

Thanks in advance. Feel free to call or email if you have questions or need additional information.

FEB 23 2012

Ms. Heather Wills
Columbia River Crossing
700 Washington Street, Suite 300
Vancouver, Washington 98660

Dear Ms. Wills,

This letter is in response to the Columbia River Crossing (CRC), Interstate 5 (I-5) Project boat survey request for information regarding the Corps Dredges Yaquina and Essayons and our navigational needs upstream of the proposed new I-5 bridge project.

We determined that the proposed bridge height outlined in the Record of Decision would have serious impacts on our federal missions to maintain the navigation channel and provide emergency dredging upstream of the new bridge. After considering dredging requirements and potential future water release impacts to the Columbia River, we determined that the minimum prism needed for the new bridge is a height of 116 feet Columbia River Datum (121.4 NAVD88) for a width of 400 feet. A more detailed explanation of our requirements is enclosed.

We will forward a copy of this letter to Rear Admiral Keith Taylor, Commander 13th District United States Coast Guard, Jackson Federal Building, 915 Second Avenue, Seattle, WA 98174-1067, John McAvoy, FHWA, 610 East 10th Street, Vancouver, WA 98661; and Dave Hendricks, Multnomah County Drainage District No. 1, 1880 NE Elrod Dr., Portland, Oregon 97211.

We look forward to resolving these navigation concerns to ensure the CRC project does not have any unacceptable impacts to our federal projects. Please feel free to contact me at (503) 808-4500 or Ms. Marci Johnson of my staff at (503) 808-4765 or via e-mail at marci.e.johnson@usace.army.mil.

Sincerely,

John W. Eisenhauer, P.E.
Colonel, Army Corps of Engineers
District Commander

U. S. Army Corps of Engineers Federal Navigation Channel Maintenance Needs
Columbia River Crossing (I-5 Interstate Bridge at Vancouver, WA)
February 2012

Summary:

Minimum prism needed for new bridge is height 116 feet Columbia River Datum (CRD) (equal to 121.4 feet NAVD88) for width 400 feet (channel width of 300 feet plus 50 feet on each side of the channel).

Authorized project:

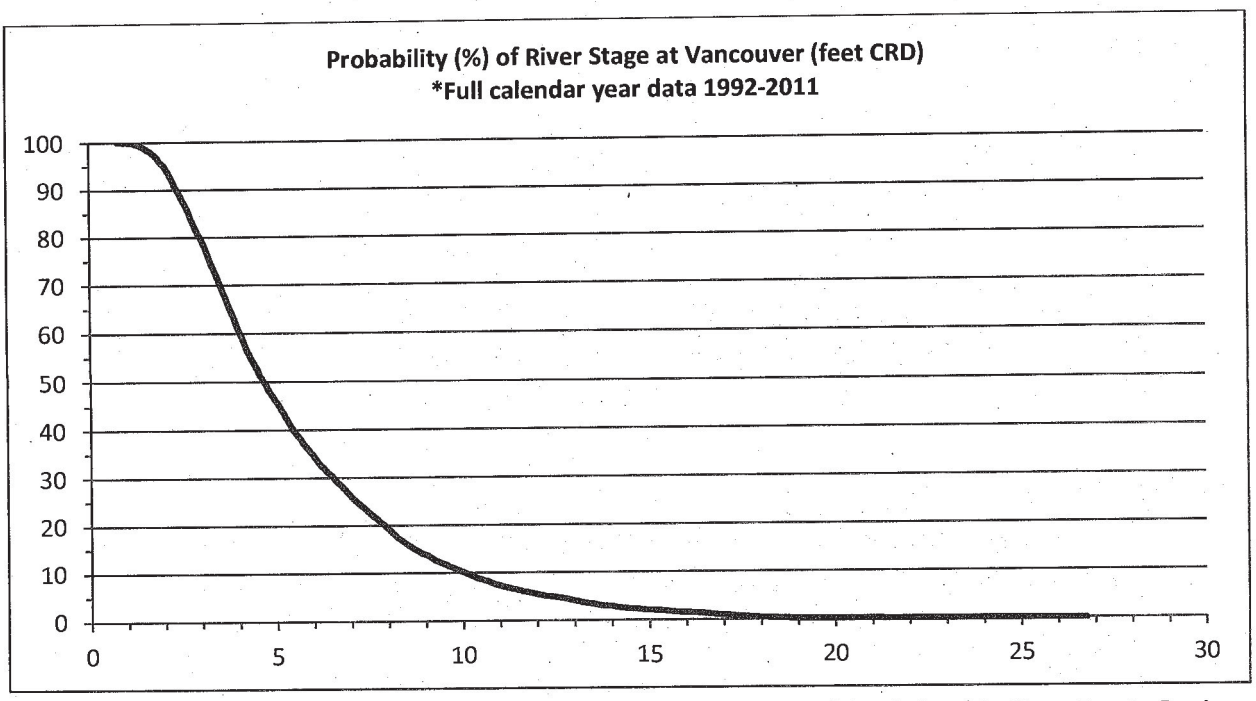
- The federal Navigation Channel immediately upstream of the Columbia River Crossing is authorized to 27 feet deep and 300 feet wide from Vancouver, WA, to The Dalles, OR. This channel supports the Columbia-Snake river system and transportation of 10 million tons of cargo annually. It is the largest wheat/barley export gateway in the U.S. and the third largest grain export gateway in the world.

Minimum bridge prism reasoning:

- The Corps' Dredge *Yaquina* performs annual channel maintenance dredging. The minimum prism needed for the new bridge is the vertical clearance required for this dredge to pass safely under the bridge at a specified river water level above CRD, and the horizontal clearance required for maintenance of the channel under the bridge.

Vertical clearance discussion:

- According to the USCG-licensed captains of the Dredge *Yaquina*, a 100-foot minimum vertical clearance from top of water to bottom of bridge is required (draft of 9 feet below the waterline gives a height of 92 feet above the waterline, plus an 8-foot minimum safety gap).
- The environmentally protective in-water work period as established by Federal and State agencies has changed in the past, and could continue to change as new species are listed, requiring work to be done during periods of higher river flow and stage.
- Year-round river flow levels must be considered as emergency operations could be required at any time. The probability of a river stage is shown below, using available data from the past 20 years.



- The uncertainty of future water levels must be considered. As part of the Columbia River Treaty Review, the Corps is collecting new data and performing studies to evaluate maintaining or potentially changing current levels of regulation for flood risk protection in this region of the Columbia River basin. The National Marine Fisheries Biological Opinion for the Federal Columbia River Power System also requires the Corps to spill water at its Columbia River dams to support salmon survival. These factors may lead to future operations resulting in elevated river levels (closer to ordinary high water) for longer durations compared with the past 20 years. Current Regulatory ordinary high water level at the Columbia River Crossing is 16 feet CRD (equivalent to 21.4 feet NAVD88).
- Bridge lift records show the lift height in feet above zero at the bridge pier elevation (39 feet CRD). Recent records show that the median lift for the Dredge *Yaquina* is 100 feet (equal to 139 feet CRD). The maximum lift shown was 136 feet (175 feet CRD). The minimum lift shown was 90 feet (129 feet CRD). Water levels shown on bridge records corresponding to these lifts ranged from 1 to 12 feet CRD.

Vertical clearance conclusion: A minimum vertical height of 116 feet CRD (121.4 feet NAVD88) is required. Year-round river level data from the past 20 years indicate that river levels were at or below 16 feet CRD approximately 98 percent of the time. Future river operations will likely increase river levels up to ordinary high water (16 feet CRD) for longer periods. Adding the 100-foot vertical clearance from waterline to bridge required for the Dredge *Yaquina* to 16 feet CRD yields a minimum vertical bridge height requirement of 116 feet CRD (121.4 NAVD88).

Horizontal clearance discussion:

- The Corps practices advanced width maintenance dredging (dredging up to 50-100 feet outside the channel width) to provide an area outside the channel for unstable side slope sloughing so that the full channel width remains clean.

Horizontal clearance conclusion: A horizontal width of 400 feet CRD is required at the vertical height specified above. This width includes the channel width (300 feet) plus 50 feet additional width on each side of the channel for advanced width maintenance dredging.

Federal Government

Brian,

Yes the Hood River USCG vessel data is correct and should be used in the IBP NIR.
BNSF is required to have an opening log that would not day and time of opening and type of vessel(s) and possibly names of vessels they have opened for. Do you need this and are unable to get it?
Good days for me are Tue, Thurs, Fri.

Thanks

Steve

Subject: [Non-DoD Source] Interstate Bridge Replacement Program

Steve - I have a few requests for you associated with the IBR Program.

1. USCG vessel river use: The 2012 CRC report (from which we are starting) does not have any data for USCG vessel use related to the I-5 Bridge. For the recently completed Hood River Bridge Navigation Impact Report we included the Juniper Class Buoy Tender as a vessel that would be required to navigate under the bridge. Can you confirm that would also be the case and whether any other USCG vessels should be considered? The vessel

information used for Hood River Bridge is attached for your information. It is also includes a blank sheet for additional vessels if needed.

2. BNSF Bridge Data: We previously discussed obtaining information on BNSF bridge openings to get a better picture of overall river traffic (not just vessel traffic required a bridge opening. BNSF indicated that they did not have this data. You indicated previously that you may be able to assist in obtaining the data. Let me know if you have any thoughts on this.
3. Notice to Mariners: Do you anticipate getting the notice previously sent published in the Local Notice to Mariners soon or did i miss it in the recent publications?
4. Meeting: Can you let me know your availability for a coordination call with the IBR team this month? We want to keep you fully informed and have a few items to discuss as we move forward.

Thanks in advance for your time.

Regards,

Brian

Nicole…I see you have the information for our largest vessel the Portland Spirit. The Columbia Gorge is very similar in size and you can mirror the Spirit characteristics as hers too. We also operate other vessels..The Willamette Star, Crystal Dolphin and the Explorer, but they are much smaller…If the new bridge has enough clearance for the Portland Spirit the bridge will handle all our vessels..current and future…Thanks, Dan

Owner: Legendary Yachts

Vessel:

- Radiance

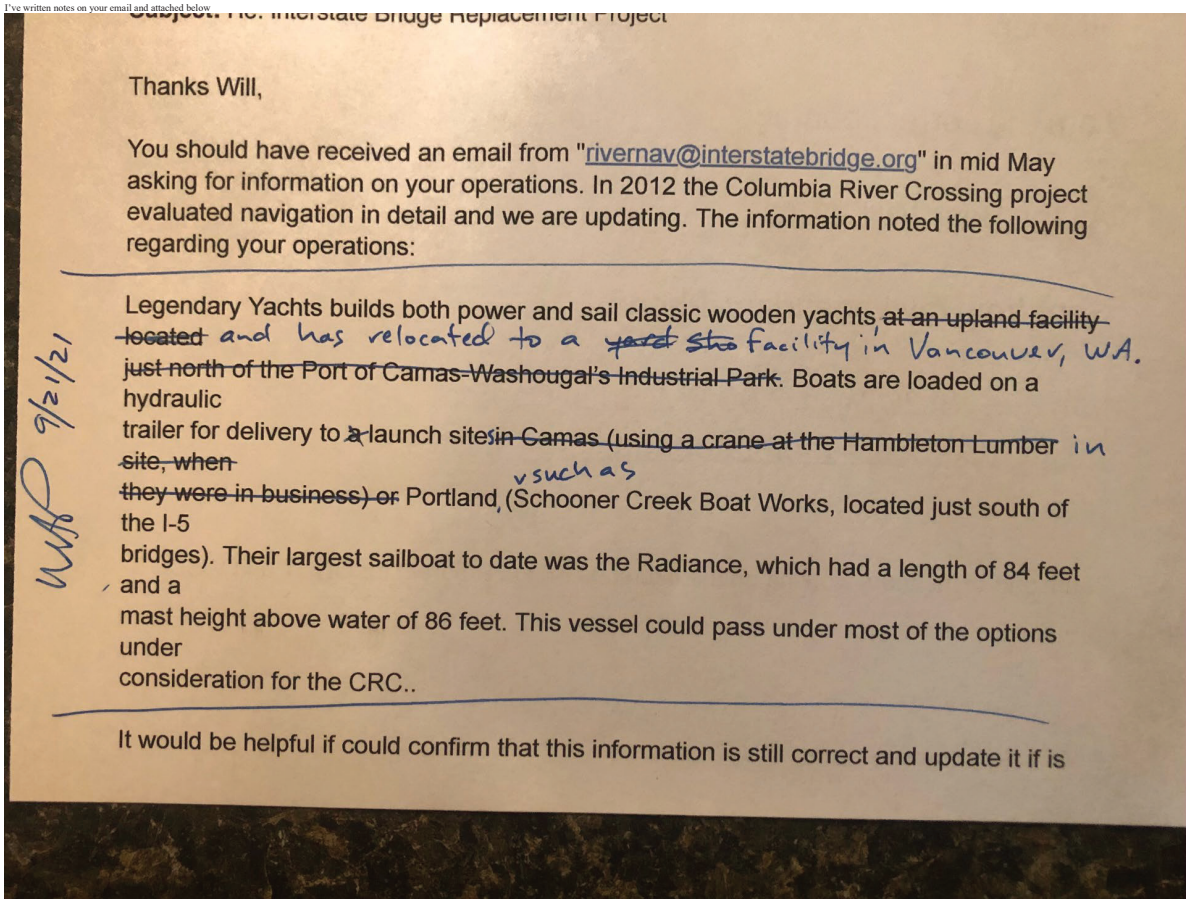
Confirmation was submitted via email to the IBR Program. Vessel characteristics were provided in the CRC NIR. Email confirmation and CRC NIR information are included below.

From: Will Pollard
To: Brian Carrico
Cc: Nicole McDermott
Subject: Re: Interstate Bridge Replacement Project
Date: Tuesday, September 21, 2021 11:22:24 AM

Hi Brian,

My apologies.

I've written notes on your email and attached below



Re: Interstate Bridge Replacement Project

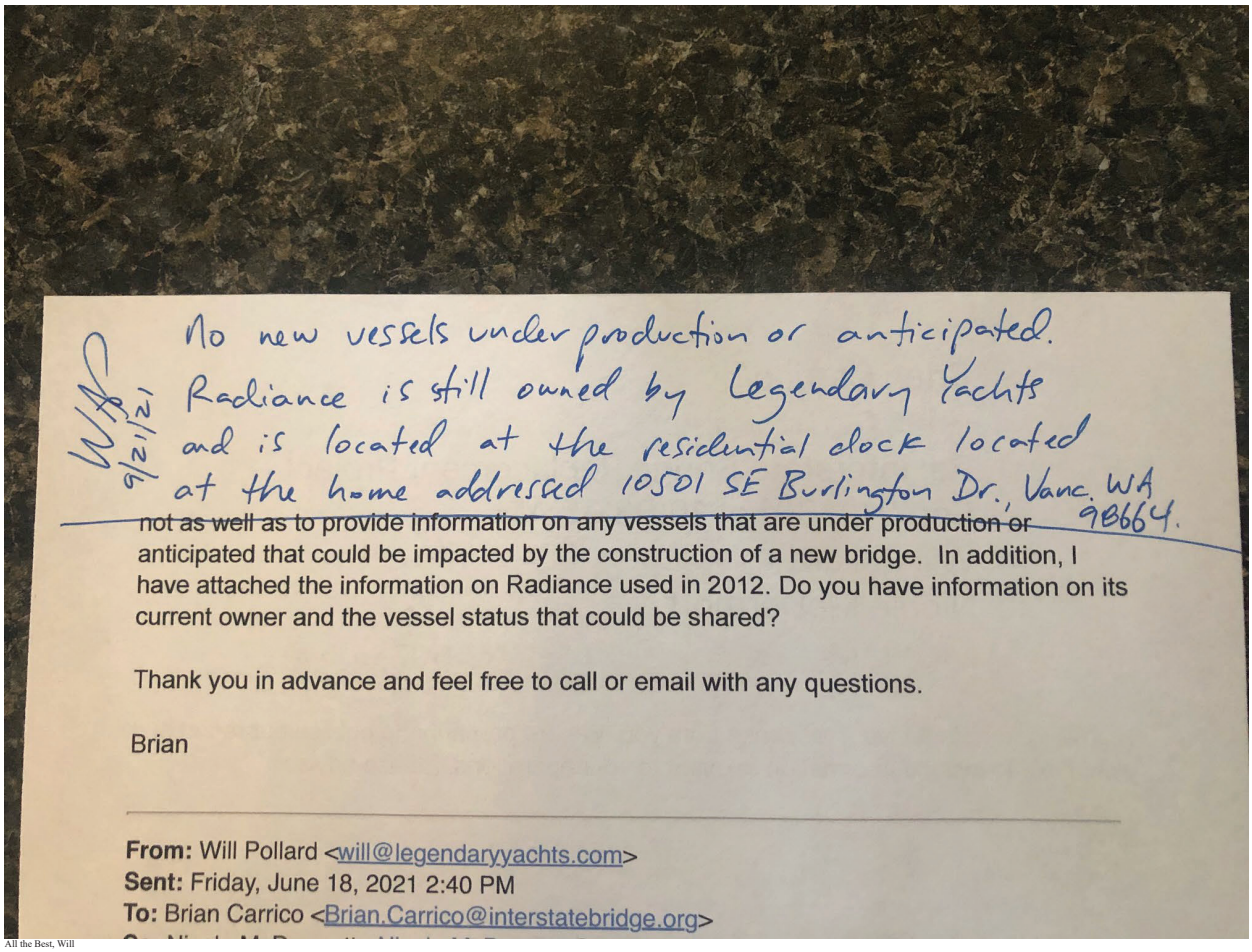
Thanks Will,

You should have received an email from "rivernav@interstatebridge.org" in mid May asking for information on your operations. In 2012 the Columbia River Crossing project evaluated navigation in detail and we are updating. The information noted the following regarding your operations:

Legendary Yachts builds both power and sail classic wooden yachts ~~at an upland facility located~~ and has relocated to a ~~yard~~ ~~site~~ facility in Vancouver, WA. ~~just north of the Port of Camas-Washougal's Industrial Park~~. Boats are loaded on a hydraulic trailer for delivery to ~~a~~ launch site ~~in Camas (using a crane at the Hambleton Lumber site, when they were in business) or~~ in Portland, such as (Schooner Creek Boat Works, located just south of the I-5 bridges). Their largest sailboat to date was the Radiance, which had a length of 84 feet and a mast height above water of 86 feet. This vessel could pass under most of the options under consideration for the CRC..

9/21/21

It would be helpful if could confirm that this information is still correct and update it if is



No new vessels under production or anticipated. Radiance is still owned by Legendary Yachts and is located at the residential dock located at the home addressed 10501 SE Burlington Dr., Vanc. WA 98664.

9/21/21

not as well as to provide information on any vessels that are under production or anticipated that could be impacted by the construction of a new bridge. In addition, I have attached the information on Radiance used in 2012. Do you have information on its current owner and the vessel status that could be shared?

Thank you in advance and feel free to call or email with any questions.

Brian

On Jun 18, 2021, at 2:00 PM, Brian Carrico <Brian.Carrico@interstatebridge.org> wrote:

I am part of the team working on the Interstate Bridge Program for ODOT and WSDOT, and we are updating information developed for the prior Columbia River Crossing project in 2012.

I am seeking information regarding the operatingstatus of Legendary Yachts and their current operations as part of the programs efforts to assess the impact of the proposed bridges on Columbia River navigation. If you could let me know if you are the correct individual with this information, it would be appreciated.

You can find out more about the program on the project website https://www.interstatebridge.org/ or by reaching out directly to me.

Regards,
Brian

APPENDIX D COLUMBIA AND SNAKE RIVER NAVIGATION CLEARANCES

Appendix D. Navigation Clearances for Facilities Crossing the Columbia and Snake Rivers

Table D-1 summarizes the navigation clearances for facilities (bridges, cables and locks) that cross or are in the Columbia River (from the mouth to Richland, Washington) and the Snake River (from the mouth to Lewiston, Idaho). This information is provided by river mile beginning at the mouth of the Columbia River and progressing upstream. Horizontal and vertical clearances are provided for bridges, horizontal clearances for navigation locks, and vertical clearances for overhead power lines. Most of the information provided in the table was obtained from the most recent National Oceanographic and Atmospheric Administration (NOAA) navigation chart available online (NOAA, 2012). Some of the bridge names (e.g., most of the railroad bridges upstream of The Dalles Dam) were obtained from the USCG bridge inspection logs available through the internet (USCG, 2011). In addition, USACE channel condition surveys were reviewed for additional information and for cross comparison with the information on the NOAA navigation charts.

Information differing materially between the NOAA charts and either the USACE charts or USCG bridge inspection logs are provided in the notes. In some cases, the reported river mile may be slightly different. The river miles provided in the tables were estimated to the nearest 1/10 statute mile based on river miles provided in the NOAA charts. In addition, the horizontal and vertical clearances were taken from the NOAA navigation charts. The datum for each reach of the river is controlled by the pool elevation of the various dams above Bonneville Dam. Below Bonneville Dam, the CRD is used except near the coast at the Astoria-Megler Bridge where Mean Lower Low Water (MLLW) is used.

APPENDIX E INTERSTATE DRAWBRIDGE OPERATIONS DATA

APPENDIX E

Interstate Drawbridge Operations Report

Appendix E includes data on I-5 bridge lift span openings collected from Jan 1, 2007 through May 24, 2022. Data from 2007 to 2011 is provided from the 2012 Columbia River Crossing dataset and includes maintenance and test lifts. Data from 2012 to 2021 was collected as part of the Interstate 5 Bridge Replacement project. This dataset does not include maintenance or test lift openings which are not relevant to vessel navigation but can be useful for other purposes related to vehicle traffic. Both datasets include time of gate closing and opening, total time opened, lift elevation, recorded vessel name, weather temperature, wind velocity, water level, vessel type and total height.

Date	lift #	gates closed	gates open	total time (min)	life elevation (feet)	vessel name	up or down	weather temp (degrees)	wind (mph)	water level	Type1
01/01/07	1	15:16pm	15:25pm	8	80	"Halsey", "Whisper", "Osprey" sailboats	up	cloudy 38	2	6.8	Sail

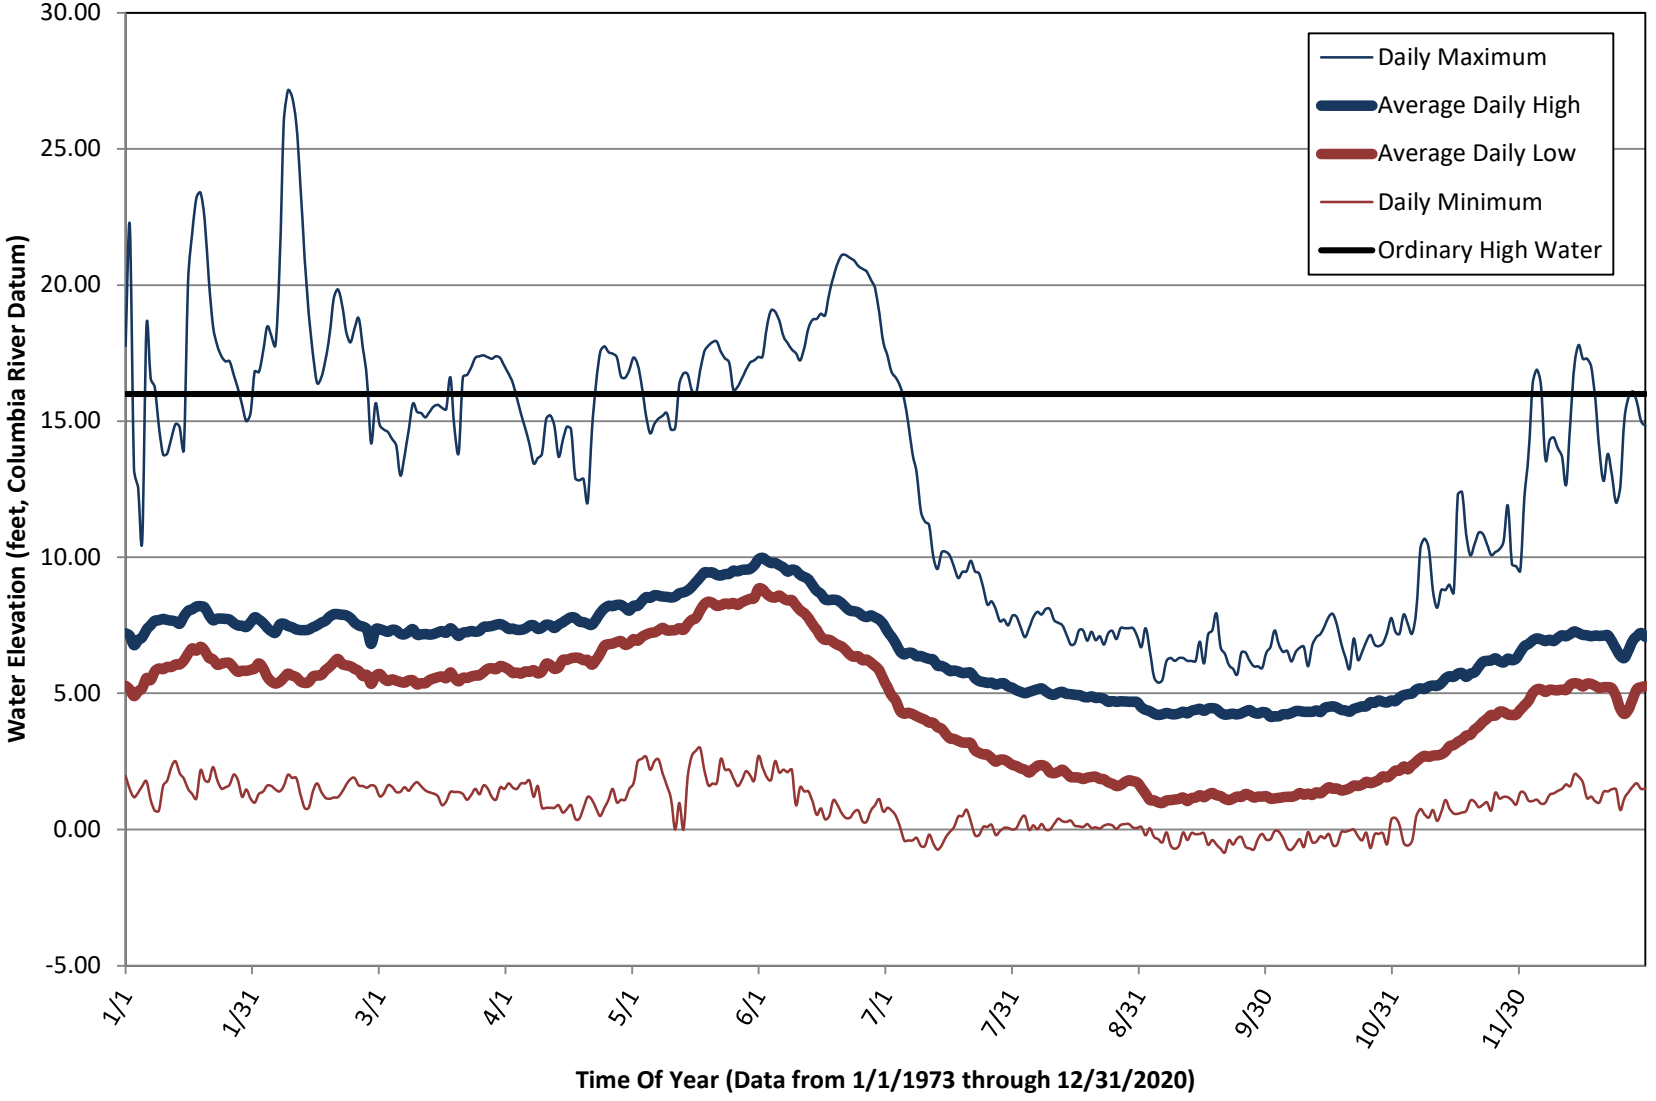
APPENDIX F COLUMBIA WATER LEVEL

Columbia River Water Elevation at the Interstate Bridges



Note: The water level went above the ordinary high water mark (16' above CRD) less than 1.2% of the time (189 days / 17,113 days) between 1973 and 2020.

Columbia River Water Elevation at the Interstate Bridges, Daily Statistics (feet, Columbia River Datum)

	Daily Maximum	Daily Minimum	Average Daily High	Average Daily Low	Average Monthly Max	Average Montly Min	Ordinary High Water
1-Jan	17.77	1.97	7.21	5.28	16.98	1.62	16

1. INTRODUCTION

The Interstate Bridge Replacement (IBR) program will replace the existing Interstate 5 (I-5) bridges crossing the Columbia River between Vancouver, Washington, and Portland, Oregon. Multiple alternatives will be considered for the bridge replacement.

As part of the preliminary phase of alternatives development, the IBR program assembled a group of engineers with international experience in tunnel design and construction to provide a comprehensive conceptual review of the suitability of an immersed tube tunnel (ITT).

Two alignments, one upstream and one downstream of the existing Interstate Bridges, were investigated from multiple perspectives, including design, construction, operations, environmental, and cost considerations.

This is an assessment of preliminary concepts. These concepts are not in design and remain at the conceptual level. They will not be advanced to design until or if it is deemed appropriate during the alternatives development process.

The following professionals participated in the development of this document:

- Coles Bales, PE(OR, WA)— IBR Deputy Geotechnical Lead
- Matt Bilson, PhD, PE(NY) — Tunnel Fire-Life Safety & Ventilation Expert
- Patrick Chan, PE(NY) — Tunnel Structures Expert
- Ian Chaney, PE(VA) — Tunnel Design & Construction Expert
- William Connell — Tunnel Systems Expert
- Brittany Cowgill, PE(OR) — IBR Civil Design Engineer
- Matt Deml, PE(OR, WA), SE(OR, WA) — IBR Deputy Structures Lead
- Angela Findley - IBR Environmental Lead
- John Horne, PhD, PE(OR, WA) — IBR Geotechnical Lead
- Bobby Melvin, PE(WA) — Tunnel Mechanical Systems Expert
- Brad Phillips, PE(WA) — IBR Civil Design Lead
- Noreen Roster — IBR Deputy Environmental Lead
- Vicky Smith, PE(OR) — IBR Transit Lead
- Jose del Solar, PE(NY) — Tunnel Mechanical Systems Expert
- Tolga Togan — Tunnel Construction and Cost Estimating Expert
- Rob Turton, PE(OR, WA), SE(WA) — IBR Structures Lead

2. DESIGN CONSIDERATIONS

The IBR program will replace the existing I-5 bridges crossing the Columbia River between Vancouver, Washington, and Portland, Oregon. In addition to vehicular traffic, the conceptual tunnel facility explored here would also accommodate high-capacity transit (HCT) and a multi-use path (MUP).

Two types of tunnels are typically considered for crossing below bodies of water. One is a bored tunnel where the tunnel is constructed using a tunnel boring machine. Given the length, size, and soil conditions present at this location, a bored tunnel is not appropriate. The other type is an ITT in which a series of prefabricated tunnel segments are constructed in a casting basin or on dry docks, and then sunk onto a prepared soil substrate. Tunnel segments are then connected underwater and the tunnel is dewatered. An ITT is assumed for this assessment.

The ITT concept reviewed here would accommodate all three transportation modes: roadway, HCT, and a MUP. The tunnel section would consist of six cells separated by concrete walls. One cell would accommodate four lanes of traffic for northbound (NB) I-5 and another cell would accommodate four lanes of traffic for southbound (SB) I-5. Two cells, one direction each, would accommodate NB and SB HCT. One cell would accommodate the MUP. One cell would accommodate the operations and maintenance/egress route. It is assumed that all these modes would be housed within a single immersed tube cross-section (see Figure 1).

The length of the facility would consist of an ITT for in-water sections, transitioning to cut-and-cover tunnel sections beyond the river, and then into a retained cut (U-section) until I-5 attains grade.

2.1 Alignments

Two alignments were evaluated: upstream and downstream of the existing Interstate Bridges. Each alignment was assessed considering highway geometry, navigation requirements, geotechnical conditions, structural design requirements, constructability, and environmental considerations. See Figure 2 for a plan showing the two alignments.

Figure 1. Immersed Tube Tunnel Typical Section

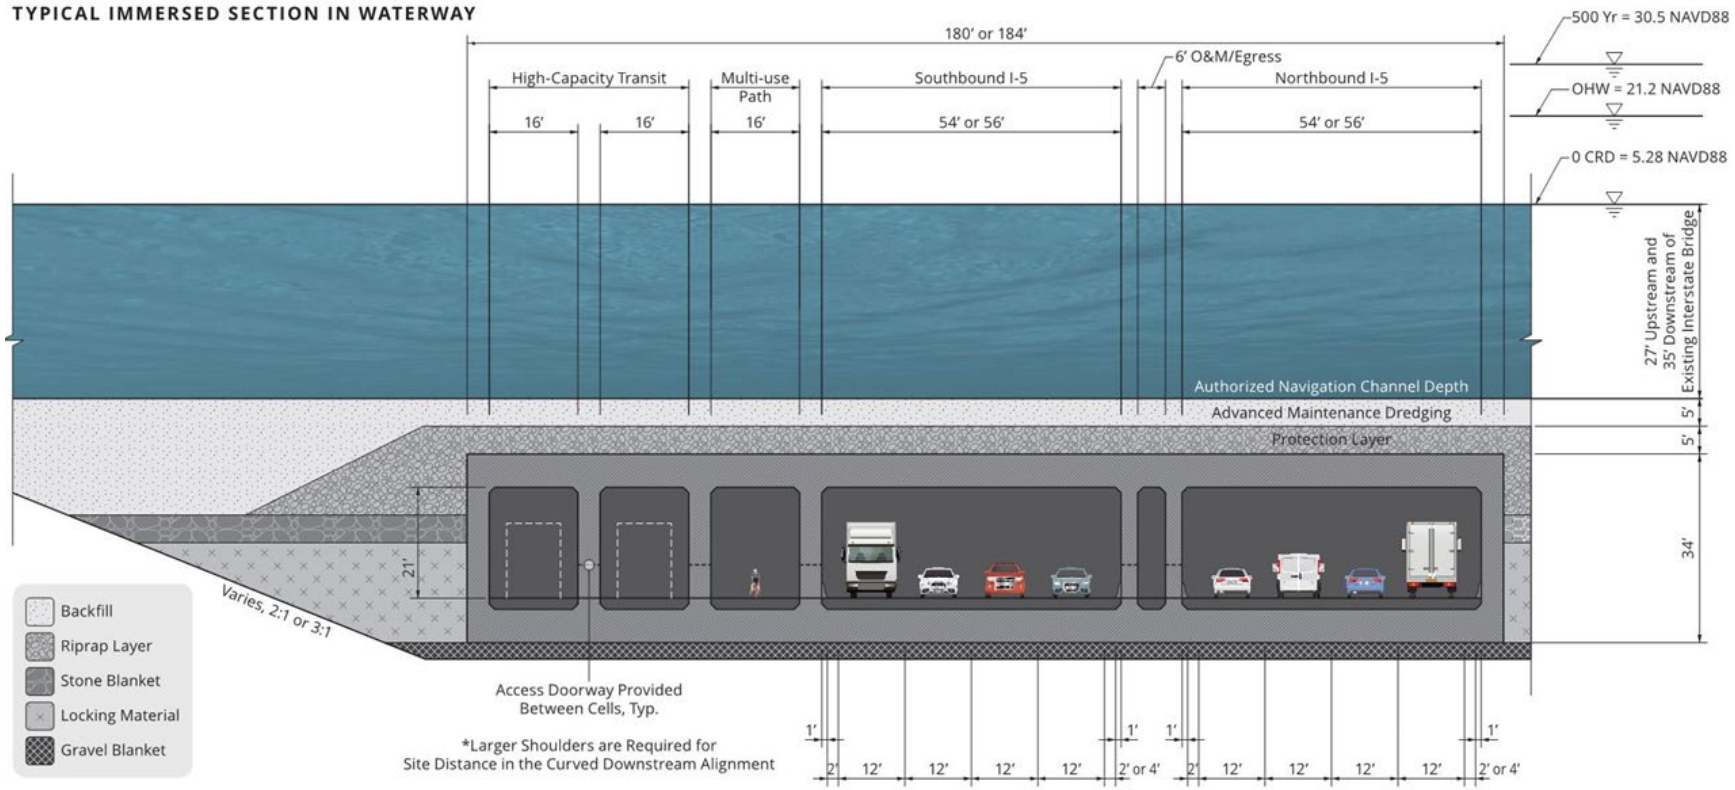

Figure 2. Upstream and Downstream Tunnel Alignments

2.2 Columbia River Navigation

Operational requirements for vessel navigation on the Columbia River define how deep a tunnel must be as it crosses below the Columbia River.

The United States Army Corps of Engineers (USACE) maintains the navigation channels on the Columbia River. River navigation features are authorized to specific locations, widths, and depths, as shown in Figure 3. Navigation features differ upstream and downstream of the existing Interstate Bridges.

Figure 3. Columbia River Navigation Channels

The Upper Vancouver Turning Basin, downstream of the existing Interstate Bridges, has an authorized depth of 35 feet (see Figure 4).

Upstream of the existing Interstate Bridge are three navigation channels: the primary channel, barge channel, and alternate barge channel. All three channels have an authorized depth of 27 feet (see Figure 5). USACE maintains the navigation channels through continuous dredging operations. Currently, USACE maintains the channels to a depth of 17 feet below zero Columbia River Datum

(CRD); however, any project must comply with the authorized depth of the channel. The authorized channel depth of 27 feet extends approximately 90 miles upriver to The Dalles, Oregon.

Figure 4. Navigation Channel for the Downstream Alignment

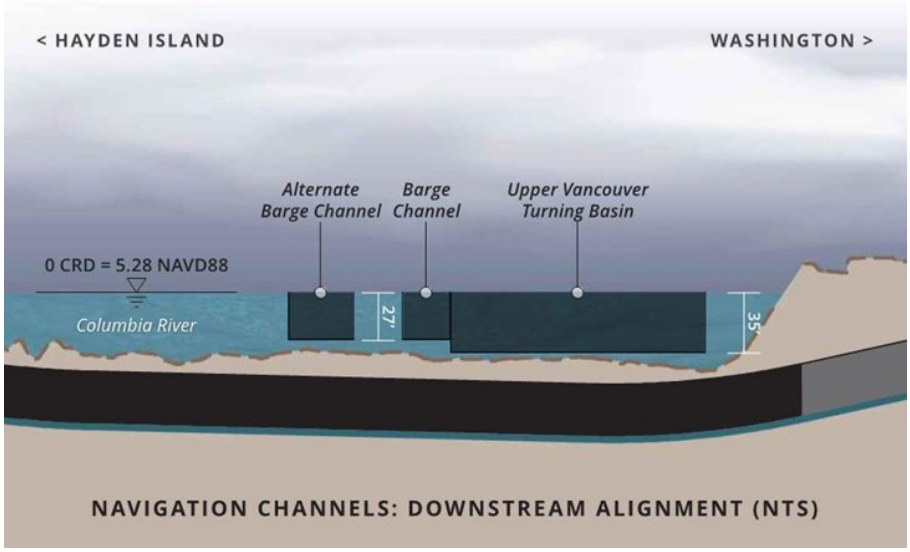

Figure 5. Navigation Channel for the Upstream Alignment

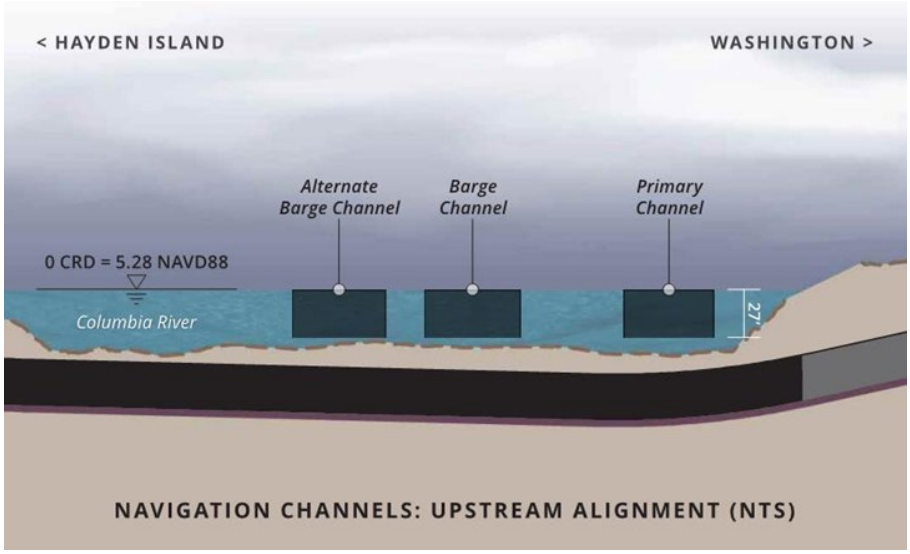


USACE requires that any civil works below the turning basin or navigation channels must be placed below the authorized depths and include an additional 5 feet of depth for advanced maintenance dredging. This is to allow for excess over-dredging required to maintain the authorized channel depth.

Below the advanced maintenance dredging depth, a 5-foot protective layer of rip rap would be required (see Figure 1). The rip rap layer would protect the ITT from unintended additional dredge

excavation, sunken vessels, dragging anchors, river scour, and other hazards that could be detrimental to the structural section of the ITT.

2.3 Highway Design

Two mainline I-5 alignments were evaluated; one upstream of the existing Interstate Bridges and one downstream. Both alignments were established to minimize impacts to the existing Interstate Bridges and facilitate construction phasing.

The ITT depth would be controlled by the authorized depths of the statutory Columbia River navigation channels. Maximum grades for the tunnel would be approximately 4.5%, controlled by highway design requirements. (This exceeds the maximum interstate grade of 4% prescribed by the departments of transportation. However, 4.5% grades can still accommodate the HCT and MUP.) A design speed of 60 miles per hour is assumed for both alignments. At the south end of the facility for both alignments, I-5 would attain grade near the south shore of Hayden Island. At the north end of the facility for both alignments, I-5 would attain grade near Evergreen Boulevard (see Figure 2).

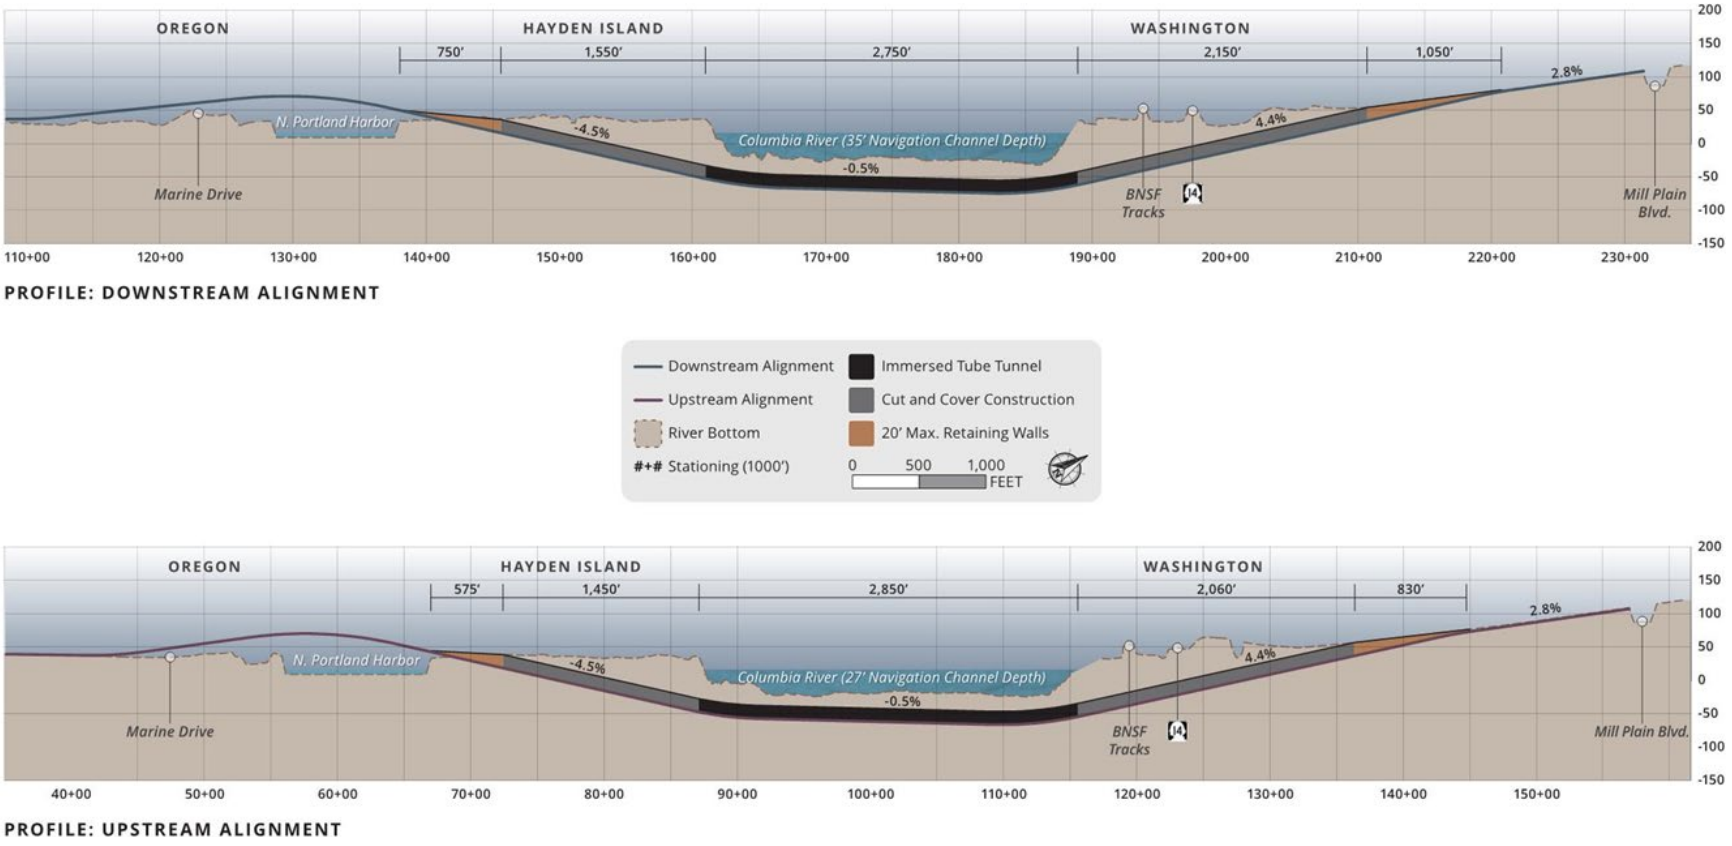
Shoulder widths in the facility are assumed to be 2 to 4 feet wide (see Figure 1). This would require a design exception from the Oregon and Washington departments of transportation, but these widths are typical of similar proposed and constructed tunnels currently in service.

2.4 Downstream Alignment

The downstream alignment as shown in Figure 2 would incorporate a horizontal curve to avoid temporary impacts to the existing Interstate Bridges during construction. This alignment would result in a portal-to-portal tunnel length of 6,450 feet. The grades associated with the downstream alignment are shown in Figure 6. Due to the horizontal curve, 4-foot shoulders would be required to accommodate site distance as shown in Figure 1.

A deeper excavation would be required for this alignment than for the upstream alignment.

Figure 6. Downstream Alignment Profile (top) and the Upstream Alignment Profile (bottom)



2.4.1 Upstream Alignment

The upstream alignment as shown in Figure 2 would follow a more direct route across the river with a shorter portal-to-portal length of 6,360 feet. The grades associated with this alignment are shown in Figure 5.

Due to the upstream USACE-authorized channel depths, this alignment would require less overall excavation. Refer to the Construction Considerations section for further details.

2.4.2 Interchanges

In this assessment of a conceptual ITT, interchanges were not addressed in detail. However, interchanges at Hayden Island, downtown Vancouver, and State Route (SR) 14 would require unconventional and complex below-grade construction. For example, at the center of Hayden Island, I-5 would be 34 feet below grade for the upstream alignment and 38 feet below grade for the downstream alignment. Where I-5 intersects SR-14, I-5 would be 71 feet below grade for the upstream alignment and 73 feet below grade for the downstream alignment (see Figure 5).

The only way to provide connectivity would be to construct cut-and-cover tunnels for ramps to achieve the required interchange connections. The ramp geometry required to accomplish this has not been verified. Large temporary excavations would be required to construct the cut-and-cover ramps. This type of construction is not typical and would have operational implications that are addressed in Chapter 4, Operational Considerations.

2.5 High-Capacity Transit

HCT, regardless of whether it is bus rapid transit (BRT) or light rail transit (LRT), would be accommodated at the 4.5% grades established for the highway profiles. (LRT has a maximum recommended grade of 5%.)

2.5.1 Multi-Use Path

The MUP can have a maximum sustained grade of 5%, which would be accommodated by the grades shown on the highway profiles. The MUP would be in a tunnel section for the entire portal-to-portal lengths described above.

2.6 Aviation

The ITT would result in removal of the obstruction caused by the existing iInterstate Bridges and would not impact permanent operations at Pearson Field or Portland International Airport.

2.7 Geotechnical Considerations

2.7.1 Regional Geology

The project area is located within the Portland Basin, approximately 5 miles east of the confluence of the Columbia River and the Willamette River. The Portland Basin is a northwest-trending structural basin, roughly 40 miles in length and 20 miles in width, flanked by the Tualatin Mountains to the west and the Cascade foothills to the east. The basin is underlain by sequences of lava flows of the Columbia River Basalt Group (CRBG).

During and following the period of extensive lava flows forming the CRBG (ca. 17 to 6 million years ago), the Portland Basin subsided and Sandy River Mudstone and Troutdale Formation were deposited [primarily] by the ancestral Columbia River. Troutdale Formation conformably overlies Sandy River Mudstone and may be up to 400 feet thick in some locations. The Troutdale Formation has been variably eroded by the ancestral Columbia and Willamette Rivers, and by a series of late Pleistocene glacial outburst floods which deposited up to 200 feet of sediment ranging from silts and sands with occasional clay interbeds (fine-grained facies) to gravels and boulders (coarse-grained facies). Following the last of the catastrophic glacial outburst floods, the sea level rose and the deep channels of the Columbia River were infilled with silty/sandy alluvium and broad floodplains were formed along the Columbia River.

2.7.2 Seismicity and Faulting

The regional seismicity is largely driven by proximity to an active convergent-plate boundary. This zone, called the Cascadia Subduction Zone (CSZ), is a broad, eastward-dipping zone of contact between the upper portion of the subducting slabs of the Gorda, Juan de Fuca, and Explorer plates and the overriding North American plate. Regional seismicity associated with the CSZ includes mega-thrust interface events as well as deeper intraslab events.

Local seismicity is generally driven by shallow crustal sources in the vicinity of or within the Portland Basin. The Portland Basin is bounded by high-angle, northwest-trending, right-lateral strike-slip faults considered to be seismogenic; however, the relationship between specific earthquakes and individual faults in the area is not well understood since few of these faults are expressed clearly at the ground surface and the foci of the observed earthquakes have not been located with precision.

2.7.3 Geologic Units

Fill

Fill materials are only anticipated to be encountered near the shoreline and where excavations extend beyond the banks of the river. The fill materials include loose to medium dense, clean to silty, sand to gravel with some wood and other debris, consistent with the historical development and frequent, local modifications to facility use type and operation.

Sand/Silt Alluvium

Sand/silt alluvium is anticipated to be present in nearly all excavation and dredging operations extending from the south end of the proposed alignments to within about 500 feet of the north riverbank. These materials include very soft/loose to stiff/dense silts and sands that are frequently interbedded and generally non-plastic to low plasticity.

Gravel Alluvium

Gravel alluvium is anticipated to be present in excavation and dredging operations extending from about 500 feet south of the north riverbank and continuing to the north. These materials include gravels with variable amounts of silt and sand, and sometimes appear as openwork gravels. This unit is documented as containing scattered cobbles and boulders.

Troutdale Formation

Troutdale may be present for a short distance at the base of dredging operations between about 1,000 feet and 500 feet south of the north riverbank. These materials may appear as a weakly to moderately cemented conglomerate which comprises gravels within a sand and silt matrix. Similar to the gravel alluvium, this unit is documented as containing scattered cobbles and boulders.

2.7.4 Geologic Hazards

Ground Shaking

An ITT would need to be designed to withstand the transient strains associated with ground shaking. Tunnels are regularly designed to account for ground behavior during a seismic event.

Liquefaction

Previous geotechnical studies conducted in this location found that saturated fill materials and silt/sand alluvium are likely susceptible to excess pore pressure development leading to liquefaction-induced strength loss, settlement and lateral spreading during a design seismic event. To mitigate against liquefaction effects, most particularly the potential for differential liquefaction-induced settlements along the tunnel alignment, it is expected that some level of ground improvement may be required. A discussion of ground improvement is provided in the Construction Considerations section.

2.8 Structural Design

A preliminary structural design was developed for the ITT cross-section. Dimensions of the section considered in-service loading and temporary conditions as the section is floated out and placed. The general arrangement and dimensions are shown in Figure 1.

The maximum interior clear height is assumed to be 21 feet with equipment niches of up to an additional 2 feet to allow for ventilation, fire suppression, signage, and lighting while maintaining the

required vertical clearance of 17 feet, 4 inches. The 2-foot equipment niches are located in the cut-and-cover sections of the facility.

2.8.1 Preliminary Analysis

Based on experience, the required structural dimensions are most often controlled by the transverse cross-sectional analysis. Because of this, a longitudinal analysis was not performed at this preliminary stage. A transverse analysis was performed for the cross-section. The section was checked for strength and service loads for moment, axial force, and shear demands, showing that the conceptual section depicted in Figure 1 is adequate.

ITTs can be subjected to several extreme load cases. These load cases are typically checked during later stages of design and were thus not checked as part of this conceptual assessment. These load cases include ship anchors, ship sinking and grounding, heat effects associated with a design fire, explosion, tunnel flooding, and loss of support during construction.

This cross-section (see Figure 1) allows for a buoyant condition during transport and would achieve an acceptable factor of safety against buoyancy during immersion.

3. CONSTRUCTION CONSIDERATIONS

The following sections identify considerations associated with construction of a tunnel facility. Focus is primarily on construction of the ITT section of the facility and the interfaces with the cut-and-cover sections on Hayden Island and in Vancouver.

3.1 Dredging and Excavation

Prior to placement of the ITT segments, a trapezoidal channel would be dredged, with the base of the trapezoid wider than the base of the immersed tunnel segment and side slopes laid back to minimize sloughing or raveling. Table 1 shows the anticipated preliminary excavation quantities on Hayden Island, in the Columbia River, and in Vancouver for the full cross-section shown in Figure 1.

Some of the dredged materials would typically be used as backfill over the rip rap protection layer. However, much of the excavated material would be replaced by engineered fill designed to protect the tunnel from scour and potential impacts, as well as to provide tunnel support both during construction and a potential seismic event. Figure 7 shows a cross-section of the conceptual dredge prism for the ITT across the Columbia River.

Table 1. Preliminary Tunnel Excavation Quantities

Location	Upstream Alignment	Downstream Alignment
Hayden Island (on land)	800,000 yd^3	1,000,000 yd^3
Columbia River (in water)	2,100,000 yd^3	2,300,000 yd^3
Vancouver (on land)	1,000,000 yd^3	1,100,000 yd^3
Total	**3,900,000 yd^3**	**4,400,000 yd^3**

3.1.1 Dredging Operations

Dredged materials are anticipated to consist primarily of loose/soft alluvial and fluvial-marine deposits that could be excavated using conventional methods. Any dredge operations would abide by jurisdictional permitting requirements, which could include the use of silt curtains and seasonal work-window limitations.

3.1.2 Dredging Configuration

For the purposes of this assessment, a 3H:1V slope was assumed for the cut slopes of the dredged prism when dredging in silt/sand alluvium and a 2H:1V slope when dredging in gravel alluvium and Troutdale Formation materials. This configuration could possibly be refined based on subsequent geotechnical and river hydraulic investigations.

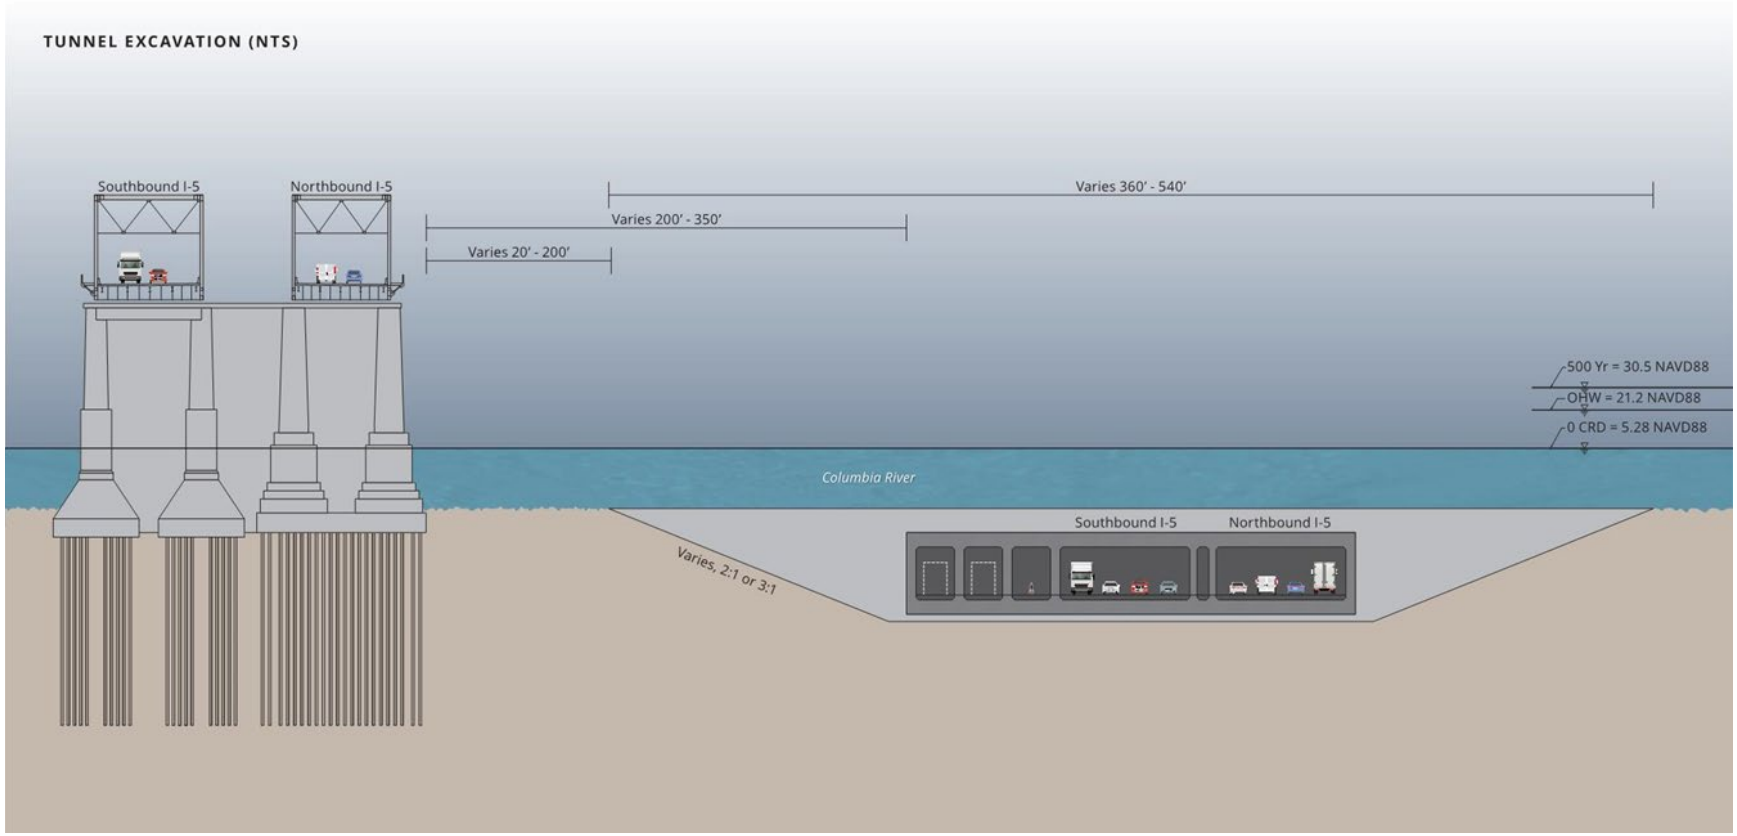
The dredge prism would continue to the north and south banks of the Columbia River. It is anticipated that the dredged prism would be approximately 2,800 feet in length. The quantities shown above in Table 1 are based on "neat line" excavation limits with a 10% allowance for over-excavation.

3.1.3 Dredging and Excavation Risks

The proximity of dredge slopes to the existing I-5 bridge foundations introduces a risk of foundation support loss or undermining. Temporary works to protect the existing foundations, if required, would be extensive, expensive, and have environmental impacts. Tunnel alignments are intended to minimize the potential for protective temporary works.

The excavation will also be under constant threat by sand perpetually swept downstream by the Columbia River. This would require supplemental dredging to clean out and re-establish the excavation geometry and possibly enlargement of the excavation to introduce intermediate benches aimed at capturing the migrating sand waves.

Figure 7. Estimated Excavation for ITT Construction



3.1.4 Shoreline Excavation

Excavation support would be required to facilitate excavations for the transition from the immersed tunnel segments to the cut-and-cover and retained cut segments. Support for excavations outside of the river would likely consist of sheet pile wall shoring systems that are anchored, braced, or some combination of the two. Potential conflicts between anchors and adjacent subsurface infrastructure were not evaluated as part of this assessment.

3.2 Ground Improvement

Ground improvement will likely be required to mitigate against liquefaction effects. Several ITTs designed and constructed in the recent past have included ground improvement programs to mitigate against these effects, such as stone columns for the Aktio-Preveza Tunnel (Greece) and the Limerick Tunnel (Ireland) or compaction grouting for the Marmaray Tunnel (Turkey). For the New George Massey Tunnel (Canada), multiple ground improvement options are being considered, including stone columns beneath the tunnel and cut-off walls on the sides of the new tunnel (to resist lateral spreading type deformations, limit the potential for interaction between the new and an existing tunnel, and limit the dredging footprint).

Any ground improvement program would need to consider and mitigate against the potential for adverse impacts during construction, including both environmental impacts and impacts to the existing Interstate Bridges. For example, grouting-type programs include the risk of cementitious material release into the river and displacement/replacement methods require vibration to advance a probe into the subsurface materials.

3.3 ITT Construction

3.3.1 Segment Fabrication

ITT segments are typically constructed in dry docks or casting basins adjacent to a navigable waterway. Many immersed tunnel projects have required the development of dedicated casting facilities designed specifically for the project, such as for the Fehmarnbelt Tunnel project (Denmark/Germany), though some have been able to utilize existing dry-dock facilities such as the Elizabeth River Tunnels project (Virginia). The cost to develop a project-specific casting facility is typically quite high. However, project constraints can often make this the only practical solution due to lack of adequate existing facilities and/or navigation challenges.

Due to the lack of suitable facilities in the region, it is expected that a new casting facility would need to be designed and constructed specifically for this project. Potential sites for a new casting facility were not identified or included as part of this assessment. It is recommended that any new casting facility developed for this project be sized to accommodate the simultaneous fabrication of multiple ITT segments as temporary float storage of segments and/or significant downtime between placement of immersed segments can increase project costs and risks.

3.3.2 Segment Delivery

The delivery of the tunnel segments would require coordination with private and public entities in the region to ensure navigation requirements were adhered to. Additionally, seasonal constraints, such as river levels, flow velocities, and in-water work windows, would need to be considered.

3.3.3 Segment Placement and Connection

After dredging is completed, a level bedding layer of gravel would be placed. The tunnel segments would be ballasted and lowered. Once the tunnel segments are aligned and set at the proper grade, any void space between the base of the segments and the gravel layer would be filled. When these phases are complete and an initial seal between tunnel segments is established, the water within the sealed zone between segments would be pumped out for construction of a final seal and structural connections.

3.3.4 Segment Cover and Backfill

The proper placement of lateral support and vertical protection and restraint materials is integral to the performance of the ITT. Lateral support is generally derived from keying/locking materials that compact naturally and that would remain stable under seismic conditions. The keying/locking materials and the tunnel segments would be covered with a blanket of well-graded stones followed by rip rap armoring to further lock the segment in place and provide protection against potential impact loads.

3.4 Cut-and-Cover and Retained Cut Construction

The ITT would be connected to the above-ground roadway network via cut-and-cover and retained cut connections at either end. Excavation support for these end connections could differ between Vancouver and Hayden Island, as excavations in Vancouver are anticipated to be primarily in gravel alluvium, whereas excavations on Hayden Island are anticipated to be primarily in silt/sand alluvium. The deepest excavations could require ground support systems consisting of braced or restrained secant pile or slurry walls, while shallower excavations may require less robust ground support systems. Ground improvement measures could be incorporated to decrease the potential for seepage through the base of the excavation and to provide long-term support for the constructed cut-and-cover and retained cut sections.

3.5 BNSF Railroad Coordination

Temporary shoring would be required to excavate and construct the cut-and-cover sections through Vancouver, including below the existing BNSF Railroad berm and tracks. Two methods of constructing the cut-and-cover tunnel below the BNSF tracks were considered. Both methods would require extensive coordination and permitting with BNSF.

The first would be a jacking procedure in which all or portions of the ITT cross-section would be advanced below ground using hydraulic jacks and a reaction structure.

The second method would reroute the existing tracks via temporary tracks, or a “shoo-fly” for the duration of construction. The cut-and-cover section could then be excavated and constructed in the BNSF right-of-way before the tracks would be restored over the newly constructed tunnel. There is limited right-of-way to accommodate a shoo-fly.

Provisions for either approach were not considered or included in this assessment.

3.6 Traffic Staging

During construction, I-5 maintenance of traffic would require complex staging, particularly south of Evergreen Boulevard in the vicinity of the historic post hospital, where the retained cut section attains grade. To maintain traffic during construction, additional right-of-way west of I-5 could be required.

4. OPERATIONAL CONSIDERATIONS

Tunnel facilities require an extensive variety of operating systems to support safe traffic operation and provide for life safety of motorists and emergency responders. The following sections address the systems required for traffic operation and fire/life safety. Information is presented based on the mode: highway, HCT, and MUP.

4.1 Highway

It is assumed that hazardous cargos would be permitted for this route. Hazardous cargos are normally banned from road tunnels, as the potential fire size is an extreme risk to both life safety and the facility itself. However, I-5 is an integral part of the Western US freight corridor. The fire size for a gasoline tanker can escalate to full heat release rate in a matter of minutes, creating a situation that is difficult, if not impossible, to manage or contain in terms of smoke control, firefighting, spill capture, and structural protection.

Certain elements of the fire protection and life safety systems have significant spatial requirements. Feasible concepts for these systems have been assessed to ensure that the conceptual tunnel structure has adequate space to accommodate them. Fire protection and life safety system elements with spatial impacts include:

- Emergency ventilation system
- Fixed fire suppression system
- Tunnel drainage system
- Emergency egress

The primary national standard for fire protection systems in road tunnels is NFPA 502, Standard for Road Tunnels, Bridges, and Other Limited Access Highways. The standard provides performance goals and general guidance for fire protection design.

For a tunnel of this length (6,500 feet, Category D), NFPA 502 mandates the following minimum road tunnel fire protection requirements:

- Emergency ventilation system sized to meet minimum ventilation requirements with one fan out of service or providing operational measures to ensure that life safety is not compromised with one fan out of service.
- Fire protection of structural elements. The structure shall be able to withstand the temperature exposure represented by the Rijkswaterstaat time-temperature curve or other recognized time-temperature curve approved by the authority having jurisdiction (AHJ), following an engineering analysis.
- Fire alarm control panel and detection, identification, and location of fire in the tunnel.
- Fire standpipe designed and installed in accordance with NFPA 14.

- Fire hose valve connections are required so that no location on the tunnel is more than 150 feet from a hose connection.
- An emergency power system in accordance with Article 700 of NFPA 70 is required, and it shall provide power to all major tunnel systems, including the ventilation system.
- Tunnel drainage collection system designed so that spills of hazardous and flammable liquids cannot spread or cause flame propagation.

The following requirements are conditionally mandatory pending the results of an engineering analysis:

- Water-based fire-fighting system
- Closed-circuit television and automatic fire detection systems

The tunnel would need to accommodate a variety of operational systems and features to support safe traffic operations and to provide the necessary level of fire protection and life safety, including:

- Emergency egress
- Normal and emergency tunnel ventilation
- Fixed firefighting system and fire standpipe
- Fire detection and alarm
- Emergency communications
- Roadway drainage
- Normal and emergency electrical power
- Supervisory control and data acquisition (SCADA)
- Roadway lighting
- Traffic control and monitoring
- Tunnel finishes and special signage
- Operations and maintenance

4.1.1 Highway Egress

The egress strategy would be a fire-rated corridor (cell) that runs between the NB and SB I-5 cells. The door spacing must be 1,000 feet or less; 600 feet is typical. Suitable emergency signage, lighting, and pressurization of the fire-rated corridor is also required.

The egress corridor should have a width of 6 feet to accommodate drainage pipes, water mains, and other services. The space above the egress envelope would house these items.

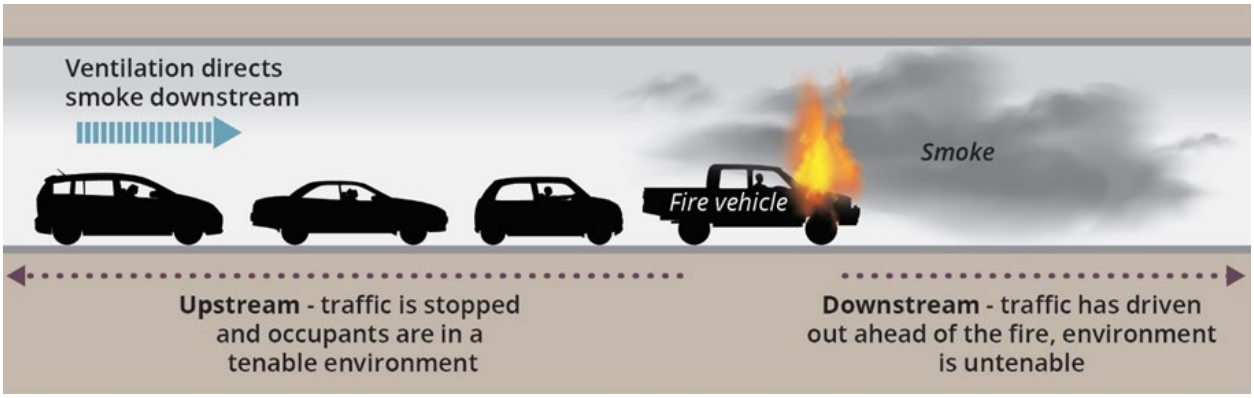
4.1.2 Highway Ventilation

Ventilation is required for normal operations (vehicle emissions management) and emergency operations (smoke management). NFPA 502 requires tenable conditions for egress and facilitation of conditions for firefighting. Achieving these conditions relies on ventilation, means of egress, and fire control. Based on the tunnel length and traffic configuration, a longitudinal ventilation system is recommended for this facility.

Portal emissions and air quality compliance in surrounding areas would be critical with a longitudinal ventilation system. If acceptable air quality cannot be achieved or maintained, then ventilation buildings at each portal would be required.

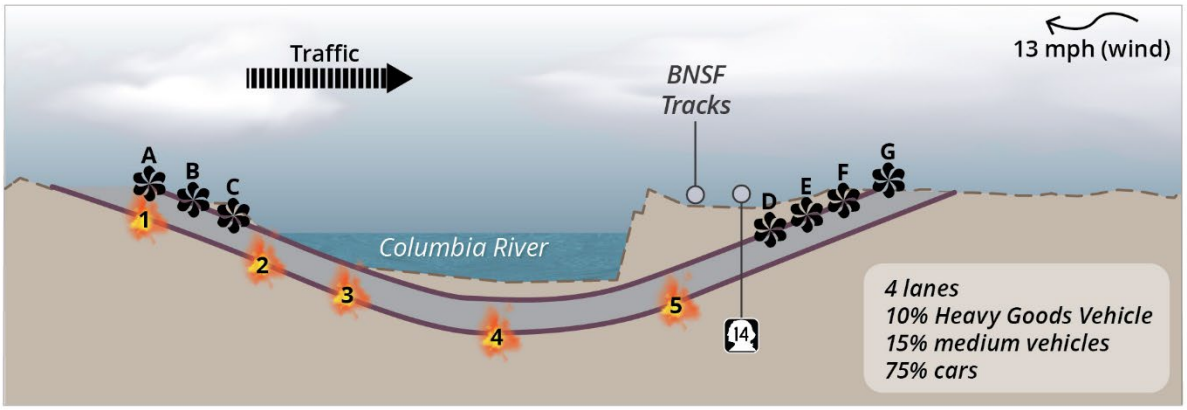
A likely ventilation concept based on one-way traffic would direct the smoke downstream of the fire site (vehicles downstream drive out ahead of the fire) in a longitudinal ventilation concept (see Figure 8).

Figure 8. Longitudinal Ventilation Concept



Jet fans would be placed in the cut-and-cover sections of the tunnel to generate the longitudinal airflow. A general fan arrangement is shown in Figure 9. Letters A through F indicate the approximate locations of the jet fan niches, while numbers 1 through 5 show approximate fire locations. There would be six to seven jet fans per niche. Assuming that hazardous materials would be permitted for this route, it would also be necessary to supplement the jet fans with an automatic sprinkler system.

Figure 9. Highway Tunnel Fan Layout



4.1.3 Highway Fire Protection Systems

NFPA sprinkler system requirements for tunnels include material properties, hydraulic performance, functional provisions for fire department interaction, system approval, and occupancy classification.

Roadway Fixed Fire Fighting System

The fixed fire fighting system (FFFS) would be an automatic sprinkler system providing water spray covering the entire roadway surface. The FFFS would be supplied with a permanent water supply from the local water utility. It is not anticipated that fire pumps or water storage tanks would be required, though holding tanks and treatment would be needed for the discharged water. The FFFS is also provided with fire department connections (FDCs) to allow responding fire departments to boost system pressure if needed.

Roadway Standpipe System

A fire standpipe system would be provided to supply fire hose valve outlets throughout both roadway cells at 275-foot intervals. The standpipe system would be supplied with a permanent water supply from the local utility. Should additional pressure be required, FDCs at the tunnel portals would be used to boost the pressure.

Structural Thermal Protection System

The extreme temperatures possible in a tunnel fire can do extensive damage to a tunnel's structural elements. Thermal protective board or other protective insulation would be required.

4.1.4 Highway Drainage Systems

Tunnel drainage systems normally consist of two independent systems: a stormwater control system and a tunnel drainage system. Stormwater control systems would be required at the tunnel portals to intercept stormwater flows that accumulate on the open approaches and transition roadways leading into and out of the tunnel. A separate tunnel drainage system, independent of inflow from sources outside the tunnel, would be required to collect and discharge water and effluents generated within the tunnel. These effluent flows would result from tunnel washing, use of fire suppression systems, vehicle carryover, and some seepage. The tunnel drainage system would also have to accommodate a potential fuel or hazardous material spill.

The profile of the selected tunnel alignment would dictate the tunnel's low point. A drainage pump station would be required at this location. Systems would also be required for the MUP, HCT, and egress cells. The tunnel drainage effluent would require some form of pre-treatment prior to discharge depending on local permitting requirements.

4.1.5 Highway Electrical Systems

Several electrical operating systems would be necessary to support safe traffic operations. Tunnel electrical systems would include:

- Normal power distribution
- Emergency power distribution
- Fire alarm and detection
- Emergency communications
- Security
- SCADA
- Communication systems

4.1.6 Highway Lighting Systems

The tunnel lighting system would provide the required illumination so that a motorist could safely navigate and maintain speed while in the tunnel. This objective must be met during daytime, nighttime, and during an emergency (loss of power). Daylight conditions require high levels of illumination at the tunnel's entry portals. Nighttime lighting levels are lower. During an emergency, lighting would be maintained at the nighttime level to allow for egress.

4.1.7 Traffic Control and Monitoring Systems

Roadway tunnels require a means for control of traffic within the tunnel, as well as traffic on the approach roadways leading into the tunnel. The types of traffic control systems and devices would likely include:

- Automatic incident identification system
- Closed-circuit television

- Variable message signs
- Lane use/control signals
- Over-height vehicle detection

4.2 Transit

The primary national standard for fire protection systems in underground trainways is NFPA 130. If LRT were selected as the HCT, these requirements would apply. (If BRT were selected as the HCT, NFPA 502 would apply; see Section 4.1 above.) NFPA 130 protection requirements include:

- Cross-passageways at a maximum spacing of 800 feet for egress
- An emergency power system for all tunnel systems
- Minimum clear walkway width of 24 inches for egress

The tunnel would need to accommodate a variety of systems to support safe operations, fire protection, and life safety. Various trainway tunnel systems would include:

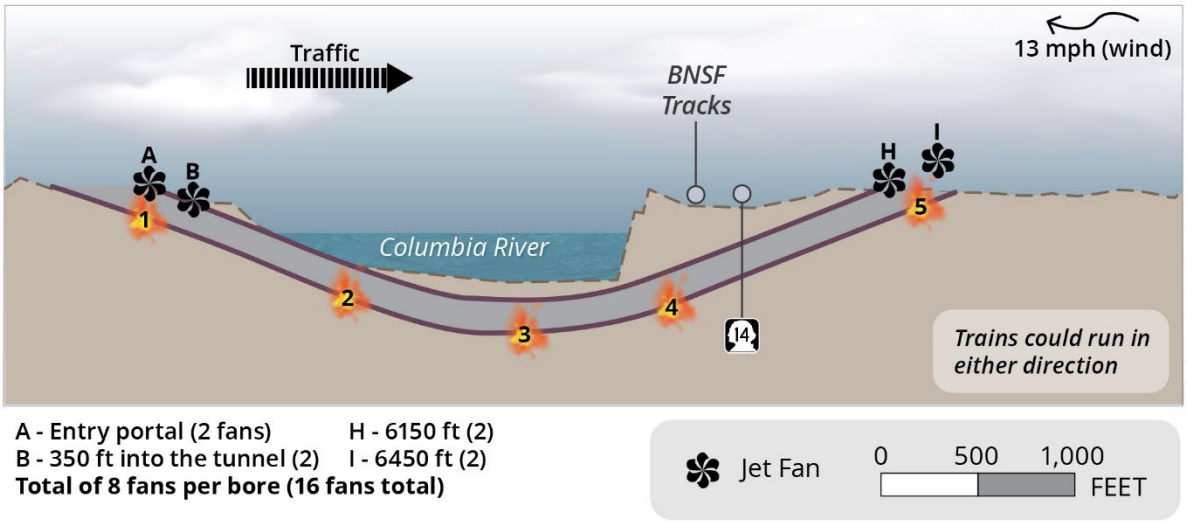
- Emergency egress
- Tunnel ventilation
- Fire protection
- Tunnel drainage
- Electrical systems
- Tunnel lighting
- Tunnel finishes (fire protection)
- Operations and maintenance

4.2.1 Transit Ventilation Systems

Ventilation is required for smoke management per NFPA 130. The design fire is representative of a fully engulfed railcar or bus.

Jet fans would be placed in the tunnel to generate the longitudinal airflow. Fans would be placed in the cut-and-cover sections. A general fan arrangement is shown in Figure 10. Letters A, B, H, and I indicate the approximate locations of the jet fan niches, while numbers 1 through 5 show approximate fire locations. There would be two jet fans per niche.

Figure 10. HCT Tunnel Fan Layout



4.2.2 Transit Fire Protection Systems

NFPA sprinkler system requirements for tunnels include material properties, hydraulic performance, functional provisions for fire department interaction, system approval, and occupancy classification.

Transit Standpipe System Configuration

A fire standpipe system would be provided to supply fire hose valve outlets throughout both HCT cells at 275-foot intervals. The standpipe system would be supplied with a permanent water supply from the local utility. Should additional pressure be required, FDCs at the tunnel portals would be used to boost the pressure.

4.3 Multi-Use Path

The MUP cell would require lighting, ventilation, drainage, security, and fire and life-safety systems.

Walkways and bikeways in tunnels are not uncommon, but there are no known MUPs in facilities of this length. Egress with respect to smoke management would need to allow people downstream of the fire enough time to reach an egress point. This is of particular concern because any doors from the MUP would lead either to the transit or roadway cells, creating a security and safety risk.

Based on experience, a ventilation system similar to that proposed for the transit tunnel would likely be enough to provide sufficient fresh air. Supply air would be provided via jet fans.

4.4 Operations and Maintenance

A comprehensive operations and maintenance program is necessary to ensure a safe, well-maintained, and reliable tunnel facility. The program would include emergency management plans, maintenance management plans, and operational procedure manuals.

A staffed operations center would be required for monitoring the mechanical, electrical, traffic control systems, and security. A tunnel system support building would be required at each end of the tunnel to house electrical distribution equipment, communications equipment, intelligent transportation system equipment, ventilation systems, fire systems, etc.

Additional facilities may include maintenance shops, garages, and storage spaces to house equipment and spare parts.

An operational ITT would require a full-time staff. A mix of personnel would be required, including electricians, mechanics, millwrights, and general maintenance staff to maintain the facilities and various systems.

5. ENVIRONMENTAL CONSIDERATIONS

This section provides a general overview of the environmental considerations associated with a tunnel alternative.

5.1 Biological

- In-water trenching during construction would disturb the river bottom across the entire width of the Columbia River, including the riverbanks.
- Dredged material would need to be placed in an in-water or upland site and may require special handling if contaminated materials are found.
- Disturbance to the river bottom and nearshore habitat would require mitigation.
- In-water construction would impact aquatic plants, fish, marine mammals, and birds.
- The tunnel would eliminate over-water shading.

5.2 Hazardous Material

- Excavation would cause disturbance and suspension of potentially contaminated sediment in the Columbia River.
- Large excavations required on land would potentially encounter contaminated soils requiring treatment and/or disposal in approved facilities.
- The volume of potentially contaminated material associated with tunnel excavation may exceed the capacity of existing disposal locations.

5.3 Historic Structures and Archaeological

- Historic structures and archaeological resources may be disturbed and permanently impacted due to the size and volume of excavation required for the tunnel.
- There are tribal concerns about burials along the Columbia River shoreline.
- Construction vibration could cause impacts to historic structures and archeological resources.
- The tunnel could impact Fort Vancouver and the Old Apple Tree Park.

5.4 Land Use

- Construction activities would impact businesses, neighborhoods, and parks and recreation areas. These impacts would include construction noise, vibration, and additional traffic congestion.
- Utility relocations would be required for the tunnel facility.
- Tunnel right-of-way would require negotiation with BNSF for construction impacts and temporary track reroutes.
- A tunnel would provide opportunities for trail connectivity on the Washington shore and increase the potential for more park space along the river.

- The tunnel provides an unimpaired viewshed along the river.

5.5 Navigation and Aviation

- A tunnel would not impact aviation operations at Pearson Field or Portland International Airport.
- The tunnel would eliminate navigation hazards in the river.

5.6 Permitting

- In-water work windows and related work restrictions would impact the construction schedule.
- It is yet to be determined whether existing dredge spoil disposal sites could accommodate the volume of sediment generated.
- Permitting a new dredge spoil disposal site may not be feasible to complete within the expected project schedule.

5.7 Safety and Emergency Response

- The tunnel would impact emergency response routes on both sides of the river.
- The MUP, which would be enclosed for over one mile, poses a safety concern for users.

5.8 Storm Water Management

- Once constructed, the tunnel would require a continuously operating low-point sump and pump system. The sump and pump system would require storm water retention and treatment facilities.

6. CONCEPTUAL COSTS

Conceptual costs were developed based on previously completed projects and the collective expertise of this team. These costs are for a facility that would accommodate I-5, HCT, and the MUP. Interchange costs are not included.

Based on the preliminary assessment, the downstream alignment would result in a deeper, longer, and therefore more expensive facility compared to the upstream alignment. As a result, conceptual costs in Table 2 are based on the upstream alignment and shown in 2021 dollars.

Ancillary facilities would include an operations building and fan plants.

The conceptual costs do not include an allowance for soft costs such as design, construction management, or right-of-way. The conceptual costs also do not include any allowance for contingency or life-cycle considerations. However, based on previous experience, operation and maintenance costs of the facility would be on the order of $465 million over a 75-year design life.

Table 2. Reasonable Order-of-Magnitude Construction Costs

Description	Conceptual Cost
ITT	$890,000,000
Cut-and-cover	$1,305,000,000
Retained cut	$170,000,000
Ancillary facilities	$150,000,000
Total cost	**$2,515,000,000**

7. SUMMARY

The following is a summary of the considerations associated with the ITT concept.

7.1 Design

- Upstream and downstream tunnel alignments were considered.
- The facility would consist of an ITT for in-water sections, transitioning to cut-and-cover tunnel sections beyond the river and then into a retained cut (U-section) until I-5 attains grade.
- At the south end of the facility, I-5 would attain grade near the south shore of Hayden Island.
- At the north end of the facility, I-5 would attain grade near Evergreen Boulevard.
- The facility would consist of six cells: four lanes for NB I-5 and four lanes for SB I-5, a MUP, NB and SB HCT, and a maintenance/egress corridor. Each mode and direction are separated by a wall.
- Maximum grades for the tunnel would be approximately 4.5% controlled by highway design requirements.
- The ITT depth would be controlled by the authorized depths of the statutory Columbia River navigation channels.
- The ITT would be designed to meet current seismic safety standards.
- The combination of the controlling grades and the depth of the river channel would require interchange access modifications. Connectivity to Hayden Island, downtown Vancouver, and SR-14 would be extremely difficult and require unconventional construction below grade.

7.2 Constructability

- Large excavations in excess of 70 feet deep at the Washington shoreline and in excess of 30 feet deep on Hayden Island would be required to facilitate construction of the cut-and-cover tunnel sections.
- The high groundwater and permeable soil would require extensive measures, such as temporary shoring and dewatering systems, to provide a suitably dry and stable excavation for construction of the cut-and-cover and retained cut sections.
- The proximity of in-water and on-land excavations to the existing Interstate Bridges' foundations could require extensive temporary works to preserve the structural integrity of the existing bridges during ITT construction. The alignments considered sought to avoid this risk.
- Washington excavations would require temporary relocation of the dual BNSF mainline tracks or complex staged and phased construction techniques.
- Maintenance of traffic on I-5 would require complex staging south of Evergreen Boulevard in the vicinity of the historic post hospital.

- Due to the lack of suitable facilities in the region, it is expected that a new casting facility would need to be developed.

7.3 Operations

- The ITT would require an operations and maintenance/egress tunnel from end to end between NB and SB I-5.
- Extensive fire and life safety systems would be required.
- The ITT would require a continuously operational low-point sump and pump system.
- Operations and maintenance equipment housing would be required at each end of the facility.

7.4 Environmental Considerations

- In-water excavation would require approximately 2 million cubic yards of material. Total excavation for the tunnel facility would be approximately 4 million cubic yards of material.
- In-water construction would impact aquatic plants, fish, marine mammals and birds.
- Excavations in the vicinity of SR-14 would likely encounter cultural resources.
- In-water work windows and related work restrictions would impact the construction schedule.
- A tunnel would not impact aviation operations at Pearson Field or Portland International Airport.
- The tunnel would eliminate navigation hazards in the river.

1. INTRODUCTION

The Interstate Bridge Replacement (IBR) program will replace the existing Interstate 5 (I-5) bridges crossing the Columbia River between Vancouver, Washington, and Portland, Oregon. Multiple design options are being considered for the bridge replacement.

In June 2022, the U.S. Coast Guard (USCG) responded to the IBR's program's Navigation Impact Report and issued a Preliminary Navigation Clearance Determination (PNCD) for the IBR program that prescribed the vertical and horizontal navigation clearance that would have a high likelihood of obtaining a favorable permit decision. The PNCD indicated that vertical navigation clearance over the Columbia River is currently, and needs to continue to be, equal to or greater than the existing I-5 bridges' clearance of 178 feet. The USCG also requires that the horizontal navigation clearance meet the U.S. Army Corps of Engineers' (USACE) requirement. The IBR program's Navigation Impact Report assumed a mid-level fixed span bridge providing 116 feet of vertical clearance (herein referred to as the Fixed Span Bridge) and a horizontal navigational clearance of 300 feet with an additional 50 foot buffer on either side of the navigation channel.[1] A movable span bridge is an option that could achieve 178 feet of vertical clearance. The purpose of this report is to clarify the implications of using a movable span bridge that would use a dynamic mechanical design to provide 178 feet of or unlimited vertical clearance as needed for vessel passage.

The IBR program assembled a group of professional engineers, including those with international experience in movable bridge design and construction, to provide a comprehensive conceptual review of the suitability of a movable bridge span that would provide a navigational opening with a vertical clearance that meets or exceeds that provided by the existing movable bridge span.

The following three movable span options were investigated from interdisciplinary perspectives, including design, construction, operations, environmental considerations, and cost considerations:

1) **Vertical lift span** (178 feet of vertical clearance)

2) **Bascule span** (unlimited vertical clearance)

3) **Swing span** (unlimited vertical clearance)

[1] The USCG made a preliminary determination of a 400-foot-wide navigation channel based on an authorized 300-foot channel plus 50-foot additional clearance on each side requested by the USACE for channel maintenance. In the event the federal agencies reconsider and allow a 300-foot-wide navigation channel, the design, construction, operation, and environmental considerations for a movable bridge span as described herein would be similar to those reported for the 400-foot-wide channel. The USACE decision to allow modification to the navigation channel buffer requirements is pending. The conceptual costs shown in this report are based on historical costs per square foot, so for comparison purposes, the cost for 300-foot-wide navigation channel options can be estimated at 75% of the cost for the 400-foot-wide navigation channel options.

The concepts assessed in this report are preliminary. They are not under design and remain at the planning conceptual level. They will not be advanced to the design stage until or unless deemed appropriate by program leadership.

2. FIXED SPAN BRIDGE

The IBR program will replace the existing I-5 bridges crossing the Columbia River between Vancouver, Washington, and Portland, Oregon. For comparison purposes, this assessment assumes a Fixed Span Bridge comprising two side-by-side fixed-span bridges as the basis for the river crossing (Figure 1). The upstream bridge would accommodate northbound I-5 lanes on the upper deck and a shared-use path (SUP) on the lower deck. The downstream bridge would accommodate southbound I-5 lanes on the upper deck and two-way light rail transit (LRT) (two tracks) on the lower deck. The roadway would consist of three through-lanes and one auxiliary lane in each direction, along with full inside and outside shoulders.

The Fixed Span Bridge's alignment provides a horizontal tangent across the river and allows for the ability to construct a new bridge and maintain traffic on I-5 during construction. The two bridges have a horizontal curvature introduced in the north two spans (between Piers 6 and 8) as the bridge approaches Vancouver. Based on past work, the Fixed Span Bridge is assumed to have a grade of just under 4% as it transitions from each land side of the river with a long crest vertical curve providing the high point for navigation at the proposed primary navigation channel.

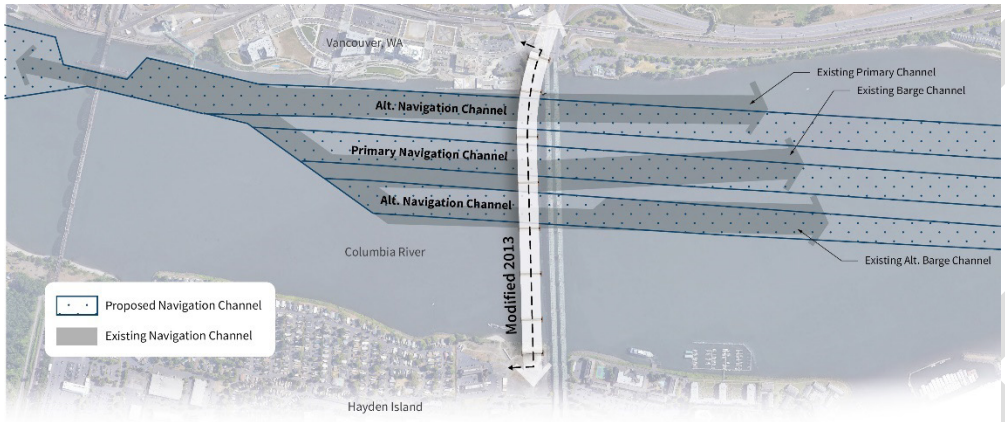
3. MOVABLE SPAN OPTIONS

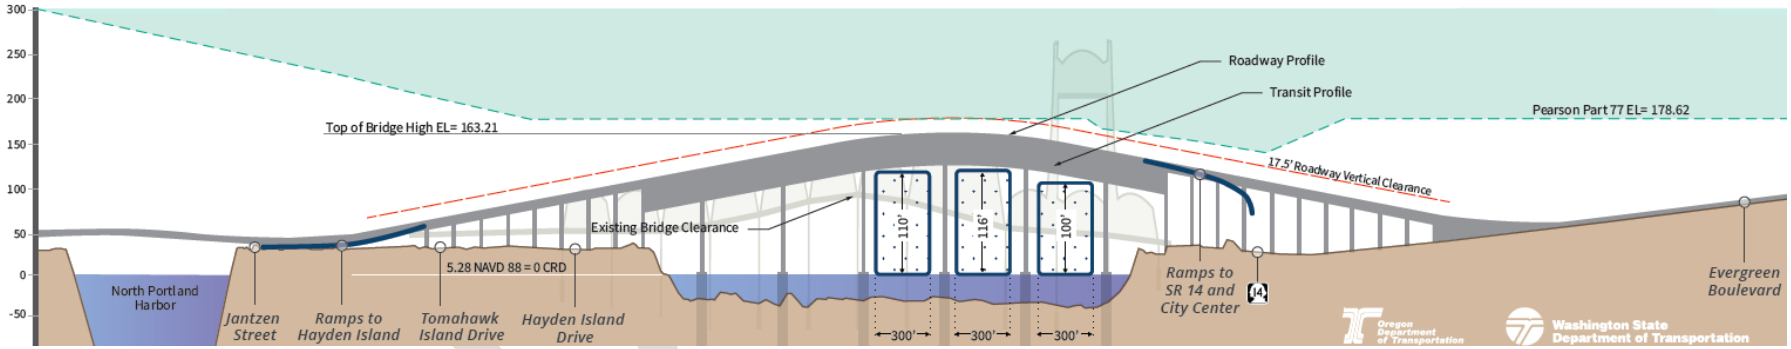
This assessment assumes that the upstream and downstream fixed spans between Piers 5 and 6 of the Fixed Span Bridge, which flank the proposed primary navigation channel, would be replaced with movable spans. The movable spans would accommodate vehicular traffic, LRT, and a SUP and would be among the largest of their kind in the world.

The three types of movable spans considered are described as follows:

1. A **vertical lift span** is similar to the type of movable span that exists on the crossing today, in which the span would rise vertically while remaining parallel with the deck.
2. A double-leaf **bascule span** would open in the middle, with each leaf rotating from a normal horizontal position to a nearly vertical position; to reach this position, each leaf would pivot around a horizontal axis on trunnion shafts attached to each side of the span.
3. A **swing span** is similar to the downstream BNSF Railway (BNSF) bridge; in this design, the span opens by pivoting on a central pier and then rotating in a horizontal plane around a center support (vertical axis). For the IBR program, two swing spans would be required in order to provide the necessary horizontal clearance.

Figure 1. Mid-Level Fixed Span Bridge Plan and Profile





3.1 Vertical Lift Span

Vertical lift span bridges have been constructed with navigation channel (horizontal) clearances in the range of up to 500 feet and vertical clearance of approximately 200 feet. This type of span would provide a predetermined vertical clearance for river navigation, which, in this case, has been prescribed by the USCG to meet or exceed that of the current lift span (178 feet).

The cross-section of a vertical lift span would be consistent with that proposed for the Fixed Span Bridge with two[2] double-deck side-by-side bridges. The upstream bridge would have northbound I-5 lanes on the upper deck and a SUP on the lower deck, and the downstream bridge would have southbound I-5 lanes on the upper deck and two-way LRT on the lower deck.

The lift spans would be located between Piers 5 and 6 to provide up to 178 feet of vertical clearance over the proposed primary channel. Vertical lift spans are required to be on a straight section of bridge that has a level (or nearly level) deck.

Figure 2 shows an example of a single double-deck vertical lift bridge in Houghton, Michigan. The IBR program would require two side-by-side double-deck vertical lift bridges to accommodate multimodal traffic.

Figure 2. Double-deck Vertical Lift Bridge Example – Portage Lake Bridge, Houghton, MI

3.2 Bascule Span

The practical limit for a double-leaf bascule span is approximately 350 feet long. If the IBR program were to use this type, the bascule spans would hinge from Piers 5 and 6 to provide unlimited vertical

[2] The combination of the length, width, and depth of the lift spans required for the IBR program would result in one of the biggest, if not the biggest, lift span in the world. A single wider lift span was not considered as it would significantly exceed the widest movable bridge span in the world.

clearance over the proposed primary channel. Bascule spans are required to be on a straight section of bridge that has a level (or nearly level) deck.

A double-leaf bascule arrangement would be needed to accommodate the required width of the navigation channel. This option could be accommodated by a two-bridge double-deck arrangement[3] similar to the Fixed Span Bridge. Figure 3 shows an example of a double-deck double-leaf bascule bridge in Chicago, Illinois.

Figure 3. Double-deck Double-leaf Bascule Bridge Example – Wells Street Bridge, Chicago, IL

3.3 Swing Span

The swing span option would require one double-deck swing span on Pier 5 and one on Pier 6. The spans would be approximately 150 feet wide to accommodate the width of both directions of I-5 on the upper deck and LRT and the SUP on the lower deck. The swing spans would pivot on Piers 5 and 6 to provide unlimited vertical clearance for river navigation on the primary navigation channel. The span would need to be approximately 550 feet long to provide the 400-foot-wide horizontal river

[3] Due to the machinery required to operate movable spans of this size, the bascule span option could also comprise three single-deck bridges by adding a third bridge, such that the upstream bridge would accommodate northbound I-5, the adjacent downstream bridge would accommodate southbound I-5, and a third bridge would be adjacent to the southbound I-5 bridge and accommodate LRT and the SUP.

navigation channel (400 feet to accommodate the authorized width of 300 feet plus a buffer of 50 feet on either side for advanced dredging as specified by the USACE).

The cross-section of a swing span would be similar to that proposed for the Fixed Span Bridge, except there would be one bridge instead of two. Northbound and southbound I-5 would be on the upper deck, and a SUP and two-way LRT would be on the lower deck.

Figure 4 shows an example of a single-deck double-swing bridge in York County, Virginia. For this assessment, the swing span would be double-deck.

Figure 4. Single-deck Double-swing Bridge Example – Coleman Bridge, York County, VA

4. DESIGN CONSIDERATIONS

4.1 Columbia River Navigation

Operational requirements for vessel navigation and channel maintenance on the Columbia River would define the length of the movable span.

The USACE maintains the authorized federal navigation channels on the Columbia River. River navigation features are authorized for specific locations, widths, and depths. Navigation features differ upstream and downstream of the existing I-5 bridges, as shown in Figure 5, Figure 6, and Figure 7. As shown, and described further below, there are three navigation channels and a turning basin designated at the location of the existing bridges.

Figure 5. Columbia River Navigation Channels

Figure 6. Navigation Channel Downstream of the Exisiting Bridge

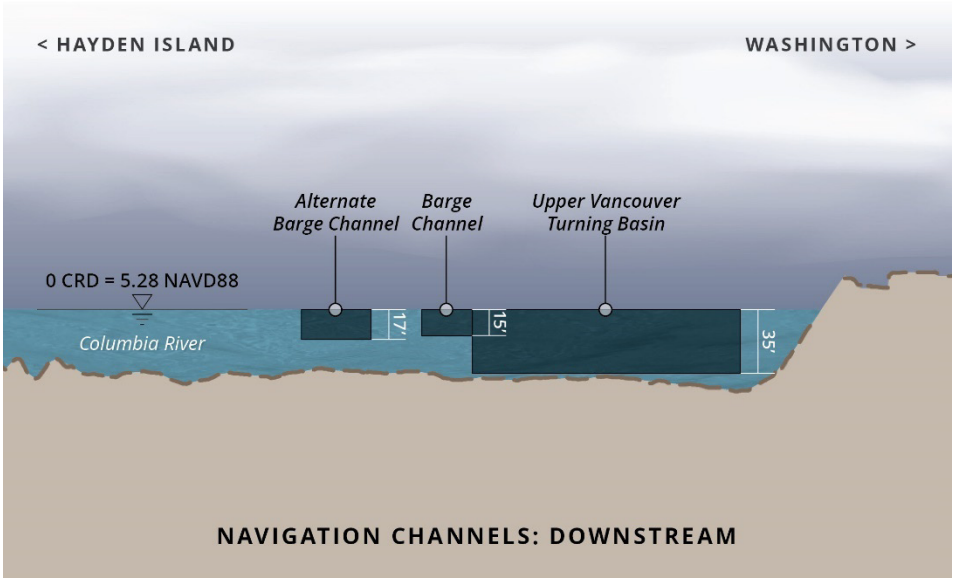


Figure 7. Navigation Channel Upstream of the Existing Bridge

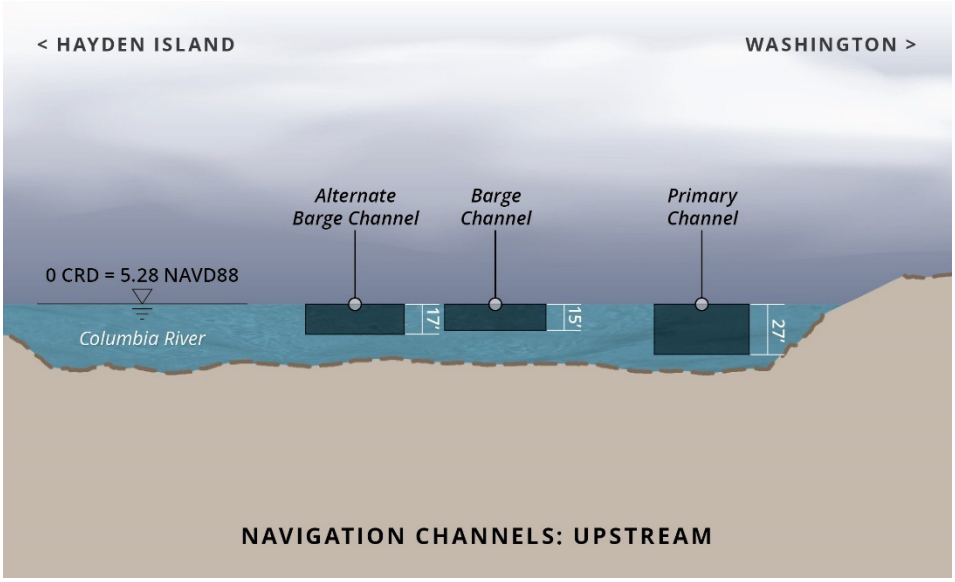


The Vancouver to The Dalles project[4] begins just downstream of the existing I-5 bridges and was originally authorized by the Rivers and Harbors Act of 1937. The authorization specifies a channel 300 feet wide and 27 feet[5] deep. The USACE maintains the channel to 17 feet deep based on current uses. However, the dredging analysis completed in 2014 for the Columbia River Crossing (CRC) project shows that the USACE has not dredged at this location for at least 25 years and that the river naturally maintains a depth greater than 17 feet. None of the movable span options would constrain dredging operations in any way.

Two alternate channels were authorized subsequent to the Vancouver to The Dalles project to accommodate vessel traffic that does not need the vertical clearance provided by the existing lift span. The Alternate Barge channel has an authorized width of 200 feet under the bridge and 300 feet upstream of the bridge, with a depth of 17 feet, and the Barge Channel has an authorized width of 300 feet and a depth of 15 feet. The Upper Vancouver Turning Basin, downstream of the existing I-5 bridges, has an authorized depth of 35 feet (see Figure 6).

The USACE has indicated that an additional 50 feet on each side of the channel is needed for advanced maintenance dredging to accommodate potential side slopes for unstable sloughing of material. Vessels navigating upstream of the BNSF railroad bridge are restricted by the 150 feet of horizontal clearance provided by that bridge. In addition, vessels with origins or destinations above Bonneville Dam are restricted by the 86 feet of horizontal clearance provided by the locks.

The USCG publishes bridge guide clearances for certain navigable waters of the U.S. Compliance with these guide clearances will ordinarily receive favorable consideration under the bridge permitting

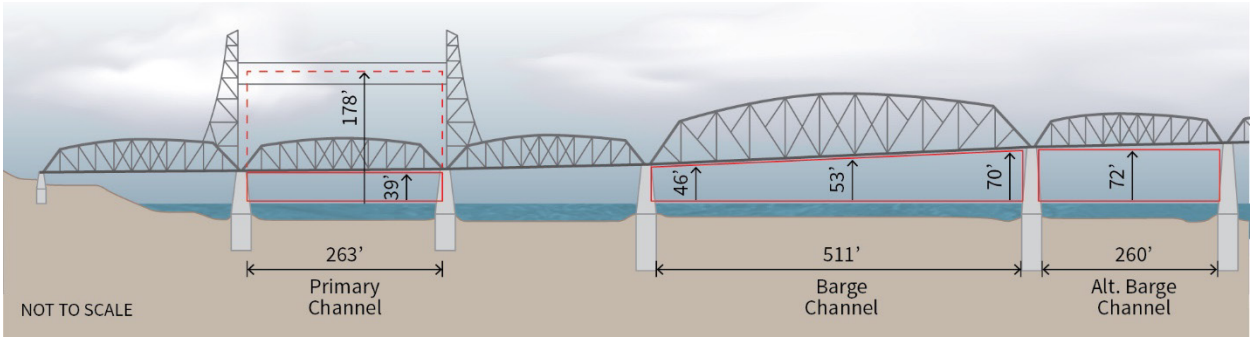
[4] https://www.nwp.usace.army.mil/Missions/Navigation/Channels/Vancouver-to-The-Dalles/
[5] All channel depths are relative to 0 feet Columbia River Datum.

process as providing for the reasonable needs of navigation. According to the clearance guide for the Columbia River, the horizontal navigational clearance is indicated as 450 feet.[6] The USCG notes that guide clearances are not intended to be regulatory, and greater or lesser clearances may be required or approved as necessary to meet navigation needs at a particular location.

The USCG's PNCD specified that the minimum required horizontal clearance must be greater than or equal to that of the current or future permitted USACE federal navigation channel projects. This results in a minimum horizontal width between bridge elements of 400 feet to accommodate the authorized width of 300 feet plus a buffer of 50 feet on either side for advanced dredging as specified by the USACE. The USACE may accept a reduction in the required buffer based on conditions at the site. The existing river depths are greater than the current depth to which the channel is maintained, and there are no side slopes present. This request would be considered as part of the Section 408 Authorization process that is required by the USACE to modify the navigation channel locations and the bridges spanning the navigation channels. If approved this could reduce the horizontal width between bridge elements.

In addition to horizontal clearance, vessels' vertical clearance requirements are relevant to the height of the movable span when open or closed and to adjacent fixed spans. As noted earlier, a movable span would provide either a vertical clearance equivalent to the existing lift span (178 feet) or unlimited vertical clearance (bascule span or swing span). The existing I-5 bridges are only opened for approximately 5% to 7% of river traffic. Because the height of the existing bridge accommodates the majority of vessel traffic, the existing clearances provided by the bridge can be used as a starting point to determine a preferred height of fixed and closed spans to be able to reduce the bridge height as much as possible for costs and other reasons while minimizing the need for an opening and resulting delays to vehicles on I-5, transit, and active transportation. Figure 8 shows the vertical clearances provided by the existing I-5 bridges at both the lift span and fixed spans that align with the federal navigation channels.

Figure 8. Vertical Clearances Provided by the Existing Bridges



*Vertical clearance shown relative to 0 feet Columbia River Datum

[6] The published guide clearance also specifies a vertical clearance of 135 feet as measured from a river stage of 600,000 cubic feet per second. This is superseded by the PNCD issued by the USCG and described in Section 1.

As part of USCG requirements for the Section 9 Bridge Permit, the IBR program completed a Navigation Impact Report that included a survey of vessels that typically pass through the location of the bridge, including their vertical clearance needs. This information can be used to inform the appropriate vertical clearance of the movable span in the closed position or alternate fixed spans so that a height can be selected that is as low as possible but still accommodates the majority of vessel traffic without the opening of a movable span. Table 1 lists the number of estimated openings per year and the number of vessels that would require an opening and could be restricted from passing at specific times when the bridge is restricted from opening per federal regulations. This does not include separate openings that may be needed for maintenance and training. The Code of Federal Regulations (CFR) stipulates that the current bridge shall not be opened for vessels Monday through Friday from 6:30 a.m. to 9 a.m. or from 2:30 p.m. to 6 p.m. (CFR Title 33 Chapter I Subchapter J, Part 117 § 117.869) corresponding to peak commute times. A replacement bridge with an opening would likely include similar restrictions and, depending on the vertical clearance provided in the closed position, may seek to further restrict openings to the period of lowest vehicular traffic (i.e., midnight to 4 a.m.).

Table 1. Number of Bridge Lifts per Year by Vertical Clearance

Bridge Height[a] (closed or highest fixed span)	Estimated Openings/Year	# of Vessels / Users Requesting a Bridge Opening
116 feet[b]	85[c]	9[d]
95 feet	154[e]	53[e]
72 feet	157[f]	270[g]

a. Bridge heights as measured from 0 feet Columbia River Datum. For purposes of calculating potential bridge openings, water is assumed to be 16 feet Columbia River Datum.

b. During the CRC Project, mitigation agreements were negotiated with the four impacted users that were unable to modify operations (such as accepting an air gap of less than 10 feet) in order to transit a bridge height of 116 feet. Three upstream fabricators entered into mitigation agreements with the CRC Project. The anticipated mitigation agreements would have resulted in payments to the companies that would be used by the companies at their business discretion and control. Payments were never made as the project was stopped. The remaining vessel owner decided to terminate negotiations that involved a payment to compensate the owner for vessel modifications and an agreement was never finalized. Compared to a fixed bridge, a movable bridge may not require mitigation to compensate for impacts to river users.

c. Based on vessels identified in the 2021 Navigation Impact Report and reported frequency of transit provided by user.

d. Represents worst case scenario. Five of the nine vessels would not require an opening based on mitigation such as accepting a lesser air gap, thereby also reducing the estimating openings per year.

e. Based on the CRC Navigation Impact Report and updated with 2012 to 2020 lift data and updated user information from the 2021 Navigation Impact Report.

f. Based on the average number of lifts for vessels for the existing bridge from 2012 to 2020 as 72 feet is the height of the highest fixed span on the existing bridge. This likely overestimates the number of openings by a small number as some openings are not due to height constraints.

g. Represents the number of distinct vessels noted in bridge logs from 2012 to 2020. Not every vessel requires a lift every year, and some vessels occur only once in the data.

The movable span would need to span the Vancouver to The Dalles channel as this is the primary channel to accommodate river navigation. To accommodate grades, roadway connections, and the need for the movable span to be located in a tangent (straight and flat) section, the Vancouver to The Dalles channel would be moved south to the approximate location of the existing barge channel.

4.2 Aviation

A movable span could result in a crossing that continues to impact the Pearson Field Part 77 Airspace.[7] The IBR program would be required to submit a Form 7460 for the program's design (by the designer) and one for construction (by the contractor). Each form would delineate any penetrations of the Part 77 Surface that would occur (permanent works relative to design and temporary works pertaining to construction). The Federal Aviation Administration (FAA) would use that information to determine if the proposed facility *poses a hazard to air navigation or causes inefficient use of airspace.* If a hazard or inefficient use of airspace determination results, adjustments to the bridge or construction means and methods may have to be incorporated. Alternatively, it may be possible to restrict construction and/or airfield operations to accommodate any temporary intrusions. Permanent intrusions could require permanent airfield operational adjustments and the bridge owner would likely have to assume liability for any mishaps associated with the penetration(s). In the event the bridge is determined to be a hazard and/or results in efficient use of airspace, the Authority Having Jurisdiction would have the option to take legal action to force a revision to or termination of the development.

With a vertical lift, the lift towers would encroach permanently into FAA airspace. Two of the movable span options—bascule and swing—would improve aviation operations into and out of Pearson Field over the existing condition. The degree of improvement depends on the associated profile, signing, and lighting on the bridge, and the hours of operation of the bascule span. When open, the bascule span leaves would encroach into FAA airspace. When closed, a bascule span would not encroach into FAA airspace. A swing span would not cause an obstruction when open or closed.

4.3 Alignment and Profile

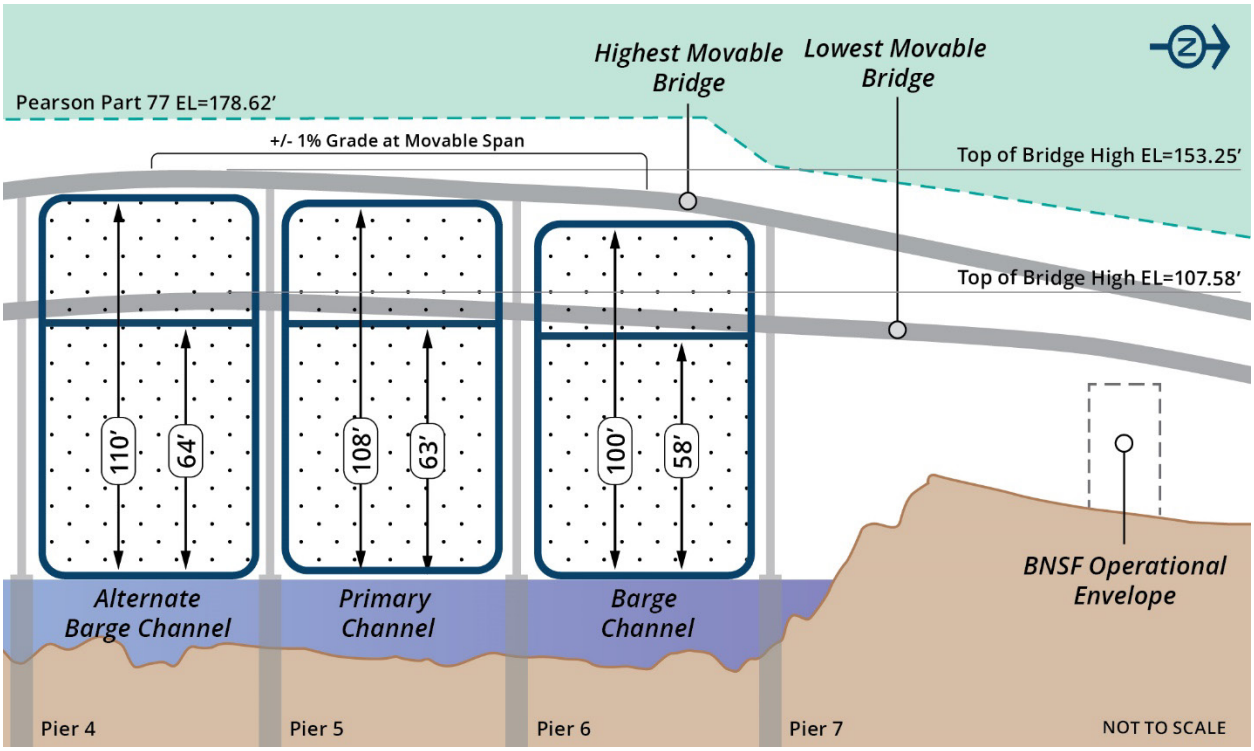
With a movable span, the I-5 alignment would be the same as that proposed for the Fixed Span Bridge (see Section 2 and Figure 1). Regardless of option, the movable span would need to be located in the straight section of the bridge (i.e., south of the current vertical lift span and current primary channel location). The Fixed Span Bridge's profile grade would also need to be altered to provide a level (or near level) profile at the movable span (between Piers 5 and 6). The Fixed Span Bridge's profile does not provide the nearly level profile necessary for a movable span. However, a lowered profile would allow a nearly level section to be located over the proposed primary navigation channel between Piers 5 and 6. A range of profiles is feasible. The profile would be determined based on the desired navigation clearance without a bridge opening. Figure 9 illustrates the bounds of moveable span

[7] Federal Aviation Administration (FAA) Title 14 CFR Part 77, Objects Affecting Navigable Airspace.

bridge heights with the highest and lowest profiles shown and the corresponding vertical navigation clearances.

Lowering the profile would improve operational grades for the highway. The length of the approximately 4% grade portion on both sides of the river would be shorter and could result in improved speed for freight vehicles as they climb the grade between land and the high point at the navigation channel. Lowering the grades would also lower the profile of I-5 over Hayden Island. However, the need to clear the BNSF rail line on the north side of the river would control the profile requirements on the Vancouver end of the bridge.

Figure 9. Movable Bridge Profiles



Note: The USCG's PNCD requires a vertical clearance of at least 72 feet from the barge channels to match the existing high fixed span clearance. Therefore, the lowest possible movable bridge elevation would increase by approximately 14 feet.[8]

4.4 Structural Considerations

The Fixed Span Bridge would have a variety of structural considerations (e.g., load, seismic, etc.). However, the Fixed Span Bridge would not include any mechanical systems to move spans of the

[8] The lowest possible movable span bridge profile shows 58 feet of vertical clearance over the Barge Channel. To provide 72 feet of vertical clearance, the bridge elevation would need to increase by 14 feet.

bridge, as would be required for the movable span options. The following sections identify some of the additional structural considerations that would need to be accounted for with the movable span options.

Vertical Lift Span

The vertical lift span option would require substantially tall towers to support the bridge in the open position. Due to machinery constraints and the counterweight rope connections, these towers would be up to 60 feet taller than the navigation clearance required, similar to existing conditions. As the height of the towers rises, their resultant cost increase at a non-linear rate. This is due to the steep increase in wind and seismic loading considerations at greater heights.

Bascule Span

Bascule bridges can experience operational problems due to span imbalance, keeping counterweight pits dry, and issues with center locks for a double-leaf bridge. The substructure of the bascule span requires larger concrete piers and massive foundations for each leaf, two machinery systems, and more moving parts (e.g., gearworks, etc.) and joints to maintain than other movable span options.

Bascule bridges must resist wind and seismic loading to a greater extent than other common movable bridge types. These load considerations require bascule bridge machinery to be more robust than it otherwise would have to be and are a bigger part of the machinery design than for vertical lift or swing bridges.

Swing Span

Swing bridges provide a low profile and do not require expensive counterweights. A swing bridge can thus be built with smaller piers than a bascule or vertical lift bridge. The swing spans can be through girders, truss, steel, or concrete, and a double-swing bridge can span up to 600 feet in length. Wider swing bridges require a wide center pier and are normally protected by an extensive fender system, which would increase the bridge length to meet the navigation channel width requirement, thus increasing the cost and time to operate the swing bridges.

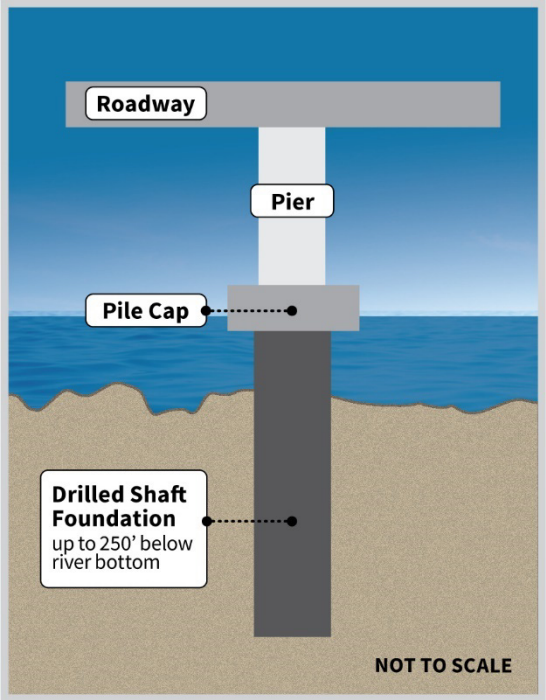
A swing bridge requires more machinery than a bascule or vertical lift bridge. The swing bridge does not automatically align itself when closing and requires an active centering device to quickly align it in the closed position, something not required for bascule bridges or vertical lift bridges. The typical swing bridge also requires end-lifting devices to hold up the ends of the bridge when carrying traffic. The end lifts must develop a positive dead load reaction, as required by the American Association of State Highway and Transportation Officials, so that deflection of the opposite arm of the swing span, due to live load, will not cause the end of the span to lift off its supports.

4.5 Geotechnical Considerations

Deep foundations would be required to support either a fixed or movable span over the Columbia River (see Figure 10). Conceptually, multiple drilled shafts approximately 10 feet in diameter and

extending up to about 250 feet below the river bottom would form the foundation for each pier for either bridge type (fixed or movable). What distinguishes a movable span is the size of the foundation needed for support. Because it is essentially a machine, a movable span would require more substantial river piers and pier foundations to support the span as compared to a fixed span because the movable parts are more sensitive to foundation settlement. This ensures smooth operation during repeated opening cycles over its lifetime. The design would favor consistent diameters of drilled shafts for the in-water work (constructability, economy of scale). The primary difference between piers that support fixed and movable spans is that the latter would require more drilled shafts to ensure adequate stiffness. More shafts translates to a larger foundation cap, which increases the footprint in the river.

Figure 10. Bridge Foundation Concept



4.6 Highway Traffic

4.6.1 Daily Traffic Profiles

Figure 11 and Figure 12 show the existing overall weekday traffic volumes (service volumes) on the I-5 northbound and southbound bridges, respectively. “Service volume” refers to the volume that is actually served during each hour, as opposed to the “demand volume,” which indicates the volume that would ideally be served.

As shown in Figure 11, between 6 a.m. and 11 p.m., there are over 2,000 vehicles per hour driving over the northbound I-5 bridge. The highest volume of northbound traffic occurs between 4 p.m. and 5 p.m. when approximately 4,800 vehicles cross the I-5 bridge from Portland to Vancouver.

Figure 12 shows there are over 2,000 vehicles per hour traveling over the I-5 southbound bridge between 4 a.m. and 9 p.m. The highest volume of southbound traffic occurs between 6 a.m. and 7 a.m., when approximately 5,500 vehicles cross the I-5 bridge from Vancouver to Portland.

The hour with the most vehicles crossing the I-5 bridges in both directions is 5 p.m. to 6 p.m., when approximately 9,000 vehicles are crossing the river.

Figure 11. Interstate Bridge Hourly Profile – Overall Northbound Weekday Service Volumes

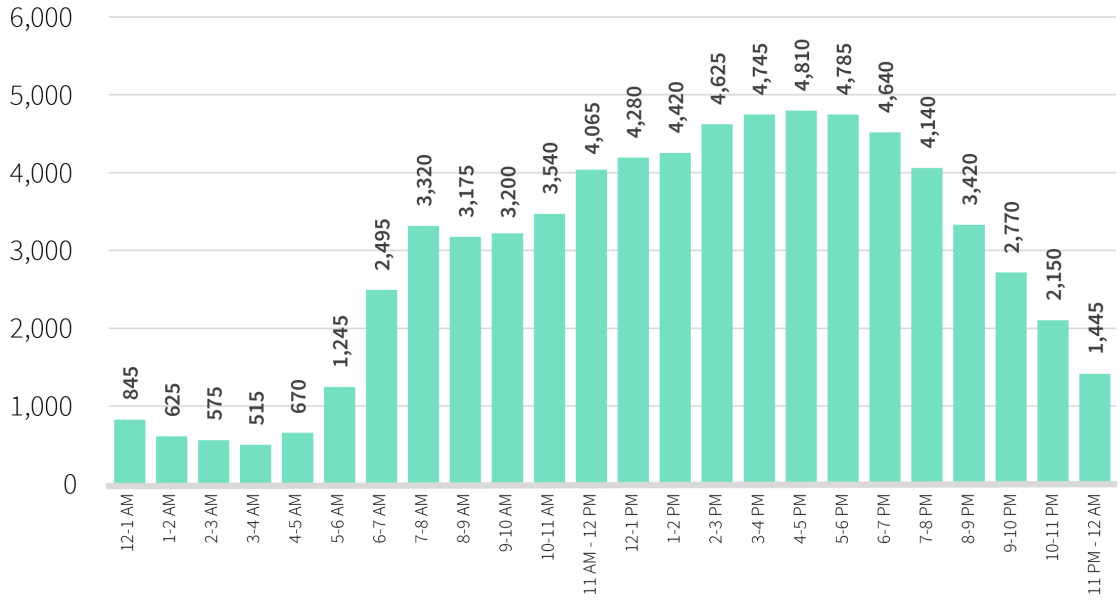


Figure 12. Interstate Bridge Hourly Profile – Overall Southbound Weekday Service Volumes

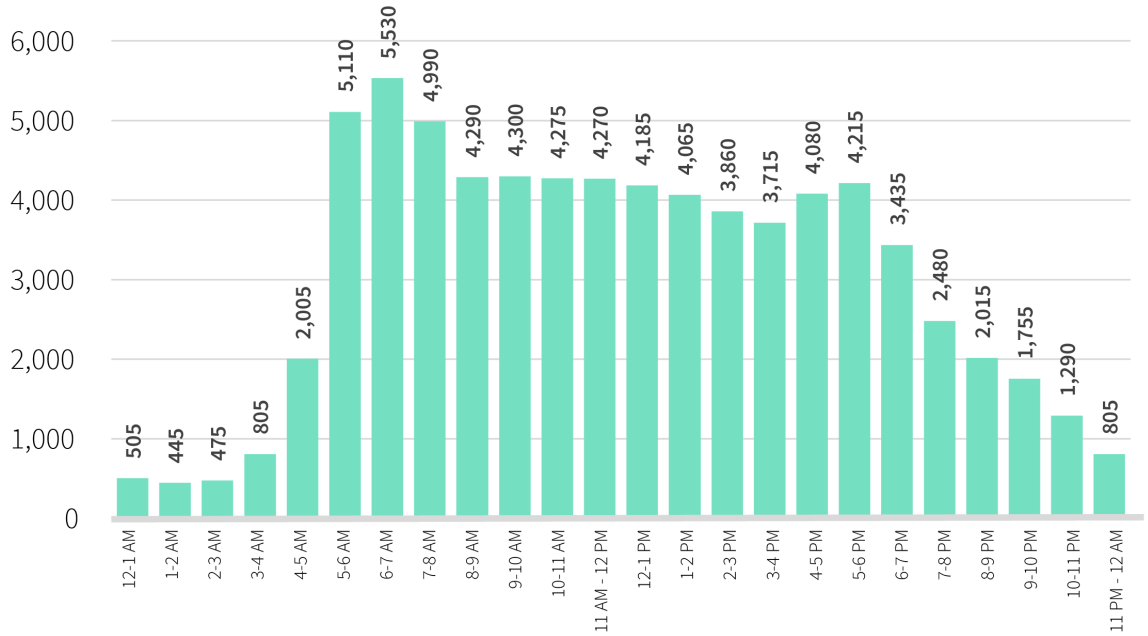

Figure 13 and Figure 14 show hourly bridge profiles across both northbound and southbound I-5 bridges for freight traffic only. As shown in Figure 13, there are more than 200 freight vehicles per hour driving northbound over the I-5 bridge between 4 a.m. and 11 p.m. The highest volume of northbound freight traffic occurs between 10 a.m. and 11 a.m. when approximately 565 freight vehicles cross the I-5 bridge from Portland to Vancouver.

In the southbound direction over the I-5 bridge, there are over 200 freight vehicles per hour between 4 a.m. and 7 p.m. and again from 8 p.m. to 9 p.m. The highest volume of southbound freight traffic occurs between 12 p.m. and 1 p.m., when approximately 520 freight vehicles cross the I-5 bridge from Vancouver to Portland.

The hour with the most freight vehicles crossing the I-5 bridges in both directions is 10 a.m. to 11 a.m., when approximately 995 freight vehicles are crossing the river.

Figure 13. Interstate Bridge Hourly Profile –Northbound Weekday Freight Service Volumes

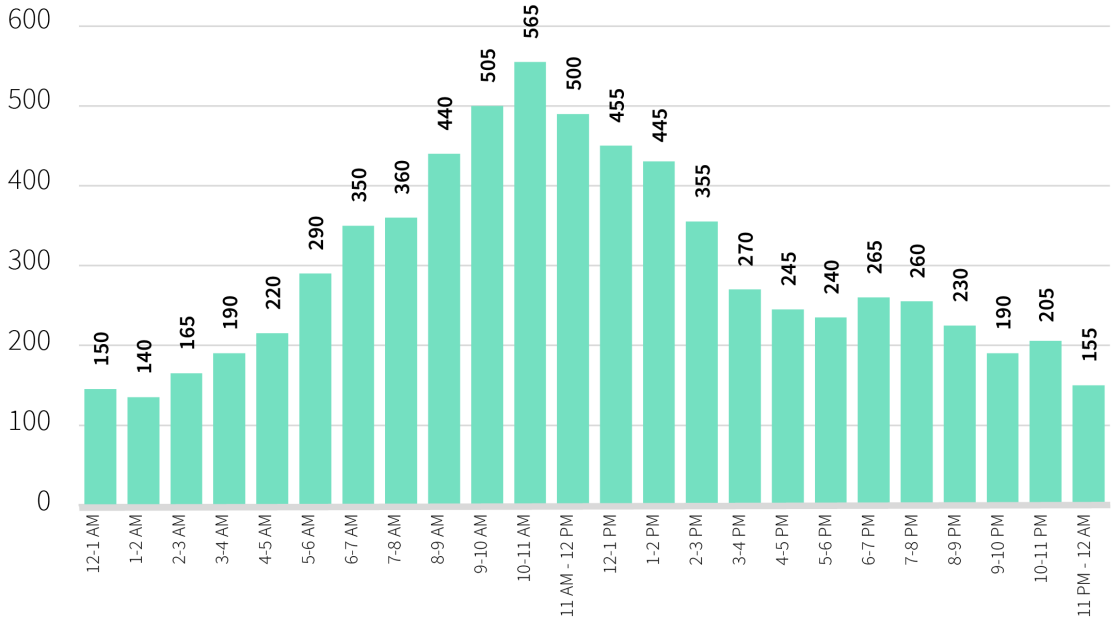

Figure 14. Interstate Bridge Hourly Profile –Southbound Weekday Freight Service Volumes

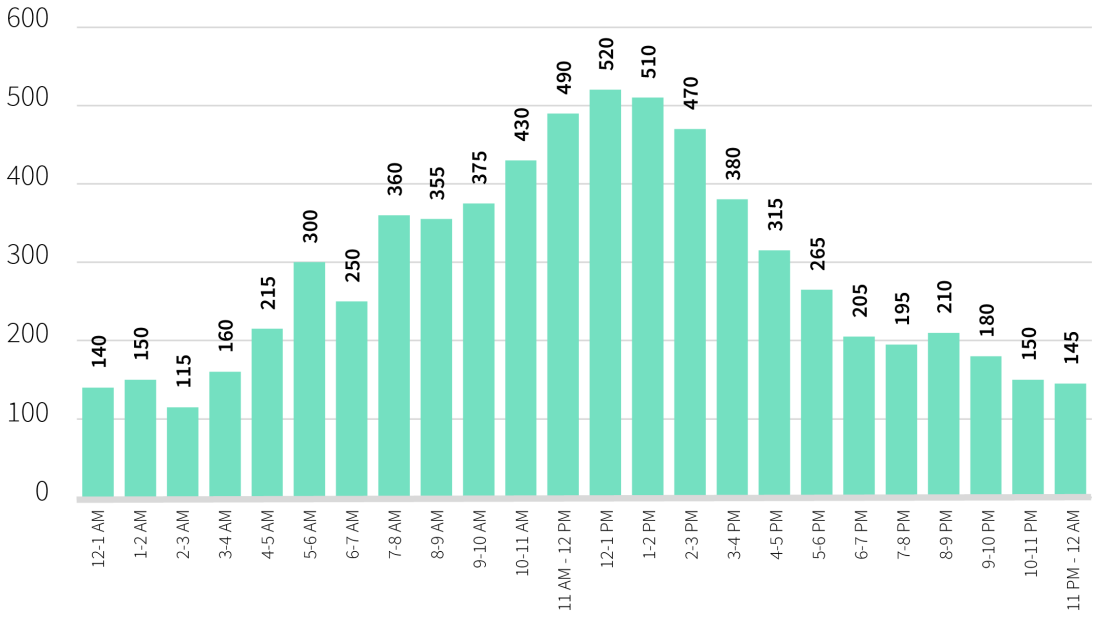
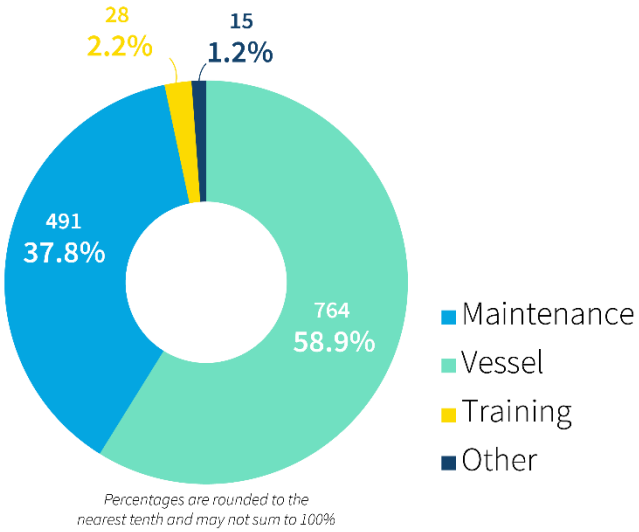


4.6.2 Bridge Lifts/Traffic Stoppages

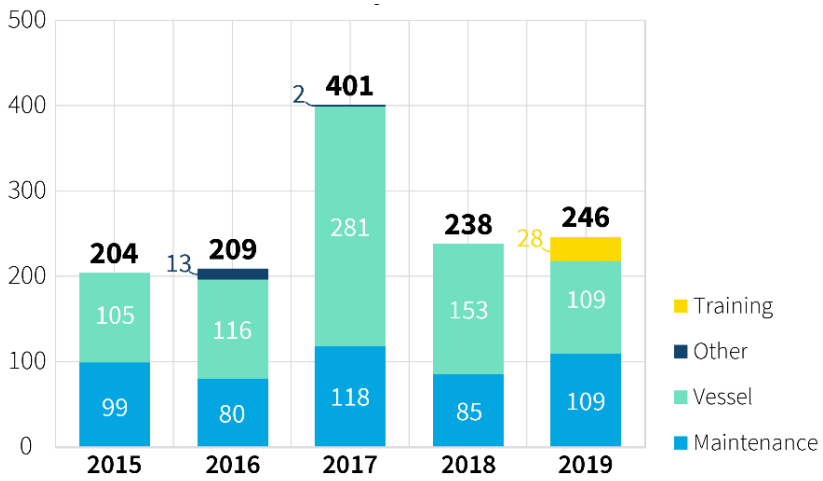
Over the five-year period from 2015 through 2019, there were almost 1,300 bridge lifts/traffic stoppages on the I-5 bridge. Bridge lift/traffic stoppages have been categorized for vessels, maintenance, training, and other purposes. Bridge lift events are those in which the bridge was physically raised, while other traffic stoppage events are those where traffic was stopped to allow for bridge-related activity without the bridge being raised. Training events are related times when the Oregon Department of Transportation (ODOT) conducts training with new employees. See Figure 15 for percentage of events by category.

Figure 15. Bridge Lift/Traffic Stoppage Event Reason, I-5 Bridge, 2015 through 2019



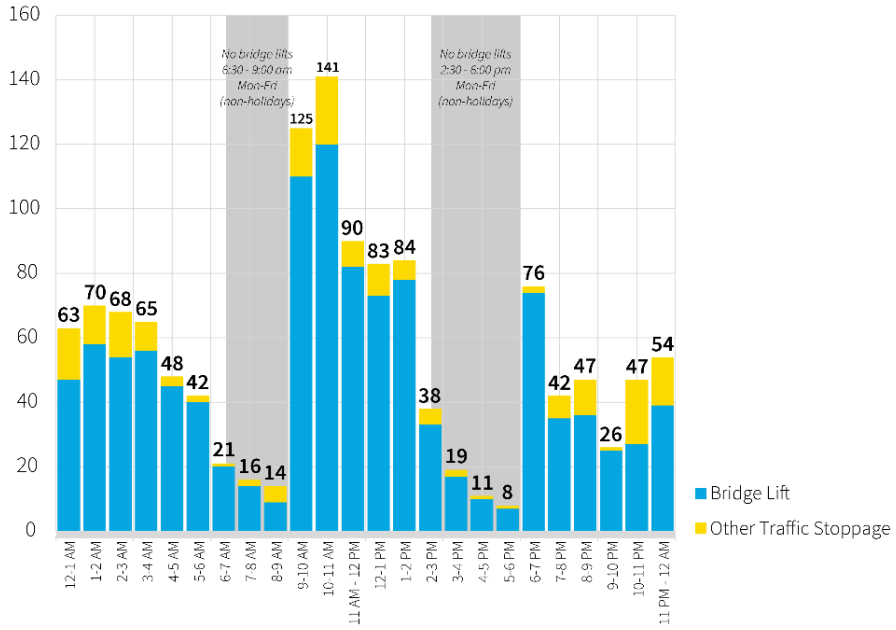
Bridge lifts/traffic stoppages vary by year depending on users, river flows, and river water levels. On average, there were about 260 events per year. Figure 16 shows the number of bridge lifts/traffic stoppages by year for the five-year period from 2015 through 2019.

Figure 16. Bridge Lift/Traffic Stoppage Events by Year



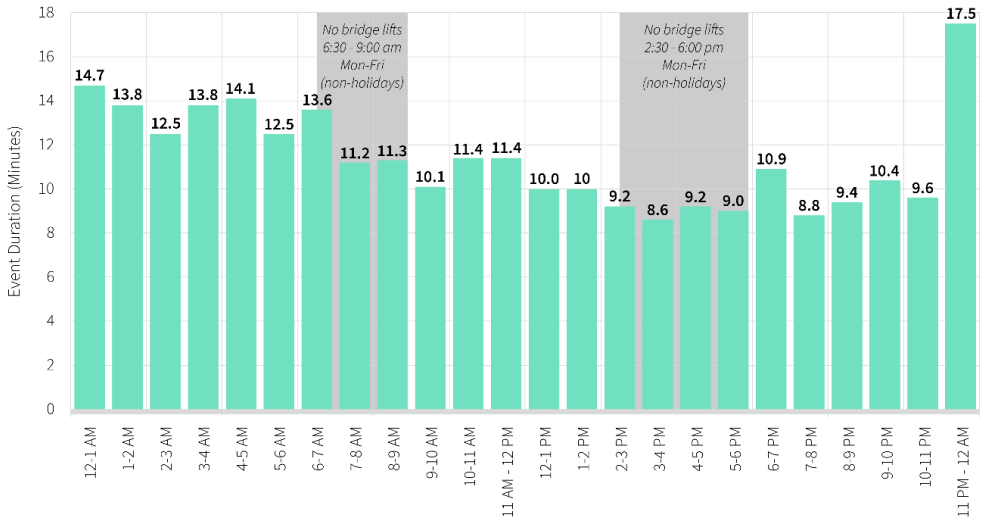
Bridge lifts/traffic stoppages were also summarized by hour to show when the bridge lifts occur. See Figure 17 for the hourly distribution of bridge lifts/traffic stoppages over the five-year period. The bridge lifts shown during the morning and afternoon peak periods (6:30 a.m. to 9:00 a.m. and 2:30 p.m. to 6:00 p.m.) occurred on weekends and federal holidays, when the restrictions on lifts imposed by federal regulations do not apply.

Figure 17. Bridge Lift/Traffic Stoppage Events by Hour



The average bridge lift/traffic stoppage for the five-year period from 2015 through 2019 lasts almost 12 minutes but ranges from 5 to 30 minutes in duration. See Figure 18 for the average event duration by hour.

Figure 18. Bridge Lift/Traffic Stoppage Events by Duration



To determine how long it takes traffic to recover to normal operating conditions from bridge lifts/traffic stoppages, the IBR team analyzed the bridge lift/traffic stoppage data and correlated that with INRIX[9] traffic speed data for days with bridge lifts. This was done for the year 2019 as it represents enough of a sample size to determine the recovery rate. The IBR team reviewed weekday volume, speed, and bridge lift data for two 1-hour periods to see if there was a difference in recovery time. The team analyzed this information for 10 a.m. to 11 a.m., and 10 p.m. to 11 p.m., on non-holiday weekdays. The analysis concluded that during the 10 a.m. to 11 a.m. time period, traffic can take 20 to 60 minutes to recover, if it can recover at all, as sometimes the bridge lift just never recovered for northbound traffic and combined with the northbound afternoon/p.m. peak-period congestion. Northbound congestion in 2019 at the I-5 bridge lasts approximately 7 hours from noon until 7 p.m. If the bridge lift occurs late in the 10 a.m. to 11 a.m. hour, it could not recover before noon. As for the 10 p.m. to 11 p.m. hour, the traffic returns to normal operating conditions in less than 15 minutes. This is based on the hourly volumes shown in Figure 11 and Figure 12, typical uncongested conditions, as well as some traffic diverting to Interstate 205 if needed during uncongested conditions.

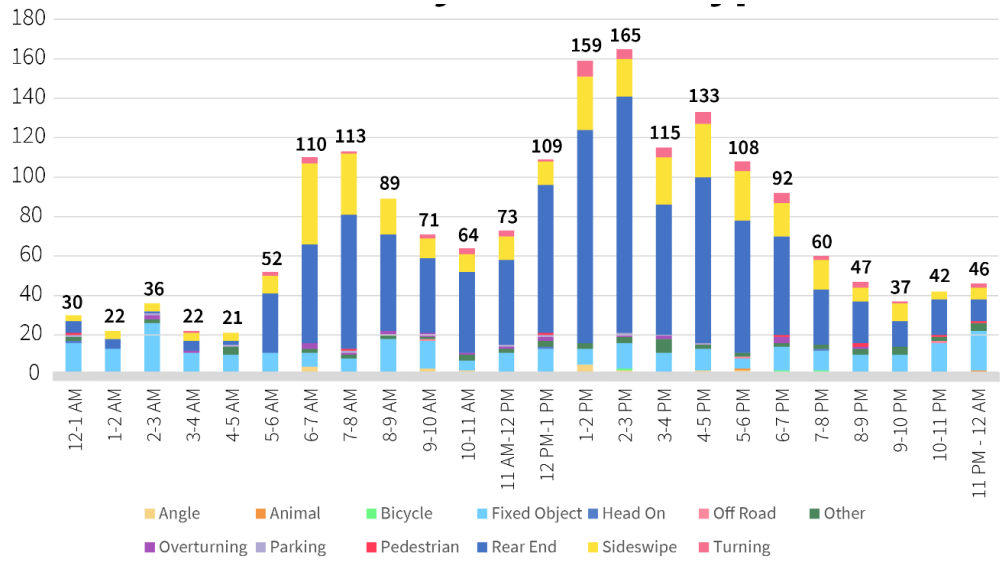
It is anticipated that the cycle time for a bridge opening for the different movable span options would be approximately 20 to 30 minutes (the bascule span would have fastest bridge opening). During the time the bridge is opened, traffic would be stopped in both directions and would be affected differently depending on the hour of the opening. Based on the 2019 traffic volumes, bridge lifts in the overnight hours would have minimal delay on traffic and transit volumes. If the bridge lift occurred during the middle of the day, it could take traffic 30 to greater than 60 minutes to recover, if it recovers at all.

[9] INRIX analyzes real time traffic data from road sensors and vehicles and summarizes this information on a daily basis.

4.6.3 Bridge Lift/Traffic Stoppages Crash Analysis

Figure 19 shows the existing number of crashes on I-5 and the ramps in the five-mile IBR program study area by hour and by type. As shown, more crashes occur during peak periods during congestion.

Figure 19. Crashes by Hour, by Type



Historical crash data gathered during the CRC Project suggests that the vehicular crash rates during bridge lifts/traffic stoppages are three to four times higher than during normal operating conditions. To determine if there was a different crash rate during days with a bridge lift/traffic stoppages and days under normal operations conditions (no bridge lifts/traffic stoppages), the CRC Project team summarized crash data for all hours between 9 a.m. and 2:30 p.m. for the five-year period from 2000 through 2004. This focused time period was chosen because bridge lifts/traffic stoppages are not allowed on weekdays (non-holidays) between 6:30 a.m. and 9:00 a.m., or 2:30 p.m. to 6:00 p.m. ODOT records exactly when bridge lifts/traffic stoppages occur, and both ODOT and the Washington State Department of Transportation (WSDOT) record crash information, including the time, type, and severity of crashes.

Table 2 shows weekday crash data from 2000 through 2004 between 9 a.m. and 2:30 p.m. that was analyzed for the CRC Project. Crash data was analyzed on weekdays when bridge lifts/traffic stoppages did not occur (columns 4 and 5 in Table 2). Using this dataset, the crash rate when bridge lifts/traffic stoppages did not occur was calculated to be approximately 0.019 to 0.021 crashes per hour. Similarly, crash data was analyzed during weekdays that had bridge lifts/traffic stoppages (columns 2 and 3 in Table 2). Using this data, the crash rate when the bridge is open is approximately 0.060 to 0.067 crashes per hour. As such, the crash rate during bridge lifts/traffic stoppages is three to four times higher than during normal operating conditions (days without a bridge lift/traffic stoppage). Crash data is similar for the most recent five-year period collected for the IBR program

(2015 through 2019), so the conclusions about crash rates during bridge lifts/traffic stoppages are assumed to be similar to what was calculated for the CRC Project.

Table 2. Bridge Lift and Traffic Stop Crash Rate Summary (9:00 a.m. to 2:30 p.m., Monday through Friday, 2000 through 2004)

Year	Number of Crashes on Days with Bridge Lifts/Traffic Stoppages	Number of Hours on Days with Bridge Lifts/Traffic Stoppages	Number of Crashes on Days without Bridge Lifts/Traffic Stoppages	Number of Hours on Days without Bridge Lifts/Traffic Stoppages
Northbound				
2000	6	110	27	1,320
2001	10	151	21	1,279
2002	7	114	36	1,316
2003	7	100	28	1,330
2004	4	95	26	1,335
Total	*34*	*570*	*138*	*6,580*
Crashes/hour	*0.060*		*0.021*	
Southbound				
2000	4	110	23	1,320
2001	12	151	26	1,279
2002	8	114	22	1,316
2003	7	100	20	1,330
2004	7	95	33	1,335
Total	*38*	*570*	*124*	*6,580*
Crashes/hour	*0.067*		*0.019*

4.7 High-Capacity Transit

With a movable span, modifications to the bridge's profile would have a nominal effect on transit operations. A decrease in the bridge's profile elevation could result in a decrease in the height of the Vancouver waterfront station, but the decrease would be minimized by clearance requirements over the nearby BNSF railroad on the north side of the river. However, the opportunity to decrease the profile elevation and grade could improve connections to the Vancouver Waterfront station for transit vehicles and transit patrons. However, introducing a movable span would affect train operations and scheduling, as well as require additional maintenance. Maintenance needs would increase over time.

Modifications to accommodate the movable span would affect train speeds. Electric light rail vehicles can sustain speeds at the approximately 4% grades proposed, so lowering the profile over the river is not anticipated to cause any change to train speed. However, introducing movable joints on the rails is likely to slow the train. Typical light rail tracks are continuous welded tracks with no joints, or joints with retainers to maintain the alignment integrity over a joint. Inserting a movable span would create two to three joints in the track that would be specially designed to be able to open. As a result, for safety reasons, the train speed would likely be slower over the movable span. Significant reductions in travel time could reduce ridership and impact the LRT project's competitiveness for federal funding. Given that there are stations proposed in proximity to each end of the bridge, it is likely that trains would travel at a reduced speed between the Hayden Island station and the Vancouver Waterfront station.

Train operations would be interrupted if a movable span opened during operating hours. Currently, TriMet operates the light rail system between 5 a.m. and 1 a.m. The hours between 1 a.m. and 5 a.m. are used for maintenance and to allow trains to travel between their respective routes and the maintenance base. Any bridge openings between 1 a.m. and 5 a.m. could impact the start of service. For example, the first train would need to arrive in Vancouver prior to 5 a.m. If a 30-minute lift occurred between 4:30 a.m. and 5 a.m., trains could be impacted at the start of service.

TriMet's Yellow line would be extended north to Vancouver as part of the IBR program. Current operating frequency on the Yellow line is as follows:

- 5 a.m. to 7 a.m.: 30-minute frequency
- 7 a.m. to 11 p.m.: 15-minute frequency
- 11 p.m. to 1 a.m.: 30-minute frequency

The IBR program proposes to increase train frequency to 12 to 15 minutes during off-peak hours and 5 to 7.5 minutes during peak hours.

The program's Yellow line extended route would begin at Evergreen Boulevard in Vancouver and connect to the Expo Station in Portland. The Yellow line continues to downtown Portland. It then changes to the Orange line, which continues to Milwaukie and Oak Grove. The total route length, with the proposed Yellow line extension, would be approximately 18 miles. A movable span could disrupt operations for the entire 18-mile segment when trains would stop for a bridge opening. Any trains on either side of the river would be held at the stations until the movable span is closed. This disruption

would affect up to five trains in each direction during peak operating hours over the river and up to two trains in each direction during off-peak hours. Riders in, and destined for, Vancouver would be delayed during the opening. If bridge openings occurred between 1 a.m. and 5 a.m., then no interruptions to riders would occur and maintenance could be scheduled around the bridge openings.

Complex designs would be required for the vehicle power and communications systems. The light rail vehicles use an overhead catenary system (OCS) for powering the trains, with the grounding system going through the rails. The OCS system is carefully designed and constructed to allow for high operating speeds. Inserting joints would affect the operation of the electrical system and would likely require extensive maintenance to keep it operational. Communications systems are required for vehicle operations and train safety. This system would require continuous communications, so the communications system would either have to be installed (directionally bored) under the river bottom (applicable for a bascule bridge or a swing span) or be suspended above the bridge (for a vertical lift span).

4.8 Shared-Use Path

To comply with accessibility standards, an SUP can have a maximum sustained grade of 5%, which would be accommodated by the highway profile grades of 4% or less. If a lower profile is used for the movable span bridge, the elevation changes required by path users would be reduced, thereby improving the walkability and rideability of the bridge. A lower bridge would also reduce the length of ramps connecting to the ground on either end of the bridge.

Bridge openings during daytime hours would delay path users as no suitable detour route is available. Current lift span operations have experienced significant safety challenges with active transportation users often attempting to go around safety mechanisms in place on the sidewalks. Additional work would be needed to determine a safe way to prevent active transportation users from entering the movable span in advance of a lift. Due to very low use during nighttime hours, late night bridge openings are not expected to adversely affect users of the path.

5. CONSTRUCTION CONSIDERATIONS

A program requirement stipulated by ODOT and WSDOT is that three lanes of I-5 traffic need to be maintained in each direction throughout construction during peak hours. It is infeasible to reduce the number of lanes of traffic on I-5 during construction because of the long-term impact this would have on regional and statewide traffic operations. During construction, reduced lane and shoulder widths are operationally permittable as needed. To maintain traffic during construction, it is assumed that the typical section will have to provide 76 feet of deck between the faces of the outside barriers on either side. This is derived from the assumption of 2-foot shoulders and three 11-foot lanes in each direction, separated by a 2-foot-wide median barrier. The permanent typical section would be restriped for three 12-foot lanes and one 12-foot auxiliary lane, consistent with the proposed Modified Locally Preferred Alternative. It is also assumed that the northbound bridge would be constructed to the same width to be able to accommodate an in-service incident or circumstance requiring the

southbound bridge to be shut down for maintenance, incidence management, emergency response, or inspection.

Incorporating a movable span would likely increase the duration of the construction schedule, regardless of the type of movable span used, due to the need for more massive foundations and the procurement, installation, and testing of the mechanical, electrical, and support systems required to operate the movable span, as well as the specialized workforce needs. The construction cost and schedule and in-water work would significantly increase—a minimum of one to two construction seasons—with a three-bridge single-level bascule bridge configuration.

Because the swing bridge would have all modes on one structure, it would need to be constructed entirely offline while using the existing I-5 bridges for maintenance of traffic. This would eliminate the need for any staging but would push the new alignment farther downstream, causing additional property impacts and challenging connections to I-5.

6. OPERATIONAL CONSIDERATIONS

Operational considerations would be similar to those required and provided for the present movable spans on the I-5 bridges. The movable span would be designed for the same seismic event(s) as a fixed span would be. However, a movable span with moving parts and machinery is more likely to suffer misalignment and/or damage from a seismic event that would be detrimental to resuming operations without significant cost and down time.

Movable bridges would also require an operator to open and close the span for marine traffic. The current lift span requires enough operators to be staffed 24 hours a day.

The annual maintenance costs of a movable bridge are greater than a fixed bridge and require expertise with mechanical and electrical systems (see Section 8). The additional annual maintenance costs associated with a movable span include performing routine lubrication of the machinery bearings, rotating elements, testing the operation of the electrical and mechanical systems, and replacing worn or broken parts.

7. ENVIRONMENTAL CONSIDERATIONS

Most environmental considerations associated with a movable span would be consistent with the Fixed Span Bridge. However, due to the larger pier foundation required for the movable span options, the intensity of some impacts would be greater. There would be six in-water piers and two land piers per bridge. Therefore, for the lift span bridge and the two-bridge bascule span bridge, there would be a total of 12 in-water piers and four land piers. For the three-bridge bascule span bridge, there would be a total of 18 in-water piers and six land piers. For the swing span bridge, there would be six in-water piers and two land piers. The total width of the three-bridge bascule span bridge would also be approximately 25% greater than the other movable span options due to the addition of a third bridge. Specific impacts that would result from the moveable span options to the environment include:

- **Air Quality and Greenhouse Gas Emissions**. Bridge openings would increase vehicular idling and associated pollutant and greenhouse gas emissions.

- **Biological Resources:**
  - For all three movable span options, the footprint of the pier foundations is expected to be larger than would be required for the Fixed Span Bridge. The increase in footprint would be greatest for the bascule span, and the three-bridge bascule span option would result in a substantially larger footprint and number of piers because of the third bridge. Larger footprints would result in greater in-water disturbance to fisheries, benthic habitat, and other marine species.
  - Overwater coverage associated with a movable bridge would likely be comparable to the Fixed Span Bridge, with the exception of the three-bridge bascule span, which would result in additional new overwater coverage (approximately 25% increase) associated with the third bridge. Larger areas of overwater coverage would create more shading of the river, which could result in greater predation of protected or culturally significant fish and other marine species.
  - The need for larger pier foundations for a movable span bridge would likely increase in-water construction durations, which would increase the extent and duration of disturbance (e.g., degradation of water quality, vibration) on aquatic species and habitat.
  - Impacts from increased foundation footprints, new overwater coverage, and longer construction duration associated with the movable span options would require additional compensatory mitigation and/or conservation measures to offset the unavoidable impacts.
- **Hazardous Materials.** For all three movable span options, the larger footprint of the bridge foundations would increase the potential to encounter hazardous material sites in river bottom sediment. There would also be an increased potential for disturbance of contaminated soil and pollution from suspended sediment, resulting in a greater potential for additional negative impacts on aquatic resources. With the three-bridge bascule span option, potential impacts would be greater due to the additional piers needed to support the third bridge.
- **Historic Structures and Archaeological Resources.** For all three movable span options, submerged historic structures and archaeological resources could have a greater level of disturbance and permanently impact due to the size and volume of excavation required for the larger bridge foundations. With the three-bridge bascule option, there could be additional disturbance by virtue of its larger footprint and additional piers (both over water and landside).
- **Land Use.** The swing span option would be located farther downstream than the other movable span options, thereby increasing impacts to development on Hayden Island and downtown Vancouver.
- **Stormwater Management.** Stormwater treatment systems for each movable span option would be more maintenance-intensive than those associated with fixed bridge designs. These systems may also not perform as well, due to the joints between the movable span and the

fixed section of the bridge; and, therefore be less effective in capturing and treating stormwater.

- **Visual Resources.** The lift span bridge would have permanent visual impacts similar to those of the existing I-5 bridges, but more impacts than the Fixed Span Bridge because the lift towers would protrude into viewsheds toward and from Vancouver, including Fort Vancouver, and toward and from Hayden Island. The bascule span would have similar visual impacts; however, they would be temporary and would only occur during a bridge opening. The swing span bridge would have no new visual impacts, and would have fewer impacts to views than the Fixed Span Bridge.

8. CONCEPTUAL COSTS

Conceptual construction costs for a movable span were developed based on previously completed projects and the collective expertise of the team. These costs are for a movable span that would accommodate I-5, LRT, and the SUP (note that the costs are for the movable span only; there would be additional costs for the other fixed spans of the bridge). The relative conceptual construction costs in Table 3 identify overall construction cost difference measured in 2022 dollars.

The construction cost implications associated with each movable span option are described below.

- A **vertical lift** is the most economical of the three movable span options studied. Planning-level estimates and review of historical unit costs indicate an approximate construction cost of $7,000 per square foot for a vertical lift span.
- A **double-leaf bascule** is more complex and costly when compared to the vertical lift due to several factors. One of the most significant cost drivers of the double-leaf bascule option is the substructure, which requires larger concrete pier foundations for each leaf. Planning-level estimates and review of historical unit costs indicate an approximate construction cost of $6,250 per square foot for a single-deck, double-leaf bascule span and $8,500 per square foot for a double-deck, double-leaf bascule span.
- A **double swing span** is the most costly of the three movable span options studied due to the length of the swing spans (two swing spans that are each 550 feet long). Planning-level estimates and review of historical unit costs indicated an approximate construction cost of $4,500 per square foot for a double swing span. Note, however, the length of the overall swing span option is longer than the vertical lift span option, resulting in a higher overall construction cost.
- For comparison purposes, planning-level estimates and review of historical unit costs indicated an approximate construction cost of $1,000 per square foot for a fixed span.

The conceptual construction costs do not include an allowance for soft costs such as design, construction management, contingency, or life-cycle considerations. However, based on previous experience, O&M costs of the movable span would increase the cost by $0.5 million to $1 million a

year[10] over a 75-year design life, adding $37 to $75 million to the overall cost of the IBR program (in 2022 dollars). Yearly O&M costs for a Fixed Span Bridge would be approximately $100,000 (in 2022 dollars).[11]

Table 3. Reasonable Order-of-Magnitude Construction Costs

Description	Construction Cost	Fixed Span Cost Equivalent to Movable Option (Baseline)*	Change in Cost
Fixed Span (Baseline): two at 450 feet	$70,000,000	--	--
Vertical Lift Span: two at 450 feet	$500,000,000	$70,000,000	+$430,000,000
Bascule Span: two at 400 feet	$550,000,000	$60,000,000	+$490,000,000
Bascule Span: three at 400 feet	$600,000,000	$60,000,000	+$540,000,000
Swing Span: two at 550 feet	$800,000,000	$170,000,000	+$630,000,000

*The Fixed Span Cost Equivalent to Movable Option is calculated by multiplying the cost per square foot of the fixed span ($1,000/square foot) by the length and width of the spans for each movable span option.

It is assumed that none of the movable bridge options would require mitigation of impacts on river users. It is estimated that mitigation for river users could be in the range of approximately $100-120 million and would take approximately six to twelve months to complete mitigation.

[10] The existing lift span bridge costs approximately $1.3 million per year (in 2022 dollars) to operate and maintain. Source: WSDOT. 2017. Columbia River I-5 Bridge Planning Inventory. (Dollars escalated from 2010 to 2022)

[11] WSDOT. 2017. Columbia River I-5 Bridge Planning Inventory. (Dollars escalated from 2010 to 2022)

9. SUMMARY

Table 4 includes a summary of the considerations associated with each movable span option.

Table 4. Summary of Movable Span Considerations

	Lift Span	Bascule Span	Swing Span
Columbia River Navigation	• Provides 178 feet or unlimited vertical clearance for navigation. • Lower vertical clearance (in the closed position) than that provided by the Fixed Span Bridge. • Requires 400 feet of horizontal clearance per the USACE (400 feet to accommodate the authorized width of 300 feet plus a buffer of 50 feet on either side for advanced dredging as specified by the USACE). • Movable span operations, and thus river navigation operations, would likely have to be restricted to nighttime openings to minimize impacts to vehicle traffic and transit operations.		
Aviation	• Lift span towers would permanently penetrate Pearson Field airspace.	• Leaves would temporarily penetrate Pearson Field airspace when open.	• No impact to Pearson Field airspace.
Alignment and Profile	• Movable span would need to be on a straight portion of the bridge (and level or near level grade), located south of the existing lift span over the relocated primary navigation channel between Piers 5 and 6. • Reduced grades would increase the ease of ramp connections, primarily on the Hayden Island end of the bridge. • Reduced length of grade of the lower profile would benefit freight and other vehicles that might be affected by the lower speeds caused by steeper grades. • Reduced grades would increase ease of access and operability of the SUP.		

	Lift Span	Bascule Span	Swing Span
Structural Considerations	• Requires more rigorous design efforts and specialty contractors.		
	• Towers up to 60 feet taller than vertical clearance required. • Counterweights in the towers would require additional seismic design considerations to mitigate earthquake impacts.	• Would be one of the largest double-leaf bascule spans in the world. • Potential for operational problems due to span imbalance, keeping counterweight pit dry, and center locks issues. • Must resist seismic and wind loading to a greater extent than other movable bridge types.	• Would be one of the largest movable spans of its type in the world. • Low profile and does not require expensive counterweights. • Less massive piers than a bascule or vertical lift bridge. • More machinery than a bascule or vertical lift bridge: an end-centering device and end-lifting devices.
Geotechnical Considerations	• Requires more substantial river piers and pier foundations to support the span as compared to a fixed span because the movable parts are more sensitive to foundation settlement. This ensures smooth operation during repeated opening cycles over its lifetime. • Requires a stiffer foundation provided by increasing both the size of the pier's footprint and number of drilled shafts contained therein.		
Highway Traffic	• The cycle time for a bridge opening would be 20 to 30 minutes. • Daytime bridge lifts could impact traffic volumes for up to an hour or more; nighttime bridge lifts would not impact traffic volumes for multiple hours a day. • Crash rate is expected to be 3 to 4 times higher during a bridge lift than during normal operating conditions. • To reduce congestion and improve mobility, movable span operations would likely need to be restricted to specific days and/or times.		
		• Fastest cycle time to open and close the bridge resulting in less congestion.	

	Lift Span	Bascule Span	Swing Span
High-Capacity Transit	• Reduced train speed over bridge. • Interruptions to operations during a bridge opening throughout 18-mile service network unless openings are restricted to nighttime only. • Extensive maintenance to keep communications systems operable. • Opportunity to decrease the profile elevation and grade could improve connections to the Vancouver Waterfront station for transit vehicles and transit patrons.		
Shared-Use Path	• Delay to SUP users during a bridge opening; no suitable detour route is available. • Lower elevation would be a benefit for path users.		
Construction Considerations	• Extended construction schedule (approximately 1 to 2 years) due to in-water work, equipment, and specialized workforce required.		
		• Additional schedule with third bridge configuration.	
Operational Considerations	• More likely to result in misalignment or damage from a seismic event. • Requires a bridge operator on site. • Requires additional maintenance associated with mechanical and electrical systems.		
Environmental Considerations	• Increased air quality pollutant and greenhouse gas emissions due to vehicular idling during a bridge opening. • Increased in-water work due to size of foundations would increase impacts to biological resources, hazardous materials, and historic structures and archaeological resources. • Challenging stormwater containment due to the bridge joints that allow the movable span to function.		
	• Permanent visual impacts due to lift towers, similar to the existing I-5 bridges.	• Additional displacement of benthic habitat with third bridge configuration. • Additional over-water shading with three bridge configuration. • Visual impact during bridge opening.	• Increased land use and development impacts due to downstream location of bridge.

	Lift Span	Bascule Span	Swing Span
Conceptual Construction Costs Change Compared to the Fixed Span Equivalent	• +$430,000,000	• +$540,000,000 (three bridge) • +$490,000,000 (two bridge)	• +$630,000,000

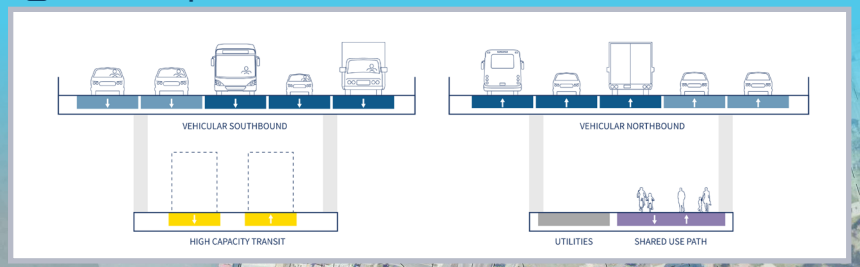
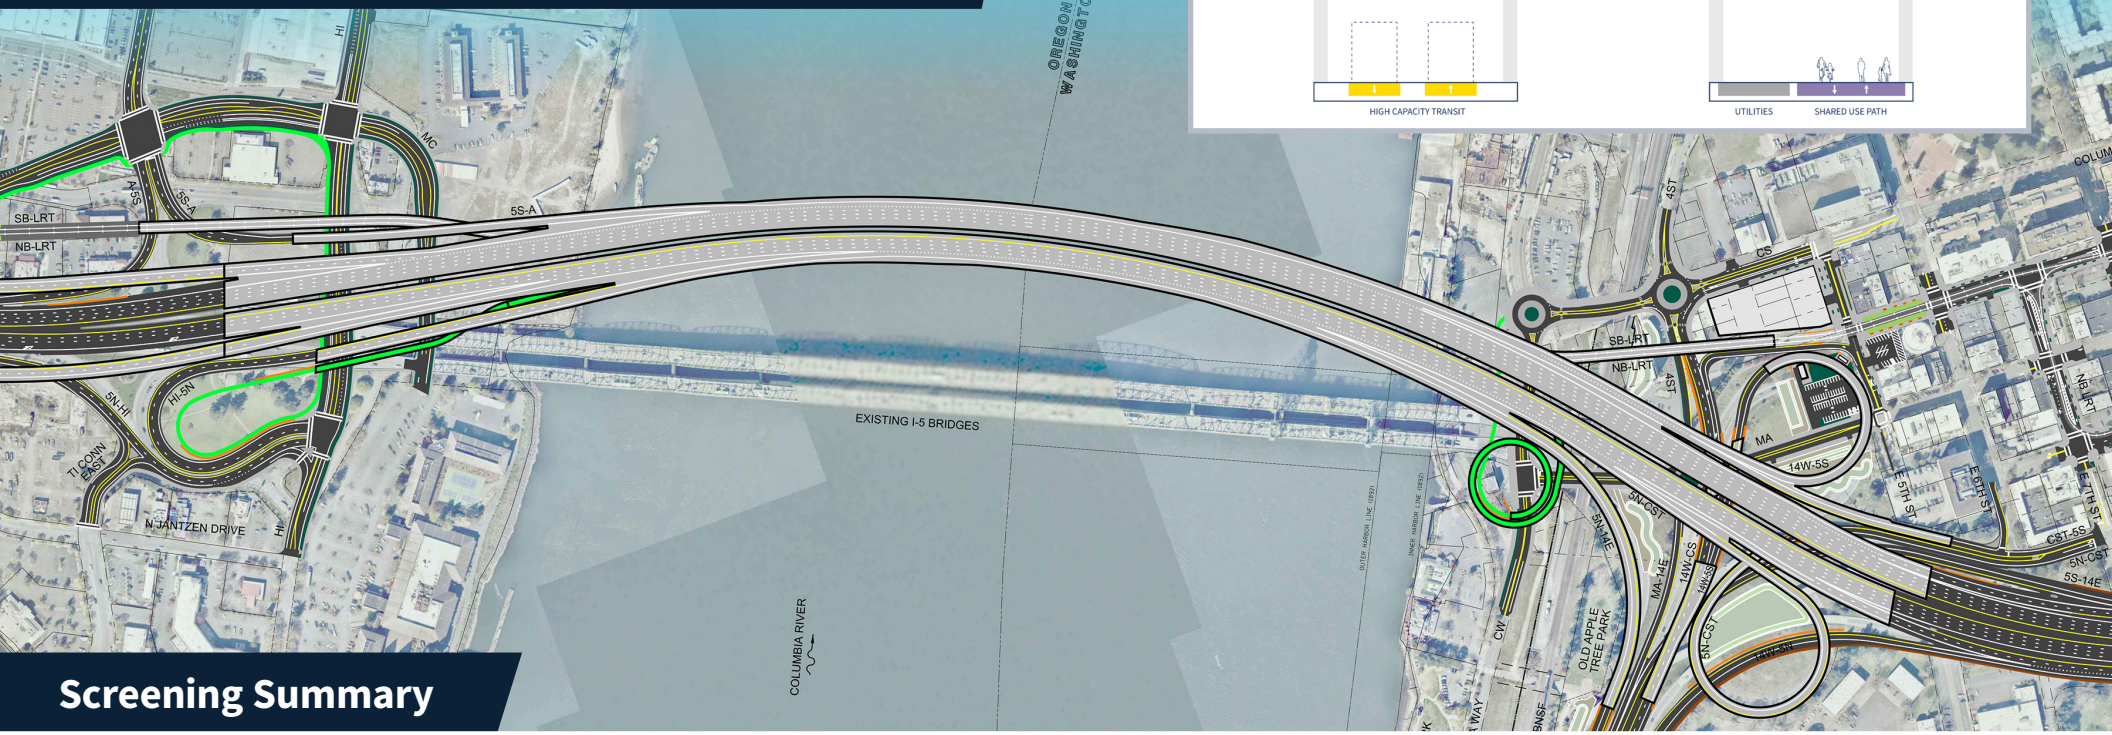
River Crossing

2013 Curved Bridge

☑ Meets Purpose and Need





Screening Summary

Climate Impacts/Adaptation	◕	- Likely uses more construction materials (based on footprint, not expected user emissions or VMT) - Improves transit and active transportation to draw mode shift - Design considers future climate disruption from flooding, extreme heat, storms and wind - Bridge elevation accounts for potential river elevation changes due to climate change
Natural Environment	◑	- More in-water piers and a larger footprint over aquatic habitat - Generates more in-water obstructions
Built Environment	◕	- Creates visually uncluttered structures on Hayden Island and scales them to surroundings **(CB, PD)** - Lowers Tomahawk Island Drive, if accommodated **(MA)** - Reduces shared use path's exposure to traffic noise **(MA)** - Main Street extension provides new downtown connection to waterfront **(CB, CC)** - More non-residential buildings impacts **(AH)**
Active Transportation	◑	- Creates a generously wide and accessible shared use path **(MA, ME)** - Shelters shared use path from elements **(MA)** - Lower deck Shared use path not visible to vehicular traffic, does not benefit from "eyes on the path" **(MA, ME)** - Curved bridge makes for a longer crossing **(MA, ME)**
Vehicles/Freight	●	- Maintains access to local streets and SR14 Compatible with Hayden Island full interchange design
Cost	◑	- Two bridges with complex bridge geometry results in high construction cost

River Crossing

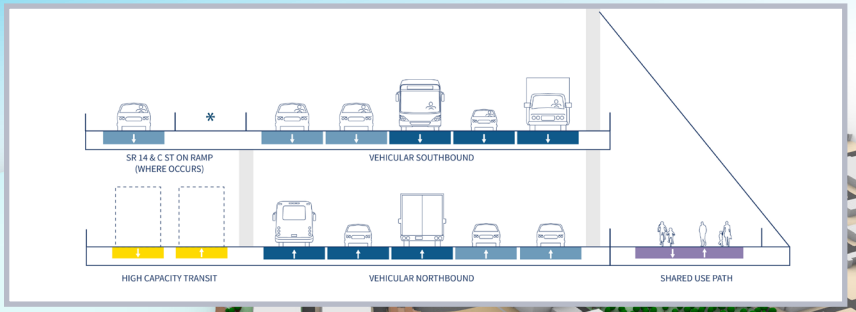
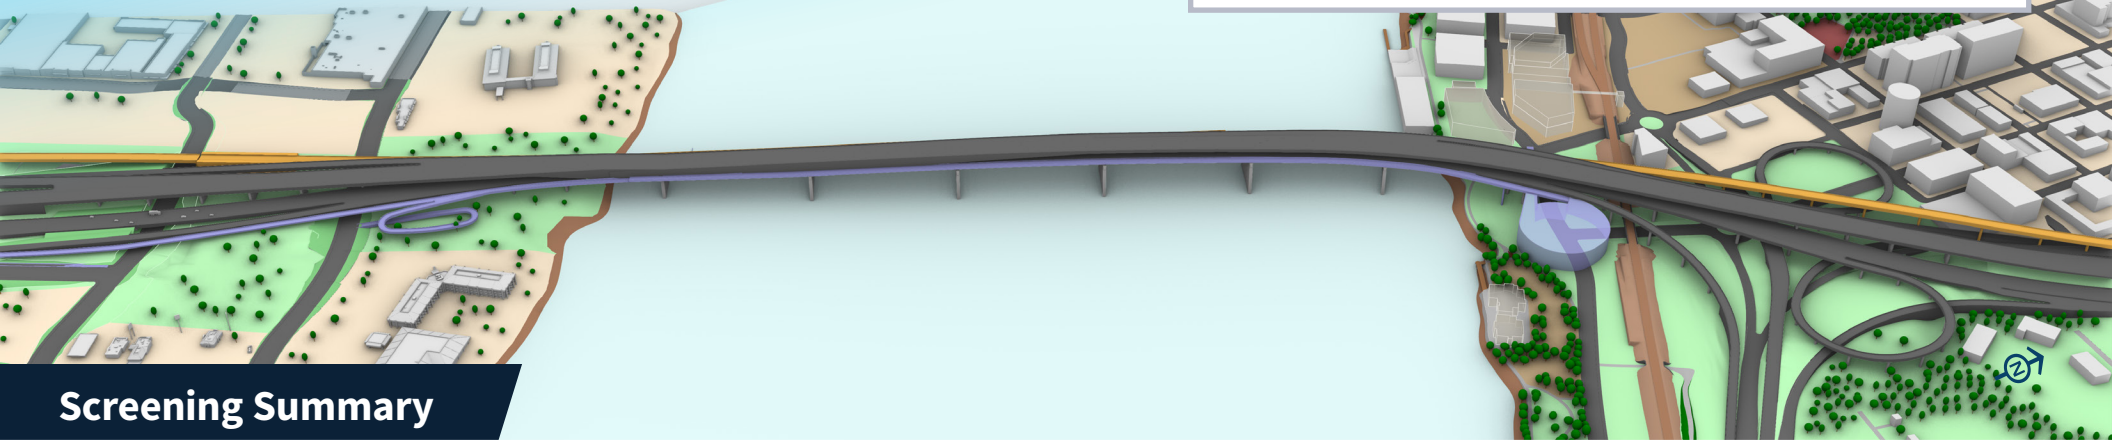
Design Option 3: One Bridge (Hybrid Stacked)

☑ Meets Purpose and Need





Screening Summary

Climate Impacts/Adaptation	◕	- Uses marginally fewer construction materials (based on footprint, not expected user emissions or VMT) - Improves transit and active transportation to draw mode shift - Design considers future climate disruption from flooding, extreme heat, storms and wind - Bridge elevation accounts for potential river elevation changes due to climate change
Natural Environment	●	- Fewest in-water piers and footprint over aquatic habitat Creates fewer in-water obstructions
Built Environment	◑	- Provides open views from the shared use path and for river users **(CB, PD)** - Results in complex bridge approaches on Hayden Island and in Vancouver **(CB, PD)** - Creates undesignated space on upper deck* - Tomahawk Island Drive crosses straight across island **(MA)** - Increases shared use path's exposure to traffic noise **(MA)** - Main Street extension provides new downtown connection to waterfront **(CB, CC)** - Fewer non-residential building impacts **(AH)**
Active Transportation	◑	- Creates a generously wide and accessible shared use path **(MA, ME)** - Allows some visibility between shared use path and vehicular traffic on lower deck **(MA, ME)** - Exposes shared use path to elements **(MA)** - Generates a higher proportion of space (openness above) **(MA)**
Vehicles/Freight	◕	- Maintains access to local streets and SR14 - Overhead structure complicates wayfinding - Compatible with Hayden Island full interchange design with design exceptions
Cost	◕	- Requires additional bridge width to accommodate shared use path - Single straight bridge design results in straightforward manufacturing and construction
Lower Downtown Vancouver Waterfront Station	N/A	- Station appears technically feasible within constraints of bridge option

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Curved Bridge	Design Option 1: Straight Alignment (Refined 2013 LPA)	Design Option 3: Hybrid Stacked Alignment	Qualitative Description
Climate							
Climate impacts of construction	CL.1, CL.2			Footprint: 84.87 acres. Volumes similar to other side-by-side bridge options ◑	Footprint: 80.19 acres. Anticipated that volumes similar to other side-by-side bridge options ◑	Footprint: 77.3 acres. Estimated to have a similar impact as double-stacked bridges (evaluating numbers 2/16) ◑	Project footprint was used as proxy for greatest construction impacts amongst the options. Differences regarded to be not
Future climate disruption/events are integrated into design performance standards	CL.3		RES	Future river elevation is contemplated in design. Low bridge deck elevation above river is same for all options. Materials endurance to variable climate conditions are the same for all options. ●	Future river elevation is contemplated in design. Low bridge deck elevation above river is same for all options. Materials endurance to variable climate conditions are the same for all options. ●	Future river elevation is contemplated in design. Low bridge deck elevation above river is same for all options. Materials endurance to variable climate conditions are the same for all options. ●	Future climate disruption events considered in design include: high and low water levels, extreme temperatures, storm events and wind.
Support long-term climate change adaptation where feasible (e.g., increased flooding, etc.)	CL.3, CL.4		RES	No identifiable differentiation for this metric among river crossing design options. ●	No identifiable differentiation for this metric among river crossing design options. ●	No identifiable differentiation for this metric among river crossing design options. ●	Future climate events requiring adaptation include: high and low water levels, extreme temperatures, storm events, wind and variable power supply. Bridge elevation, materials selection and operational limits under future climate scenarios are similar/same for all options.
Constructability							
I-5 traffic operations can be maintained during construction				Yes	Yes	Yes	The constructability of Design Options 2 and 3 have not been fully vetted at this time. A MOT plan is in development that allows three I-5 lanes in each direction throughout construction. Staging and phasing would be required from Marine Drive to about Evergreen including temporary detours and connections, and may impact construction packaging and order of construction. It is assumed that MOT for Design Option 1 will be similar to what was established for the 2013 Curved Bridge. At this time is appears that the MOT/staging and phasing for Design Options 2 and 3 would be more complicated and have more impacts than Design Option 1
Environment and Community Health							
Built Environment							
Aesthetics				◑	●	◑	
User experience on the structure	EQ.3	MA	CC, ACT	◑	◑	●	
				SUP location below highway limits open views to sky and horizon	SUP location below highway limits open views to sky and horizon	SUP location adjacent to highway has open views toward the east	
				Underdeck SUP has perceived personal safety challenges	Underdeck SUP has perceived personal safety challenges	Open environment for SUP more positive for perceived personal safety	
				All vehicles within one consistent environment on and off bridge	All vehicles within one consistent environment on and off bridge	Sudden changes in vehicles environment on and off bridge	
User experience surrounding the structure	EQ.3	AH, PD	CC	◑	●	◑	
				Curved alignment clutters visual appearance of bridge and clear (legible) identity is lost	Uncluttered river crossing with legible identity	Uncluttered river crossing with legible identity	
				Piers block views beneath the bridge and of the river	Piers block views beneath the bridge and of the river	Reduction in number of piers will improve 'transparency' of bridge and views of the river.	
				Unclear main I-5 structures across Hayden Island	Clear and identifiable main I-5 structures across Hayden Island	Unstacking of road detrimental to clarity of structures across Hayden Island	Design Option 1 scoring depends on full vs. partial interchange configuration.
				Consistent I-5 cross section off main bridge allows for simple and consistent pier structures	Consistent I-5 cross section off main bridge allows for simple and consistent pier structures	Unstacking and varied I-5 cross section off main bridge results in complex and cluttered pier structures

	Teal highlighting is used to identify which design option has the highest score for a given metric						
	Grey highlighting it used when a metric is not a differentiator of design options						

Climate Objectives for Screening Criteria

ACT = Supports mode shift to low or no emission travel (i.e., active transportation: walking, rolling, biking)
CC = Supports complete communities
CONST = compatible with low carbon construction
ITS = Supports intelligent transportation systems
O&M = Supports low emission operations and maintenance
RES = Improves resilience to uncertain climatic conditions
RID = Reduces idling of vehicles (freight, single-occupancy vehicles, transit)
TRA = Supports mode shift to transit (i.e. improves access, travel time, reliability, etc.)

Equity Objectives for Screening Criteria

AH = Avoid further harm: Avoid rather than simply mitigate disproportionate impacts on equity priority groups.
CB = Community benefits: Find opportunities for and implement local community improvements in addition to required mitigations
EO = Economic opportunity: Ensure that economic opportunities generated by the program benefit minority and women owned firms, BIPOC workers, workers with disabilities, and young people.
MA = Mobility and accessibility: Improve mobility, accessibility, and connectivity, especially for lower income travelers, people with disabilities, and communities who experience transportation barriers.

Alignment Description	2013 CRC LPA project assumes fully dedicated LRT guideway extending from Expo Center to a terminus near McLoughlin/I-5 via Vancouver CBD.	Express bus operating as Bus on Shoulder in BIA (both directions). Route 60 in auxiliary lanes between Vancouver CBD and Hayden Island, Delta Park.	Fully dedicated Bus Rapid Transit (BRT) guideway between Expo Center and a terminus at Turtle Place in downtown Vancouver.	Fully dedicated Bus Rapid Transit (BRT) guideway between Expo Center and a terminus Near McLoughlin Blvd. / I-5. Dedicated guideway on Vancouver segment will be adjacent to I-5 with a connection to Hayden Island and Expo Center similar to 2013 LPA.	Fully dedicated Bus Rapid Transit (BRT) guideway between Expo Center and a terminus near McLoughlin/I-5 with station locations similar to 2013 CRC LPA project.	Fully dedicated LRT guideway between Expo Center and a new station at Hayden Island and fully dedicated Bus Rapid Transit (BRT) guideway between Hayden Island and Turtle Place.	Fully dedicated LRT guideway between Expo Center and a terminus near Turtle Place in downtown Vancouver.	Fully dedicated LRT guideway between Expo Center and a terminus near I-5/McLoughlin. Dedicated guideway on Vancouver segment will be adjacent to I-5 with a connection to Hayden Island and Expo Center similar to 2013 LPA.	Fully dedicated LRT guideway between Expo Center and a terminus near I-5/Kiggins Bowl. Dedicated guideway on Vancouver segment will be adjacent to I-5 with a connection to Hayden Island and Expo Center similar to 2013 LPA.	Fully dedicated LRT guideway between Expo Center and a terminus near I-5/McLoughlin. Dedicated guideway on Vancouver segment will be adjacent to I-5 with a connection to Hayden Island and Expo Center similar to 2013 LPA.	Fully dedicated LRT guideway between Expo Center and a terminus near I-5/ Evergreen. Dedicated guideway on Vancouver segment will be adjacent to I-5 with a connection to Hayden Island and Expo station similar to 2013 LPA.
Proposed Initial Stations	Five(5) - same as 2013 CRC LPA alignment; I-5/McLoughlin, Washington/ Broadway & 15th, Washington/Broadway & Evergreen, Washington/5th, Hayden Island	None	Three (3) - Turtle Place, Hayden Island, Expo Center	Six (6) - Kiggins. Measure 1 Project Ridership	Project ridership will be developed as an output from the Regional Travel Demand Model. Project ridership is measured as the number of daily linked trips (complete trips from origin to destination including transfers) using any part of the proposed project. Project is defined as routes or portions of routes that include capital and/or service investments funded by the IBR Program. These may include infrastructure or service enhancements. The definition of a project trip will be clearly identified for each option to allow for a better understanding of what is being measured. For example, an option that includes the operation of a new HCT route in its own right-of-way that also allows for Express Bus use of the right-of-way would capture Project ridership from both the HCT route as well as the Express routes that benefit from the capital investment. Project trips will be summarized for both and combined to arrive at a total for the option.
Measure 2 New System Ridership	New system riders will be developed as an output from the Regional Travel Demand Model. This measure is calculated using total daily linked transit trips for each build option as compared to total daily linked transit trips from the no build option.
Measure 3 Station Activity & Mode of Access / Egress	Total boardings at each station will be developed as an output from the Regional Travel Demand Model. A boarding is defined as a single passenger who boards a transit vehicle. Boardings are counted each time a passenger boards a vehicle no matter how many vehicles they use to travel from their origin to their destination.
Measure 4 / Measure 5 / Measure 6 I-5 Columbia River **Transit** Crossings	Average weekday person trips crossing the Columbia River will be developed using select link and segment assignments as an output from the Regional Travel Demand Model. The specific location of this assignment will be on I-5 at the Columbia River crossing between the City of Vancouver and Hayden Island. Person trips will be reported by mode. A person trip is defined as a trip made by one person between an origin and destination. Measuring the average weekday crossings will illustrate the demand for the I-5 Columbia River crossing throughout the entire day and capture non-commute trips that may be missed by only looking at peak period demand. Project volumes of transit person trip origins and destinations, including park and rides, will be mapped.
Measure 7 Corridor Transit Trips	Transit person trips for the IBR corridor will be developed as an output from the Regional Travel Demand Model. This measure will be calculated as a comparison against the 2045 No Build condition. Transit person trips are a subset of all person trips, focusing only on those trips for which transit is the mode. Corridor transit trips are generally defined as trips that have a trip end within the project area including portions of Clark County, City of Vancouver, north Portland, and the Portland Central City (see Map 1). The transit trip productions will be summarized in aggregate and mapped at a Transportation Analysis Zone (TAZ) level for the region with the corridor outlined to show changes compared to the No Build option. Reported at the corridor level for totals and mapped at the TAZ level.
Measure 9 Park & Ride Demand	Total park and ride demand will be developed as an output from the Regional Travel Demand Model. This measure will be reported as average weekday vehicle demand at each lot location in the project corridor. Park and ride demand will also be mapped to show origins of users of each assumed parking facility. Reported and mapped at the station level.
Measure 12 Capital Cost	This measure is a quantitative analysis of the capital cost of the design option. The methodology for developing this measure is TBD based on available cost information at the time of developing the option summary. Reported at the project level.
Measure 13 Operating & Maintenance Costs	In coordination with TriMet and C-TRAN operations staff, operating costs will be estimated. Reported at the project level.

Transit Performance Evaluation

All Transit Options

Numbers below represent raw data from high-level analysis of scenarios using a regional travel demand model. The model used to develop this information does not account for things such as displacements, more detailed transit operations and transit connectivity along with a number of other important considerations that will be developed in more detail through the use of other tools and analysis during the environmental process.

**Transit numbers presented in these tables assume that demand can be met by the service being provided. Given assumed headways and capacities in the network for these options, some of the demand generated by the model would not be served. Therefore, these numbers reflect more transit demand than could be accommodated based on service levels in the options.*

***When considering operations and maintenance costs **per rider**, LRT is typically less expensive than BRT because LRT vehicles can carry more than 2.5 times as many passengers than BRT vehicles.*

Attachment E. Auxiliary Lanes Screening and Evaluation Materials - Tolling Sensitivity Analysis

TOLLING SENSITIVITY ANALYSIS

June 2022

Tolling Scenarios Analyzed

The tolling sensitivity analysis for initial screening for the IBR program used toll rates developed during the Columbia River Crossing (CRC) Final Environmental Impact Statement (FEIS) process and documented as part of the CRC Locally Preferred Alternative (LPA) in the 2040 Financially Constrained Regional Transportation Plan (RTP) for both Metro and the Southwest Washington Regional Transportation Council (RTC). The IBR program was requested by project partners to complete model sensitivity tests that include higher tolls than those developed during the CRC FEIS process, as well to include congestion pricing on other regional freeways; this is similar to what is being studied in the ODOT Regional Mobility Pricing Project (RMPP). The toll sensitivity scenarios run through the travel demand model included different toll levels on the I-5 bridge only, as well as separate sensitivity tests with different toll levels with the inclusion of congestion pricing on I-5 and I-205 south of the Columbia River though the Portland metropolitan area.[1] The purpose of the sensitivity tests was not to recommend a toll rate structure, and the results of this analysis should not be used to estimate revenue. Initial results should be considered draft and will be updated based on travel demand modeling assumptions that will change between the screening phase and the future environmental and traffic and revenue study phase.

The IBR toll scenarios assumed the following:

- Toll rates were assumed to vary by time of day with higher values during peak periods and lower values in off-peak periods.
- Toll rates for northbound and southbound traffic were assumed to be the same.
- Toll rates are expressed in 2010$ and are assumed to keep pace with inflation out to year 2045.

[1] The starting point for modeling conducted as part of the tolling sensitivity analysis was the RTP adopted by both Oregon Metro and RTC with updates to land use to extend the forecasts to the year 2045. These metropolitan planning organizations have coordinated this process in a manner consistent with underlying comprehensive plans and information provided by their jurisdictions as part of the RTP process. The LPA analyzed in this process reflects highway, tolling, and transit assumptions from the CRC LPA that was approved in 2008 and that received a Record of Decision (ROD) in 2011. The 2045 No Build analyzed reflects the RTP without the LPA highway, tolling, and transit elements of the CRC LPA. The 2045 No Build and 2045 LPA that were the initial scenarios used in this tolling analysis are what was used for developing traffic (volumes, travel times, heat maps) and transit results that have been used for analysis during the IBR screening process.

- Consistent with tolling assumptions during the CRC FEIS and pending further direction and inputs from the two state transportation commissions, toll rates for medium-sized trucks (three to four axles) were assumed to be twice the rate of passenger vehicles and toll rates for large trucks (over four axles) were assumed to be four times the rate of passenger vehicles.
- The Metro/RTC regional travel demand model includes 2015 base transit fares in the Portland metropolitan region expressed in 2010$ consistent with other costs in the travel demand model. It is assumed that transit fares keep pace with inflation out to the year 2045. In addition, for the 2045 forecast year, RTP policies include assumptions that result in the reduction of transit fares for all trips to the central city, regional centers, and other areas that have been designated in the RTP to include such transit fare-reduction policies. For example, the transit fare for trips to the Portland central business district reflect a reduction of 60 percent of the base full fare.
- Auto costs include tolls plus parking charges at the trip destination, as well as operating costs reflecting gas, maintenance, registration, insurance, etc. It is assumed that auto costs keep pace with inflation.

Table 1 shows the tolling scenarios analyzed in this study.

Table 1. Tolling Scenarios Analyzed

Scenario	Description
2045 No-Build [1]	Background network assumptions included in the Metro 2040 RTP without IBR highway, tolling, and high-capacity transit in place.
2045 No-Toll	CRC LPA as included in the RTP (both highway and transit improvements in place) without a toll on the I-5 bridge.
Tolled Scenarios	
2045 LPA [1]	FEIS toll rates on I-5 bridge only – CRC LPA as included in the RTP (highway, tolling, high-capacity transit improvements).
2045 LPA + OR Congestion Pricing (representation of RMPP)	FEIS toll rates on I-5 bridge + congestion pricing representation of work being done for the RMPP (pricing on I-5 and I-205 from the Columbia River to the I-5/I-205 merge point at the south end of the Portland metropolitan area).
2045 Higher Bridge Toll Only	Higher toll rates on I-5 bridge (approximately 1.5 x FEIS rates).

Scenario	Description
2045 Higher Bridge Toll + OR Congestion Pricing (representation of RMPP)	Higher toll rates on I-5 bridge (approximately 1.5 x FEIS rates) + congestion pricing representation of work being done for the RMPP (pricing on I-5 and I-205 from the Columbia River to the I-5/I-205 merge point at the south end of the Portland metropolitan area).
Partner agency–requested scenario (2045 Higher Bridge Toll + OR Congestion Pricing)	Higher I-5 toll rate scenario (approximately 4.5 x FEIS rates) to determine if this would reduce auto volumes on I-5 so eight-lane option operates adequately.

[1] The 2045 No Build and 2045 LPA scenarios used for tolling analysis are the same scenarios that have been used for the evaluation of traffic impacts and analysis to support the greater IBR program during the screening phase of the project.

Tolling Sensitivity Preliminary Results

The tolling sensitivity analysis compared the IBR tolling impacts of No-Build to the No-Toll and Toll scenarios. All scenarios reflect 2045 horizon year conditions. In general, with the inclusion of tolls or the inclusion of higher tolls on the I-5 bridge, vehicle volumes crossing the I-5 bridge are reduced. Some auto trips divert to I-205, some auto trips shift to transit, and some choose different destinations that do not require a river crossing. In general, when congestion pricing is introduced on I-5 and I-205 south of the Columbia River through the Portland metropolitan area in addition to the I-5 bridge toll, more vehicles stay on the I-5 bridge rather than diverting to the I-205 bridge, more trips shift from auto to transit, and more trips choose a different destination that does not require a river crossing. Trips that choose to not cross the river under either tolling concept (I-5 only or I-5 bridge with congestion pricing in Oregon) are more likely to be discretionary trips.

Table 2 shows the magnitude of change for auto, transit, and river crossings under each toll sensitivity test as compared with the No-Build Alternative. Note that transit increases in each scenario reflect the demand that would exist without regard for whether there is capacity to serve that demand. All 2045 scenarios would need increased transit service over what was initially modeled to accommodate the resulting demand.

Table 2. Draft IBR Tolling Impacts from Sensitivity Tests – 2045 Toll Scenarios vs. 2045 No-Build*

Scenario	I-5 Average Weekday Vehicle Trips (% change[2])	I-205 Average Weekday Vehicle Trips (% change[2])	Total Average Weekday Vehicle Trips (% change[2])	Total Average Weekday Transit Trips (% change[2])	Total Average Weekday Trips and River Crossing Change1 (% change[2])
2045 No-Build	-	-	-	-	-
2045 No-Toll [3]	+16%	-7%	+4%	+41%	+6%
2045 LPA [4]	-0.6%	-4%	-2%	+63%	+1%
2045 LPA [4] + OR Congestion Pricing	-2%	-15%	-9%	+88%	-4%
2045 Higher Toll Rate	-14%	-1%	-7%	+76%	-3%
2045 Higher Toll Rate + OR Congestion Pricing	-16%	-12%	-14%	+106%	-8%

* Initial DRAFT Post-Processed impacts

[1] Trips that change crossing the Columbia River because of change in trip distribution due to transit/tolling.

[2] Change compared to No-Build Scenario.

[3] Assumes IBR is constructed but not tolled ("Build-No-Toll option").

[4] CRC LPA

Figure 1 and Figure 2 show tolling impacts to traffic volumes on I-5 southbound and I-5 northbound, respectively, under all tolling sensitivity testing scenarios analyzed by the program. The 2019 Existing Scenario in each figure reflects current volumes. The highest volumes occur in the AM peak southbound and in the PM peak northbound with the 2045 No-Toll and 2045 LPA with congestion pricing (OR CP). The 2045 No-Toll Scenario implements the CRC LPA (highway and transit elements) but does not include a toll to cross the bridge; no toll is attractive to drivers and results in higher volumes on the I-5 bridge. The 2045 LPA with congestion pricing has higher volumes similar to the No-Toll Scenario because the implementation of congestion pricing on I-5 and I-205 south of the Columbia River effectively creates a toll to cross the I-205 bridge, as well as for I-5, so vehicles are less likely to divert to avoid paying the toll on I-5.

Figure 1. Tolling Impact on I-5 Southbound Vehicle Volumes

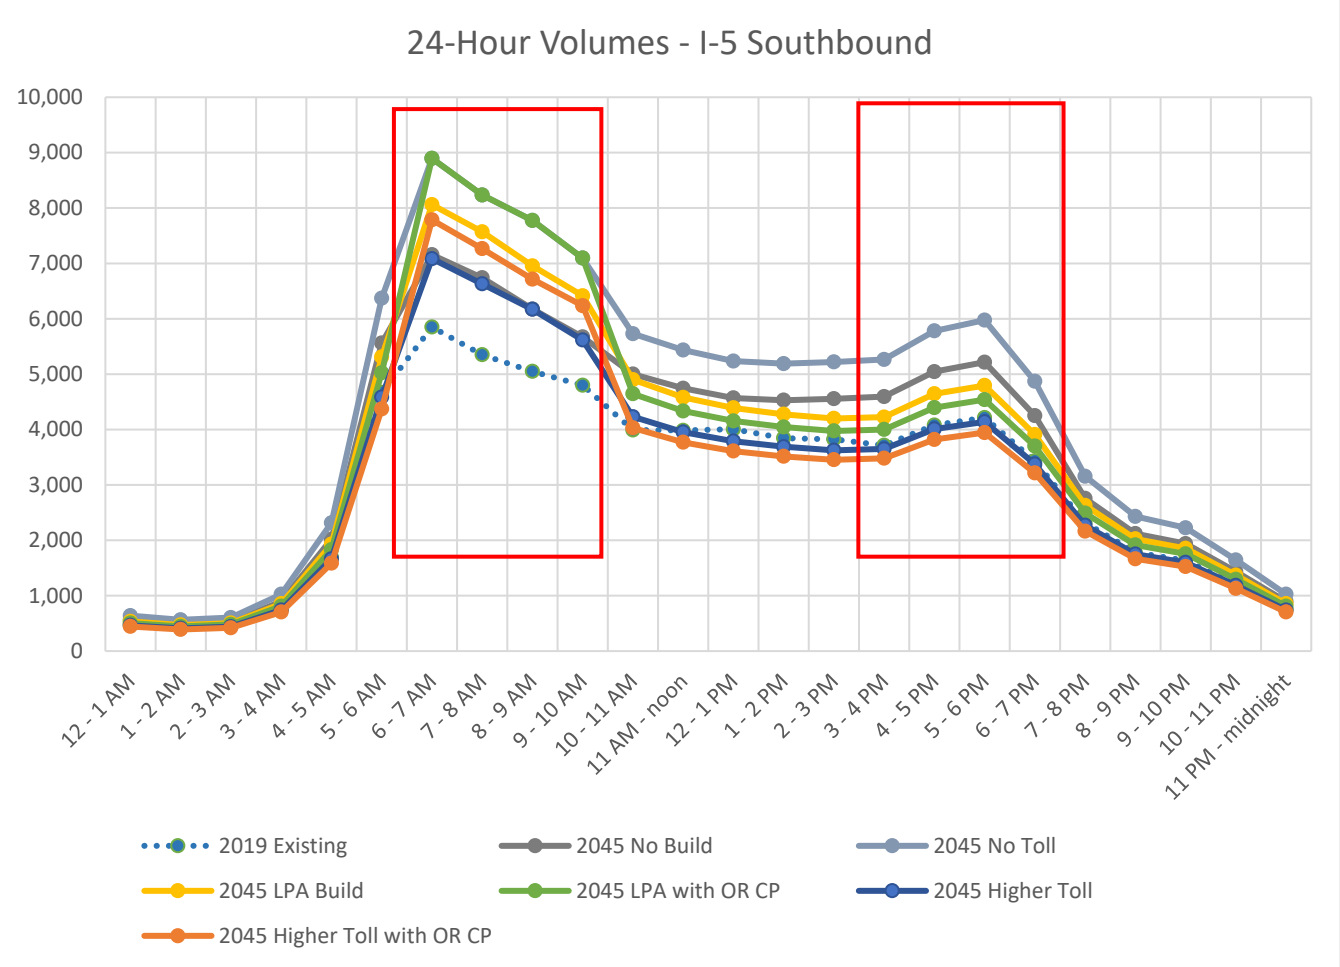

Figure 2. Tolling Impact on I-5 Northbound Vehicle Volumes

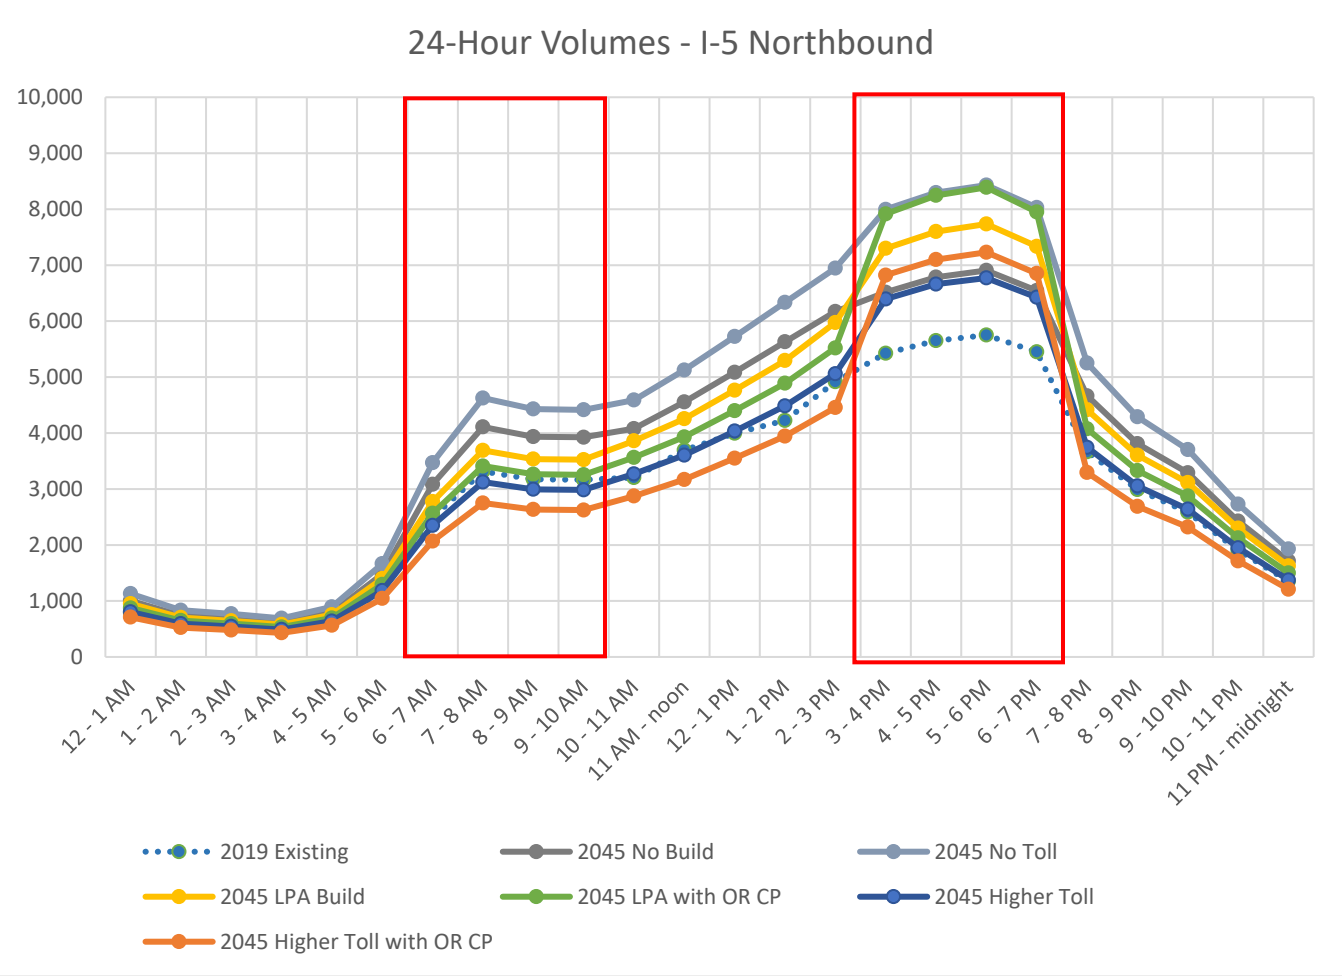

Figure 3 and Figure 4 show tolling impacts to traffic volumes on I-205 Southbound and I-205 Northbound, respectively, under all tolling sensitivity testing scenarios analyzed by the program. The No Build and 2045 Higher Toll scenarios show the highest vehicle volumes on I-205 in both the AM peak southbound and PM peak northbound peak periods. The scenarios with the lowest traffic volume during the AM peak period include the 2045 LPA with OR CP and 2045 Higher Toll with OR CP. As noted previously, the inclusion of congestion pricing on I-205 in Oregon results in more vehicles staying on I-5 to cross the river than if only I-5 is tolled.

Figure 3. Tolling Impact on I-205 Southbound Vehicle Volumes

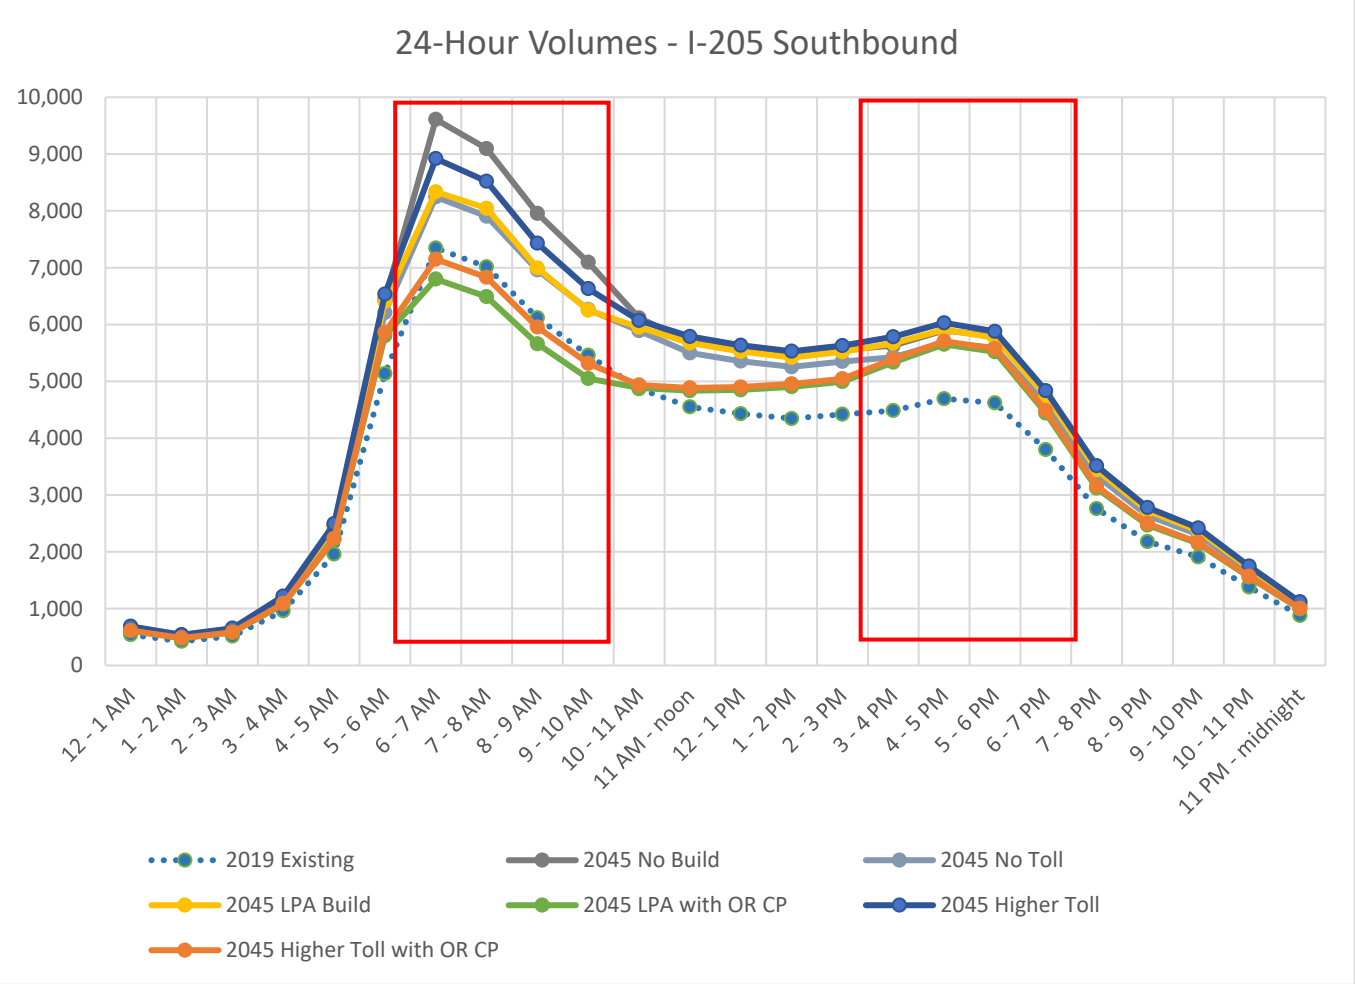

Figure 4. Tolling Impact on I-205 Northbound Vehicle Volumes

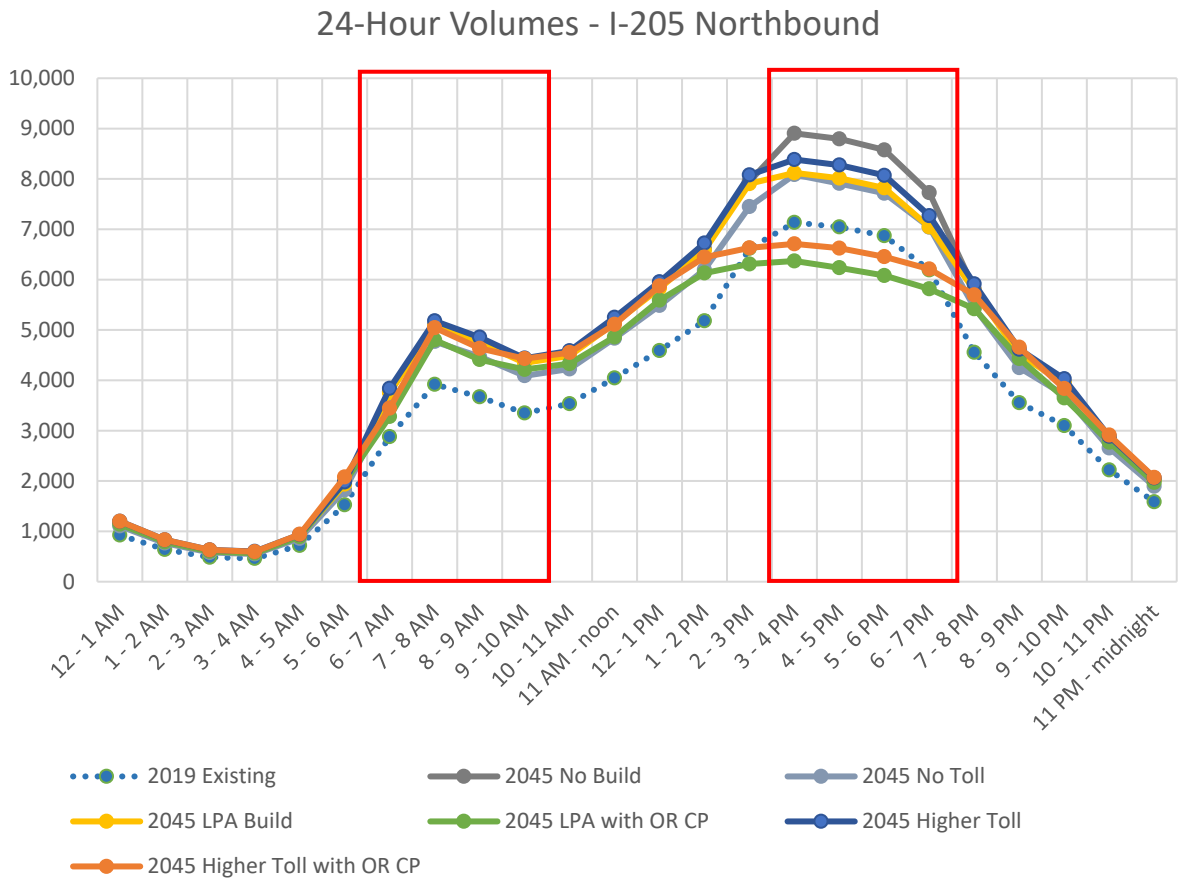

Takeaways

When comparing all tolling sensitivity scenarios against a No-Build Scenario, the results of the travel demand model show reductions in daily vehicle trips across the Columbia River from between -2 percent (2045 LPA) to -14 percent (2045 Higher Toll with OR CP). While vehicle trips decrease under these scenarios, transit trips increase which leads to overall river crossing demand changes from between a 1 percent increase under the 2045 LPA scenario to a -8 percent decrease with the 2045 Higher Toll with OR CP scenario. The transit increases in these scenarios reflect demand for transit service which exceeds transit capacity based on the transit service that was assumed in the travel demand model runs to date. Additional work will need to be completed to determine how much of this transit demand can be accommodated and the impact to vehicle trips crossing the river.

It is worth noting that the reduction in trips crossing the river is primarily related to discretionary (optional) travel with much smaller reductions in non-discretionary trips (e.g., home-to-work and work-to-home). Since

tolling and increased rates do not significantly reduce peak-period auto trips even with higher mode shares going to transit, safety improvements that include auxiliary lanes (ramp-to-ramp connections) are still needed to address the numerous safety issues experienced by travelers in the corridor. These safety issues include close interchange spacing that does not allow drivers adequate time to make on/off decisions; short merge, weave, and diverge spacing that does not allow space needed to accelerate to freeway speeds; and high on- and off-ramp volumes all entering the freeway in short distances between ramps.

LIST OF PREPARERS

Name (Registration)/Affiliation	Project Role	Education	Years of Experience
Josh Ahmann (GISP)/Parametrix	Author, Acquisitions Technical Report	B.S. Geography; Master of Urban and Regional Planning	20
Louis Alcorn (AICP)/WSP	Author, Draft SEIS	B.A. Urban Studies; M.S. Community and Regional Planning; M.S. Transportation Engineering	10
Adam Alsobrook (Licensed Professional Architect)/Willamette CRA	Author, Historic Built Environment Tech Report	B.S. Architectural Studies	20
Liz Antin/WSP	Deputy Environmental Task Lead; Author, Draft SEIS	B.A. Economics; M.A. Urban and Environmental Policy and Planning	15
Nadine Appenbrink/Parametrix	Author, Draft SEIS, Economics Technical Report	Master of Urban and Regional Planning	14
Sarah Bailey/WSP	Editor, Draft SEIS and technical reports	B.A. English and Comparative Literature; M.F.A. Creative Writing; Certificate in Professional Editing	10
Lindsey Benjamin/Parametrix	Geographic Information Systems, Draft SEIS	B.A. Anthropology; Masters in Library Information Science; Certificate in GIS	11
Isabella Beshouri/WSP	Environmental Technical Team	B.A. Environmental Studies	1
Brian Carico/WSP	Author, Draft SEIS, Navigation Impact Report	B.A. Geography	30
Kelly Carini/Parametrix	Author, Public Services Technical Report	B.A. Environmental Studies	8
Agustin Castro Hernandez (EIT)/Parametrix	Author, Transportation Technical Report	B.S. Civil Engineering	2.5
Amy Cook (BELS)/WSP	Editor, Draft SEIS and technical reports	B.A. Linguistics; Ph.D. English Literature	15
Colin Drake/WSP	Environmental Technical Team	B.A. Human Biology; Master of Urban Planning	20

Name (Registration)/Affiliation	Project Role	Education	Years of Experience
Dusty Day (Professional Wetland Scientist)/WSP	Author, Wetlands and Waters Technical Report	B.S. Biology; M.S. Environmental Management	24
Cassandra Dobson/Parametrix	Section 4(f) Evaluation	B.A. Political Science; Master of Urban and Regional Planning	6
J. Tait Elder, MA, RPA (SOI Qualified)/Parametrix	Section 4(f) Evaluation	B.A. Anthropology; Masters in Arts in Anthropology	20
Erinn Ellig/Parametrix	Author, Draft SEIS, Economics Technical Report, Neighborhoods and Populations Technical Report	B.A. Geography; Master of Urban and Regional Planning	12
Caitlyn Ewers (SOI Qualified)/ARG	Section 4(f) Evaluation	B.A. Art History and Latin; M.S. Historic Preservation	5
Angela Findley (PMP)/WSP	Environmental Task Lead	B.A. Mathematics; M.S. Forest Resources	27
Conrad Fischer/WSP	Author, Geology and Groundwater Technical Report	B.S. Geology, M.S. Earth Sciences - Oceanography	38
Rebecca Frohning/WSP	Author, Air Quality Technical Report, Energy Technical Report	B.S. Earth & Atmospheric Science	22
Langston Geuttinger (SOI Qualified)/Willamette CRA	Author, Historic Built Environment Technical Report	B.A. History of Art & Architecture and English Literature	6
Dan Gunderson, PWS/WSP	Author, Ecosystems Technical Report	B.S. Biology	22
Rachel Haukkala (AICP)/WSP	Environmental Technical Team	B.S. Community and Regional Planning; Secondary Major in Environmental Studies	7
Guy Horchy, PE (OR&WA)/Parametrix	Author, Aviation Technical Report, Utilities Technical Report	B.S. Civil Engineering	20
Katie Jensen/Parametrix	Author, Draft SEIS	B.S. Environmental Sciences/Earth Sciences; Master of Urban and Regional Planning/Environmental Planning	19
Jennifer John/Parametrix	Author, Transportation Technical Report	B.S. Economics	30

Name (Registration)/Affiliation	Project Role	Education	Years of Experience
Emma Johnson (AICP) LEED Green Associate/WSP	Environmental Technical Team; Author, Draft SEIS, Cumulative Effects Technical Report	B.S. Urban and Regional Planning; Master of City Planning	11
Paula Johnson (Registered Professional Archaeologist)/Willamette CRA	Author, Archaeology Technical Report	B.A. Anthropology; M.A. Museology	32
Larissa King Rawlins (AICP)/WSP	Environmental Technical Team; Author, Draft SEIS	B.A. Environmental Planning	24
Mara Krinke/Parametrix	Author, Climate Technical Report	B.A. Botany & Economics; M.A. Public Affairs	25
Laura Lamorette/WSP	Graphics, Draft SEIS	B.A. Visual Communications	18
Ryan LeProwse (PE, PTOE)/Parametrix	Traffic Lead; Author, Transportation Technical Report	B.S. Civil Engineering	24
Irina Leschuk/IML Services	Author, Utilities Technical Report	B.S. Civil Engineering; M.S. Hydrogeology/ Engineering	20
Ella Lisac/ WSP	Environmental Technical Team	B.S. Urban Planning (2026)	0
Glen Leverich (Oregon Registered Geologist, Washington Registered Geologist)/Wolf Water Resources	Author, Water Quality and Hydrology Technical Report	B.S. Environmental Sciences; M.S. Applied Geosciences	21
Jillian Martin/Parametrix	Section 4(f) Evaluation	Master of Applied Anthropology	19
Kaylie Matthews (OSHA 40 Hour HAZWOPER; OSHA 30 Hour Construction Health and Safety)/WSP	Environmental Technical Team	B.S. Environmental Science	4
Jodi Mescher (AICP)/WSP	Environmental Technical Team	B.S. Environment and Natural Resources; Master of Urban and Regional Planning	4
Sean McElroy/WSP	Environmental Technical Team; Author, Draft SEIS; Cumulative Effects Technical Report	B.A. Sustainability; M.S. Transportation Technology and Policy	2
Jason Medema (LEED AP)/Parametrix	Author, Land Use Technical Report, Draft SEIS	B.A. International Affairs; M.S. Environmental Studies	17
Becky Mellinger/Parametrix	Editor, Draft SEIS and technical reports	B.A. Geology; M.S. Geosciences	26

Name (Registration)/Affiliation	Project Role	Education	Years of Experience
Eddie Montejo/Parametrix	Author, Environmental Justice Technical Report	B.S. Environmental Studies & Renewable Energy; Master of Urban and Regional Planning	10
Todd Ogle (SOI Qualified, Registered Professional Archaeologist)/Willamette CRA	Author, Historic Built Environment Technical Report	B.A. History and Anthropology; M.A. Anthropology	24
Sadie Mae Palmatier/WSP	Environmental Technical Team	B.A. Environmental Economics and Ecology; Masters in Community and Regional Planning	2
Morgan Quirk (SOI Qualified)/ARG	Section 4(f) Evaluation	B.S. Policy, Planning and Development (Urban Planning); M.S. Historic Preservation	4
Hayli Reff (SOI Qualified)/ODOT	Cultural Resources Program Manager	B.A. Architectural History; M.S. Historic Preservation	10
Chris Regan (MS, CPM)/WSDOT	Environmental Program Manager	B.S. Biology; M.S. Restoration Ecology	30
Kassandra Rippee (SOI Qualified, Oregon & Washington Qualified Archaeologist)/ODOT	Tribal Liaison	B.S. Anthropology; M.A. Anthropology; M.L.S. Indigenous Peoples Law; Geographic Information Systems: Defense and Intelligence	16
Dana Rivera/Parametrix	Author, Draft SEIS	B.A. Communication Studies; M.A. Urban and Regional Planning	1
Grace Roberts/WSP	Author, Draft SEIS, Navigation Impact Report	B.S. Marine Biology; M.A. Science Oceanography	14
Patrick Romero (INCE, Environmental SP)/WSP	Author, Noise & Vibration Technical Report	B.S. Environmental Science; M.S. Environmental Policy and Management	24
Adam Romey (Registered Geologist, OR; Licensed Geologist, WA)/Parametrix	Author, Hazardous Materials Technical Report	B.A. Anthropology; B.S. Biology	20
Noreen Roster/WSP	Environmental Technical Team, Permitting Manager	B.S. Environmental Ecology	30
Sam Rubin (AICP)/WSP	Geographic Information Systems, Draft SEIS	B.S. Community and Regional Planning; Master of Community and Regional Planning	10

Name (Registration)/Affiliation	Project Role	Education	Years of Experience
April Ryckman/WSP	Author, Parks and Recreation Technical Report	B.S. Environmental Science	7
Zahra Sadegh, ENV SP/WSP	Section 4(f) Evaluation	B.A. Environmental Engineering; M.S. Agroecology; M.S. Environmental Science	7
Ethan Spoo (AICP)/WSP	Author, Draft SEIS, Section 4(f) Evaluation	B.A. Economics; Master of Urban Regional Planning - Transportation	22
Lawrence Spurgeon/WSP	NEPA Advisor	B.S. Industrial Engineering; M.S. Civil/Environmental Engineering	30
Rebecca Steiner (AICP)/WSP	Environmental Technical Team	B.A. Environmental Studies; Master of Urban Planning; Graduate Certificate in Historic Preservation	4
Kathleen Stephanick/Parametrix	Author, Draft SEIS	B.A. Geography; M.A. Geography	17
January Tavel (SOI Qualified)/Parametrix	Deputy Cultural Resources Manager	Masters of Historic Preservation	15
Breanne Taylor (SOI Qualified, Registered Professional Archaeologist)/Willamette CRA	Author, Archaeology Technical Report	B.A. Anthropology; M.A. Heritage Resource Management	13
Melissa Uland/WSP	Graphics, Draft SEIS	B.A. Graphic Design	22
Dawn Walters/WSP	Environmental Technical Team	B.S. Theatre and Business Administration; Master of Urban and Regional Planning	1
Bill Warncke/ODOT	Deputy Environmental Manager	B.S. Natural Resource Management; M.S. Fisheries Science	32
Jake Warr/Espousal Strategies LLC	Author, Equity Technical Report	B.S. Sociology; Master of Urban and Regional Planning	10
Essie Weiss-Tisman (SOI Qualified)/Willamette CRA	Author, Historic Built Environment Technical Report	B.A. History; M.A. Preservation Studies	2
Ryan Weston/WSP	Author, Visual Quality Technical Report	B.S. Horticulture; Master of Urban and Regional Planning	10
Brian Woodburn (PE, PTOE)/Parametrix	Author, Transportation Technical Report	B.A. Mathematics & Physics; M.S. Engineering	17

Name (Registration)/Affiliation	Project Role	Education	Years of Experience
Alyssa Worsham/Parametrix	Author, Environmental Justice Technical Report	B.S. Environmental Science	7
Silvia Yanez/WSP	Author, Electromagnetic Fields Technical Report	B.S. Chemical Engineering; M.S. Development and Environment	20
Emily Yokum (ODOT Qualified FAHP Consultant, WSDOT Fish Passage/Stream Design, CESCL)/ Wolf Water Resources	Author, Water Quality and Hydrology Technical Report	B.S. Botany	11
Jenifer Young/Parametrix	Environmental Technical Team; Author, Draft SEIS	B.A. English; MPA Public Administration	34

- Noise and Vibration Technical Report
- Parks and Recreation Technical Report
- Public Services Technical Report
- Transportation Technical Report
- Utilities Technical Report
- Visual Quality Technical Report
- Water Quality and Hydrology Technical Report
- Wetlands and Other Waters Technical Report

Appendix I

GLOSSARY

This appendix provides informal definitions of technical terms used in this Draft Supplemental Environmental Impact Statement (SEIS).

Note: Bold text indicates a term or phrase also defined in the table.

Term	Definition
303(d)	Section 303(d) of the federal Clean Water Act requires each state to monitor and regulate the quality of water in its rivers and streams. If a waterbody does not meet a particular water quality standard, as determined by the state, that waterbody is "303(d) listed." See also **total maximum daily load (TMDL)**.
Active transportation	Human-powered modes of transportation, such as walking, bicycling, or using a wheelchair.
Add/drop lane	See **auxiliary lanes**.
Aggregate (geology)	A rock-like mixture of minerals and rock fragments.
Alignment (transit)	The route that the **high-capacity transit guideway** for light-rail would follow.
Alternative	For the purposes of the IBR Program, an alternative is a specific set of bridge, transit, and highway solutions. The **Modified Locally Preferred Alternative** (LPA) is the **build alternative** that was analyzed as part of the Draft **SEIS** process.
Amended Record of Decision (ROD)	After a **ROD** is signed, new information may be received or generated that could affect implementation of the alternative selected in the ROD or could prompt the reassessment of the selected alternative. This new information is documented in a supplemental **NEPA** document (for example, an **SEIS**) and an Amended ROD may then be signed by the **lead agencies**. The decisions made in the prior ROD remain unaltered except for the supplemental environmental review addressed in the Amended ROD.
Anadromous	Fish species that hatch in fresh water, enter the ocean for a portion of their life cycle, then return to fresh water to spawn. Common anadromous species include but are not limited to salmon, steelhead, lamprey, eulachon (smelt), and shad.
Aquifer	An underground layer of water or layer of permeable material (gravel, sand, silt, some rock) that holds water, from which water can be extracted, usually by means of a well or spring.
Auxiliary lanes	A dedicated lane between highway interchanges—from one on-ramp to the next off-ramp—that provides motorists with more time and extra room to accelerate or decelerate and merge when entering or exiting a highway. These ramp-to-ramp connections allow vehicles to enter and exit the roadway outside of through-traffic lanes. They can improve safety and reduce **congestion** by accommodating cars and trucks entering or exiting the highway or traveling short distances between adjacent interchanges and reduce conflicting movements from merging or changing lanes.
Average (traffic)	The average traffic condition is the vehicle flow on a weekday, usually Tuesday, Wednesday, or Thursday, for a given time period.

Term	Definition
Benthic organisms (benthos)	In freshwater biology, benthic organisms are those organisms living in a waterbody's **benthic zone**. Types of benthic organisms in the IBR Program area include some species of snails, shrimp, and crayfish.
Benthic zone	The ecological zone at the lowest level of a waterbody. The benthic zone includes surface sediment on the bed or floor of the waterbody, as well as some subsurface layers beneath the surface sediment.
Best management practice (BMP)	A method or activity that is generally acknowledged to be the most effective and practical at achieving a given outcome.
Biofiltration swale	A depressed area with mild slopes that treats stormwater runoff through filtration and sorption as stormwater runoff flows through the vegetated surface. These areas are typically dry between storm events and are typically planted with grasses.
Bioslope	Like **filter strips**, a bioslope is a sloped area used to treat stormwater runoff from an adjacent roadway surface. Bioslopes are also known as ecology embankments. The stormwater runoff percolates through a special mixture of materials, which slows down the flow and promotes the filtering of pollutants.
Bi-State Legislative Committee (BSLC)	A panel composed of eight Washington and eight Oregon legislators who provide guidance and feedback on key IBR Program decisions.
Braided ramp	An on-/off-ramp design where an on-ramp passes over an off-ramp, or vice versa. Braided ramps separate merging and diverging traffic by creating a bridge for some traffic to cross over and other traffic to cross under. This improves safety by eliminating lane weaving.
Build alternative	A set of proposed transportation improvements (bridge, transit and highway) that the IBR Program is evaluating in the NEPA document.
Bus rapid transit (BRT)	A type of **high-capacity transit** that uses large buses and makes fewer stops for fast, frequent service. Buses stop at transit stations or platforms. Reliable travel times are ensured when buses operate in a lane dedicated to bus use. BRT buses also have the flexibility to travel in high-occupancy-vehicle lanes, expressways, or ordinary streets.
Climate change	A long-term shift in global or regional climate patterns. Examples of changes in weather, oceans, and ecosystems include changing temperature and precipitation patterns; increases in ocean temperatures, sea level, and acidity; melting of glaciers and sea ice; changes in the frequency, intensity, and duration of extreme weather events; shifts in ecosystem characteristics such as the length of the growing season, timing of flower blooms, water temperatures for fish, and migration of birds.
Climate Framework	The IBR Program's methodology for analyzing the impacts of the **Modified LPA** on **greenhouse gas emissions** and **climate change**.
Cobbles	Pieces of rock between 2.5 and 10 inches in diameter; informally, rock sized between gravel and boulders.
Cofferdam	A temporary, watertight enclosure for excluding water from an area that is normally submerged. Cofferdams are one method of isolating an area within a waterbody for construction or other activities.

Term	Definition
Collector-distributor	A roadway parallel to a larger-capacity roadway. A collector-distributor is designed to remove weaving from a highway mainline and reduce the number of entrances and exits.
Columbia River bridges	The newly constructed bridges that would be built west of the existing **Interstate Bridge**.
Columbia River Crossing (CRC)	A multimodal project conducted by Oregon and Washington, from 2005 to 2014, that studied options for replacing the Interstate Bridge. The CRC project completed the federal environmental review process (**NEPA**) and reached a federal **ROD** in 2011 on a **locally preferred alternative**. The CRC project did not secure adequate state funding for construction and was discontinued in 2014. The IBR Program supplements the prior work from the CRC project's NEPA process.
Columbia River Crossing Locally Preferred Alternative (CRC LPA)	The CRC Selected Alternative identified in the 2011 ROD, as revised by the 2012 and 2013 re-evaluations.
Columbia River Datum (CRD)	The plane of reference from which river stage is measured on the Columbia River from the lower Columbia River up to Bonneville Dam, and on the Willamette River up to Willamette Falls. The datum equals 1.82 feet above mean sea level (equivalent to National Geodetic Vertical Datum [NGVD]) at Vancouver, Washington (USACE 2014).
Community Advisory Group (CAG)	One of three advisory groups formed to guide the IBR Program. The CAG consists of a group of community members from the greater Portland and Vancouver region that provides advice and recommendations to the **Executive Steering Group** and IBR Program administrator on issues of importance to the community.
Community cohesion	The ability of people to communicate and interact with each other in ways that lead to a sense of community as reflected in the neighborhood's ability to function and be recognized as a singular unit.
Community connector	A structure over a highway that helps to maintain or improve connectivity between the two sides of a highway, that provides visual and cultural landscape connectivity, and/or that mitigates for visual impacts of new highway construction. For the IBR Program, the proposed Community Connector, located just south of Evergreen Boulevard, would serve as a pedestrian connection between the communities on the east and west sides of I-5.
Community engagement	The IBR Program's ongoing efforts to hear community concerns, values, and interests; maintain open, two-way communications; and reflect community interests in key Program decisions.
Community resources	Services and gathering places such as educational, religious, health care, cultural, recreational, and commercial institutions.
Community survey	A data-driven public survey of diverse community members and organizations conducted by the IBR Program to assess public concerns and interests related to the region's transportation system.
Community-based organizations (CBO)	Groups representing varied local interests and concerns such as the environment, businesses, labor, social services, affordable housing, recreation, transit, etc.

Term	Definition
Congestion	Congestion occurs when the demand is greater than the transportation system's capacity. For highways, congestion occurs when the average speed along a section falls below a specified speed, generally below 35 miles per hour. Recurring congestion is caused by constant excess volume of vehicles compared to capacity. Nonrecurring congestion is caused by actions such as special events and/or traffic incidents.
Contributing impervious area (CIA)	All impervious surface associated with a project that contributes stormwater, including impervious surface areas within the project limits and impervious surface areas contiguous to the project that discharge stormwater runoff into the project area. Non-highway-related impervious areas (commercial development, residences, agricultural land) and certain non-triggering impervious areas (such as areas where pavement is not replaced to its full depth) are not part of the CIA.
Construction staging	A designated area where vehicles, supplies, and construction equipment are positioned for access to and use on a construction site.
Cooperating agencies	One of three designations of agencies under the **NEPA** environmental review process. A cooperating agency is typically a federal agency, other than a **lead agency**, that has jurisdiction by law (with permitting or land transfer authority) or special expertise with respect to an environmental impact involved in a proposed project or project alternative. A state or local agency of similar qualifications—or when the effects are on lands of tribal interest, a Native American tribe—may, by agreement with the lead agencies, also become a cooperating agency. All cooperating agencies are also considered **participating agencies**.
Crash	A collision, typically between vehicles, but may also involve pedestrians or bicyclists Crashes may be analyzed for a single location such as an intersection, for a specified section of highway, for a particular type of transportation facility (e.g., for interstate highways), or for a specified area such as a region or state. Such analyses help to identify needed safety improvements. Crashes may be analyzed in a number of ways: by frequency, by number of collisions, by number of collisions per mile or per **vehicle miles traveled**, by severity, and by type (rear-end, turning conflict, etc.).
Cultural resources	Collectively refers to historical and archaeological resources. Cultural resources are broadly divided into the historic built environment (buildings, structures and objects), archaeological sites, and defined features or areas that are important to maintaining cultural identity.
Cumulative effect (impact)	An effect on or impact to the environment resulting from the incremental impact of an action when added to other past, present, and reasonably foreseeable future actions. Cumulative effects can result from individually minor but collectively substantial actions that take place over a period of time.
Deadheading	Trips made by a transit vehicle (bus, light-rail, streetcar, etc.) when the vehicle is out of service and no passengers are on board. This is also referred to as a non-revenue trip, dead mileage, or dead running.
Demand (transportation)	The total number of users attempting to access the transportation system, including those caught in **congestion**.

Term	Definition
Demographics	Statistical data relating to the population and particular groups within it. The IBR Program uses demographic data to understand the general characteristics and geographic locations of communities potentially affected by the Program and to inform community engagement strategies.
Diamond interchange	A common type of interchange used where a highway crosses a minor road. The highway is grade-separated from the minor road, and off-ramps diverge gently from the main highway, intersect directly with the minor road, and beyond the minor road continue as a gently merging on-ramp. The name "diamond" is used because, seen from the air, the pattern of major highway, minor road, and associated on- and off-ramps form a diamond shape.
Direct effects	Effects that are caused by a project action and that occur at the same time and place as the action.
Distinct population segment (DPS)	A population of organisms that is considered distinct from similar organisms for purposes of conservation. In the Pacific Northwest, populations of several species, including steelhead and bull trout, are further subdivided into **Evolutionarily Significant Unit** (ESUs) for purposes of management and recovery.
Diversity	Includes all the ways in which people differ and encompasses all the different characteristics that make one individual or group different from one another.
Easement	The legal right to use property belonging to another person for a stated purpose. An easement may grant the right to use the property surface, the property's subsurface for a given depth range below the surface, or the airspace above the property surface for a given range of elevations.
Ecosystem	A portion of the physical environment that includes both biological and nonbiological elements working together as a stable system. Ecosystems can be defined to be quite small (e.g., a single wetland) or quite large (e.g., an entire forest).
Eminent Domain	In Washington, eminent domain is the right of a government to acquire private property for public purpose following payment of just compensation to the property owner (Washington Constitution article 1 § 16). In Oregon, "an authority may acquire, by the exercise of the power of eminent domain, any real property which it deems necessary for its purposes after adoption by it of a resolution declaring that the acquisition of the real property described therein is necessary for such purposes" (Oregon Revised Statute 456.145).
Endangered species	A species (population of organisms) that is in danger of becoming extinct. Causes of endangerment can include population size, excessive predation, loss of supporting habitat, or other threats.
Endangered Species Act (ESA)	A 1973 federal law designed to protect threatened and **endangered species** of fish, wildlife, and plants.
Environmental Impact Statement (EIS)	A document that outlines the impacts of a proposed action on the surrounding natural and built environments. It also describes potential measures to reduce or mitigate those impacts. See also **Supplemental EIS**.

Term	Definition
Environmental Justice (EJ)	Refers to identifying and addressing disproportionately high and adverse effects of programs, policies, and activities on minority populations and low-income populations to achieve an equitable distribution of benefits and burdens. EJ helps to ensure full and fair participation by including potentially affected communities in the decision-making process.
Equity	When one's identity cannot predict the outcome. The IBR Program further defines equity in terms of both process and outcomes. Together, **process equity** and **outcome equity** contribute to addressing the harmful impacts of and removing longstanding injustices experienced by **historically underserved communities**.
Equity Advisory Group (EAG)	One of three advisory groups formed to guide the IBR Program. The EAG is a diverse group of community members who make recommendations to IBR Program leadership regarding **equity** considerations and processes, policies, and decisions that potentially could affect **equity priority groups** or **historically underserved communities**.
Equity priority communities or **historically underserved communities**	Communities, populations, and individuals who have been historically excluded from transportation decision-making and systematically discriminated against, and who experience social, economic, and health disparities. These groups include: • Black, Indigenous and people of color (BIPOC). • **People living with disabilities.** • Communities with **limited English proficiency.** • Persons with lower income. • Houseless individuals and families. • Immigrants and refugees. • Young people (individuals 24 years old or younger). • Older adults (individuals 65 years old or older).
Ethnicity	The fact or state of belonging to a social group that has a common national or cultural tradition.
Eutrophication	An increase in the concentration of chemical nutrients in an ecosystem to a degree that the primary productivity of the ecosystem is affected. Effects of eutrophication can be beneficial to some species but harmful to others. For example, one chemical nutrient may nourish one species, but in high concentrations may be toxic to other species. In the Pacific Northwest, for example, certain algal blooms—so-called red tides—can cause chemicals harmful to humans to accumulate in shellfish.
Evolutionarily Significant unit (ESU)	A population of organisms that is considered distinct from similar organisms for purposes of conservation. In the Pacific Northwest, species of salmon (Chinook, coho, chum, etc.) are further subdivided into ESUs for purposes of management and recovery. See also **distinct population segment**.
Executive Steering Group (ESG)	One of three advisory groups formed to guide the IBR Program. The ESG is a panel of representatives from regional partner agencies and the **Community Advisory Group** co-chairs. The ESG provides guidance and recommendations on key IBR Program issues.
Express bus	A bus that operates point-to-point service—generally during peak times—that typically connects outlying points to business cores without intermediate stops.

Term	Definition
Extradosed bridge	A bridge type that is a hybrid superstructure that fills the gaps between spans, usually accommodated by girder spans and cable-stayed spans. It supports superimposed loads of the superstructure through a combination of girder action and cable-supported action between pylons. In contract, a cable-stayed bridge supports all of the superimposed load on the superstructure between the pylons through the cable stays.
Federal navigation channel	A U.S. Army Corps of Engineers (USACE) Civil Works project authorized by the U.S. Congress under which USACE is responsible for the establishment and ongoing maintenance of navigation channels in navigable waterbodies.
Filter strip	A vegetated strip of land between a potential source of polluted runoff, such as a highway, and a receiving waterbody. The filter strip is planted with vegetation that slows the runoff and aids in removing sediment or other pollutants before the runoff enters the receiving waterbody.
Finback bridge	A variant of an **extradosed bridge** where the stays are grouped and encased.
Floodplain	A flat or nearly flat area adjacent to a stream or river that is subject to periodic flooding during high stream or river flows.
Flyover ramp	A ramp that crosses over (above) another ramp or portion of a highway.
Gantry	Structures used to support overhead signs. Gantry signs are commonly used on highways and can also be used to hold cameras for toll road entrances or exits.
Geographic information system (GIS)	An electronic (computer) system that stores and displays information linked to a location.
Greenhouse gases (GHG)	Gases that, when released into the atmosphere, contribute to global warming. They generally include six specific gases: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF6). GHGs are not the only air pollutants of concern; others include ozone and particulate matter, which can affect human health.
Guideway	A transit right-of-way separated from general purpose vehicle transit. A guideway may have train tracks or separated bus lanes.
Headway	Scheduled time between two transit vehicles passing the same point traveling in the same direction on a given route.
High-capacity transit (HCT)	A public transportation service that operates in a dedicated **guideway** and moves a large number of people at high frequency; examples include **bus rapid transit** and **light-rail transit**.
High-occupancy vehicle (HOV)	Motorized vehicles designed to carry more than a specific minimum number of passengers, mainly buses, vanpools, and carpools, and permitted to use a travel lane reserved for such vehicles.
High-occupancy vehicle (HOV) lanes	One or more lanes of a roadway that have restrictions on use to encourage ridesharing and can reduce **vehicle miles traveled**. Traffic lanes may include restrictions for the number of occupants allowed in the vehicles, and enforcement may vary by time of day.

Term	Definition
Hydrology	The flow of water in and through a given area, including the volume of water, where it drains, and how quickly the flow rate changes in a storm.
Inclusion	Elimination of barriers that prevent the full participation of all people.
Indirect effects	Reasonably foreseeable effects caused by an action, but that are later in time or farther removed in distance. Indirect effects may include induced growth, changes in land use or population patterns, and effects on air, water, and ecosystems.
Induced growth/ development	Population growth or development that results from one or more project actions. For example, building or improving a highway may result in easier access to the area, which may in turn lead to the growth of business or residential uses near the highway.
Interchange Area Management Plan (IAMP)	A joint ODOT and local government long-term land use and transportation plan designed to balance and manage transportation and land use decisions in areas planned for future use as a highway interchange. An IAMP helps to ensure that local land use plans and actions are and remain compatible with the eventual use of the land for transportation purposes.
Interstate 5 (I-5)	The main north-south interstate highway on the West Coast of the United States. I-5 runs largely parallel to the Pacific Coast of the contiguous United States from Mexico to Canada.
Interstate Bridge Replacement (IBR) Program	A joint effort by the states of Oregon and Washington to replace the aging, structurally vulnerable Interstate Bridge over the Columbia River with modern, seismically resilient, multimodal structures that can reliably serve the Portland-Vancouver region into the next century.
Interstate Bridge	The existing I-5 river crossing over the Columbia River that consists of two bridge spans. One of the bridge spans is at least 105 years old and is at risk of collapse in the event of a major earthquake. Both bridge spans no longer serve the needs of commerce and travel.
Jurisdictional waters	Waters under the jurisdiction of the U.S. Army Corps of Engineers as granted by the federal Clean Water Act. Although specific determinations must be made, jurisdictional waters typically include waterways and their associated wetlands.
Lahar	A flow of volcanic material (such as rock debris and gases) and water that travels quickly and can cover great distances. Lahars typically flow downstream of a volcano within a river valley.
Landscape unit	A portion of a given landscape considered separately from the entire landscape for purposes of analysis and comparison.
Lead agency	One of three designations of agencies under the **NEPA** environmental review process. A lead agency is the agency carrying out the federal action and is responsible for complying with the requirements of NEPA. In some cases, such as the IBR Program, more than one federal agency is designated as a federal lead agency. Federal agencies, together with state agencies, local agencies, and/or tribes, may act as joint lead agencies. Lead agencies prepare the environmental documentation for a project and oversee the NEPA process.

Term	Definition
Level of service (LOS)	A qualitative measure of the effectiveness of one or more elements of transportation infrastructure. LOS is most commonly used to describe roadway performance, but it can also be applied to transit, intersections, or other infrastructure elements. The American Association of State Highway and Transportation Officials defines the following levels of service: A Free flow B Reasonably free flow C Stable flow D Approaching unstable flow E Unstable flow F Forced or breakdown flow
Light-rail transit (LRT)	A form of **high-capacity transit** that operates in its own fixed **guideway** and is powered by overhead electrical current. TriMet operates light-rail in the Portland metropolitan area.
Limited English proficiency	Individuals who do not speak English as their primary language and who have a limited ability to read, speak, write, or understand English. Federal laws prohibit discrimination based on national origin. Many individual federal programs, states, and localities also have provisions requiring language services for individuals with limited proficiency in English.
Liquefaction	A phenomenon associated with earthquakes in which sandy to silty, water-saturated soils lose strength and behave like a fluid. As seismic waves pass through saturated soil, the structure of the soil distorts and spaces between soil particles collapse causing ground failure. In general, young, loose sediment and areas with high water tables are the most vulnerable to liquefaction.
Local bus	Operates throughout the day and week with frequent stop spacing.
Locally Preferred Alternative (LPA)	A project alternative chosen by local and regional supporting agencies as the best overall alternative to meet a project's purpose and need. The FTA- and FHWA-preferred alternative is the same as the LPA. Once chosen, the LPA is advanced for more detailed study. Selection of the LPA does not constitute selection or approval by a project's lead agency(ies) or commitment of funding for a project. The decision whether to construct a project and the precise alternative to be constructed are documented in the **ROD** after the Final **EIS** or Final **SEIS** is approved.
Micromobility	A term encompassing alternate modes of transportation including bicycles, electric bicycles, electric scooters, electric skateboards, and shared bicycles.
Mitigation	Actions taken to minimize or compensate for negative or undesirable effects of an action. Mitigation may be required by law for unavoidable effects on the environment or on members of the public who are displaced or disadvantaged by project actions. Environmental mitigation may be conducted at the site of impact or at a different site in the general project area.
Mode	A singular, well-defined method or form of transportation. Common modes are car, truck, bus, light-rail, bicycle, and pedestrian.

Term	Definition
Modified Locally Preferred Alternative (LPA)	Refers to an agreed-upon set of components for further evaluation through the NEPA environmental review process. For the IBR Program, the Modified LPA is not the final design, but it is a key milestone setting the direction to test and evaluate plans for a new multimodal river crossing system.
Moment magnitude scale	A scale that represents the amount of energy released by an earthquake. It has replaced the use of the Richter scale because it measures a wider range of energies. Like the Richter scale, the moment magnitude scale is a logarithmic scale; units are represented as Mw. An increase of 1.0 on the scale represents roughly a 32 times increase in the amount of energy released. Moment magnitude scale measurements are similar to but not precisely equal to Richter scale values.
Multimodal	Refers to a transportation system—in whole or in part—that provides for more than one mode of transportation. For example, the **Modified LPA** would provide infrastructure for several **modes** (single-occupancy vehicles, trucks, light-rail, bus, bicycles, and pedestrians) to cross the Columbia River.
National Environmental Policy Act (NEPA)	Enacted in 1970, NEPA requires federal agencies to integrate environmental values into their decision-making processes by considering the environmental impacts of their proposed actions and reasonable alternatives to those actions. To meet this requirement, federal agencies prepare a detailed environmental document, which can be an environmental assessment or **Environmental Impact Statement**.
National Historic Preservation Act (NHPA)	A 1966 federal law designed to protect historic, cultural, and archaeological sites.
National Register of Historic Places (National Register)	This official list of historic places worthy of preservation is part of the National Park Service's program to coordinate and support public and private efforts to identify, evaluate, and protect America's historic and archaeological resources. The National Register and the efforts of the National Park Service to develop and maintain the register are authorized by the **National Historic Preservation Act** of 1966.
Neighborhood cohesion	The ability of people to communicate and interact with each other in ways that lead to a sense of community as reflected in the neighborhood's ability to function and be recognized as a singular unit.
NEPA re-evaluation	Joint **NEPA** regulations from the FHWA, FTA, and Federal Railroad Administration include a process for re-evaluating environmental documents or decisions to determine whether the original document or decision remains valid or if a supplemental or new analysis (e.g., a **supplemental environmental impact statement**) is required.
No-Build Alternative	The alternative under which no project-related action would be built. The No-Build Alternative is carried through the **NEPA** process and analyzed for effects as a way to formally compare the effects of the proposed **build alternative** with what is likely to happen if the build alternative is not constructed. Note that "no-build" does not mean "do nothing." The No-Build Alternative analysis considers other projects that are already planned and that are reasonably certain to be constructed, as well as other anticipated changes in conditions (e.g., projected population growth).
No-build conditions	Conditions that are predicted to occur if no project-related action is constructed. No-build conditions and conditions predicted to occur under the build alternative(s) are generally compared for a specific time in the future; year 2045 for the IBR Program.

Term	Definition
Notice to supplement (NTS)	A published document, similar to a new **EIS**'s Notice of Intent, informing the public of an upcoming supplemental environmental analysis for a proposed project.
Noxious weeds	Invasive plant species that have been designated by county, state, or national agricultural authorities as injurious to agricultural or horticultural crops, natural habitats, ecosystems, humans, or livestock.
Nuisance species	Non-native species that are invasive and that threaten the diversity or abundance of native species, or that cause adverse effects on human health or use of the environment.
OR	Highway designation in Oregon, e.g., OR 140.
Ordinary high water mark	The water level that a non-tidal waterbody reaches with sufficient frequency to leave visible evidence on the landscape. Typically, this is not the peak water level, but the level that a waterbody reaches twice in a given water year.
Outcome equity	In the context of the IBR Program, the result of successful **process equity** is demonstrated by tangible transportation, community, and economic benefits for **equity priority communities**.
Participating agency or **participating tribe**	One of three designations of agencies under the **NEPA** review process. Participating agencies and tribes are federal, state, and local agencies and tribal governments that have an interest in the Program under review. Each participating agency or tribe has the opportunity to participate in Program meetings, open houses, and workshops, in addition to reviewing and providing comments on various NEPA documents. Non-governmental organizations and private entities cannot serve as participating agencies.
Peak period	Informally known as "rush hour," this term refers to the time of the day when traffic volumes in an urban area are greatest and when travel patterns generate the most traffic, especially in a certain direction.
People living with disabilities	People who have a physical or mental impairment that substantially limits one or more major life activities, people who have a history or record of such an impairment, or a person who is perceived by others as having such an impairment.
Performance standards	Local traffic impacts are measured by impacts to intersection **level of service**, delay, and queuing. WSDOT, ODOT, the City of Vancouver, and the City of Portland have adopted performance standards for intersections. Further description of these standards can be found in the Transportation Technical Report.
Piles	Wooden, concrete, or metal supports that are pushed or driven into the ground to support a permanent or temporary structure. Piles are typically driven deep into the soil until they reach dense soil or bedrock.
Pleistocene age	A period of time in the Earth's history. The Pleistocene age extended from approximately 1.6 million to approximately 11,000 years before the present. During this time an occurrence of one of the earth's ice ages during which ice and glaciers advanced and retreated over a significant portion of the earth's surface
Precast (concrete)	A concrete structure that is cast into shape before being moved into place as a complete unit or as part of a larger structure.

Term	Definition
Primary study area	The 5-mile segment of I-5 from State Route 500 in Vancouver to approximately Columbia Boulevard in Portland.
Process equity	Means that the IBR Program centers and prioritizes access, influence, and decision-making power for **historically underserved communities** throughout the Program in establishing objectives, design, implementation, and evaluation of success.
Purpose and Need	A formal statement adopted by the **lead agencies** that identifies and describes the transportation problems that a program or project is seeking to address. The IBR Program's purpose and need statement, which was developed for the CRC project, identifies six transportation problems: growing travel demand and congestion; impaired freight movement; limited public transportation operation, connectivity, and reliability; safety and vulnerability to incidents; substandard bicycle and pedestrian facilities; and seismic vulnerability.
Queuing	A line of waiting vehicles. Examples of common locations for queues to form include at a **ramp meter**, a traffic signal, or waiting to turn from a left-turn lane.
Ramp meter	A signaling device at a highway on-ramp, usually a red-green stoplight, that regulates the flow of traffic entering the highway. The signaling device is connected to a traffic sensor that registers the volume of traffic on the highway and adjusts the signal timing to allow smooth entry and merging of vehicles onto the highway.
Recognized Environmental Conditions (REC)	Defined by ASTM E1527-21 as, "...the presence or likely presence of any hazardous substances or petroleum products on a property under conditions that indicate an existing release, a past release, or a material threat of a release of any hazardous substances or petroleum products into structures on the property or into the ground, groundwater, or surface water of the property."
Record of Decision (ROD)	A formal public document issued by the regulating agency(ies) that constitutes federal approval of an **environmental impact statement** for a proposed highway or transit project under **NEPA**. The ROD is the document that authorizes the relevant state transportation department(s), local jurisdiction(s), or transit agency(ies) to proceed with the design, property acquisition, construction, and transit operation (if applicable) of the project, based on the availability of funding.
Regulatory agencies	Federal, state, and local agencies that can monitor and enforce laws and regulations affecting a capital project.
Reliability	The ability of users to predict the travel times required for particular trips when referring to transportation or transit.
Riparian	The area between a stream or river and the adjoining upland areas. Riparian habitats provide important ecological functions for aquatic and terrestrial species.
River mile (RM)	The measure, in miles, of the distance from the mouth of a river or stream, following the course of the river or stream. The mouth of the river or stream is RM 0.
Screening criteria	A set of metrics used to evaluate and score the effectiveness of various transportation improvement options, usually weighed against a **no-build option**.

Term	Definition
Section 106	Section 106 of the **National Historic Preservation Act** of 1966 requires that federal agencies consider the effects of their undertakings on historic resources. This includes identifying any such resources—historic properties, buildings, structures, etc.—that could be affected by the project, assessing the possible adverse effects of the project on these resources and finding ways to avoid, minimize, or mitigate these adverse effects.
Section 4(f)	Section 4(f) of the U.S. Department of Transportation (USDOT) Act concerns transportation projects that would use or impact any significant public park, recreation area, wildlife or waterfowl refuge, or historic site. Section 4(f) applies to impacts caused by programs and policies undertaken by the USDOT.
Section 6(f)	Section 6(f) of the Land and Water Conservation Fund Act concerns parks and recreational facilities that have received funding through this act. Section 6(f) applies to impacts caused by programs and policies of a federal agency.
Special status species	A species with special regulatory status due, for example, to its rarity, sensitivity, or other factors. Special status species or their habitat may be especially sensitive to development.
Shared-use path	A path that accommodates more than one mode of travel or type of use. In the IBR Program, a shared-use path is typically a path that accommodates walkers, bicyclists, and rollers.
Signal priority	Signal priority refers to traffic signal timing that adjusts red and green lights to give preference to transit vehicles such as buses or light-rail trains and to provide preferential green lights for emergency response vehicles.
Single-point urban interchange (SPUI)	Also called a single-point diamond interchange, this type of highway interchange is similar to a **diamond interchange**, but it allows left turns to proceed simultaneously by compressing the two "diamond" intersections into a single intersection over or under the free-flowing road. The term "single-point" refers to the fact that all through traffic on the minor road and left-turning traffic is to be controlled by a single set of traffic signals.
Sole source aquifer	An underground water supply designated by EPA as the sole or principal source of drinking water for an area.
Species of concern	An informal term referring to species that are considered at risk by agencies concerned with their conservation or survival.
Staging	See **construction staging**.
State Environmental Policy Act (SEPA)	A Washington state law that identifies and assesses environmental impacts associated with private or public construction projects.
State Route (SR)	A Washington state highway designation (e.g., SR 20).
Stormwater	Flowing surface water that results from precipitation events (i.e., rain and snow) or from snowmelt. Stormwater management is a concern of transportation projects and of municipal water systems, as untreated stormwater that flows off of highways, parking lots, or other impervious surfaces can carry pollutants into soils or groundwater.

Term	Definition
Stormwater infiltration	The process by which stormwater sinks into the soil and becomes groundwater that, in turn, feeds rivers, streams, lakes, and underground water sources such as **aquifers**.
Supplemental Environmental Impact Statement (SEIS)	A supplement to a draft or final **EIS** is required when either an agency makes substantial changes to the proposed action that are relevant to its environmental concerns or there are significant new circumstances or information relevant to the environmental concerns that have relevance to the proposed action or its impacts. Following an agency's decision to supplement its **EIS**, it prepares, publishes, and files the supplement in the same fashion as a draft or final **EIS**.
Swale	A marshy or moist land, or a shallow, narrow trough-like depression that carries stormwater runoff or snow melt.
Terminus or termini	The end point of a transit service line. Termini is the plural form.
Thalweg	The deepest part of a river cross section.
Threatened species	A species that is vulnerable to extinction in the near future.
Throughput	The number of users being served at any time by the transportation system.
Title VI	Refers to Title VI of the Civil Rights Act of 1964. This law prohibits the exclusion of anyone from participation or benefit from a federally funded program on the grounds of race, color, or national origin. **Environmental justice** is a component of Title VI.
Tolling	The practice of charging a fee for use of a transportation facility such as a highway. There are several types of tolling: charging a fixed fee; charging a variable fee based on the type of vehicle, time of day, or volume of traffic; tolling a section of highway; and so-called cordon pricing which charges a fee to enter a particular area such as a metropolitan area. Tolling is generally used to help meet the cost of constructing or operating the facility, but it is also as a **transportation demand management** tool.
Total maximum daily load (TMDL)	Under the U.S. Clean Water Act, the maximum amount of a given pollutant that a body of water can receive and still meet published water quality standards.
Transfers	Funds from local or regional sources spent on a project that would otherwise be spent by residents and businesses on other economic activities within the region.
Transit-oriented development (TOD)	Urban development that is designed to provide access to and encourage the use of public transit such as buses or light-rail trains.
Transportation demand management (TDM)	Measures that seek to reduce the number of vehicles using the road system, especially single-occupancy vehicles, while providing alternative options to auto travel.
Transportation system management (TSM)	Measures that attempt to improve the efficiency of existing roadways. These include a variety of techniques focused on keeping drivers informed and moving as safely, efficiently, and reliably as possible.
Troutdale aquifer	An **aquifer** that underlies a portion of the city of Vancouver and Clark County, Washington. The Troutdale aquifer is a critical water resource for this area and, according to EPA, provides approximately 99% of the available drinking water to people in this area. The EPA has designated this resource as a **sole source aquifer** for Clark County. Considered as a geologic feature, this is referred to as the Troutdale Formation.

Term	Definition
Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (as amended) (Uniform Act)	This act provides protections and assistance for people whose real property is acquired or who must move as a result of projects receiving federal funds. The act requires that such people be treated fairly and equitably, and that they receive assistance in moving from the property they occupy.
Vehicle miles traveled (VMT)	The total number of miles that residential vehicles are driven in a specified period of time for a given area or transportation facility.
Viewer sensitivity	Considers the combined effect of the activities a viewer is engaged in, the visual context, and the values, expectations, and interests of the viewer.
Viewshed	The portion of the landscape that can be seen from within a project area and that has views of the project area. The boundaries of a viewshed are determined by the surrounding topography, vegetation, and built environment.
Visual quality	What viewers like and dislike about visual resources that compose the visual character of a particular scene. Different viewers may evaluate specific visual resources differently based on their interests in natural harmony, cultural order, and project coherence. Neighbors and travelers may, in particular, have different opinions on what they like and dislike about a scene.
Volatile organic compound (VOC)	Organic (i.e., carbon-based) compounds that are easily volatilized and that can affect human health or the environment.
Voltage	Voltage is like the “electrical pressure” in an electrical line. It is measured in volts (V) or kilovolts (kV). This pressure produces an electrical field that extends out from the line and is measured in volts per meter (V/m). Current in an active electrical line also produces a magnetic field around the line.
Volume/capacity (V/C) ratio	The ratio of the traffic demand at a given intersection, that is, the number of vehicles attempting to pass through the intersection in an hour, under prevailing conditions, to the number of vehicles that can actually pass through that intersection in an hour. With a V/C ratio of < 0.85, vehicles can generally pass through the intersection without significant delays or queues. But as the V/C ratio nears 1.0, traffic flow slows, and with a V/C ratio > 1.0, traffic flow becomes unstable and vehicles can expect to wait at least one signal cycle to pass through the intersection.
Water column	A conceptual column of water from the surface to the bottom of the waterbody. This concept is useful in analyzing the thermal or chemical strata and mixing in a waterbody.
Water quality	Refers to the characteristics of the water such as its temperature and oxygen levels, how clear it is, and whether it contains pollutants.
Waters of the State/U.S.	Waters determined to be under the jurisdiction of the U.S. Army Corps of Engineers, or of a state regulatory authority. These waters are protected under the Clean Water Act and by various state statutes. They generally include navigable waters, interstate waters, wetlands, and tributaries. Activities that would impact such waters require permitting by the appropriate agency(ies).

Term	Definition
Watershed	An area of land from which all water under or on that area drains to the same place, generally the same waterbody. Watersheds vary in shape and size as determined by topography and geology, and can cross city, county, state, or even national boundaries.
Wetland	An area of land that is inundated or saturated at such a duration that hydric soil conditions form and that hydric vegetation can develop. Specific regulatory criteria must be met for an area to be delineated as a wetland. Wetlands generally include areas such as marshes, bogs, and swamps, and they provide important ecological functions such as groundwater recharge.
Wetland buffer	An area adjacent to a wetland that provides support functions for species that live in and around wetlands and reduces the impacts of human disturbance on the wetland.
Wildlife corridor	An area of habitat that connects wildlife populations separated by human activities or structures.
