[4] The IBR Program has made a commitment to the community to place equity at the center of the Program, beyond legal and statutory requirements. A foundational component of this commitment was the formation of an Equity Advisory Group, which developed a Program-specific definition of equity and identified "equity priority communities" as those who experience and/or have experienced discrimination and exclusion based on identity or status. The communities include Black, Indigenous, and People of Color (BIPOC); people with disabilities; communities with limited English proficiency; persons with lower incomes; houseless individuals and families; immigrants and refugees; young people; and older adults.

capacity transit, increased availability of active transportation, and highway and driving travel time reductions. Burdens to equity priority communities include potential displacement of encampments of houseless populations, residential displacements, and the additional transportation cost from tolling. See Section 3.05, Neighborhoods and Equity, for additional details on direct and indirect impacts to neighborhoods and equity priority communities.

The Modified LPA is expected to continue the positive trend in the corridor of improving neighborhood access and mobility. The provision of a light-rail station, the connection of N Tomahawk Island Drive under I-5, and the improved access and capacity of the Hayden Island interchange may contribute to the viability and success of redevelopment plans for the island (see Section 3.4, Land Use and Economic Activity). However, the Modified LPA would displace sufficient commercial and residential activities to constitute an adverse impact. One major difference between the Modified LPA and past actions is that past actions were not always planned and implemented with meaningful input from and communication with the public, including equity priority communities. Involving communities and understanding impacts is an essential part of the IBR Program.

Cumulative Effects Conclusion – Neighborhoods and Equity

Past transportation projects, such as the original construction of I-5, had significant effects on neighborhoods and communities in the I-5 corridor, including equity priority communities, leading to a loss of community cohesion and displacement of businesses and homes. Recent, present, and reasonably foreseeable future actions typically seek to avoid, minimize and mitigate impacts to communities through closer analysis of how a project could affect neighborhoods and specific populations. Most of the reasonably foreseeable future actions are anticipated to improve connectivity and cohesion, either as their intended purpose (e.g., Waterfront Gateway) or through required mitigation (e.g., the I-5 Rose Quarter Improvement Project). Local land use plans, including neighborhood plans in Portland and Vancouver, will continue the trend of improving neighborhood access and mobility.

The No-Build Alternative would not contribute to adverse or beneficial cumulative effects on neighborhoods and equity created by past, present, and reasonably foreseeable future actions. The Modified LPA would contribute to adverse cumulative effects from past and reasonably foreseeable future actions that have displaced commercial and residential uses. Reasonably foreseeable future actions that would affect neighborhoods and equity would be required to follow federal and state guidelines for potential displacement and other adverse impacts. The Modified LPA and other reasonably foreseeable future actions would also contribute to the positive trends of improving neighborhood access and mobility, and providing public engagement opportunities for neighborhoods and equity priority communities

Under the No-Build Alternative, the cumulative effects on neighborhoods and equity from past, present, and reasonably foreseeable future actions, would continue to be adverse due to displaced commercial and residential uses. Compared to the No-Build Alternative, the cumulative effects on neighborhoods and equity from the Modified LPA would be beneficial due to improved access, pedestrian-oriented development, and other amenities and slightly more adverse due to potential displacement.

Public Services and Utilities

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Past population growth has incrementally increased demand on public services and utilities. Effects from most of the reasonably foreseeable future projects would include changes to traffic patterns and increased demand on public services and utilities. Adopted land use plans and projected population growth are expected to create an increased demand for public services and utilities. However, since those increases are planned, it is reasonable to assume that the public service sector and utility providers would have adequate time to plan and adjust for future conditions.

Forecast population and development patterns reflected in the long-range comprehensive plans of the jurisdictions served by each public service and utility provider will affect public services and utilities. Service providers evaluate future population growth and calculate provider needs such as increased numbers of police officers, expanded treatment plants, new equipment, or new station locations. Anticipated density increases in downtown Vancouver and on Hayden Island are consistent with current long-range plans and growth assumptions, and increased services for new development would occur in urbanized areas that already have public services and utilities. This anticipated development would not require the extension of service to a new geographic area.

Current emergency response time trends are increasing. Annual performance reports by the City of Portland Fire and Rescue show that from 2017 to 2022, fire and medical emergency response times at the 90th percentile increased. The City of Vancouver Fire Department reports an increase in standard response times from 2022 to-2023. Similarly for law enforcement, the Portland Police Bureau's Dispatched Calls Dashboard indicates that the average emergency response times within the study area increased between 2017 and 2022. Forecasted changes in response times are not available, although service providers are anticipated to plan for future needs based on forecast population and development patterns found in long-range comprehensive plans.

No-Build Alternative

The No-Build Alternative would not change existing utility connections and would, therefore, not have a cumulative effect on utilities. While the No-Build Alternative would not change the types of public services provided, increased congestion could slow response times for emergency vehicles, and ongoing bridge openings would continue to disrupt traffic and cause potential delays for emergency vehicles, which would have an adverse effect on public services. I-5 is an important north-south access route through the study area, and it is the only emergency access route to and from Hayden Island. Increased congestion under the No-Build Alternative would decrease the ability of the public, particularly Hayden Island residents, to reliably reach or receive public services due to increased travel times and lower travel speeds.

Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on public services and utilities (identified above) would continue under the No-Build Alternative. Impacts from those actions would be included in long-range plans and growth assumptions.

Modified LPA

The Modified LPA would enhance transit service that provides access to public service facilities such as medical facilities, police and fire facilities, or schools. The Modified LPA would provide transportation reliability improvements through changes in roadway and traffic operations to critical access routes that would generally improve emergency response times to serve the planned growth. The direct physical impacts to public services from the Modified LPA would be minor. The IBR Program would work with affected communities to ensure that Program-related changes do not impair existing overall levels of public service. Utilities would be protected in place or relocated during construction; following completion of construction, utilities are expected to operate as well as or better than they do currently.

Cumulative Effects Conclusion – Public Services and Utilities

Past actions, including population growth, have incrementally increased the demand on public services and utilities. Current trends in emergency response times show an increase in response times, and, consistent with current practices, public service providers will continue to evaluate reasonably foreseeable future population growth to meet demand. Reasonably foreseeable future actions in the study area that could affect public services and utilities include increased service and associated new or improved facilities as well as an increase in utility services based on forecast population and development patterns found in comprehensive

long-range plans. The Cascade Renewable Transmission Project would provide renewable energy and additional energy capacity to the Oregon and Washington electrical grid.

The No-Build Alternative, combined with past, present, and reasonably foreseeable future actions, would not contribute to cumulative effects on utilities but would contribute to cumulative effects on public services (Table 3.6-5). Under the No-Build Alternative, increased congestion in the study area would continue to slow response times for emergency vehicles, ongoing bridge openings would continue to disrupt traffic and cause potential delays for emergency vehicles, and the public would have a decreased ability to reliably receive or reach public services. The Modified LPA and other reasonably foreseeable future actions would support planned growth in the study area by providing new light-rail service, improving the reliability of bus transit, and facilitating the types and densities of development envisioned in local and regional land use plans, especially in Hayden Island and downtown Vancouver.

The No-Build Alternative, including past, present, and reasonably foreseeable future actions, would have cumulative adverse effects on public service as a result of increases in emergency response times. The Modified LPA would provide beneficial improvements in transportation reliability serving emergency access routes and expanded access to high-capacity transit. There would be little to no cumulative effects on utilities from either alternative.

Parks and Recreation

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Park and trail development efforts in the region have been ongoing and will continue consistent with current plans and programs. Some of the parks and recreation facilities are regulated and protected by Section 4(f) of the U.S. Department of Transportation Act, Section 6(f) of the Land and Water Conservation Fund Act, and/or the Federal Lands to Parks (FLP) program. These protections, along with state and local goals to increase access to recreation facilities, have led to an increase in acreages of parks and recreation facilities in both Vancouver and Portland over the past decade (City of Vancouver 2021; City of Portland 2022).

Recent projects that have added or expanded facilities include public open space at the Vancouver waterfront and a new amphitheater at Terminal 1, both of which are connected by new segments of the Renaissance Trail. Planned expansions of park and recreation facilities in adopted plans include park and trail development at the North Portland Harbor waterfront, Hayden Island, the Vancouver National Historic Reserve, and Kiggins Bowl. None of the identified reasonably foreseeable future projects are anticipated to reduce the number or size of park or recreation facilities in the study area (including those protected under Section 4(f), Section 6(f), or the FLP program). Several of the reasonably foreseeable future projects would create new parks and recreation facilities, including a new sports and cultural complex at Expo Center, 2 acres of public space at Waterfront Gateway, and public spaces and trails proposed as part of Terminal 1 and Renaissance Boardwalk. Planned extensions or improvements to the trail systems in Portland and Vancouver will connect many of the new recreation facilities.

No-Build Alternative

The No-Build Alternative would not require the conversion of parks and recreation resources to transportation use. Access to parks and recreation resources would remain as is, with limited public transit service and active transportation facilities. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on parks and recreation (identified above) would continue under the No-Build Alternative.

Modified LPA

The Modified LPA would require the acquisition of approximately 1.3 acres of parkland for a transportation use. Permanent acquisitions would be required from East Delta Park, the Fort Vancouver National Historic Site, Old Apple Tree Park, Marshall Community Center and Park, and Kiggins Bowl. Some acquisitions would affect lands protected by Section 4(f) and/or Section 6(f) (see Chapter 4 for the draft Section 4(f) evaluation and Section 3.21, Section 6(f) and Federal Lands to Parks). These acquisitions would be used for transportation uses, including improved connections across the active transportation network in the study area.

The Modified LPA would improve access to regional recreational resources including the Portland International Raceway, East Delta Park, and the Vancouver National Historic Reserve. Notably, it would improve access and connections to the Portland Expo Center, which would support Metro's plans to redevelop the site into a sports and cultural complex. The Modified LPA would also improve access to the Vancouver waterfront and connect parks on both the east and west sides of the bridges, which would essentially restore the once-connected waterfront that was bifurcated by the existing bridge.

Cumulative Effects Conclusion – Parks and Recreation

While some past actions reduced recreational areas due to conversion to other uses, recent projects have typically increased the number of recreation and park resources. Present actions include routine maintenance of parks and recreational facilities. Current trends suggest that parks and recreation sites in the study area will continue to be expanded and improved by reasonably foreseeable future actions.

The No-Build Alternative would not contribute to cumulative effects as access to parks and recreation resources would remain as is and there would be no change to existing resources. However, other actions would continue to result in net expansions, and improve access to, parks and recreation facilities. The Modified LPA would contribute to current trends by improving connectivity between existing and planned facilities through new and improved active transportation facilities.

Under the No-Build Alternative, the cumulative effects on parks and recreation from past, present, and reasonably foreseeable future actions, would continue to be beneficial through increased number and size of parks and recreation facilities. The cumulative effects on parks and recreation from the Modified LPA would have a net incremental beneficial effect through additional access and connections.

Cultural Resources

Archaeological Sites

Effects from Past, Present, and Reasonably Foreseeable Future Actions

The Archaeology Technical Report identifies and assesses effects on archaeological sites protected under Section 106 of the National Historic Preservation Act. While there is archaeological evidence that Native Americans inhabited the Pacific Northwest more than 10,000 years ago, the archaeological record for Native American land use in the lower Columbia River begins around 3,500 years ago. The Native American groups inhabiting the cultural resource area of potential effects (APE)[5] were part of an extensive network of villages, trade, and harvesting, fishing, and resource sites. Villages consisted of multifamily houses and other structures such as fish-drying sheds or scaffolds, sweat and menstrual lodges, and temporary dwelling houses. Starting in the late 18th century, maritime expeditions by Europeans and European Americans began

[5] The APE is defined as "the geographic area or areas within which an undertaking may directly or indirectly cause alteration in the character or use of historic properties, if any such properties exist." (936 CFR 800.16(d)) APE is analogous to "study area," which is the term commonly used for other resources.

to interact with Native Americans along the Oregon coast and the mouth of the Columbia River. European American settlement along the Columbia River's southern bank remained sparse in the mid-1800s and the area remained sparsely developed throughout the 19th century. More extensive development began in the 20th century, including rapid development associated with World War II and construction of I-5 in the 1950s.

Past construction activities have involved earthmoving on a massive scale, which impacted the presence and preservation of archaeological sites in the APE. Many archaeological sites have been lost or altered by construction projects, though some have been preserved underground and, recently, some have been recovered, studied, and archived. Additional studies are in progress to verify known archaeological resource presence and dimensions, and to identify unrecorded terrestrial and marine archaeological sites. Further studies will be performed through phased identification as allowed under Section 106 of the National Historic Preservation Act (36 CFR 800.4 (b)(2)) and would be stipulated in the Section 106 Programmatic Agreement (PA).

While none of the identified reasonably foreseeable future actions are known to affect a documented archaeological site, it is likely that reasonably foreseeable future actions in the APE could encounter additional sites, which could be preserved, recovered, disturbed, or destroyed. The environmental assessment for the USACE levee system improvements acknowledges that these improvements could disturb or destroy known or presently unknown archaeological resources (USACE and CCDD 2021). Ground disturbance associated with any of the reasonably foreseeable future actions, as well as ongoing development in the area consistent with adopted land use plans, may affect archaeological sites. Current local, state, and federal cultural resources laws and regulations that protect archaeological sites reduce the likelihood of destruction, but cannot completely prevent it.

No-Build Alternative

The No-Build Alternative would not affect archaeological sites in the APE and would therefore not contribute to a cumulative effect. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on archaeological sites would continue under the No-Build Alternative, though any impacts from those actions would be subject to regulatory requirements for the protection of archaeological sites.

Modified LPA

Construction-related physical ground disturbance is anticipated to be the primary source of potential permanent and temporary direct effects on archaeological sites. As discussed in Section 3.8, 15 archaeological sites are located within the Washington portion of the APE; of these 15 sites, 12 are within the Modified LPA footprint and have the potential to be impacted by construction-related physical ground disturbance based on the anticipated nature and extent of ground disturbance associated with the Modified LPA. The remaining three resources are located within the APE but are outside of the Modified LPA footprint. FHWA and FTA are consulting to complete the Section 106 process and resolve adverse effects on historic properties through the development of a PA, pursuant to 36 CFR 800.14(b).

Cumulative Effects Conclusion – Archaeological Sites

The archaeological record for Native American land use in the lower Columbia River begins around 3,500 years ago. European and European American settlement in the area began in the late 18th century and remained sparsely developed throughout the 18th and 19th centuries. More extensive development began in the 20th century, including rapid development associated with World War II and construction of I-5 in the 1950s. Past construction activities have impacted the presence and preservation of archaeological sites in the APE and ground disturbance from ongoing development could disturb or destroy known or unknown archaeological resources in the area. Recent studies have recovered, studied, and archived archaeological sites and

additional studies are in progress to verify known archaeological resource presence and dimensions, and to identify unrecorded terrestrial and marine archaeological sites.

The No-Build Alternative would not contribute to cumulative effects on archaeological sites, as no known archaeological sites in the APE would be affected; however, it would not change the overall trends in disturbance to archaeological sites from other past, present, and future actions. Although local, state, and federal regulations are in place to protect archaeological sites, ground disturbance during construction of the Modified LPA and other reasonably foreseeable future projects may result in adverse effects on known or unknown sites.

Under both the No-Build Alternative and the Modified LPA, cumulative effects on archaeological sites from past, present, and reasonably foreseeable future actions would be adverse due to a pattern of large-scale ground disturbance in the study area.

Historic Built Environment

Effects from Past, Present, and Reasonably Foreseeable Future Actions

The historic built environment (HBE) includes built resources protected under Section 106 of the National Historic Preservation Act. Some of the historic sites are also regulated and protected by Section 4(f) of the U.S. Department of Transportation Act. There is a wide variety of HBE resources in the APE in Oregon and Washington, reflective of the area's historic development. The land now known as Vancouver became an important post in the Hudson's Bay Company's inland trade routes, succeeded thereafter by a U.S. military installation, and was the center of life and commerce in the region. The region became an important area for trading in the 18th and 19th centuries, with ample resources provided by the rivers and adjacent valleys. Further growth and development in the region in the 20th century was driven by the introduction of wartime industries, such as the Kaiser shipyards, and the completion of major infrastructure projects, including railroad bridges and the Interstate Bridge. The 1917 Interstate Bridge span is listed on the National Register of Historic Places in both Oregon and Washington, and the 1958 span has been determined eligible for listing.

Past activities of settlement and development both created the existing HBE and have dramatically affected the preservation of HBE resources in the APE. Many resources were demolished or their historic contexts largely altered. The original construction of I-5 divided Vancouver's downtown from the Vancouver National Historic Reserve and separated the major commercial and civic center from the historic resources and context of the fort and barracks. Recent development, including the Vancouver Community Library and the Aegis/Providence Academy redevelopment, has affected the HBE through changes in the historic setting of downtown Vancouver.

Several of the identified reasonably foreseeable future actions are anticipated to affect known historic resources, namely redevelopment of the Expo Center, which is recommended as eligible for listing on the National Register of Historic Places, and the USACE levee system improvements, which would affect contributing resources in the Columbia Slough Drainage Districts Historic District (note that the Modified LPA would have no adverse effect on this district). It is also likely that reasonably foreseeable future actions could alter the context and setting of historic resources, and ongoing development in the area consistent with adopted land use plans may affect historic resources, ranging from demolition, preservation and restoration, to changes in the historic setting.

No-Build Alternative

The No-Build Alternative would retain the existing infrastructure, including the existing historic Interstate Bridge, which would continue to operate. There would be no direct impacts on the character-defining features or integrity of the HBE properties and, therefore, no contribution to cumulative effects. A seismic event could adversely affect the two historic bridge spans. Other reasonably foreseeable future actions in the

study area that could contribute to cumulative effects on the HBE (identified above) would continue under the No-Build Alternative, though any impacts from those actions would be subject to regulatory requirements for the protection of historic sites and features.

Modified LPA

The Modified LPA is being designed to avoid direct effects on HBE resources and minimize impacts that cannot be avoided. However, activities proposed for the Modified LPA would result in adverse effects, as defined under 36 CFR 800.5, on 12 HBE properties, including demolition of the northbound and southbound Interstate Bridge (and the Normandy Apartments under the I-5 shifted west design option). Other changes include affecting the historic features or settings of various resources. There are some differences in effects on historic properties across the design options, but no design option would completely avoid adverse impacts, and therefore all would contribute to adverse cumulative effects.

Cumulative Effects Conclusion – Historic Built Environment

HBE resources in the APE in Oregon and Washington are reflective of the growth and development in the region, particularly trading in the 18th and 19th centuries and the introduction of wartime industries during the 20th century. Despite substantial development over the past decade, many historic resources and districts remain in the study area. Ongoing development has led to an incremental loss of the area's historic fabric, and this will continue into the future as more development and redevelopment occur. The No-Build Alternative would not directly contribute to cumulative effects on the HBE; however, it would not change the overall past, present, and reasonably foreseeable future trends of HBE properties being affected by other transportation and land redevelopment actions. While reasonably foreseeable future actions, including the Modified LPA, will be required to meet regulatory requirements, the Modified LPA will contribute to changes in the context and setting of the study area over time.

Under both the No-Build Alternative and the Modified LPA, the cumulative effects on the HBE from past, present, and reasonably foreseeable future actions would be adverse due to specific impacts to HBE resources and changes in the surrounding historic setting.

Visual Quality

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Visual quality impacts occur when the visual character of a place changes (for example, from an agricultural landscape to a residential development) as perceived by viewers. In the Portland and Vancouver areas, visual character has steadily evolved from a primarily natural environment to rural and agricultural, and then to suburban and urban. The I-5 corridor has steadily grown in development intensity and in use as a major transportation route. Reasonably foreseeable future development projects will continue the study area's visual transformation. Identified reasonably foreseeable future actions that would alter the existing and cumulative visual character in the study area include development and redevelopment projects in downtown Vancouver and north Portland. Reasonably foreseeable future projects such as Terminal 1, Waterfront Gateway, Renaissance Boardwalk, and Portland Expo Center Redevelopment would add new buildings or redevelop existing buildings adding to the development intensity along the I-5 corridor and existing visual character of the project environment in downtown Vancouver, along the Vancouver waterfront, and in north Portland. Reasonably foreseeable future transportation projects within the study area would contribute to changes in the visual character of the physical and project environment through visual changes from traffic congestion and constructed elements within the road, public transit, and active transportation network.

All of the identified reasonably foreseeable future projects would alter the existing and cumulative visual character in the study area to some degree; however, projects would be required to be consistent with

existing zoning and design standards, which would maintain visual consistency with existing development and minimize additional adverse effects to visual quality.

No-Build Alternative

While the existing bridges, ramps, interchanges, roadways, and other structures would remain in place, the visual environment would not be static or unchanging with the No-Build Alternative. Ongoing and upcoming development within the Area of Visual Effect (AVE) would continue to impact the visual character. Furthermore, the No-Build Alternative would lead to heightened traffic congestion within the AVE, potentially diminishing the overall visual cohesiveness of the project environment. However, the No-Build Alternative would not significantly influence the existing visual character and would not contribute to cumulative adverse effects on visual quality.

Other reasonably foreseeable future actions in the study area could contribute to cumulative effects on visual quality as identified above, although impacts from those actions would be subject to applicable regulatory requirements within existing zoning and design standards.

Modified LPA

The primary elements of the Modified LPA that would affect visual character and quality are new highway bridges across North Portland Harbor and the Columbia River; revised I-5 interchanges; and light-rail transit guideway, stations, and park-and-ride facilities. The visual quality of the entire length of the study area and all landscape units would be affected.

In general, the Modified LPA is expected to have a range of visual quality impacts from neutral to beneficial for most viewers in the Columbia Slough, Columbia River, Vancouver Downtown, Burnt Bridge Creek, and Ruby Junction landscape units. With the Modified LPA, the higher Columbia River bridges' decks and the more visually complex SR 14 interchange represent an increase in the scale of visual elements of the project environment. These new elements are likely to be notably more visible to adjacent recreational viewers in the Greater Central Park landscape unit. As a result, impacts to visual quality are expected to be adverse for these sensitive viewers.

Cumulative Effects Conclusion – Visual Quality

Past actions transitioned the visual character of the study area from a natural environment to an urban environment as Portland and Vancouver developed and as rail routes and the I-5 corridor were constructed. The current trend of urban development will continue, and present and reasonably foreseeable future projects would continue to change visual character as the area continues to develop and transition to a denser urban environment.

The No-Build Alternative would not change the overall trends in visual quality with reasonably foreseeable future actions continuing the trend of urban development in the study area. The Modified LPA and reasonably foreseeable future actions would add to beneficial and adverse cumulative effects on visual character through ongoing and upcoming urban development creating new visual elements. To the extent that projects would be consistent with existing zoning and design standards to maintain visual consistency with existing development, their visual character would be consistent with the long-standing trend of an increasingly urban landscape.

Under both the No-Build Alternative and the Modified LPA, the cumulative effects on visual quality from past, present, and reasonably foreseeable future actions, would be either beneficial or adverse, depending on the viewers' location, activity, and visual sensitivity.

Air Quality

Effects from Past, Present, and Reasonably Foreseeable Future Actions

In the 1800s, there were limited air pollutant emissions as the study area and region was characterized by natural wilderness landscapes and human settlements were significantly smaller than they are in the present day. Since the 1950s, actions including the construction of I-5 and increased urbanization have resulted in the incremental introduction of air pollutants from vehicles and development. Starting in the early 1970s, regulatory controls on air pollutant emissions have substantially reduced emissions, including industrial and vehicle emissions. Long-term monitoring has shown that air quality has improved over the years. The Oregon Department of Environmental Quality (DEQ) measures air pollutant levels with a network of air monitoring and sampling equipment at more than 40 sites throughout the state, including the study area. The Washington State Department of Ecology (Ecology) does not operate many monitors in the Vancouver area because the monitors operated by DEQ fulfill the federal monitoring requirements for the metropolitan area. Over the last 10 years, pollutant concentrations have been trending mostly downward for most locations, with most exceptions corresponding to wildfire smoke events.

The implementation of current regulations will continue to reduce pollutant emissions from mobile sources and other sources into the future and, along with vehicle electrification, are expected to yield additional vehicle emission reductions over the next 25 to 30 years (DEQ 2021; FHWA 2016).

The air quality analysis is based on projected land use and employment information, expected overall growth in the region and the study area, and the effect of the transportation projects identified as reasonably foreseeable future actions. Non-transportation projects may increase emissions, such as general commercial and residential development in the area. Tolling of I-205 (Abernethy Bridge), if advanced in Oregon, may reduce overall emissions through a mode shift away from single-occupancy vehicles to carpooling, public transit, and active transportation, as well as a reduction in emissions associated with congestion.

No-Build Alternative and Modified LPA

Under both the No-Build Alternative and the Modified LPA, air pollutant emissions are expected to be substantially lower in the future than under existing conditions for most mobile source air toxics and criteria pollutants. For all pollutants analyzed, future (2045) emissions are projected to be lower than existing conditions under both the Modified LPA and No-Build Alternative.

The Modified LPA would result in lower pollutant emissions than the No-Build Alternative. Reductions in vehicle miles traveled (VMT) and improved traffic flow under the Modified LPA would result in lower emissions of mobile source air toxics and criteria pollutants in the region, with decreases ranging from 1% to 16%, varying by pollutant. The Modified LPA may also contribute to beneficial cumulative effects through the expansion of public transit and active transportation networks or other projects, resulting in changes to emissions and beneficial effects on air quality. However, traffic volumes on some roadway links would increase with the Modified LPA, which could increase localized air pollutant concentrations.

Regional improvements, such as increased transit capacity and extension of active transportation networks, would further reduce additional future emissions and have a positive effect on air quality. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on air quality (identified in the air quality analysis) would continue under the No-Build Alternative, though any impacts from those actions would be subject to applicable regulatory requirements for air pollutant emissions from mobile sources or other sources.

Cumulative Effects Conclusion – Air Quality

Past actions affecting air quality in the study area and region include population growth and accompanying development leading to an increase in the number of emission sources, including single-occupancy and

freight vehicles, industrial sites, and the expansion of and demand for utilities. Recent actions have started to reverse course and reduce air pollutants, primarily due to the implementation of programs and regulations to control pollutant emissions. In addition, recent and reasonably foreseeable future regional improvements to transportation supply through increased roadway and transit capacity, active transportation networks, and measures such as regulations on other source types would reduce additional future emissions and have a positive effect on air quality. Long-term monitoring of air quality over the last 10 years is showing a downward trend in pollutant concentrations. Reasonably foreseeable future actions in the study area that affect air quality would be required to meet applicable regulations that control air pollutant emissions.

Due to long-term air quality trends and other actions, future air pollutant emissions under the No-Build Alternative are expected to be reduced for most mobile source air toxics and criteria pollutants. The Modified LPA would further reduce emissions compared to the No-Build Alternative, through reductions in VMT, improved traffic flow, and expansion of public transit and active transportation networks.

Under the No-Build Alternative, the cumulative effects on air quality from past, present, and reasonably foreseeable future actions would be beneficial due to an anticipated reduction in pollutant emissions. Compared to the No-Build Alternative, the cumulative effects on air quality from the Modified LPA would be incrementally more beneficial due to reduced VMT, improved traffic flow, and a mode shift to public transportation and active transportation.

Noise and Vibration

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Past actions include urban development in the region that led to the introduction of urban noise sources in the study area. In addition to existing urban noise sources, residential and commercial construction activities in the study area could be a substantial, intermittent source of noise and vibration into the future.

Noise in the study area is typical of urban noise sources and noise levels. Sources include traffic on I-5, SR 14, SR 500, Martin Luther King Jr. Boulevard, N Marine Drive, and various arterials and other roadways. Air traffic associated with Portland International Airport (PDX) and Pearson Field is also a substantial source of noise that has increased over time. Marine vessels on the river, trains on two rail lines, industrial uses, and the Portland International Raceway further add to the cumulative noise environment. Many residences and other uses in the study area, including those adjacent to I-5 and the proposed light-rail transit line, have experienced increasing noise levels over time, resulting from steady growth in vehicle traffic, air traffic, and other urban noise sources. If the land use plans for the City of Vancouver and Hayden Island are realized, then residential and commercial construction activities could be a substantial, intermittent source of noise and vibration into the future.

Present and reasonably foreseeable future transportation and transit projects are required to evaluate noise and vibration impacts resulting from permanent facility improvements and from construction activities. If cumulative transportation noise levels exceed thresholds established by ODOT, WSDOT, FHWA, and FTA, then mitigation analysis must be conducted. Past projects were not always subject to these requirements; thus, present and reasonably foreseeable future projects, through required mitigation analysis and implementation, are often able to reduce overall transportation noise, as the applied mitigation would also reduce noise produced by existing transportation sources.

Identified reasonably foreseeable future actions in the study area that could contribute to cumulative effects on noise and vibration include the following:

- Transportation improvements to public transit, state highways, local road networks, and active transportation facilities as identified in the2018 RTP. These projects are included into the transportation analysis of the Modified LPA and No-Build Alternative.

- Metro's future redevelopment of the Expo Center, which may include a sports and cultural complex, could replace or expand the exhibition hall use that currently occurs at this location.
- Two concurrent efforts are underway to improve the existing levee system along the Columbia River near the Interstate Bridge: the USACE and UFSWQD Portland Metro Levee System project and Flood Safe Columbia River. Proposed improvements include raising the elevation of the levees.
- The City of Portland's 2009 planning for Hayden Island calls for redevelopment of the commercial core from the current large-scale retail land use pattern to a more urban form with more mixed uses, pedestrian-scale design, and transit orientation. The plan identifies a replacement bridge over the Columbia River and the addition of high-capacity transit, both of which the IBR Program would provide, as important elements of future development on the island.
- Several developments are planned for the Vancouver waterfront, including (1) the Port of Vancouver's Terminal 1 mixed-use (i.e., hotel, office and retail space, outdoor gathering areas, and a public marketplace) project, which also includes a trail connection to the Vancouver Waterfront Renaissance Trail; (2) the Renaissance Boardwalk, which is public-private partnership for a mix of apartments, retail, and underground parking: and (3) the Waterfront Gateway Project run by the Vancouver City Center Redevelopment Authority to redevelop an area between the waterfront and downtown Vancouver with mixed-use office, retail, and residential uses. These future Vancouver waterfront developments would continue to expand the present and recent past developments to create more commercial-residential uses compared to past industrial uses along the waterfront.

No-Build Alternative

Under the No-Build Alternative, increased noise and vibration levels in the future would be expected to increase as population, employment, highway traffic, public transit service, air traffic, and freight rail traffic continue to grow and planned development and redevelopment are implemented. The No-Build Alternative would result in highway noise impacts to 215 sensitive receptors (e.g., residences, parks, schools, and hotels) where noise levels approach or exceed noise abatement criteria thresholds established by ODOT, WSDOT, and FHWA. No new transit-related noise and vibration impacts would occur under the No-Build Alternative. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects related to noise and vibration would continue under the No-Build Alternative. There would be permanent noise and vibration effects associated with highway traffic, and temporary effects associated with construction of transportation facilities.

Modified LPA

The noise analysis described in Section 3.11 incorporated regional growth and foreseeable transportation projects; therefore, the noise modeling results include transportation-related cumulative effects associated with noise and vibration from the Modified LPA in combination with other transportation projects in the study area. Noise and vibration impacts under the Modified LPA would include permanent impacts such as increased noise to sensitive receptors along I-5, existing and new transit facilities, and along local streets that would be modified in the study area. Approximately 198 sensitive receptors would experience highway-related noise levels that approach or exceed noise criteria thresholds established by ODOT, WSDOT, and FHWA. Transit-related noise would have moderate-level impacts to approximately 12 sensitive receptors (this would be reduced to 0 with mitigation) and vibration impacts to 13 sensitive receptors along the extended light-rail transit facilities. Construction activities would result in increased noise and vibration due to construction equipment, drilling or pile driving, and other related construction activities. Construction-related noise impacts are regulated by local jurisdictions through permits or variance requests.

Noise abatement proposed for the Modified LPA, such as noise walls, would reduce traffic noise to below the noise abatement criteria levels at 77 of the 198 noise-impacted sensitive receptors. Mitigation measures

would be developed in accordance with the FHWA highway noise mitigation regulations and the FTA transit noise and vibration impact assessment manual (see Section 3.11.7).

Cumulative Effects Conclusion – Noise and Vibration

Past actions include urban development in the region that led to the introduction of urban noise sources in the study area. Many residences and other uses in the study area have experienced increased noise levels over time, driven by the growth in urban noise sources. Under the No-Build Alternative, no new transit-related noise and vibration impacts would occur, although continued population, employment, highway traffic, public transit service, air traffic, and freight rail traffic growth and planned development and redevelopment would contribute to increased noise and vibration levels in the future. The No-Build Alternative would result in highway noise impacts to 215 sensitive receptors in the study area.

While the Modified LPA would increase transportation noise in and introduce transit vibration to the study area, it would also provide mitigation that would reduce noise levels at sensitive receptors affected by cumulative transportation noise from past, present, and reasonably foreseeable future actions. Including mitigation benefits, the Modified LPA would result in cumulative highway noise impacts to 121 sensitive receptors as compared to 160 existing impacts and 215 with the No-Build Alternative (Table 3.11-8).

Past, present, and reasonably foreseeable future actions have introduced transportation noise creating adverse effects in the study area, which would continue with the No-Build Alternative. The Modified LPA would have both adverse and beneficial cumulative effects. It would increase existing noise and vibration generated by highway and transit sources, but it also would provide noise abatement measures that would reduce the number of sensitive receptors affected by cumulative highway noise levels.

Energy

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Regional energy demand and use in the study area have grown as a result of general development patterns, including suburban residential growth, increases in the VMT of single-occupancy vehicles, and increase in renewable energy sources used. However, even though cumulative energy demand and use in the study area has increased, the expansion of C-TRAN's bus service in Vancouver (including the introduction of bus rapid transit and electric express buses) and improvements in TriMet's bus and light-rail system (including the extension of light-rail to the Expo Center and the use of wind-generated electricity for the Metropolitan Area Express [MAX]), contribute to a small incremental benefit for cumulative energy demand and use due to the use of alternative energy sources, and supporting a mode shift from personal vehicles to public transit. These strategies are consistent with and reflective of action items in the City of Vancouver's 2022 Climate Action Plan and climate emergency priorities in the City of Portland's Climate Emergency Workplan 2022–2025.

Tolling of I-205 (Abernethy Bridge), if advanced in Oregon, may reduce energy use through a reduction in the number of single-occupancy vehicles on the road caused by a mode shift to carpooling, public transit, and active transportation.

The Cascade Renewable Transmission Project will help achieve Oregon and Washington's clean energy goals by adding 1,100 megawatts (MW) of east-to-west energy transfer capability in the region and assisting in the distribution of increased power flows on the networked transmission system, especially during extreme heat events.

The future demand for energy will depend on trends in population, economic activity, energy prices, and adoption and implementation of technology. The U.S. Energy Information Administration projects that energy consumption in the transportation sector will remain lower than 2019 levels through 2050 due to

improvements in fuel economy. As a result, energy consumption by light-duty and heavy-duty vehicles is projected to remain lower than 2019 levels through 2045.

No-Build Alternative and Modified LPA

The energy analysis in Section 3.12 incorporates projected increases in traffic, regional growth, and reasonably foreseeable future transportation projects. The analysis showed that under both the No-Build Alternative and the Modified LPA, energy consumption and GHG emissions in 2045 are expected to be substantially lower than existing values for the region, which is consistent with national trends. Although the annual VMT in the study area would increase, GHG emissions would decrease substantially compared to baseline conditions (2015) due to the implementation of fuel and engine efficiency regulations. On a regional basis, future emissions would be similar under the No-Build Alternative and Modified LPA.

Operation of the Modified LPA would lower the transportation demand for petroleum relative to the No-Build Alternative because of the mode shift to public transportation and active transportation options. Energy required to power light-rail transit operations is more than offset by the reduction in petroleum demand from roadway users. Daily regional VMT would decrease by approximately 0.16%, and total regional transportation energy consumption would decrease by approximately 0.28% in 2045 under the Modified LPA compared to the No-Build Alternative.

Construction of the Modified LPA would require up to 2.6 million British thermal units to power construction equipment and transport materials to and from project locations. This increased demand for petroleum during construction would be offset by the benefits achieved from roadway user energy demand after 15 years of operations.

Cumulative Effects Conclusion – Energy

Past actions have increased regional energy demand and use in the study area, largely as a result of general development patterns, which have been increasingly dense and urban. Current trends from present and reasonably foreseeable future actions include the adoption of renewable energy sources and public transit improvements, which are increasing the use of alternative energy sources and supporting a mode shift from personal vehicles to public transit. Reasonably foreseeable future actions will continue to incrementally decrease energy demand and GHG emissions.

Energy consumption and GHG emissions under the No-Build Alternative would continue to decline due to other past, present, and reasonably foreseeable future actions. The Modified LPA would further reduce energy consumption and GHG emissions compared to the No-Build Alternative, through reductions in VMT and a mode shift to public transit and active transportation.

The Modified LPA and other actions would contribute to adverse cumulative effects on energy through the energy demand required to construct the projects, as well as beneficial cumulative effects on energy by contributing to other projects that lower the transportation demand for petroleum due to mode shift.

Under the No-Build Alternative, the cumulative effects on energy from past, present, and reasonably foreseeable future actions would be beneficial due to reduced energy consumption and GHG emissions from the implementation of fuel and efficiency regulations. Compared to the No-Build Alternative, the cumulative effects on energy from the Modified LPA would be incrementally more beneficial due to reduced VMT and a lower transportation demand for petroleum due to mode shift to public transportation and active transportation options.

Electric and Magnetic Fields

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Federal regulations addressing electromagnetic fields (EMF) were introduced in response to incremental increases in the presence of EMF sources such as AM and FM radio, television, and wireless sources. Sensitive receptors to EMF include hospitals and research facilities. The existing EMF environment in the study area varies depending on location, as EMF levels are site- and time-specific. Sensitive receptors to EMF, such as hospitals and research facilities, are not known to be located within the study area. The main transportation sources of EMF within the study area are the traction power system and traction power substations associated with the TriMet MAX light-rail transit system.

Present and reasonably foreseeable future actions that could contribute to cumulative effects on EMF would be new sources of high-voltage power or high-frequency transmission, or the introduction of new EMF-sensitive receptors. None of the reasonably foreseeable future actions are anticipated to create new sensitive receptors, and only the Cascade Renewable Transmission Project would create potential new sources of EMF, as the project would install an underwater and underground cable bundle through the study area. However, the cables will be shielded so that they produce no external electric fields (Cascade Renewable Transmission n.d.).

No-Build Alternative

The No-Build Alternative would not change EMF sources as a result of Program activities. Other reasonably foreseeable future actions in the study area that could contribute to a cumulative effect on EMF would continue under the No-Build Alternative, but no proposed significant sources or sensitive facilities have been identified.

Modified LPA

The extension of the light-rail line under the Modified LPA would result in the generation of additional EMF within the study area. EMF levels from Portland's light-rail system are well below the International Commission on Non-Ionizing Radiation Protection (ICNIRP) and American Conference of Governmental Industrial Hygienists exposure standards. There is no evidence to indicate that light-rail-generated EMF would change the human health risk associated with cumulative EMF exposure. Therefore, as with the existing light-rail system, the Modified LPA would not have adverse effects associated with EMF emissions.

Cumulative Effects Conclusion – Electric and Magnetic Fields

Past actions, primarily electrification in the twentieth century and the introduction of light-rail transit, led to an increase in EMF exposure in the environment. None of the present or reasonably foreseeable future actions in the study area are anticipated to contribute to EMF levels in the study area. Sensitive receptors to EMF, such as hospitals and research facilities, do not exist in the study area and none are currently proposed.

The No-Build Alternative would not contribute to cumulative effects on EMF exposure, and it would not change the overall trends in EMF exposure from other actions. The Modified LPA would introduce a new source of EMF variation.

The cumulative effects from EMF exposure created by past, present, and reasonably foreseeable future actions, including the Modified LPA, are negligible because of the lack of evidence indicating a change in human health risk associated with cumulative EMF exposure and the absence of existing or proposed EMF-sensitive facilities in the study area.

Water Quality and Hydrology

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Historic land use changes and increasing urbanization have decreased the number of natural areas and the natural flow of water bodies in the study area. Over the past 150 years, historic off-channel areas have been filled, rechanneled, diverted, and otherwise developed for agricultural and urban use. Flood-control measures have been implemented that affect the entire lower Columbia River area. Levees and river embankments were constructed in the early 1900s on both sides of the Columbia River, which isolated most of the floodplain from all but the highest flows. Development of the hydropower system on the Columbia River has also significantly influenced peak seasonal flows in the river, as well as their velocity and timing. The channelization of the watershed, combined with the development of the hydropower system, dramatically altered the historic hydrologic regime.

The enactment of environmental laws beginning in the 1960s (such as the Clean Water Act), combined with decreases in upstream heavy industrial activities, has reduced contamination sources and improved water quality in study area water bodies. However, most of the water bodies within the study area are "303(d)-listed," meaning they fail to meet the water quality standards for one or more pollutants under the Clean Water Act. There are approximately 180 acres of existing contributing impervious area (CIA) in the study area; stormwater runoff from over 80% of the CIA (approximately 150 acres) is untreated.

Most present and reasonably foreseeable future projects would improve water quality and hydrology in the study area as new development is held to stricter standards for stormwater management and treatment than past actions. The redevelopment of the Expo Center and Waterfront Gateway properties, for example, would likely improve runoff from these sites, which are mostly impervious surfaces at present. While individual actions are required to mitigate and treat their stormwater runoff, increased development could still lead to an increase in pollutant discharges to local water bodies as a result of increased congestion and traffic on existing roads that lack sufficient treatment.

Anticipated projects that would improve water quality in the study area include restoration activities along Burnt Bridge Creek in Vancouver and the Columbia Slough in Portland (Ecology 2021; Lee and Stamberger 2018). For Burnt Bridge Creek, Ecology recommends sampling and monitoring of water quality, implementing best management practices for stormwater management in the watershed, completing watershed evaluations, conducting windshield surveys and desktop analysis, achieving system potential riparian vegetation of 85% tree canopy, and completing additional studies to identify priority areas for streamflow restoration activities.

Future projects from the Columbia Slough Watershed Council may include slough cleanup and stormwater management projects such as the Expand for a Bigger Great Slough Clean Up program, Portland Water Bureau's Main Pump Station riparian restoration, and a volunteer trash monitoring program. In addition, cleanup of the Portland Harbor Superfund Site will improve water quality in the Willamette River, which flows into the Columbia River downstream of the Interstate Bridge.

Future hydrologic projects in the study area include maintenance of the existing drainage system as well as the levee system improvements proposed by the USACE and UFSWQD. These projects would maintain and improve the flood-control systems in the study area.

No-Build Alternative

The No-Build Alternative would continue to degrade water quality through untreated stormwater runoff from existing impervious roadway surfaces within the study area. However, it is assumed that the No-Build Alternative would maintain existing water quality conditions and would not result in long-term changes (either increased or decreased impacts) as there is not a reliable method to quantify future emissions or other pollutants, such as 6PPD-quinone. Other reasonably foreseeable future actions in the study area that could

contribute to cumulative effects on water quality and hydrology (identified above) would continue under the No-Build Alternative, though impacts from those actions would be subject to applicable regulatory requirements.

Modified LPA

The Modified LPA would increase impervious roadway surfaces within the study area to approximately 200 acres, which could result in increased stormwater runoff rates and volumes. However, the Modified LPA includes stormwater treatment facilities for new and resurfaced existing roadways, including the new Columbia River bridges, which would remove pollutants from stormwater runoff and improve water quality in the Columbia Slough, Columbia River, North Portland Harbor, Burnt Bridge Creek, and Fairview Creek. With the Modified LPA, all stormwater runoff from the CIA would be treated to remove pollutants before being discharged into water bodies, reducing the area of untreated CIA by 150 acres. With new stormwater treatment and infiltration, the Modified LPA would improve surface water quality, increase groundwater recharge, and help restore natural flow to water bodies, thus reducing impacts of past actions.

Based on a preliminary hydraulic assessment, there may be a small net rise to the base flood elevation of the Columbia River and North Portland Harbor, which would be confirmed with a Location Hydraulic Study prior to the Final SEIS. If the hydraulic analysis showed a resulting rise in the base flood elevation, mitigation would be explored, such as improving hydraulic efficiency and compensate for flood storage capacity.

Cumulative Effects Conclusion – Water Quality and Hydrology

Hydrological function in the study area has been heavily influenced by past development, hydropower projects, and flood-control projects. Past development has also increased impervious surfaces and the number of pollutant sources in the study area, including industrial sites and vehicles, leading to many of the water bodies failing to meet water quality standards under the Clean Water Act. Because recent, present, and reasonably foreseeable future projects are subject to stricter regulatory standards for pollutants and hydrological effects, it is anticipated that water quality will continue to improve in the study area and hydrological effects will continue to be managed by existing and planned hydropower and flood-control projects. Due to the lack of a reliable method to quantify future emissions or other pollutants, it is assumed that existing water quality conditions would be maintained under the No-Build Alternative (see Section 3.14).

The No-Build Alternative would contribute to adverse cumulative effects on water quality and hydrology through the continued release of pollutants and untreated runoff from past development, and would not contribute beneficial cumulative effects created by present and reasonably foreseeable future actions, which are held to stricter regulations.

Under the No-Build Alternative, the cumulative effects on water quality and hydrology from past, present, and reasonably foreseeable future actions would be beneficial due to reasonably foreseeable future actions that would provide more stringent treatment of stormwater runoff. Compared to the No-Build Alternative, the cumulative effects on water quality and hydrology from the Modified LPA would be incrementally more beneficial due to improved stormwater treatment within the CIA.

Wetlands and Other Waters

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Urbanization and land use changes have reduced the acreage of wetlands in the study area since the 1800s (Morlan et al. 2010). Between the 1780s and 1980s, Oregon and Washington lost an estimated 38% and 31% of their wetlands, respectively (Dahl 1990). In the 1970s through the 1990s, stricter federal and state protections reduced the annual wetland loss in the Willamette Valley but did not stop the loss of wetlands (Morlan et al. 2010). Since 1958 (the base year of I-5 construction), some wetland restoration has occurred near the

southern portion of the study area. The Port of Portland completed a wetland restoration project at the 90-acre Vanport wetlands parcel, located immediately west of the existing highway and light-rail line. Other historic wetlands east of the highway, in the Delta Park area and on Hayden Island, have experienced increased development, draining, or filling since 1964.

Identified reasonably foreseeable future actions in the study area that could contribute to cumulative effects on wetlands and other waters include:

- Planned restoration activities near the Columbia Slough and the Smith and Bybee Wetlands Natural Area, which would improve wetland functions.
- The Portland Metro Levee System project is estimated to result in the loss of approximately 0.5 acres of wetlands that would be mitigated through compensatory mitigation (e.g., the purchase of credits from a wetland mitigation bank) (USACE and CCDD 2021). Mitigation would be required to completely offset any loss of functions or value, and USACE issued a Finding of No Significant Impact in 2022.
- The Renaissance Boardwalk mixed-use development has been proposed near the Columbia River in Vancouver; it is close to wetlands. While more detailed information is not yet available for this project, impacts to wetlands or waters would have to meet Washington state requirements for no net loss of functions or value.
- Future dredging projects, such as the potential deepening of the navigation channel by USACE, that would disturb sediment in the Columbia River waterway. USACE and affected ports are conducting environmental reviews for a Dredged Material Management Plan for the Lower Columbia River, which would document effects to wetlands and waters as well as proposed mitigation. However, these environmental reviews are not yet complete, so specific information regarding the potential impacts from the dredging project are not known at this time.
- The Cascade Renewable Transmission Project would install an underwater cable at the bottom of the Columbia River. This project has not gone through environmental review yet, and more specific impacts are not known at this time; however, this proposed project would likely involve disturbing the river bottom sediment to create an approximately 18-inch trench for the cable (Cascade Renewable Transmission n.d.).

The Oregon Department of State Lands recorded a net loss of wetlands over the past decade in Oregon (approximately 45 acres), although there has been a net gain in the last 5 years (approximately 47 acres). Based on the data, statewide wetland gains and losses are highly variable year to year (ranging from a net loss of 42 acres to a net gain of 60 acres). While all recorded wetland losses are compensated, this is often achieved through the purchase of credits from mitigation banks or in-lieu fee programs, and wetland enhancement and preservation are not counted as wetland gains as they do not result in gains in wetland acres (Pelton 2024). Similar data for Washington State were not located; however, the state's regulatory agencies are charged with ensuring no net loss of wetland value or function. USACE, Ecology, and some Washington jurisdictions (including the City of Vancouver) encourage the use of mitigation banks and in-lieu fee programs over on-site mitigation because they can offer greater assurance for mitigation (Hruby et al. 2009; USACE and EPA 2008). Therefore, a loss of wetlands can be reliably offset in another location within the watershed without a loss of overall value and function.

No-Build Alternative

The No-Build Alternative would not result in further filling of wetlands or the fill or reduction of wetland buffers within the study area due to Program activities. Untreated stormwater from over 150 acres of CIA within the study area would continue to be discharged into wetlands and other waters. Increased development, traffic volumes, and congestion could increase pollutant discharge to wetlands and waters, including 6PPD-quinone (a byproduct of tire dust that is toxic to salmonids). Other reasonably foreseeable

future actions in the study area that could contribute to cumulative effects on wetlands and other waters (identified above) would continue under the No-Build Alternative, although impacts from those actions would be required to meet applicable regulatory requirements for no net loss of functions or value.

Modified LPA

The Modified LPA would require the fill of relatively small areas of wetlands and wetland buffers (approximately 0.58 acres and 7.39 acres, respectively), which would adversely affect wetland functions. In addition, the Modified LPA would increase the impervious surface area in the vicinity of wetlands and decrease the distance between wetlands and roadway traffic, which could increase stormwater flow and pollutants. However, the Modified LPA would also provide stormwater facilities that would treat stormwater runoff for both new and existing impervious surfaces created by the original construction of I-5 in the study area, which would improve water quality flowing into wetlands. In addition, the double-deck fixed-span configuration would result in a net restoration of approximately 0.13 acres of waterway in the Columbia River and North Portland Harbor due to the smaller footprint of the replacement structures compared to the existing Interstate Bridge. The single-level fixed-span and single-level movable-span configurations would both result in a small net loss (less than 0.1 acres).

Mitigation for wetland fill is regulated by federal, state, and local jurisdictions and would typically require purchasing credits from an agency-approved mitigation site or completing on-site or off-site mitigation to compensate for lost or degraded functions. Fill of the Vanport wetland would require increased mitigation ratios because it is an existing wetland mitigation site. Unavoidable impacts to wetlands and other waters would be offset through one or more compensatory mitigation projects, which are currently being developed in coordination with federal, state, and local regulatory agencies, tribes, and community members. With mitigation, it is anticipated that the Modified LPA would result in a net beneficial effect on quality and ecological function of wetlands and waters.

The net reduction of fill in the Columbia River and improved stormwater treatment would improve the current functions of wetlands and waters, helping to mitigate some past actions.

Cumulative Effects Conclusion – Wetlands and Other Waters

Past actions, including construction of I-5 and the existing Interstate Bridge, led to a decline in the amount and function of wetlands and other waters. Present actions are required to adhere to more stringent regulations, with the current requirements being no net loss in wetland function and value and treating stormwater runoff from roadways. Reasonably foreseeable future actions in the study area that affect wetlands and other waters would also be required to comply with regulations to achieve no net loss of wetland function or value and treat stormwater.

While the No-Build Alternative would not result in filling of wetlands or other waters, it would not improve wetland functions, and untreated stormwater would continue to be discharged into wetlands and other waters. The Modified LPA would result in the fill of some wetlands, and would provide mitigation to improve the current value and functions of wetlands, and would improve stormwater treatment.

Under the No-Build Alternative, the cumulative effects on wetlands and other waters from past, present, and reasonably foreseeable future actions would be beneficial due to reasonably foreseeable future actions that would provide more stringent stormwater treatment for water that flows into wetlands and other waters. Compared to the No-Build Alternative, the cumulative effects on wetlands and other waters from the Modified LPA would be incrementally more beneficial due to improved stormwater treatment within the CIA and mitigation to replace lost functions and values of fill placed in wetlands and waters.

Ecosystems

Fish, Wildlife, and Vegetation

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Ecosystem resources include fish, wildlife, plants, and their habitats. Ecosystem resources within the study area include habitat for a variety of plants, terrestrial wildlife, birds, fish, marine mammals, rare plants, and noxious weeds. This discussion of ecosystem resources includes aquatic and terrestrial species.

Native Americans lived in the study area for more than 10,000 years before the arrival of Euro-American settlers. Since the Euro-American settlement in the mid-1800s, human population growth and land development have gradually displaced and reduced the quality and quantity of wildlife habitat. Historically, many activities, including deforestation, urbanization, dams for hydroelectricity, irrigation and flood control, hatchery operations, and overfishing have contributed to the loss of habitat and reduction in fish and wildlife species. These past actions have made significant changes to the region's ecosystems. Compared to their historic conditions, natural habitats in the area are generally small and fragmented.

General growth and development in the region will continue to affect species and habitats in the study area. Current and reasonably foreseeable future projects, such as the Portland Metro Levee System project, Flood Safe Columbia River, Port of Vancouver Terminal 1, Cascade Renewable Transmission Project, dredging, and maintenance of existing waterfront structures could include activities that would affect aquatic or terrestrial species and their habitats. For example, additional impervious surface area could increase the quantity of stormwater runoff, affecting aquatic habitat function. Of the reasonably foreseeable future actions, only the Portland Metro Levee System project is identified as increasing impervious surfaces (by less than 1 acre); the remaining projects (including the Renaissance Boardwalk, Waterfront Gateway, and Expo Center) are located in areas that currently consist primarily of impervious surfaces and redevelopment may ultimately improve runoff if it includes stormwater detention and treatment.

Substantive legislation to protect natural resources began in the 1960s and has since expanded. Projects that are subject to federal, state, and/or local permits require a mitigation sequencing process consisting of avoidance, minimization, and mitigation to reduce effects on species and their habitats. Reasonably foreseeable future projects would be required to provide stormwater quality treatment consistent with applicable stormwater regulations, which would reduce pollutants being discharged into water bodies and improve water quality and aquatic habitat for aquatic species. Because requirements typically include treatment for existing untreated impervious surfaces, reasonably foreseeable future projects may lead to a net beneficial effect on water quality and aquatic habitat for aquatic species. Reasonably foreseeable future projects constructed over time would also be legally required to avoid, minimize, and mitigate impacts to fish and wildlife to achieve no net loss in habitat function. Planned restoration in the study area includes cleanup at the Portland Harbor Superfund Site and smaller projects along Burnt Bridge Creek in Vancouver and the Columbia River Slough in Portland (EPA n.d.; Ecology 2021; Lee and Stamberger 2018).

No-Build Alternative

The No-Build would continue to contribute to an adverse cumulative effect on ecosystem resources, particularly aquatic habitat and aquatic species, from untreated stormwater runoff from I-5 and disturbance of fish and wildlife during intermittent bridge and highway maintenance activities. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on fish, wildlife, and vegetation (identified above) would continue under the No-Build Alternative, though any impacts from those actions would be subject to applicable regulatory requirements. Untreated stormwater from over 150 acres of CIA within the study area would continue to be discharged into wetlands and waters, negatively affecting these natural habitats and species within them. Increased development, traffic volumes, and congestion

could increase pollutant discharge to wetlands and waters, including 6PPD-quinone (a byproduct of tire dust that is toxic to salmonids).

Modified LPA

Construction of the Modified LPA would result in temporary impacts (e.g., increased noise, turbidity, overwater shading) to aquatic and terrestrial species and their habitats. The Modified LPA would result in both permanent and short-term disturbance to sensitive terrestrial habitats, including riparian buffers, trees, wetlands, and wetland buffers. To minimize the impacts to fish and wildlife species and their habitats during construction, as described in the Ecosystems Technical Report and required in the permits that would be issued, best management practices would be followed.

Long-term effects on aquatic ecosystem resources would include displacement of benthic habitat from the new bridge piers and new overwater shading from the bridges' shaft caps and bridge decks. The Modified LPA would create new impervious surfaces, which would generate stormwater runoff but would also provide water quality treatment for new and existing impervious surfaces, including those created by the original construction of I-5 that did not include stormwater treatment. The Modified LPA would reduce pollutants (including dissolved copper) associated with highway runoff, improving aquatic habitat. Impacts to fish and wildlife species and their habitats would be avoided, minimized, and offset through compensatory mitigation, as required by compliance with federal, state, and local regulatory requirements. These mitigation measures would result in no net loss of habitat function. A compensatory mitigation approach is currently in development with federal, state, and local regulatory agencies; tribes; and community members.

Mitigation measures required for the Modified LPA would reduce harmful effects and even improve parts of the local ecosystem relative to existing conditions. The Modified LPA would have a net beneficial effect on fish and wildlife species and habitat, considering the proposed improvements treating stormwater entering the Columbia River and North Portland Harbor.

Cumulative Effects Conclusion – Fish, Wildlife, and Vegetation

Past actions, such as deforestation, urbanization, and construction of dams for hydroelectricity, have resulted in loss of habitat and reduction in fish and wildlife species. Although regulations have been implemented to protect species and their habitat, present actions include development that would continue to affect species and their habitat. Reasonably foreseeable future actions, such as the Portland Metro Levee System Project and the Cascade Renewable Transmission Project, which both involve extensive over-, near-, and in-water work, would also affect species and their habitat.

The No-Build Alternative would contribute to adverse cumulative effects on ecosystem resources, particularly aquatic habitat and aquatic species, from continued untreated stormwater runoff from I-5 and disturbance of fish and wildlife during intermittent bridge and highway maintenance activities. The Modified LPA would not impact sensitive terrestrial habitats and species. The Modified LPA would displace some benthic habitat for aquatic species, and result in new overwater shading from shaft caps, in the Columbia River; however, the Modified LPA would also provide water quality treatment that would improve aquatic habitat.

Under the No-Build Alternative, the cumulative effects on fish, wildlife, and vegetation from past, present, and reasonably foreseeable future actions would be adverse, due to actions that remove or disrupt habitat, but also beneficial, due to new development being held to stricter stormwater management and treatment standards. Compared to the No-Build Alternative, the cumulative effects on fish, wildlife, and vegetation from the Modified LPA would be incrementally more beneficial due to the additional treatment of stormwater from roadways within the CIA.

Aquatic and Terrestrial Species of Interest

Species of Interest (SOI) is not a specific category of governmental or nongovernmental organization-designated species, but refers to native species identified through tribal, local, state, and federal coordination as having particular importance because of their regulatory status, rarity, and/or special habitat considerations. Examples of aquatic and terrestrial SOI species include those species listed under the federal Endangered Species Act, species with other federal regulatory protections (such as marine mammals, bald eagles, and migratory birds), species with special state regulatory status in Oregon or Washington, and other species that consulting tribes have identified as warranting particular focus.

Effects from Past, Present, and Reasonably Foreseeable Future Actions

The effects from past, present, and reasonably foreseeable future actions on fish, wildlife, and vegetation (described above) are anticipated to have similar effects on SOI. Many SOI are subject to additional legal protections (e.g., the Endangered Species Act) and require additional evaluation and mitigation for impacts caused by present and reasonably foreseeable future actions. Compliance with the relevant laws, regulations, policies, and codes in force would help minimize or mitigate the effects of other actions on SOI and their habitats. However, even if a project has a net beneficial impact on these species, many of them would continue to face threats to their continued long-term survival.

No-Build Alternative

The No-Build Alternative would continue to contribute to an adverse cumulative effect on aquatic and terrestrial SOI from untreated stormwater runoff from I-5 and direct disturbance of aquatic and terrestrial SOI during intermittent bridge and highway maintenance activities. As noted above for non-SOI species, reasonably foreseeable future actions in the study area that are identified above and could contribute to cumulative effects on ecosystems would continue under the No-Build Alternative, though any impacts from those actions would be subject to applicable regulatory requirements. Within the study area, untreated stormwater with various pollutants would continue to be discharged into aquatic habitats, including 6PPD-quinone.

Modified LPA

Construction of the Modified LPA would result in temporary impacts (e.g., increased noise, turbidity, and overwater shading) to aquatic and terrestrial SOI. Long-term effects on aquatic and terrestrial SOI species and their habitats would include displacement of benthic habitat from the bridge piers and new overwater shading. The Modified LPA would reduce pollutants associated with highway runoff (including dissolved copper), improving water quality and habitat function for aquatic SOI.

Mitigation measures under the Modified LPA would reduce harmful effects and even improve parts of the local ecosystem relative to existing conditions. The Modified LPA would have a net beneficial effect on habitat function for aquatic SOI, considering improved treatment of stormwater entering the Columbia River and North Portland Harbor.

Cumulative Effects Conclusion - Aquatic and Terrestrial Species of Interest

Past actions on aquatic and terrestrial SOI have resulted in the same effects as non-SOI fish, wildlife, and vegetation, including deforestation, urbanization, and construction of dams for hydroelectricity, that have resulted in loss of habitat and reduction in the populations of SOI. Although regulations have been implemented to protect SOI, present actions include development that would continue to affect SOI and their habitat. Reasonably foreseeable future actions would affect SOI ecosystem resources, particularly the Portland Metro Levee System Project and the Cascade Renewable Transmission Project, which both involve extensive in-water work in the Columbia River.

The No-Build Alternative would contribute to adverse cumulative effects on aquatic and terrestrial SOI from continued untreated stormwater runoff from I-5 and direct disturbance of fish and wildlife during intermittent bridge and highway maintenance activities. The Modified LPA would not impact sensitive terrestrial habitats and terrestrial SOI. The Modified LPA would displace some benthic habitat, and result in new overwater shading from shaft caps, in the Columbia River that would affect aquatic SOI; however, the Modified LPA would also provide water quality treatment that would improve aquatic habitat.

Under the No-Build Alternative, the cumulative effects on aquatic and terrestrial SOI from past, present, and reasonably foreseeable future actions would be adverse, due to actions that remove or disrupt habitat, but also beneficial, due to new development being held to stricter stormwater management and treatment standards. Compared to the No-Build Alternative, the cumulative effects on aquatic and terrestrial SOI from the Modified LPA would be incrementally more adverse due to in-water habitat loss and incrementally more beneficial from additional stormwater treatment.

Geology and Groundwater

Effects from Past, Present, and Foreseeable Future Actions

Past activities in the study area that have affected geological conditions and groundwater include settlement and development of the region, filling of lowland areas, grading of slopes, and construction in earthquake-prone areas. The study area consists of soils with high relative earthquake hazard rating that are susceptible to severe ground shaking and liquefaction during a major seismic event. The steep slopes and soils susceptible to erosion in the Burnt Bridge Creek area have been disturbed in the past from the construction of I-5 and SR 500. Current infrastructure, including roads, bridges, and buildings, was constructed under seismic codes applicable at the time of construction. The existing bridges and other I-5 structures, such as overpasses and retaining walls, were built before design standards addressed the impacts associated with subduction zone earthquakes, including severe liquefaction. More recent development, such as the mixed-use buildings along the Vancouver waterfront, was constructed to current design standards and should withstand a major seismic event.

Past actions such as the Vanport Flood, the siting of the Hayden Island Landfill, and industrial activities along the Columbia River resulted in contamination of groundwater through the spillage or leakage of gasoline and other petroleum products stored at commercial sites or industrial facilities. Contaminants from historical commercial and industrial activities in both Vancouver and Portland have diminished groundwater quality. Reasonably foreseeable future actions, such as the Waterfront Gateway, levee system improvements, and the Renaissance Boardwalk, may include development and regrading that could lead to soil erosion, even with erosion control best practices in place. These actions may also continue to sustain existing impacts to degradation of the groundwater quality from stormwater runoff in the study area. These and other reasonably foreseeable future actions would also be constructed to current seismic standards and would contribute to the beneficial cumulative effect of improved resiliency throughout the study area.

No-Build Alternative

The No-Build Alternative would not include the construction of new Columbia River bridges and other structures built to current seismic safety standards. Therefore, the No-Build Alternative would leave I-5 vulnerable to earthquakes and other geologic hazards that would have an adverse cumulative effect. In addition, the No-Build Alternative would continue to leave stormwater runoff untreated, which would continue contributing to an adverse cumulative effect on groundwater. The identified reasonably foreseeable future actions in the study area that could contribute to cumulative effects on geological and hydrogeologic conditions would continue under the No-Build Alternative, subject to applicable regulatory requirements for water quality and current seismic design standards.

Modified LPA

The Modified LPA would construct new Columbia River bridges and other I-5 structures to current seismic design standards that would substantially improve the region's seismic resiliency to withstand a major seismic event. The design of the Modified LPA would address potential non-seismic settlement to avoid impacts to levees. The Modified LPA would expose approximately 415 acres of near-surface soils to potential erosion from excavation, fill, clearing, and grading during construction. Impacts to geology and geologic hazards (such as steep slopes, soil erosion, and landslides) would be mitigated and avoided to the extent feasible by the Modified LPA. Construction on steep slopes would be minimized and the roadway design would include retaining walls or other stabilization techniques to reduce the potential for soil erosion and slope failure hazards. Landslides are not known to occur within the study, area and the Modified LPA would address the risks of increased scour that could result from potential landslides upstream caused by a major Cascadia Subduction Zone event. No long-term effects on geologic hazards are anticipated in the Ruby Junction Maintenance Facility expansion area.

The Modified LPA would have beneficial effects on groundwater quality, including for the Troutdale Sole Source Aquifer, through stormwater facilities that would manage stormwater volume and flow rates and treat stormwater runoff to reduce pollutants. The Modified LPA could also improve groundwater quality by remediating some existing contamination.

Cumulative Effects Conclusion – Geology and Groundwater

Past actions that have affected geological and groundwater conditions include regional development that has graded slopes and occurred in earthquake-prone areas and commercial and industrial activities that have resulted in groundwater contamination. Present actions in the study area are required to meet current, stricter standards for water quality, erosion control, and seismic safety. Reasonably foreseeable future actions, including new construction and redevelopment of existing sites, would continue to bring buildings and infrastructure throughout the study area up to current seismic design standards and comply with regulatory requirements related to discharges into groundwater.

The No-Build Alternative would not include the construction of new Columbia River bridges or other structures, leaving I-5 vulnerable to earthquakes and other geologic hazards and stormwater runoff that enters into groundwater would remain untreated. The Modified LPA would improve the seismic resilience of the Columbia River bridges and other I-5 structures and would treat stormwater runoff within the CIA that enters into groundwater.

Under the No-Build Alternative, the cumulative effects on geology and groundwater from past, present, and reasonably foreseeable future actions would be adverse because I-5 infrastructure would continue to age and be increasingly vulnerable to damage in an earthquake and untreated stormwater would enter into groundwater. Compared to the No-Build Alternative, the cumulative effects on geology and groundwater from the Modified LPA would be beneficial due to improved seismic resiliency of structures in the I-5 corridor and the treatment of stormwater that enters into groundwater.

Hazardous Materials

Effects from Past, Present, Reasonably Foreseeable Future Actions

Past actions in the study area, including spills and releases of hazardous materials from commercial and industrial land uses, have caused soil and groundwater contamination and pose a risk to human health. There are 579 sites that could contain hazardous materials within the study area, and the Ruby Junction Maintenance Facility is a small-quantity generator for hazardous wastes, including solvents, batteries, and paints. High-priority hazardous materials sites include the U.S. Army Vancouver Barracks, Hayden Island landfill, and Jantzen Beach car wash, among others. Many of these contaminated areas have been

documented, and in some cases cleanup actions have been initiated or completed. There may also be unknown contamination caused by past land uses and actions in the study area that poses additional risks. Reports of spills and releases of hazardous materials within the study area vary by location and year, averaging approximately zero to three incidents annually. Reported incidents of hazardous substances are managed by the Oregon State Fire Marshal's Hazardous Substance Incident database and reported spill incidents are managed by Ecology's Reported Spills to Water database.

Identified reasonably foreseeable future actions in the study area that could contribute to cumulative effects on hazardous materials include development and redevelopment of existing buildings and paved areas, particularly on sites with a history of industrial use. Properties in older urban areas, such as downtown Vancouver or Hayden Island, would be more likely to contain existing contamination. However, new development and redevelopment would be required to remediate known or discovered hazardous materials, including lead or asbestos-containing materials, to comply with local land use plans.

Development in the study area may involve the management of legacy sites, which are hazardous materials sites where the owner is or should be undertaking long-term cleanup actions. Sites for which the responsible party has not yet complied may require additional investigation and cleanup. These sites may also be considered "orphan" sites, which are being managed by regulatory agencies. Reasonably foreseeable future development in the study area could add exposure risks but also provide cleanup and remediation benefits. The discovery of new legacy sites would be the responsibility of the property owners, including ODOT and WSDOT, who would need to comply with all applicable federal, state, and local requirements for managing and mitigating contamination. In addition, population and employment growth could cause increased traffic that may result in slightly more incidents of hazardous material spills from vehicle collisions as congestion remains at current levels or worsens over time.

No-Build Alternative

Under the No-Build Alternative, there would be no acquisitions or displacements, no potential for hazardous materials liability resulting from property acquisition, and no cleanup of previously contaminated locations. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on hazardous materials would continue under the No-Build Alternative, though any activities on contaminated sites would be subject to applicable regulatory requirements for managing and mitigating contamination.

Modified LPA

The Modified LPA would require ODOT and WSDOT to acquire properties or portions of properties that have been identified as contaminated sites. Contamination may also exist within portions of WSDOT's existing right of way. Properties to be disturbed or acquired that have contamination above levels defined in regulatory standards would be subject to remediation and cleanup prior to construction. The discovery of contamination within new or existing right of way would be the responsibility of the property owners, including ODOT and WSDOT, who would be subject to applicable remediation and cleanup requirements. The Modified LPA would have beneficial effects due to the cleanup and remediation of previously contaminated areas on disturbed or acquired sites (consistent with state requirements). This cleanup would reduce the risk of future contamination and risks to human health.

Construction of the Modified LPA, or other reasonably foreseeable future construction actions, creates a potential for the release of hazardous substances or petroleum products into the environment from the improper transfer of fuel or spills from construction equipment. Other pollutants, such as paints, acids for cleaning masonry, solvents, raw concrete, paving, striping products, and concrete-curing compounds, are often present at construction sites and may enter the environment if not managed correctly.

The Modified LPA would improve safety and operations on I-5, which could reduce hazardous material spills as a result of highway crashes.

Cumulative Effects Conclusion – Hazardous Materials

Past actions include spills and releases of hazardous materials from commercial and industrial land uses, which have resulted in contaminated sites in the study area. Present actions include continued spills and releases of hazardous materials (reported incidents of hazardous substances and spills vary by location and year) and also efforts to clean up contaminated sites in the study area. Reasonably foreseeable future actions in the study area that would affect hazardous materials would include the continued potential for spills and cleanup efforts to meet applicable regulatory requirements for managing and mitigating contamination.

The No-Build Alternative would not result in the potential disruption of contaminants on properties within the study area and would not cleanup previously contaminated property. The Modified LPA would cleanup and remediate previously contaminated areas on disturbed or acquired sites and would improve safety and operations on I-5, which would potentially reduce spills as a result of highway crashes.

Under the No-Build Alternative, the cumulative effects on hazardous materials from past, present, and reasonably foreseeable future actions would be beneficial for the environment and human health through the reduction and cleanup of hazardous materials as a result of redevelopment. Compared to the No-Build Alternative, the cumulative effects on hazardous materials from the Modified LPA would be incrementally more beneficial because acquired sites that are contaminated within the study area would be cleaned up.

Climate Change

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Substantially rising GHG concentrations from human activities have been a primary driver of global warming. Both Ecology and the Oregon Global Warming Commission publish reports every 2 years measuring their states' GHG emissions and progress toward state and federal goals to reduce these emissions. Transportation (including highway, rail, and air transport) is the greatest contributor to GHG emissions nationally and in Oregon and Washington; other major contributors include electric power generation, industrial uses, residential and commercial energy consumption, and agriculture. Multiple federal, state, regional, and local regulations and policies have been enacted to guide the development and evaluation of transportation projects and local communities' management of GHG emissions. NEPA and many state environmental policy regulations now require project sponsors to quantify the GHG emissions of their projects. Policy efforts aimed at reducing transportation GHG emissions include incentives for purchasing electric vehicles, funding of electric vehicle charging infrastructure, and funding to increase less-polluting travel modes like transit, walking, and biking.

Reasonably foreseeable future actions related to the policies and plans of state, regional, and local jurisdictions have the potential to influence the decrease in GHG emissions in the transportation and land use sectors. Policies that directly regulate the emissions of vehicles, such as a clean fuels standard, have the greatest potential to reduce GHG emissions. Additional ancillary benefits may also come from transitions to renewable energy sources in the energy sector. For example, the Cascade Renewable Transmission Project will transfer approximately 1,100 MW of large-scale wind, solar, and other renewable energy sources to help meet renewable energy goals in Washington and Oregon. Renewable energy sources emit fewer upstream GHGs than energy generated from fossil fuels. Other actions currently being legislated or encouraged to reduce GHG emissions include limits on industrial emissions, strategies to reduce home and commercial energy use or switch to green sources, and efforts to curb methane production by the agricultural industry. Collectively, these efforts have reduced emissions in the U.S. by approximately 3% since 1990 (EPA 2024). This trend is expected to continue as a result of stronger regulation of emissions.

Compared to existing conditions, GHG emissions associated with the transportation sector are expected to decline in future years due to improvements in vehicle fuel technologies and the transition away from using

gasoline and diesel fuels to power vehicles. As more of the vehicle fleet is composed of electric cars, the decarbonization of the electric grid in Washington and Oregon will further decrease GHG emissions associated with vehicle travel.

Because the effects of regional growth and reasonably foreseeable future actions are incorporated into the transportation modeling, the results of the GHG emissions modeling for both the No-Build Alternative and the Modified LPA reflect cumulative effects on annual GHG emissions in the study area that include projected vehicle volumes in 2045.

No-Build Alternative

Although VMT would increase in the study area by 2045 under the No-Build Alternative, GHG emissions are expected to decline substantially over this period due to the implementation of fuel and engine regulations. However, the No-Build Alternative would not contribute to this cumulative reduction in GHG emissions. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on climate change (identified above) would continue under the No-Build Alternative, though any impacts from those actions would be subject to regulatory requirements to reduce emissions and improve resiliency.

Modified LPA

The Modified LPA would result in fewer user GHG emissions than the No-Build Alternative because of a mode shift to public transit and active transportation, as well as decreases in VMT, congestion, and vehicle idling. While the sources of GHG emissions during construction would be temporary, the GHG emissions would remain in the atmosphere. GHG emissions from construction would include exhaust from construction equipment and vehicles used to transport materials to and from the study area. There would also be GHG emissions associated with the embodied carbon of construction materials, which refers to emissions due to material production. GHG exhaust during construction would be mitigated and reduced by following current standard specifications and regulatory guidance from ODOT and WSDOT to conserve the use of construction materials and fuels and by implementing best management practices.

The Modified LPA includes features that would improve local and regional resiliency to the anticipated effects of climate change. These features would help to avoid fragmentation and degradation of floodplain hydrology by sensitively locating new and modified transportation and utility project components; maximizing management of stormwater by restoring existing unused impervious paved areas to natural, permeable, and vegetated conditions during the design phase; and ensuring that the bridge design would accommodate potential effects of climate change, such as larger water volumes from winter storms and more frequent snow and ice storms.

Cumulative Effects Conclusion – Climate Change

Past actions, primarily transportation projects and population growth and development, have led to an increase in GHG emissions and climate hazards. Present actions include additional transportation projects which could increase GHG along with efforts, such as the Cascade Renewable Transmission Project, that seek to lower GHG emissions and/or improve climate resiliency. Reasonably foreseeable future actions are expected to generate GHG emissions as well as seek to reduce VMT and GHG emissions as roadways users shift to transit and active transportation modes and a reduction in roadway congestion

The No Build Alternative would not contribute to a reduction in GHG emissions; it would continue past trends of car-centric transportation networks. While construction of the Modified LPA would generate GHG emissions from construction equipment and materials, in the long-term the Modified LPA would provide transit and active transportation options to lower VMT and GHG emissions and improve climate resiliency.

Under the No-Build Alternative, the cumulative effects on climate change from past, present, and reasonably foreseeable future actions would be beneficial as a result of other actions that would reduce

GHG emissions. Compared to the No-Build Alternative, the cumulative effects on climate change from the Modified LPA would be incrementally more beneficial due to reduced VMT and GHG emissions in the I-5 corridor and improvements in climate resiliency.

Environmental Justice

Effects from Past, Present, and Reasonably Foreseeable Future Actions

The original construction of I-5 and I-205 through Portland had significant effects on the populations in and adjacent to the highway's path, including environmental justice (EJ) populations.[6] ODOT cleared entire blocks for development of the roadway, dividing neighborhoods, displacing residences, and affecting businesses in the historic center of Portland's Black community. The construction of I-5 through Vancouver changed the city by closing 5th Street (the route heading east) and encouraging development of housing to the north of downtown. Fewer displacements occurred in Vancouver than Portland because the area was less densely developed than Portland at that time.

One socioeconomic impact attributed to the cumulative effect of population growth and development is an increase in the cost of living. Between 2000 and 2021, median gross rent increased 52% in Portland, 48% in Multnomah County, 40% in Vancouver, and 41% in Clark County (adjusted for inflation) (U.S. Census Bureau 2000, 2021). In the same period, median household income increased by only 15% in Portland and 11% in Multnomah County, while median household income decreased by 4% in Vancouver and 7% in Clark County (U.S. Census Bureau 2021). As the cost of living increases, low-income households often move farther from jobs and services to find affordable housing. This can result in longer commute times and higher transportation costs for low-income households.

Tolling of I-205 (Abernethy Bridge), if advanced in Oregon, could increase transportation costs for EJ populations. The tolling project may implement low-income or equitable tolling policies to subsidize or offset the economic burden of tolling on low-income and minority populations. There are no other known reasonably foreseeable future projects within the study area that would contribute to a cumulative effect on EJ populations, such as displacement or increasing the cost of living. Reasonably foreseeable future transportation actions would follow federal and state guidelines, such as the Uniform Relocation Act, to provide replacement housing and relocation benefit packages.

Reasonably foreseeable future development and redevelopment projects include projects in downtown Vancouver and north Portland. Future projects such as Terminal 1, Waterfront Gateway, Renaissance Boardwalk, and Portland Expo Center Redevelopment would add new buildings or redevelop existing buildings. There is not enough information at this time to determine the exact impacts; however, reasonably foreseeable future development projects may lead to the displacement of encampments of houseless populations and the Renaissance Boardwalk could displace an existing commercial property.

No-Build Alternative

The No-Build Alternative would not change the existing conditions that affect EJ populations. It would not acquire or displace residences or businesses or provide an extension of light-rail, improvements to active transportation facilities, and improved bus service in the corridor. Therefore, the No-Build Alternative would not contribute to beneficial or adverse cumulative effects on EJ populations. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on EJ populations would continue under the No-Build Alternative, although impacts from actions subject to review would follow federal and state guidelines to provide mitigation for displacement or other adverse impacts.

[6] Environmental justice populations include low-income and minority groups.

Modified LPA

The Modified LPA would have both beneficial and adverse effects on EJ populations. Some populations, including minority and low-income individuals, would be adversely affected by displacement of businesses and residents and by noise, dust, and traffic during construction. However, in general, the Modified LPA would likely improve conditions (such as air pollution, poor access to affordable housing and transportation, and poor transit service) for populations and neighborhoods that have historically been adversely affected by other past actions.

For low-income populations, among which Black, Indigenous, and people of color (BIPOC) communities are overrepresented, the impacts of tolling associated with the Modified LPA, such as the share of total household income spent on transportation costs, may be a disproportionate and adverse impact. The IBR Program is considering a low-income toll program to address these impacts.

EJ populations would benefit from the Modified LPA through the construction of light-rail transit; increased transit frequencies; improved travel times on I-5; improved bicycle and pedestrian facilities; and safer vehicle, bicycle, and pedestrian travel.

Cumulative Effects Conclusion – Environmental Justice

Past actions, such as the original construction of I-5 and I-205 led to the displacement of residences, affected businesses, and influenced development patterns and growth in Portland and Vancouver. Present actions include population growth and continued development that include residential and/or business displacements and increases in the cost of living. Reasonably foreseeable actions include continued development and population growth that could impact low-income households and their access to affordable housing, and result in longer commute times and higher transportation costs. Present and reasonably foreseeable future actions in the study area that affect EJ populations would be required to follow state and federal guidelines to provide mitigation for displacement and other adverse impacts.

The No-Build Alternative would not result in displacements that would affect EJ populations or improvements to the transportation system, including active transportation facilities and transit, that would improve mobility for EJ populations. The Modified LPA would effect EJ populations, including minority and low-income individuals, through the displacement of businesses and residents by noise, dust, and traffic during construction. For low-income populations, tolling of the Columbia River bridges would affect transportation costs. The IBR Program is considering a low-income toll program to address these impacts. The Modified LPA would improve conditions (such as air pollution, poor access, and poor transit service) for EJ populations and neighborhoods. The Modified LPA would provide beneficial cumulative effects to EJ populations through a variety of transportation improvements to public transportation, traffic congestion, active transportation, and traffic safety.

Under the No-Build Alternative, the cumulative effects on EJ populations from past, present, and reasonably foreseeable future actions would be adverse due to the potential for displacements that could affect EJ individuals and businesses and rising transportation costs. Compared to the No-Build Alternative, the cumulative effects on EJ populations from the Modified LPA would be adverse due to the potential displacement of EJ individuals and businesses and beneficial through improvements in access, traffic safety, transit service, air quality, and noise.

Aviation

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Two airports are located near the study area: Pearson Field and Portland International Airport (PDX). Both airports were in operation prior to construction of I-5 in the early 1950s (though improvements at both airports have occurred since then), and both the airports and the existing Interstate Bridge pre-date federal

aviation regulations. Past actions affecting aviation in the study area include development that penetrates the airspace of aircraft landing or departing at Pearson Field. The towers of the existing Interstate Bridge and several buildings in downtown Vancouver currently penetrate Pearson Field Part 77 airspace. There are no known planned reasonably foreseeable future projects in the area that would contribute to cumulative effects on airspace.

No-Build Alternative

The No-Build Alternative would not alter existing aviation conditions. The towers of the Interstate Bridge would continue to penetrate into Pearson Field Part 77 airspace, which requires special departure procedures to help aircraft avoid the towers. The Interstate Bridge creates no intrusion or hazard for aircraft navigation at PDX. There are no other known reasonably foreseeable future actions in the study area that could contribute to cumulative effects on airspace; however, any impacts from reasonably foreseeable future actions would be subject to federal aviation regulations, in addition to local airport overlay zoning regulations and Pearson Field departure procedures.

Modified LPA

The Modified LPA would have no effect on aviation at PDX. The Modified LPA with a single-level or double-deck fixed-span configuration would contribute to beneficial cumulative effects on operations at Pearson Field by removing the lift towers that were introduced when the existing Interstate Bridge was constructed. The Modified LPA with the movable-span configuration would also remove the existing lift towers but would introduce new penetrations into the Pearson Field airspace and would contribute to existing cumulative effects on aviation. The lift towers for the vertical lift span, based on the preliminary design, would be similar in elevation to the existing lift towers and permanently penetrate the Pearson Field airspace. The Modified LPA would reduce wildlife strike risk at Pearson Field by including bridge design features to reduce the potential for bird nesting and roosting combined with continued deterrence measures.

Cumulative Effects Conclusion – Aviation

Past actions, including development in downtown Vancouver and construction of I-5, led to airspace penetrations for aircraft landing or departing at Pearson Field. Present actions would comply with Federal Aviation Administration requirements to ensure compliance with airspace regulations. There are no reasonably foreseeable future actions in the study area that would affect aviation airspace.

The No-Build Alternative would not change existing airspace conditions; several buildings in downtown Vancouver and the existing Interstate Bridge would continue to penetrate the Pearson Field Part 77 airspace and require specific departure procedures to help aircraft avoid the bridge towers. The Modified LPA could reduce bird nesting and bird strike risk at Pearson Field. The Modified LPA would have no effect on aviation at PDX but, depending on the bridge configuration, could result in new airspace penetrations for Pearson Field airspace.

Under the No-Build Alternative, the cumulative effects on aviation from past, present, and reasonably foreseeable future actions would be negligible as other actions would continue to comply with Federal Aviation Administration requirements. Compared to the No-Build Alternative, the cumulative effects on aviation from the Modified LPA would be minor and beneficial due to reduced potential for bird nesting and, if a movable-span configuration is selected, adverse through continued penetration into protected airspace.

3.23.4 Temporary Cumulative Effects

Cumulative effects during construction may result when simultaneous or sequential construction projects have an additive effect on the temporary effects of constructing the Modified LPA. Construction of the

Modified LPA, which includes construction of the new bridges and removal of the existing bridges, is anticipated to overlap with the construction of several of the reasonably foreseeable future projects listed in Section 3.23.2. These include Vancouver Waterfront, Terminal 1, Renaissance Boardwalk, Waterfront Gateway, the various levee system improvements, Portland Expo Center, and the Cascade Renewable Transmission Project. In addition, numerous transportation projects in the 2018 RTP are scheduled for construction in the same timeframe.

Simultaneous or sequential construction projects can increase congestion, cause temporary delays and disruptions to local residents and businesses, create more temporary employment opportunities, impact community and natural resources, and require additional public and private spending. Temporary cumulative effects on the community may result from local traffic congestion and rerouting, as well as noise and air quality impacts, when construction of the Modified LPA overlaps with the construction of other projects in the area. Other projects would have their own traffic control plans, but some may influence the travel routes of commuters and freight and could place more traffic in the study area. Likewise, some projects are on planned haul routes and could influence the delivery of supplies and materials to the job sites for the Modified LPA.

As more detailed plans are developed, traffic control plans would need to be coordinated with these projects and their timelines. Mitigation plans, including coordinated traffic control plans and business assistance, would reduce the temporary negative consequences of construction, while the employment demands would result in positive economic outcomes for the region.

Construction of the Modified LPA could also result in increased employment and spending in the study area during construction. The extent of these effects depends on the funding sources and the makeup of work crews used during construction. This could affect the ability of other projects to obtain skilled workers.

Construction of the Modified LPA is likely to affect marine commerce, including disruptions and delays for vessels during the in-water work (projected to be periodic over 4 years). Several other projects will require in-water work that may occur at the same time, including the Renaissance Boardwalk, the levee system improvements, and the Cascade Renewable Transmission Project.

In addition to marine commerce, overlapping in-water work can also create temporary cumulative effects on fish and wildlife. For each project, most construction-related natural environment impacts would be localized in extent and magnitude such that cumulative effects from other projects would be minimal. Other projects in the area, such as the two levee improvement projects and the Cascade Renewable Transmission Project, could directly impact the same waters or wetlands or regulated habitats that the Modified LPA would affect. Cumulative effects related to construction activities would only occur if such activities were being conducted simultaneously and near construction being conducted for the Modified LPA. Temporary cumulative effects to aquatic habitats may include underwater noise from pile driving, physical benthic impacts, and shading from temporary in-water and overwater structures.

Any project that requires substantial in-water construction work would require federal approvals for work within the river and would therefore undergo Endangered Species Act consultation. To minimize impacts to aquatic species and their habitats, certain work below the ordinary high water mark of the Columbia River and North Portland Harbor would be restricted to defined timing restrictions, referred to here as the in-water work window. The USACE, NOAA Fisheries, USFWS, ODFW, and WDFW all can recommend and/or require restrictions on the timing of in-water work during their regulatory review processes.

Upland ground-disturbing activities (including clearing, grubbing, and excavation) have the potential to cause erosion, which in turn may introduce sediment into adjacent water bodies. However, reasonably foreseeable future projects would require project-specific erosion and sediment control plans, which would reduce the potential for upland construction to cause turbidity in the Columbia River.

If construction of reasonably foreseeable future projects does occur simultaneously with IBR Program-related construction, adverse cumulative effects would be temporary and minimized through construction coordination between ODOT, WSDOT, and other agencies.

3.23.5 Irreversible and Irretrievable Commitments of Resources

NEPA regulations from the Council on Environmental Quality require the environmental analysis to identify "…any irreversible and irretrievable commitments of resources that would be involved in the proposed action should it be implemented" (CFR 1502.16). Irreversible and irretrievable resource commitments include the use of nonrenewable resources throughout a project that may be irreversible if removal of the resources occurs and cannot be replaced within a reasonable timeframe (for example, extinction of a threatened or endangered species) or if obstruction of the use of resources occurs after construction. Implementing the Modified LPA would involve committing natural, physical, human, and fiscal resources.

The proposed improvements would involve a long-term conversion of approximately 47 acres of land to provide right of way for the Modified LPA. Although these transportation facilities could revert to urban land and open space, that is unlikely and would require resources to make happen. Fossil fuels used to power construction, operate vehicles, and manufacture materials are the major nonrenewable resources that would be consumed by construction of the Modified LPA and the resulting daily vehicle operations.

Considerable amounts of labor and material, including cement, aggregate, asphalt, sand, fill materials, lime, and steel, would be used for construction. For demolition of the existing infrastructure, reuse options are relatively limited, but many materials can be recycled. As construction packages and plans are developed, construction bid document specifications or performance requirements could include measures such as maximizing the inclusion of recycled material to reduce new material production, such as recycling existing concrete and asphalt pavements to be used as aggregate base, subbase, backfill materials, etc. The use of these construction materials would not have an adverse impact upon continued availability of these resources. Construction would also require a substantial one-time expenditure of both state and federal funds that may not be retrievable. Retrievability is possible if the improved transportation facilities spur economic growth and toll revenues are bonded to provide capital funding for bridge construction.

4. DRAFT SECTION 4(F) EVALUATION

This chapter provides analysis and information to comply with Section 4(f) of the U.S. Department of Transportation Act (49 U.S. Code [USC] 303 and 23 USC 138).

4.1 Introduction

Chapter Contents

4.1 Introduction
4.2 Summary of 2011 Final Section 4(f) Findings
4.3 Section 4(f) Properties
4.4 Evaluation of Use of Section 4(f) Properties
4.5 Avoidance Alternatives
4.6 Measures to Minimize Harm
4.7 Least Overall Harm Analysis
4.8 Coordination
4.9 Preliminary Section 4(f) Findings

Section 4(f) of the Department of Transportation Act (49 USC 303 and 23 USC 138) and its implementing regulations at 23 Code of Federal Regulations (CFR) Part 774 require U.S. Department of Transportation (USDOT) agencies, such as the Federal Transportation Administration (FTA) and Federal Highway Administration (FHWA), to avoid any use of Section 4(f) property unless there is no feasible and prudent alternative to using the land, or unless the impact will be *de minimis*. Where there is no feasible and prudent alternative to the use of Section 4(f) property, USDOT may approve only the alternative that causes the least overall harm, which is determined by balancing various factors as described in 23 CFR § 774.3(c).

A Section 4(f) property is one that includes any publicly owned parks, recreation areas, and wildlife and waterfowl refuges of national, state, or local significance, as determined by the federal, state, or local officials having jurisdiction, or any land from a historic site of national, state, or local significance, as determined by the State Historic Preservation Officer. The latter include historic properties or archaeological sites listed or eligible for listing in the National Register of Historic Places (NRHP), though archaeological sites must warrant preservation in place to be subject to Section 4(f) requirements.

Once Section 4(f) properties have been identified in the study area, it is necessary to determine whether any of them would be used by the Program activities. A Section 4(f) use is defined and addressed in the FHWA/FTA regulations in 23 CFR 774.17 and the term has a very specific meaning. A "use" of Section 4(f) property occurs when one of the following occurs:

- Land is **permanently incorporated** into a transportation facility.
- There is a **temporary occupancy** of land that is adverse in terms of the Section 4(f) statute's preservationist purposes (23 CFR 774.13(d)).
- There is a **constructive use** of land as determined by criteria in 23 CFR 774.15.
- Permanent incorporation, temporary occupancy, and constructive use are further described in FHWA's *Section 4(f) Policy Paper* (FHWA 2012) and FTA's Standard Operating Procedure No. 18 (FTA 2016).

USDOT agencies may not approve the use of Section 4(f) property with greater than *de minimis* impact unless the agency determines that (1) there is no prudent or feasible alternative, and (2) the project includes all possible planning to minimize harm to these resources resulting from such use (23 CFR 774.3).

If a project will use Section 4(f) property, the first consideration is whether the use of a Section 4(f) property would be so negligible as to constitute a *de minimis* impact or qualify as a temporary occupancy.

A Section 4(f) evaluation must be completed when a project requires the use of Section 4(f) property that will result in a greater than *de minimis* impact. This evaluation considers whether a feasible and prudent avoidance alternative exists and identifies a reasonable range of project alternatives, including those that avoid using Section 4(f) property. For each potential avoidance alternative identified, this chapter evaluates whether avoiding the Section 4(f) property is feasible and prudent. See 23 CFR 774.17.

If there are no prudent and feasible alternatives that can avoid all Section 4(f) properties, then the Section 4(f) analysis must determine which alternative, after measures to minimize harm, results in the least overall harm to Section 4(f) properties. Assessment of least overall harm must consider seven factors—ability to mitigate adverse impact (including any measures that result in benefits to the property); relative severity of the remaining harm, after mitigation, to the protected activities, attributes or features of each Section 4(f) property; relative significance of each Section 4(f) property; views of the officials with jurisdiction over each Section 4(f) property; degree to which the alternative meets the Purpose and Need of the Program; impacts on other important non-Section 4(f) properties after reasonable mitigation; and whether there are substantial differences in cost between the alternatives. See 23 CFR 774.3(c)(1).

Project effects on a Section 4(f) property may be so negligible as to constitute a *de minimis* impact or qualify as a temporary occupancy. Temporary occupancy exceptions are defined under 23 CFR 774.13(d) as occupancies of land that are so minimal as to not constitute a use within the meaning of Section 4(f) given that five conditions detailed in 5.1.3 are satisfied.

Permanent incorporation, temporary occupancy, and constructive use are further described in FHWA's *Section 4(f) Policy Paper* (FHWA 2012) and FTA's Standard Operating Procedure No. 18 (FTA 2016).

4.1.1 Permanent Incorporation

Land is permanently incorporated into a transportation project when it has been purchased as right of way or when sufficient property interests have been otherwise acquired for the purpose of project implementation. An example would be a permanent easement that is required for project construction or that grants a future right of access onto Section 4(f) property, such as for the purpose of routine maintenance by the transportation agency.

4.1.2 *De Minimis* Impact

Title 23 USC Section 138 and Title 49 USC Section 303 allow for a simplified process and approval for projects that have only *de minimis* impacts on lands subject to protection under Section 4(f). *De minimis* impacts are of such a minor extent they do not require a full Section 4(f) evaluation. Section 4(f) use is assessed in terms of the magnitude of impact to determine whether the use is "*de minimis*" or not "*de minimis.*" For historic sites, a *de minimis* impact means that the Administration has determined, in accordance with 36 CFR part 800 (a.k.a. Section 106) that no historic property is affected by the project or that the project will have "No Adverse Effect" on the historic property question. For parks, recreation areas, and wildlife and waterfowl refuges, a *de minimis* impact is defined under 23 CFR 774.17 as "one that will not adversely affect the features, attributes, or activities qualifying the property for protection under Section 4(f)." Avoidance, minimization, mitigation, and enhancement measures must be considered in assessing the net impact to the Section 4(f) property to make a *de minimis* determination. FHWA/FTA is required to consider the net impact after measures to minimize harm are applied.

A finding of *de minimis* impact must include concurrence by the officials with jurisdiction. After providing an opportunity for public comment, the official(s) with jurisdiction issues their concurrence in writing for the proposed *de minimis* impact determination. *De minimis* impact determinations can be made for permanent incorporations or temporary occupancies.

The requirements of Section 4(f) are satisfied if it is determined that a transportation project would have only a *de minimis* impact. Therefore, if a project would have only a *de minimis* impact on a Section 4(f) property, there is no obligation to analyze feasible and prudent avoidance alternatives or all possible planning to minimize harm to the property because, by definition in 23 CFR 774.17, impacts on the Section 4(f) property are reduced to a *de minimis* level.

4.1.3 Temporary Occupancy

Temporary occupancy occurs when a property is required for a limited amount of time for project construction-related activities. There is no permanent acquisition of property, but the temporary use of the property is adverse to the preservation purpose under Section 4(f). In some situations, temporary occupancy may not constitute a use under Section 4(f) if it meets the following five conditions of the temporary occupancy exception criteria in 23 CFR 774.13(d):

1. Duration must be temporary, i.e., less than the time needed for construction of the project, and there should be no change in ownership of the land;
2. Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal;
3. There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis;
4. The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and
5. There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

In cases where the five conditions of the temporary occupancy exception criteria are met, there is no use of Section 4(f) properties. If one or more of the conditions for the exception cannot be met, then the temporary occupancy becomes a use of the Section 4(f) property even though the duration is temporary. Documented concurrence of the official(s) with jurisdiction is necessary to demonstrate that the temporary occupancy exception criteria are met and must be kept on file as part of the project. Concurrence documentation is typically included in the Final Section 4(f) evaluation.

4.1.4 Constructive Use

Constructive use occurs when there is no physical use of a Section 4(f) property, as would be the case when there is a permanent incorporation or temporary occupancy, but there are proximity impacts on an adjacent or nearby Section 4(f) property, after incorporation of impact mitigation, that are so severe that they result in a substantial impairment of the property's activities, features, or attributes that qualify it for protection under Section 4(f). Constructive use includes proximity impacts such as noise, access restrictions, vibration, ecological intrusions, and visual impacts. Not all proximity impacts result in a constructive use—only those that will "substantially diminish" the activities, features, and attributes of a Section 4(f) property. For instance, a park whose central features include views and quiet where a transportation project would block views and devalue the serenity of the park due to noise could be a proximity impact, whereas merely a change in views or incremental increases in noise likely would not be a proximity impact.

For historic sites, a constructive use does not occur when compliance with the requirements of 36 CFR 800.5 (Assessment of adverse effects) for proximity impacts of the proposed action, on a site listed in or eligible for the NRHP, results in an agreement of "No Effect" or "No Adverse Effect" (23 CFR Section 774.15). Therefore, where permanent incorporation or nonexempt temporary occupancy occurs for a given Section 4(f) property and/or there is "No Effect" or "No Adverse Effect," this evaluation does not further discuss constructive use. Constructive use is an extremely rare occurrence.

The evaluation to determine whether there is a constructive use is subject to the criteria in 23 CFR 774.15(e). These criteria are provided below and are referenced for constructive use evaluations in Section 4.3 of this evaluation. These criteria focus on noise, aesthetics, access, vibration, and ecological intrusion.

> *(e) The Administration has reviewed the following situations and determined that a constructive use occurs when:*
>
> > *(1) The projected noise level increase attributable to the project substantially interferes with the use and enjoyment of a noise-sensitive facility of a property protected by Section 4(f), such as:*
> >
> > *(i) Hearing the performances at an outdoor amphitheater;*
> >
> > *(ii) Sleeping in the sleeping area of a campground;*
> >
> > *(iii) Enjoyment of a historic site where a quiet setting is a generally recognized feature or attribute of the site's significance;*
> >
> > *(iv) Enjoyment of an urban park where serenity and quiet are significant attributes; or*
> >
> > *(v) Viewing wildlife in an area of a wildlife and waterfowl refuge intended for such viewing.*
> >
> > *(2) The proximity of the proposed project substantially impairs esthetic features or attributes of a property protected by Section 4(f), where such features or attributes are considered important contributing elements to the value of the property. Examples of substantial impairment to visual or esthetic qualities would be the location of a proposed transportation facility in such proximity that it obstructs or eliminates the primary views of an architecturally significant historical building, or substantially detracts from the setting of a Section 4(f) property which derives its value in substantial part due to its setting;*
> >
> > *(3) The project results in a restriction of access which substantially diminishes the utility of a significant publicly owned park, recreation area, or a historic site;*
> >
> > *(4) The vibration impact from construction or operation of the project substantially impairs the use of a Section 4(f) property, such as projected vibration levels that are great enough to physically damage a historic building or substantially diminish the utility of the building, unless the damage is repaired*
> >
> > *and fully restored consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties, i.e., the integrity of the contributing features must be returned to a condition which is substantially similar to that which existed prior to the project; or*
> >
> > *(5) The ecological intrusion of the project substantially diminishes the value of wildlife habitat in a wildlife and waterfowl refuge adjacent to the project, substantially interferes with the access to a wildlife and waterfowl refuge when such access is necessary for established wildlife migration or critical life cycle processes, or substantially reduces the wildlife use of a wildlife and waterfowl refuge.*

4.1.5 Summary of 2011 Final Section 4(f) Findings

Where details of the CRC Final Section 4(f) Evaluation for a given property are still relevant and accurate, they have been included to support the Draft Section 4(f) Evaluation for the IBR Program.

The CRC project's Final Section 4(f) evaluation identified 11 park and recreation facilities and 36 historic sites.

- The CRC evaluation analyzed the use of Section 4(f) properties for five different alternatives: The CRC LPA: Included a new river crossing over the Columbia River and the I-5 highway improvements, including improvements to seven interchanges, north and south of the river and enhancements to the local street network, as well as light-rail extension from the Expo Center to Clark College, bicycle and pedestrian improvements throughout the corridor, tolling for the river crossing, and transportation demand management measures.
  - LPA Option A included local vehicular access between Marine Drive and Hayden Island on a multimodal bridge.
  - LPA Option B did not have traffic lanes on the light-rail bridge, but would provide direct auto access between Marine Drive and Hayden Island with collector-distributed lanes on two new bridges adjacent to I-5.
- Alternative 2: Included a full replacement crossing downstream (west) of the current I-5 alignment. The new crossing would include three bridges (two northbound and southbound traffic and a third for transit, bicycles, and pedestrians) or a stacked, two bridge configuration with transit, bicycle and pedestrian decks suspended beneath the vehicle deck. This alternative would use bus rapid transit; it would not include light-rail transit (LRT).
- Alternative 3: Similar to Alternative 2 except that LRT would be used instead of bus rapid transit.
- Alternative 4: Retained both existing I-5 bridges and add one new bridge. Existing bridges would be restriped to provide two northbound lanes on each bridge and provide safety shoulders for disabled vehicles. A new, wider bicycle and pedestrian facility would be added to the east side of the existing northbound (eastern) bridge. A new supplemental bridge would be constructed downstream of the existing bridges and would include four southbound traffic lanes, safety shoulders, and bus rapid transit; it would not include LRT
- Alternative 5: Similar to Alternative 4 except that LRT would be used instead of bus rapid transit.

The CRC Section 4(f) evaluation determined that:

- Land from 36 Section 4(f) properties (10 park and recreation properties and 26 historic sites) would be used under the CRC LPA, with 11 properties experiencing a use with greater than *de minimis* impact and 25 experiencing a *de minimis* impact. One park and recreation property (East Delta Park) and ten historic sites would not experience a use under Section 4(f).
- As part of the CRC LPA, no park and recreation properties or historic sites would experience a constructive use.

There were no prudent and feasible alternatives that would avoid all Section 4(f) resources. All prudent and feasible alternatives would use Section 4(f) properties. The CRC Final Section 4(f) evaluation analyzed several alternative options to evaluate avoidance and minimization of impacts to some of the Section 4(f) properties.

The evaluation considered the following measures to minimize harm to Section 4(f) properties in Portland:

- Moving the Marine Drive/I-5 Interchange ramps farther east or west.
- Other measures specified in the Section 106 Memorandum of Agreement, including:
  - Documenting a historic property prior to deconstruction using the Historic American Building Survey/ Historic American Engineering Record standards,
  - Attempting to relocate and adaptively reuse elements of a historic property,

  - Developing interpretive materials, and
  - Developing multiple property documentation for postwar boat and automobile dealership showroom buildings.

Measures to avoid or minimize harm to the northbound Interstate Bridge included:

- Reusing the existing bridge and crossings in alternative locations and keeping the existing bridge and providing a supplemental crossing. These were determined not to meet the Purpose and Need.
- Documenting the bridge; preparing a marketing plan to find alternative uses for the bridge or individual spans; incorporating decorative or interpretive elements of the existing bridge into the new bridge; communicating the structure's history through interpretive programs and a web site; and developing multiple property documentation for bridges in Oregon and Washington.

The evaluation identified measures to minimize harm to properties in Vancouver—in particular, the Waterfront Renaissance Park and Trail and Marshall Community Center and Park—including:

- Reduce harm to the west edge of the Vancouver National Historic Reserve (VNHR), by selecting the supplemental crossing, shifting the replacement crossing alignment to the west, or stacking northbound I-5 on-ramps from SR 14 vertically instead of aligning them horizontally.
- Reduce harm to the west edge of the VNHR and the Barracks Post Hospital, by reducing I-5 lane width or shoulder widths below standards, or eliminating one or more of the proposed auxiliary lanes from I-5 between SR 14 and Mill Plain.
- Reduce acquisitions of VNHR and to reduce harm to the Fort Vancouver Village area and Old Apple Tree Park, select the SR 14 left-loop interchange design, refine its design, or reorient the I-5/SR 14 interchange.
- Assist with the redevelopment and relocation of Waterfront Park and Trail.
- Minimize impacts to Marshall Community Center and Park, realign and narrow the Mill Plain to Fourth Plain interchange ramps, restripe the Community Center parking lot to reduce off-street parking spaces lost, and enter into a shared agreement with Clark park and ride to reduce lost on-street parking.

Several of the alternatives evaluated required design deviations within the study area and often resulted in (1) additional impacts to properties that would otherwise not be affected, (2) unacceptable safety or operational problems, or (3) were not consistent with the project's Purpose and Need. Reasonable minimization measures were identified during the CRC evaluation and were incorporated into the LPA. The CRC project team coordinated with parties that had jurisdiction over identified Section 4(f) properties, including Portland Parks and Recreation (PP&R), the National Park Service (NPS), Vancouver-Clark Parks and Recreation Department, Vancouver Public Schools, Washington State Department of Archaeology and Historic Preservation, Oregon State Historic Preservation Office, and the City of Vancouver to refine the proposed project footprint that reduced the number of Section 4(f) uses and resulted in a *de minimis* determination for many of the Section 4(f) uses. The CRC project team analyzed the LPA, Alternatives 2 and 3 (Replacement Crossing), and Alternatives 4 and 5 (Supplemental Crossing) following the seven factors in 23 CFR 774.3(c) to determine which alternative would cause the least overall harm. After evaluating each CRC alternative, FHWA and FTA determined that the LPA would result in the least overall harm of all alternatives, for the following reasons:

- *Ability to mitigate impacts to Section 4(f) properties, including any benefits to properties:* All alternatives were found to have similar ability to mitigate impacts, but the LPA and Alternatives 2 and 3 would provide the most benefit to Section 4(f) properties.
- *Severity of remaining harm after mitigation:* All alternatives were found to have generally equivalent severity of impacts after mitigation.

- *Relative significance of each Section 4(f) property:* Relative significance of 4(f) properties was found to be similar for all alternatives.
- *Views of officials with jurisdiction:* Officials with jurisdiction who expressed a preference generally preferred the LPA (modified version of Alternative 3).
- *Degree to which alternative meets the purpose and need for the project:* The LPA was found to best meet the project's Purpose and Need. Alternatives 4 and 5 were found to be considerably less effective at meeting the Purpose and Need.
- *Magnitude of impacts to non-Section 4(f) properties after mitigation:* The magnitude of non-Section 4(f) impacts was found to be lowest for Alternatives 2 and 3 (fewer acquisitions) and generally equivalent for the LPA and Alternatives 4 and 5.
- *Substantial cost difference among alternatives:* No substantial cost difference among alternatives was found.

4.1.6 IBR Draft Section 4(f) Evaluation

In 2011, FHWA issued a Final Section 4(f) determination on park and recreation properties and historic sites for the Columbia River Crossing (CRC) project. There were no wildlife or waterfowl refuges in the CRC project study area and there are none in the IBR Program study area. Where details of the CRC Final Section 4(f) Evaluation for a given property are still relevant and accurate, they have been included in the Draft Section 4(f) Evaluation for the IBR Program.

The analysis included in this Draft Section 4(f) Evaluation for the IBR Program incorporates relevant information for Section 4(f) properties from CRC to the degree that information is still accurate, but a new evaluation was prepared due to changes in:

- The affected environment, including changes in the eligibility of properties for protection under Section 4(f). The addition of sites due to sites aging in to historic eligibility account for the majority of changes.
- Regulations or guidance that have occurred since the 2011 determination including clarifications regarding *de minimis* impacts provided in FHWA's *2012 Section 4(f) Policy Paper.*
- The use of properties by the IBR Modified LPA with all design options as a result of changes in eligibility or other conditions described in Chapter 2.

This Section 4(f) Evaluation is being made available to the public to review and comment concerning the effects on the protected activities, features, and attributes for park and recreation properties and historic sites and preliminary *de minimis* impact findings for these properties as required by 23 CFR 774.5(b)(2) during the review period for the IBR Program's Draft Supplemental Environmental Impact Statement (SEIS) to provide an opportunity for wide public distribution.

4.2 IBR Section 4(f) Properties

4.2.1 Section 4(f) Park and Recreation Properties in the IBR Program Study Area

This section provides an overview of the Section 4(f) properties that were evaluated for potential use by the IBR Program Modified LPA with all design options, hereafter referred to as the Modified LPA, within the IBR Program study area for Parks and Recreation. The Park and Recreation Study Area is defined in the Parks and Recreation Technical Report. The IBR Program Parks and Recreation Technical Report discusses additional recreational properties in the IBR Program study area that are not subject to protection under Section 4(f) properties.

Table 4-1 summarizes the Section 4(f) park and recreation properties in the IBR Program study area. There are a total of 11 park and recreation facilities in the IBR Program study area including one park and recreation property in Portland and nine park and recreation properties in Vancouver.

Table 4-1. Summary Information about Section 4(f) Park and Recreation Properties in the IBR Program Study Area

State	Name	Facility Type	Location	Agency with Jurisdiction	Protected Site Features, Attributes, or Activities
Oregon	Marine Drive Trail	Regional Trail	Portland, Oregon	City of Portland	5-mile multiuse trail that includes sections with both transportation and recreational primary purposes. Only recreational sections are protected.
Oregon	East Delta Park	Regional Park	10737 N Union Court, Portland, OR	City of Portland	• 85 acres. • Softball and soccer fields, control-line flying field, sand volleyball courts, playground.
Washington	Vancouver Landing at Terminal 1	Public Dock and Park	100 Columbia Street, Vancouver, WA	Port of Vancouver	• Public dock and park located on the Columbia River to the west of I-5. • Updated in 2022 to include link to the Columbia River Renaissance Trail and a new “Rotary Way” walkway. • Also includes a small boat dock and serves river cruise vessels. • The Port plans to replace the dock with one that will support a public market.
	Vancouver Waterfront Park	Regional Park	Vancouver, WA	City of Vancouver (VPR&C)	• 7.3 acres. • Includes public open spaces, benches, a fountain, and 0.5 miles of trail connecting to the Columbia River Renaissance Trail. • Completed in 2018 as part of the Waterfront Vancouver development.

State	Name	Facility Type	Location	Agency with Jurisdiction	Protected Site Features, Attributes, or Activities
	Fort Vancouver NHS	National Park	800 Hathaway Road, Building 722, Vancouver, WA	NPS	• 209 acres (largely overlapping with the VNHR). • Historic interpretive sites and replica structures, multiuse trails, picnic tables, event and recreation fields, and reservable picnic shelter. • Newly constructed main visitor parking lot and improvements to E 5th Street, including repaving, new sidewalks, reoriented parking spaces, and bicycle and pedestrian routes completed in fall 2022. • NPS has reconstructed two replica village dwellings in the western portion of the property and maintains a tree alley that visually buffers the area.
	Old Apple Tree Park	Urban Natural Area	112 Columbia Way, Vancouver, WA	City of Vancouver (VPR&C)	• 1.3 acres. • Passive recreation, bicycle parking, and viewing; was the site of possibly the oldest apple tree in the Northwest (Heritage Apple Tree), which died in 2020—the tree was removed, leaving a stump and newly planted saplings that share a genetic makeup with the original tree. • The park is accessible from the Fort Vancouver NHS and using the Confluence Land Bridge.
	Marshall Community Center, Luepke Senior Center, and Marshall Park	Community Center and Public Swimming Pool, Senior Center, and Community Park	1015 E McLoughlin Boulevard, Vancouver, WA	City of Vancouver (VPR&C)	• 19 acres. • Community center, play equipment, community gardens, loop trail, picnic tables, horseshoe pits, and ball fields and the Marshall and Luepke Centers. • The community center contains a swimming pool, fitness center, two basketball courts, commercial kitchen, meeting rooms, offices, and studios for aerobics and arts and crafts. Luepke is a full-service senior center with multipurpose and meeting rooms. • The City of Vancouver installed new accessible play equipment in the park in fall 2022.

State	Name	Facility Type	Location	Agency with Jurisdiction	Protected Site Features, Attributes, or Activities
	Clark College Recreational Fields	Sports Fields and Courts	1500 E Mill Plain Boulevard, Vancouver WA	Clark College	• 13.5 acres. • Sports fields, courts.
	Leverich Community Park	Community Park	39th and M Streets, Vancouver, WA	City of Vancouver (VPR&C)	• 16 acres. • Disc golf course, picnic tables, paved walkways, reservable picnic shelter, restroom, and play equipment.
	Arnada Neighborhood Park	Neighborhood Park	610 E 25th Street, Vancouver, WA	City of Vancouver (VPR&C)	• 3-acre park. • Includes a gazebo, picnic shelter, play equipment, sport court, benches, and a paved walkway.
	Burnt Bridge Creek Trail	Multiuse Trail	Vancouver, WA	City of Vancouver (VPR&C)	• 8-mile paved multiuse trail that passes through the Burnt Bridge Creek Greenway on the east and west sides of I-5 with a pedestrian and bicycle-only bridge over the freeway.

I-5 = Interstate 5; NHS = National Historic Site; VPR&C = City of Vancouver Parks, Recreation, and Cultural Services

Complete descriptions and additional information for these facilities are available in the Parks and Recreation Technical Report, and further descriptions are contained in Section 4.3 of this evaluation. Figure 4-1 maps the locations of park and recreation properties in the IBR Program study area.

Figure 4-1. Section 4(f) Park and Recreation Properties: IBR Program Study Area

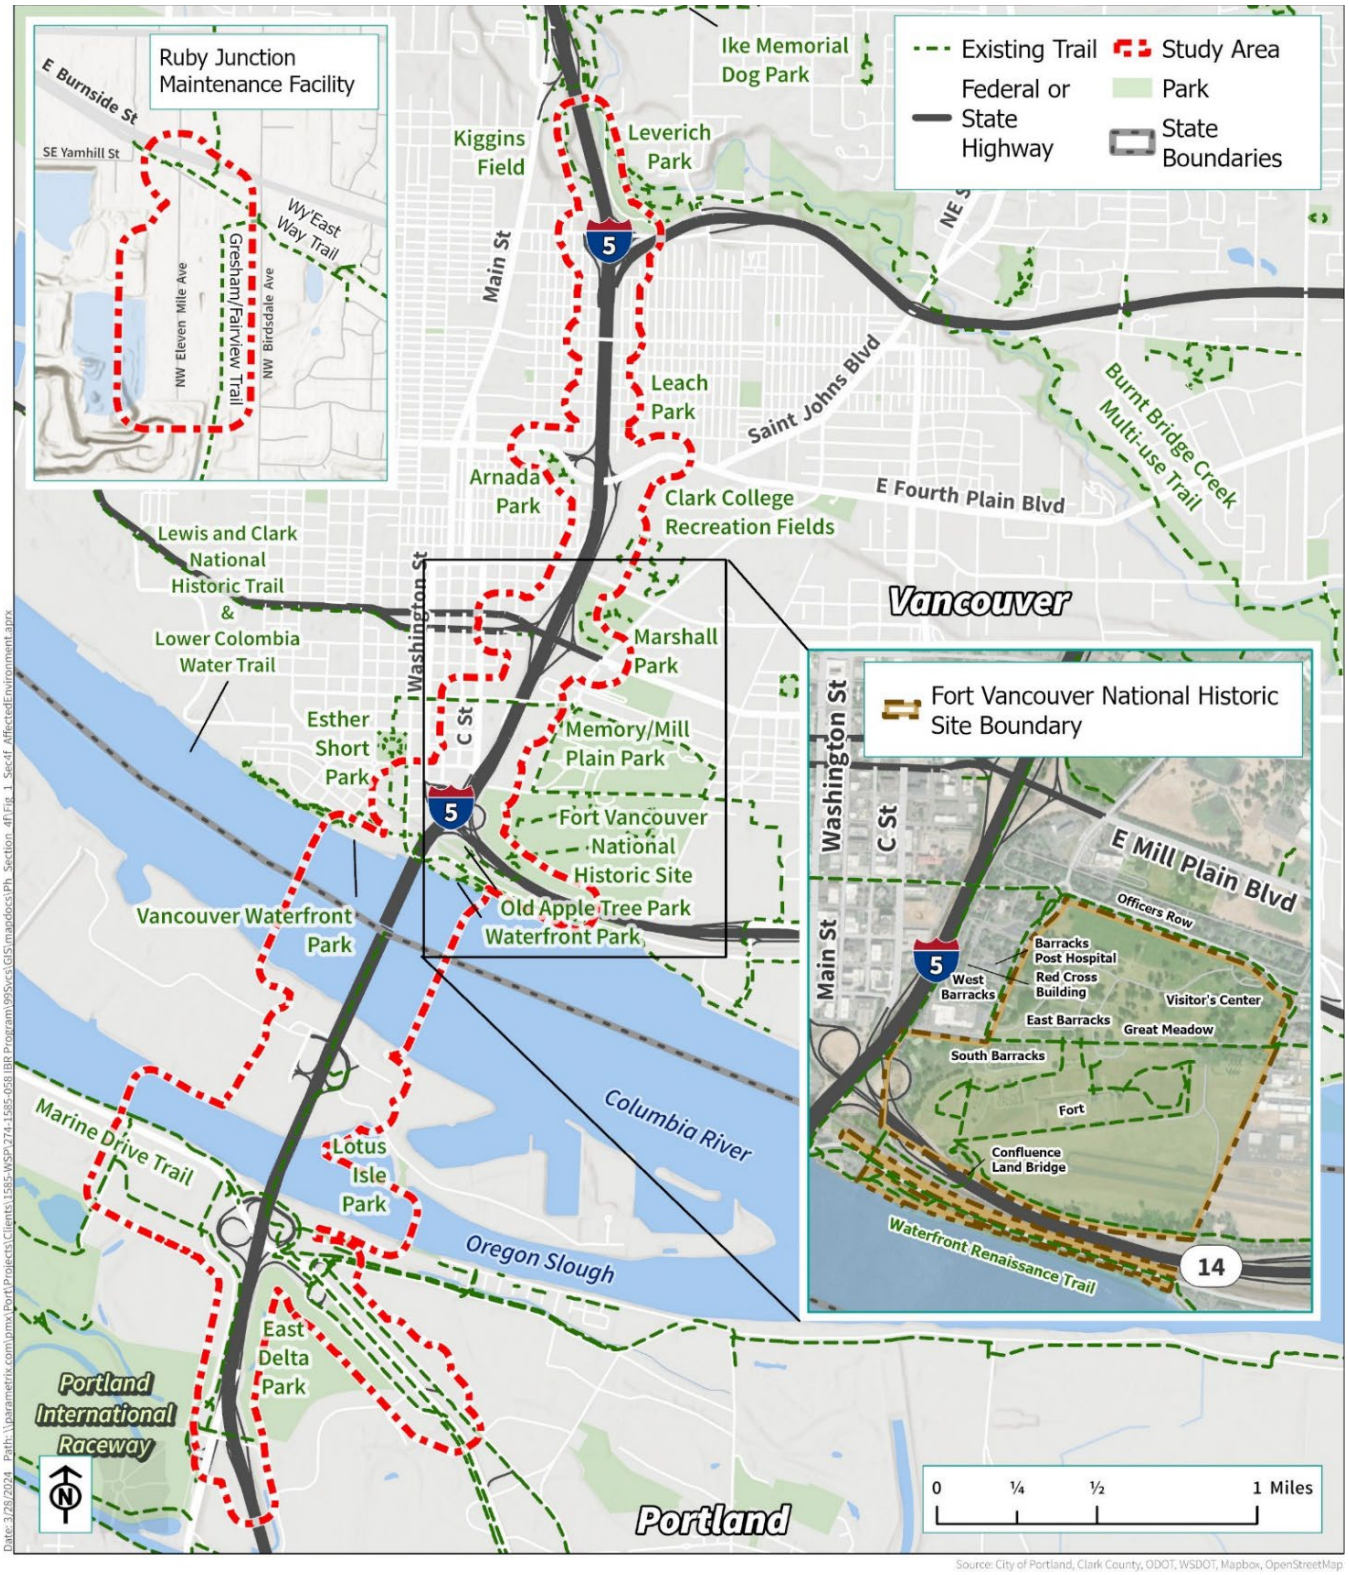

Figure 4-2 through Figure 4-5 provide more detailed maps of the Section 4(f) park and recreation properties in Oregon, of the Fort Vancouver National Historic Site (NHS), between Mill Plain Boulevard and Fourth Plain Boulevard, and north of Fourth Plain Boulevard (respectively).

Figure 4-2. Section 4(f) Park and Recreation Properties: Oregon

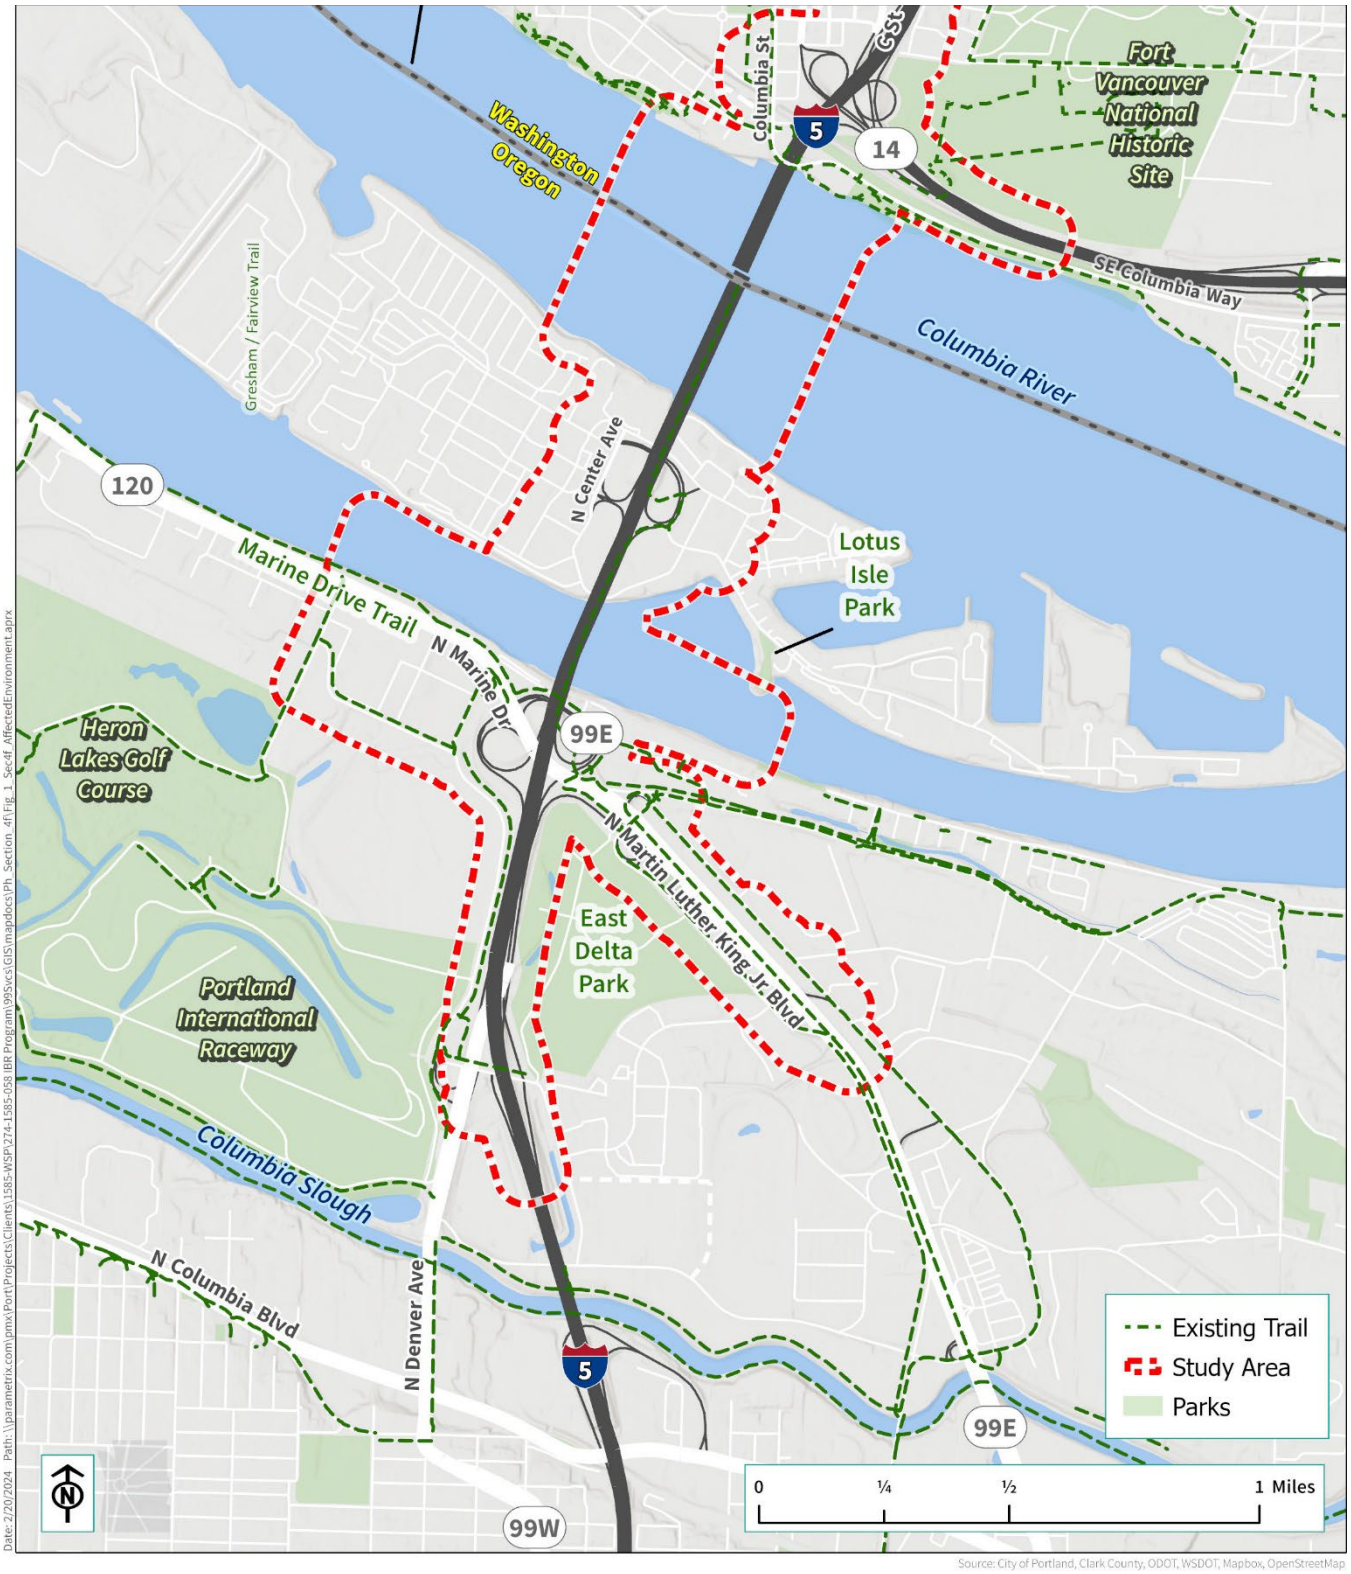

Figure 4-3. Section 4(f) Park and Recreation Properties: Fort Vancouver National Historic Site

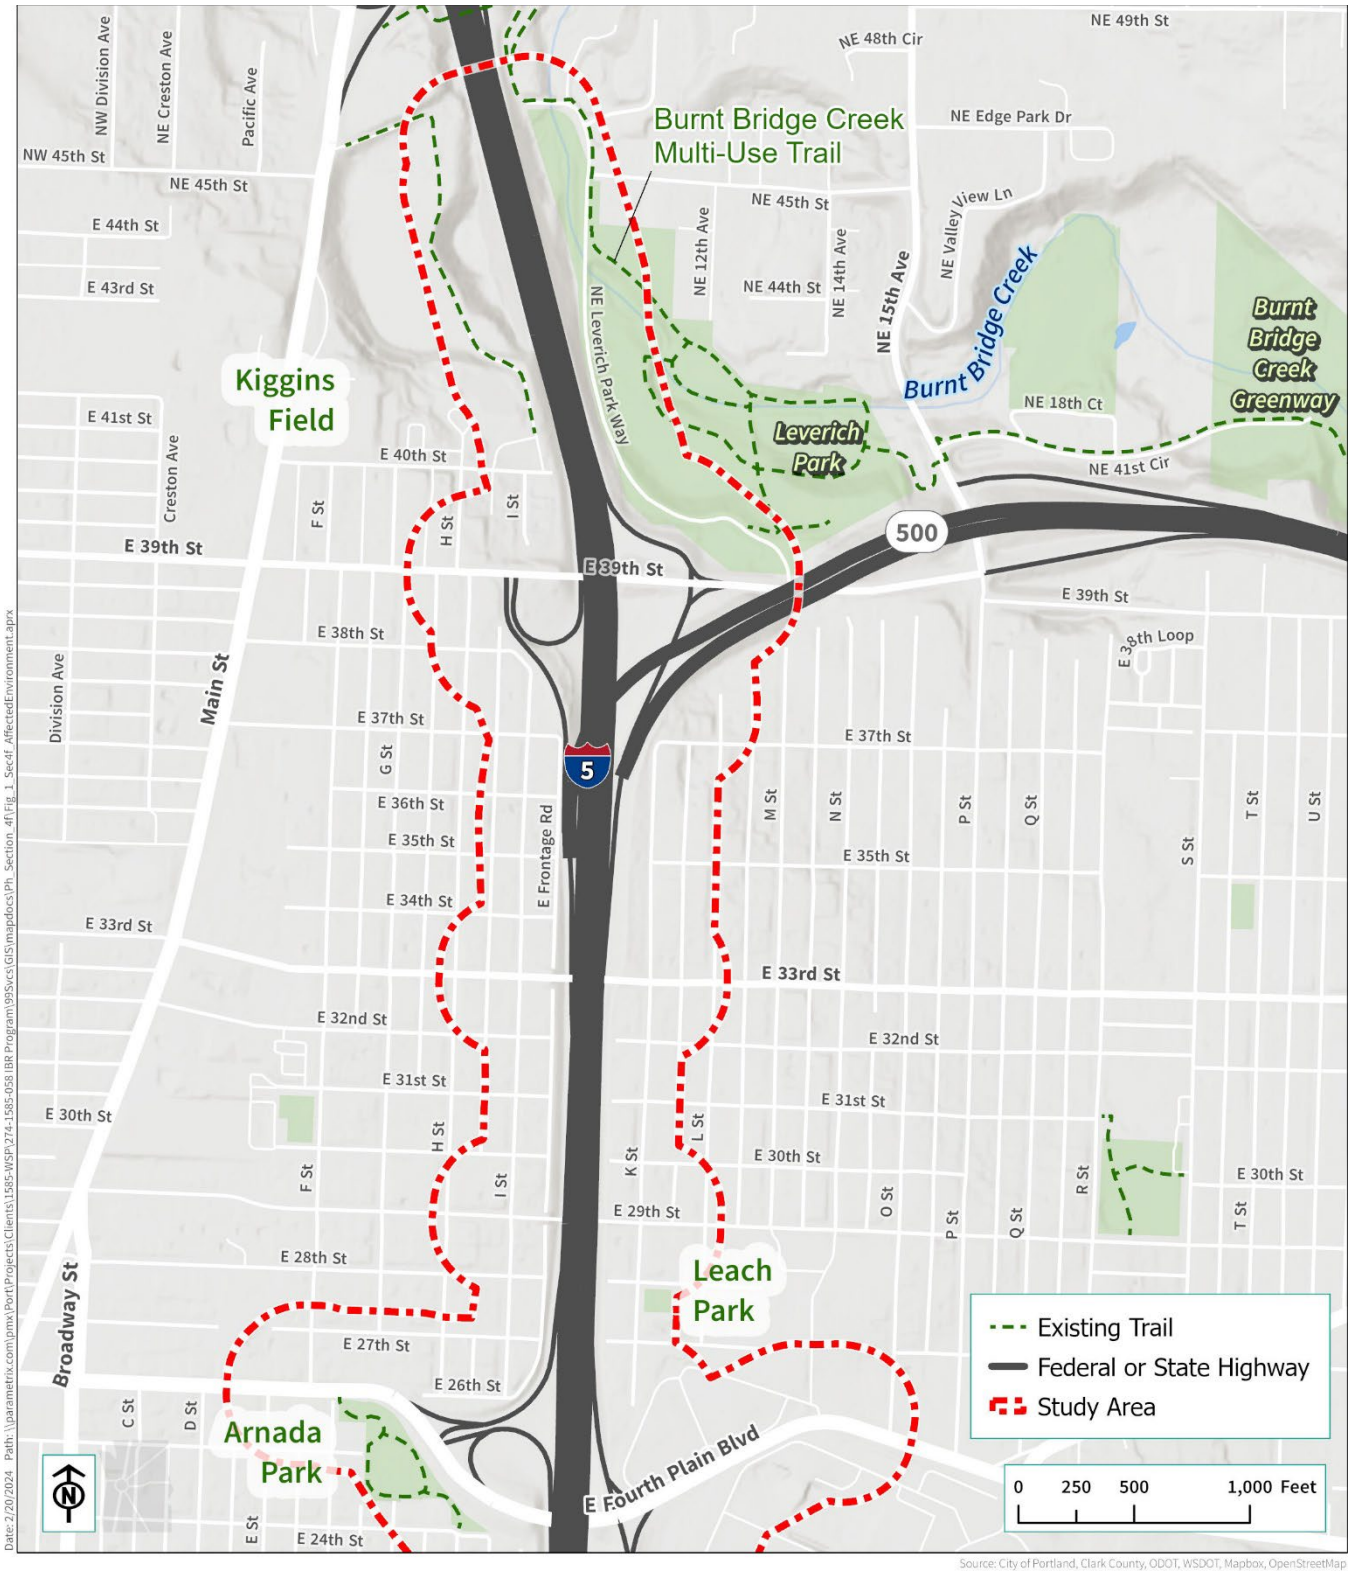
Figure 4-4. Section 4(f) Park and Recreation Properties: Mill Plain Boulevard to Fourth Plain Boulevard

Figure 4-5. Section 4(f) Park and Recreation Properties: North of Fourth Plain Boulevard



The VNHR was created by Congress in 1996 and includes the Fort Vancouver NHS and related properties. The VNHR is cooperatively managed by the NPS, the Washington State Department of Archaeology and Historic Preservation, the Department of the Army, and the City of Vancouver.

A portion of the VNHR was listed as a historic district on the NRHP in 2008, whereas the NPS identifies the Fort Vancouver NHS as a park. For these reasons, the IBR Program's Draft Section 4(f) Evaluation treats the VNHR Historic District as a historic site inclusive of the Fort Vancouver NHS and treats the Fort Vancouver NHS separately as a park and recreational property to explicitly address both the public park and the historic significant activities, features, and attributes of the property. Table 4-1 provides summary information on Section 4(f) park and recreation properties in the IBR Program Study area.

Facilities within the study area that qualify for an exception under 23 CFR 774.13 and are not evaluated further for a use under Section 4(f) in Section 4.3 of this document are described below.

Wy' East Way Path: The Wy'East Way Path is a 2-mile path located in Gresham that runs along the light-rail line from Ruby Junction Station in Rockwood south to Cleveland Station in downtown Gresham. The City of Gresham's website emphasizes the Wy'East Way Path as a connection to the Gresham/Fairview Trail and Springwater Corridor, creating a continuous 6-mile loop through Gresham. The path is described as being an alternative transportation route to get around Gresham; the path provides easier access to local parks, trails, public transit, schools, and businesses. Per 23 CFR 774.13(f)(4), trails that are part of the local transportation system and function primarily for transportation are not required to receive Section 4(f) approval; therefore, the Wy'East Way Path, as trail that functions primarily for transportation, is not subject to Section 4(f).

Gresham-Fairview Trail: The Gresham-Fairview Trail is a 3.29-mile trail in Gresham that connects to the Springwater Trail at SW 10th Avenue and can also be accessed at Northeast Halsey Street at 201st Avenue from the north. Oregon Metro (Metro), the Portland area's regional government, emphasizes the purpose of the trail as connecting origins and destinations. The trail connects town centers, schools, employment centers, and housing in east Multnomah County with the MAX light-rail, provides access to the Columbia River for residents in Gresham and Fairview, connects to six other regional trails (including Springwater Corridor, Marine Drive Trail and Sandy River Connection), and provides access to major recreational and scenic resources including the Columbia River and local parks. The Gresham-Fairview Trail is part of the Metro's 40-Mile Loop Trail, which connects more than 30 parks in Multnomah County along the Columbia, Sandy, and Willamette Rivers, Johnson Creek, and the Tualatin Mountains.

Per 23 CFR 774.13(f)(4), trails, paths, bicycle lanes, and sidewalks that are part of the local transportation system and that function primarily for transportation do not require Section 4(f) approval. The Gresham-Fairview Trail primarily serves as a trail for movement of people through active transportation modes and connecting origins and destinations in the area and, therefore, does not require approval under Section 4(f).

Lower Columbia River Water Trail: The Lower Columbia Water Trail traverses the Columbia River, running underneath both the new and proposed bridges. Guidance provided by FHWA in the *Section 4(f) Policy Paper*, Question 21A indicates that Section 4(f) generally does not apply to rivers, but that it would apply to portions of publicly owned rivers, which are designated as recreation trails. The Lower Columbia Water Trail is not designated as part of the National Water Trail System. Because the Lower Columbia River Water Trail is informally designated by the Lower Columbia River Partnership, a nonprofit organization, and not an official with jurisdiction over a park and recreation area (which is an agency as defined under 23 CFR 774.17), the water trail is not protected under Section 4(f).

Columbia River Renaissance Trail (formerly referred to as Waterfront Renaissance Trail): The Columbia River Renaissance Trail is a 5-mile-long, 14-foot-wide multiuse paved trail starting at the intersection of Columbia Way and Columbia Street and extending east to Marine Park and Wintler Park. The trail is open from 7:00 a.m. to dusk, connects Vancouver's downtown to the Columbia River waterfront, and offers multiple benches for viewing. The Columbia River Renaissance Trail is a portion of the Discovery Historic Loop Trail and connects to the Fort Vancouver NHS. The portion of the trail in the study area is designated along the public sidewalk on the south side of Columbia Way. After construction is complete, the trail and Columbia Way would be realigned and reconstructed. The newly constructed portion of trail would continue to be located within City of Vancouver right of way for Columbia Way. In accordance with 23 CFR 774.13(f), and as per Question 15A of the *Section 4(f) Policy Paper*, "Section 4(f) would apply to a publicly owned, shared-use path or similar facility (or portion thereof) designated or functioning primarily for recreation…" (FHWA 2012). While considered in the CRC Final Section 4(f) Evaluation, because the affected portion of trail is located within public right of way that is a sidewalk and functions primarily for an active transportation purpose connecting to and between downtown Vancouver, the Vancouver waterfront, and several parks in the region, and the trail would remain as a sidewalk after construction, the Columbia River Renaissance Trail is not subject to Section 4(f).

Discovery Historic Loop Trail: The Discovery Historic Loop Trail is a 2.9-mile trail that connects the Fort Vancouver NHS and the VNHR with the Vancouver waterfront and downtown. The trail is located within and is a feature of the Fort Vancouver NHS Park for much of its extent. It also overlaps with the Columbia River Renaissance Trail along the waterfront. Because it is contained within the Fort Vancouver NHS and overlaps the Columbia River Renaissance Trail, it is not counted as a separate recreational property. The trail follows sidewalks on local streets in downtown Vancouver outside of the Fort Vancouver NHS and the Renaissance Trail. While considered in the CRC Final Section 4(f) Evaluation, per 23 CFR 774.13(f)(4), trails that are part of the local transportation system and function primarily for transportation, such as the Discovery Historic Loop Trail, are not subject to Section 4(f) approval.

Kiggins Bowl Sports Fields/Stadium: Located northwest of the I-5 and E 39th Street interchange, the Kiggins Bowl Sports Fields/Stadium is a Vancouver Public Schools facility that sits on the same property as Discovery Middle School. The Discovery Middle School property contains the school, parking lots bordering the school entrance on E 40th Street, internal vehicle circulation areas, and recreational facilities. The recreational facilities include sports fields, natural areas, a trail connecting to the Burnt Bridge Creek Trail, a track around an artificial turf soccer field, a football field, a 4,000-square-foot field house at the northern end of the football field, team rooms, public restrooms, and locker rooms. Planned improvements include modernizing the existing stadium to include seismic upgrades, a secondary press box, a new traffic surface over the seating risers, and upgrades to the lower-level locker rooms. Only the track surrounding the football fields is open to the public, with the remaining facilities requiring a contract with Vancouver Public Schools for their use.

Where public properties are managed for multiple purposes, such as for the Discovery Middle School property that contains the Kiggins Bowl Sports Fields/Stadium, Section 4(f) only applies to the portions of these lands that "function for, or are designated in the plans of the administering agency as being for, significant park, recreation, or wildlife and waterfowl refuge purposes" as per 23 CFR 774.11(d). Thus, only the portion of the property that contains the sports fields, natural areas, trail connection, track, football field, field house, team rooms, restrooms, and locker rooms are subject to Section 4(f), and not the portion of the property containing the school, as shown on Figure 4-6. Both the permanent land acquisition and the temporary easement needed by the Modified LPA, including all design options, would be small portions of the Discovery Middle School property that are located at the far southeastern corner, which is not within the area managed for recreational use.

While considered in the CRC Final Section 4(f) Evaluation, due to the shared use on the property, Discovery Middle School is not a Section 4(f) property under 23 CFR 774.11(d). The acquisition area and temporary easement from the facility would be located on the portion of the property used for school purposes and therefore would not meet the applicability criteria for Section 4(f).

Nearby Parks: The IBR Program Park and Recreation Technical Report notes that Lotus Isle Park, Esther Short Park, Leach Park, and Ike Memorial Dog Park "are located near to, but outside of the IBR Program study area and would not be affected by the Modified LPA or design options." These parks are not further discussed in this evaluation.

Figure 4-6. Kiggins Bowl Sports Fields/Stadium Modified LPA with Design Options

4.2.2 Section 4(f) Historic Sites in the IBR Program Study Area

This section summarizes the Section 4(f) historic sites evaluated for potential use by the IBR Program Modified LPA, including all design options, within the Section 106 cultural resources area of potential effect (APE), which is the Section 4(f) study area boundary for historic sites. See Section 3.8, Cultural Resources, of the Draft SEIS, which discusses how the cultural resources APE boundary was established. There are a total of 32 historic sites including four historic districts that include multiple sites eligible or listed under the NRHP within the cultural resources APE. Of these, 10 historic sites are in Portland and 22 historic sites are in Vancouver. Figure 4-7 through Figure 4-9 depict the geographic location of Section 4(f) historic sites in the IBR Program cultural resources APE, and Table 4-2 provides a summary description of these historic sites.

Figure 4-7. Summary of Section 4(f) Historic Sites in the IBR Program Study Area – Oregon

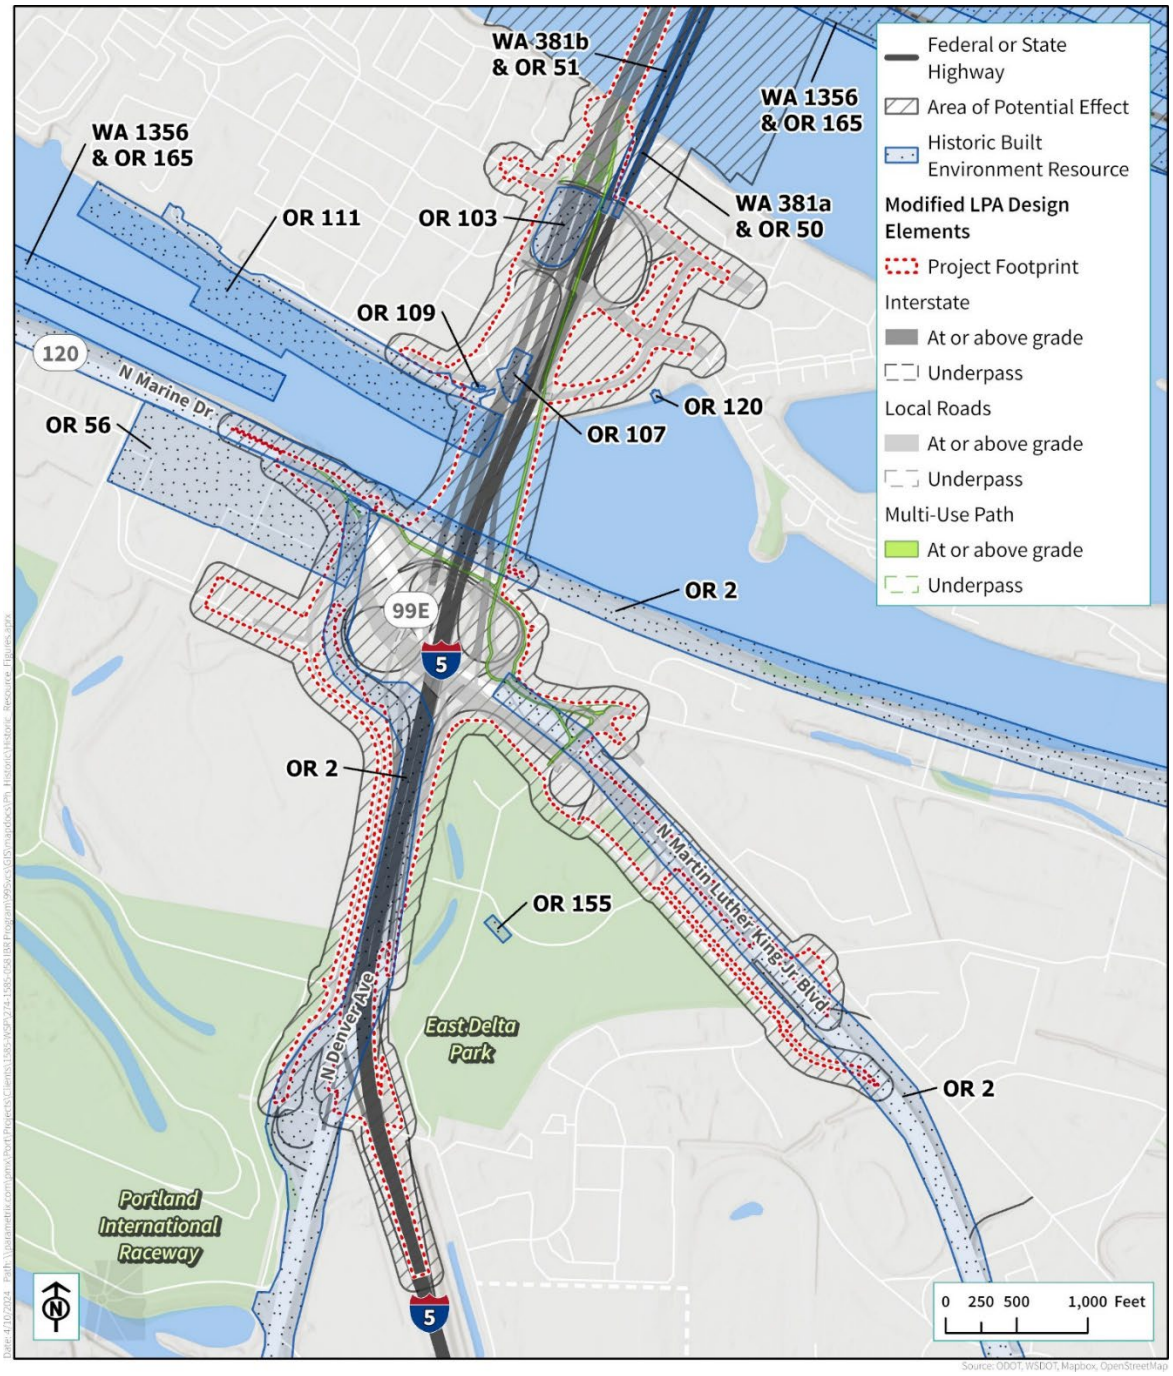


Figure 4-8. Summary of Section 4(f) Historic Sites in the IBR Program Study Area – Downtown Vancouver

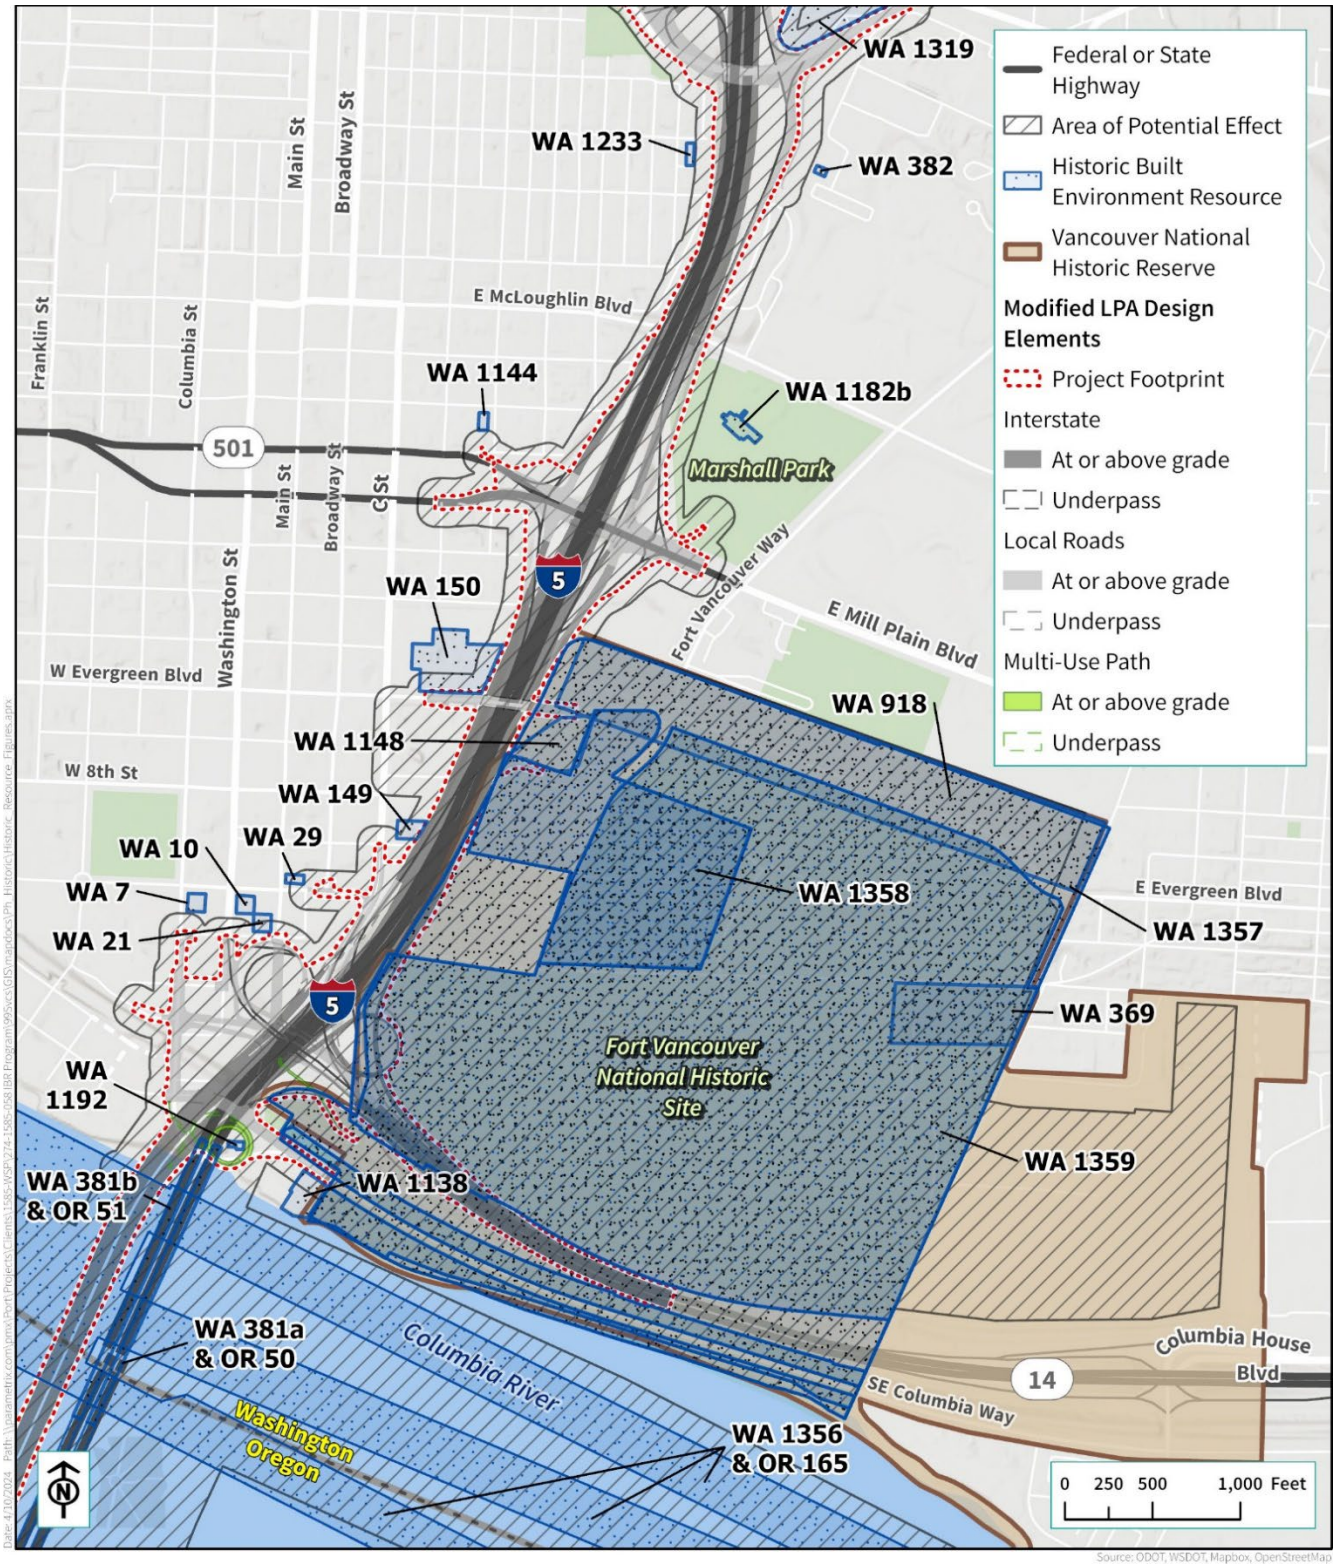

Figure 4-9. Summary of Section 4(f) Historic Sites in the IBR Program Study Area – Upper Vancouver

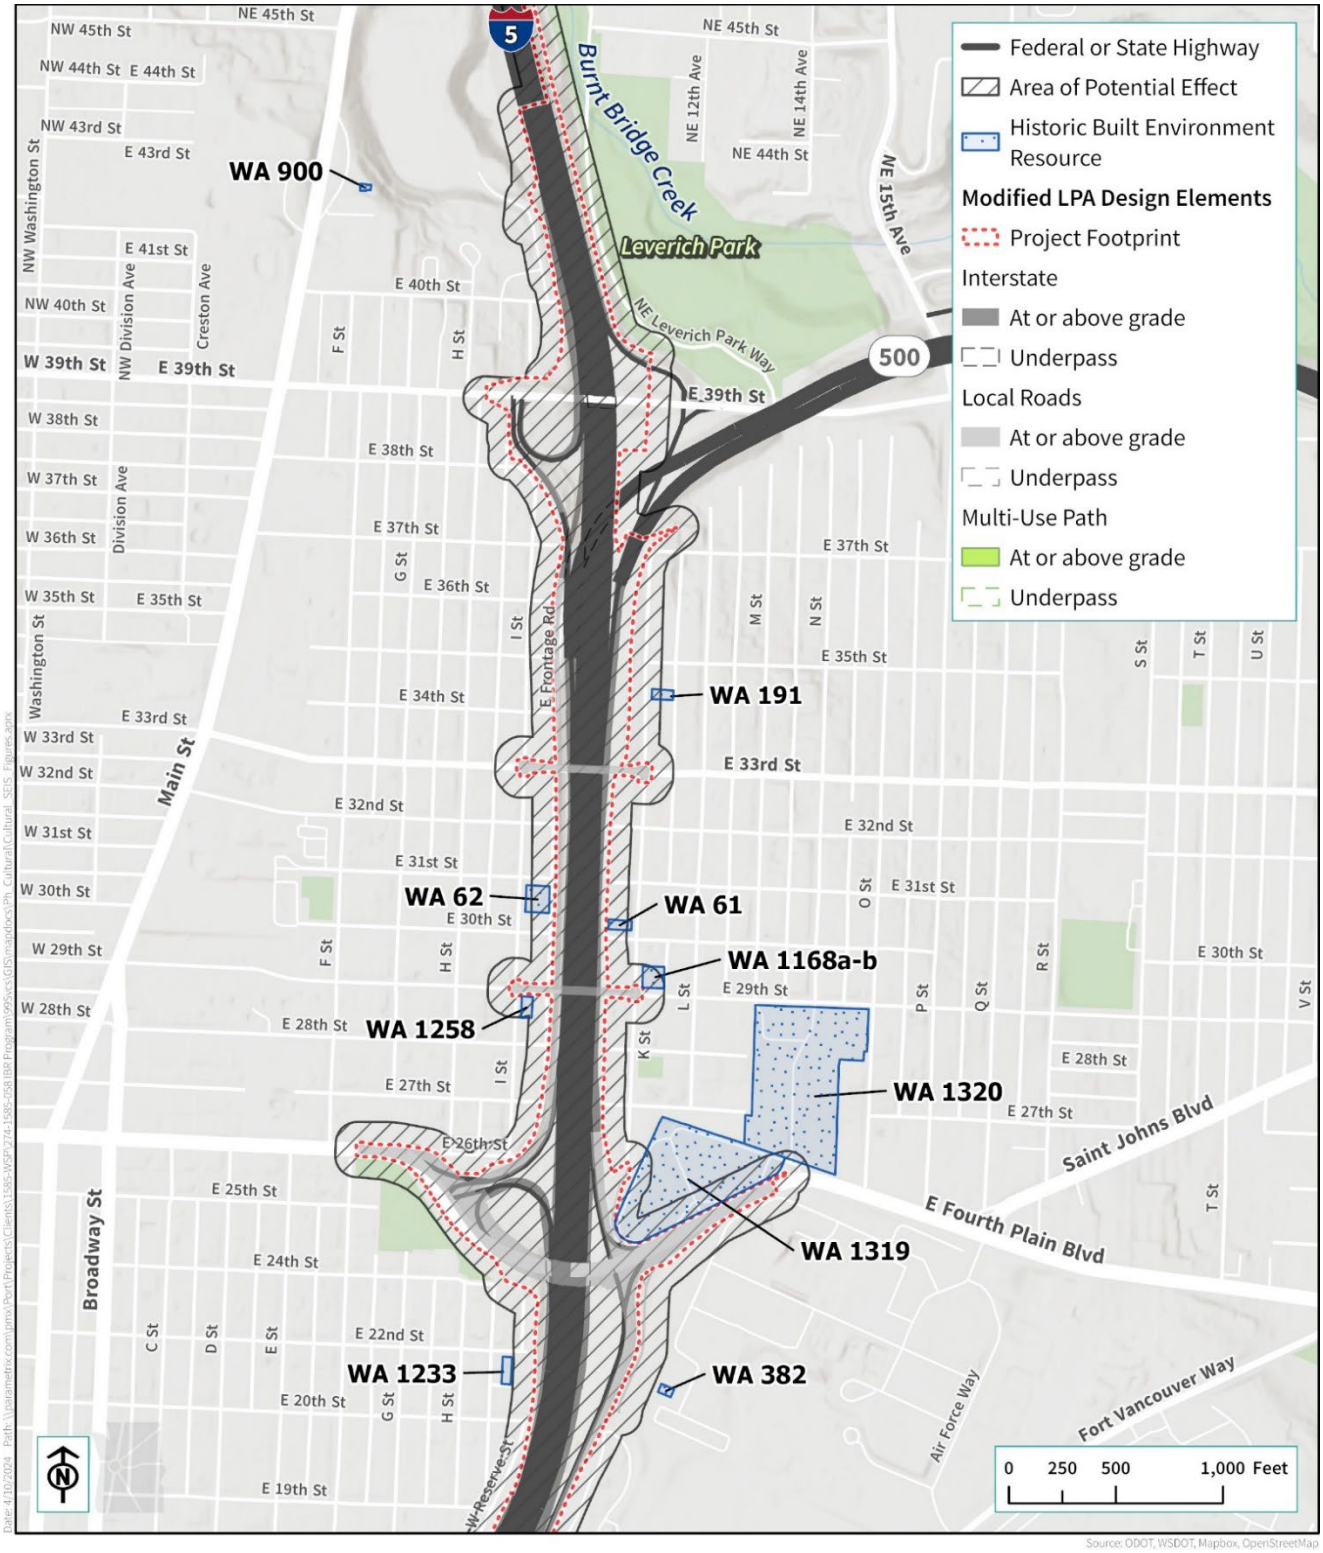

Table 4-2. Summary Information about Section 4(f) Historic Sites in the IBR Program Study Area

State ID	Name	Location	Description
OR 2	Columbia Slough Drainage Districts Historic District, Portland		The district consists of a group of four geographically contiguous Columbia Slough drainage districts that are located on the Columbia River floodplain between the Willamette and Sandy Rivers, occupying approximately 10,000 acres. Within the Columbia Slough Drainage Districts Historic District are six resource types: sloughs, canals, levees/ fills, pumping plants, weirs/dams, and ditch systems. The Columbia River Levee, North Denver Avenue Cross Levee, and Union Avenue/Martin Luther King Fill/Cross Levee are each an historic contributing element to the Columbia Slough Drainage Districts Historic District within the IBR Program study area.
OR 50	Northbound Interstate Bridge		The northbound Interstate Bridge is a steel truss bridge that crosses the Columbia River between Portland and Vancouver. Completed in 1917 and modified in 1958, the bridge is composed of a span across the Columbia River that measures 3,538 feet in length. The main span of the bridge in Vancouver is a steel through truss vertical lift span of the Pennsylvania-Petit type. The vertical lift span, when fully raised, creates a waterway clearance channel that measures 250 feet laterally and 178 feet vertically (OLW). The bridge is also composed of 10 steel through Pennsylvania truss secondary spans that range in length from 266 to 531 feet. The bridge was retrofitted in 1958 to mimic the design of the westerly, southbound bridge.
OR 56	Portland Assembly Center	2060 N Marine Drive, Portland	The Portland Assembly Center is a 1919 Georgian Revival and Modern building that is a complex of five interconnected exposition halls built between 1924 and 2001 and commonly known as the “Portland Expo Center.” The period of significance for the NRHP-eligible Portland Assembly Center is limited to 1942, corresponding to the period of Japanese American incarceration at the site.
OR 103	Toll Administration Building/ODOT Permit Center	12348 N Center Avenue, Portland	The Toll Administration Building/ODOT Permit Center is a Modern-style two-story building with a penthouse. The building was constructed in 1959 to administer tolling of vehicular traffic across the 1917 northbound Interstate Bridge and 1958 southbound Interstate Bridge and is located at the southern end of Hayden Island.
OR 107	Harbor Shops	11915 N Center Avenue, Portland	The Harbor Shops building is a Postmodern-style strip mall located at 11915 N Center Avenue in Portland. Constructed in 1978, this one-story building features an irregular footprint with an elongated “zigzag shape” and a flat roof with a high parapet.
OR 109	Jantzen Beach Water Tank	N Center Avenue, Portland	The Jantzen Beach Water Tank and Pump House are utilitarian structures located near the intersection of North Center Street and North Jantzen Avenue on Hayden Island in Portland. Initial construction of the water tank was completed in 1968.
OR 111	Jantzen Beach Moorage	1501 N Jantzen Avenue/1525–2055 N Jantzen Avenue, Portland	The Jantzen Beach Moorage is located at North Portland Harbor in the Columbia River. Originally built in 1935, the moorage offered leasable and—eventually—privately owned slips for floating homes starting in 1958. The property is 27.3 acres, and encompasses a linear dock, multiple finger piers, a parking lot, and associated hardscaping and landscaping. The moorage is host to approximately 175 floating homes located on the water of North Portland Harbor.

State ID	Name	Location	Description
OR 120	Hayden Island Yacht Club Clubhouse	12050 N Jantzen Drive, Portland	The Hayden Island Yacht Club Clubhouse is a yacht club clubhouse constructed in 1972. The building has a rectangular footprint measuring approximately 75 feet from north to south and approximately 60 feet from east to west. It has a split-level form, with the southern two-thirds of the building being single-story and the northern one-third structured as one-and-one-half stories.
OR 155	East Vanport Commercial Center	10850 N Denver Avenue, Portland	The East Vanport Commercial Center at 10850 North Denver Avenue was constructed in 1943 as the commercial core for the wartime housing project of East Vanport in the East Columbia neighborhood of Portland. The one-story building features a concrete slab foundation and a generally rectangular footprint measuring approximately 216 feet from northwest to southeast by approximately 64 feet from northeast to southwest.
OR 165	Lower Columbia River Federal Navigation Historic District	Columbia River from River Mile (RM) 3 to RM 145	The Lower Columbia River Federal Navigation Historic District (LCR Nav Historic District) is a series of structures built and maintained by USACE since in 1873. The boundary for the LCR Nav Historic District encompasses a series of noncontiguous structures, including navigation channels, six turning basins, 41 pike dike systems, and nine landforms created from dredge materials.
WA 7	Fendrich's Furniture	209 W 6th Street, Vancouver	Fendrich's Furniture is a two-story, square-in-plan commercial building constructed in 1947 with elements of Stripped Classical, Art Deco, and Streamline Moderne styles. It is constructed of reinforced concrete clad in brick veneer on the street-facing elevations, and it has a metal-capped parapet on its flat roof.
WA 10	Smith Tower	515 Washington Street, Vancouver	The building at 515 Washington Street, known as Smith Tower, is a Modern-style residential apartment complex constructed in 1966 and located in the Esther Short neighborhood of Vancouver. The principal form of the building is a 15-story cylindrical tower measuring approximately 100 feet in diameter and 158 feet in height; the distinctive building is visible from many areas of downtown Vancouver.
WA 21	Evergreen Hotel	500 Main Street, Vancouver	The Evergreen Hotel is an Italian Renaissance–style hotel located in downtown Vancouver and was constructed in 1928. The hotel has not undergone any major alterations and retains its character-defining features. These features include the site's central downtown location, two primary entrances with six broad bays (on the south and east elevations), marble balconies, arched motifs, sandstone style finish, projecting roof forms clad in Spanish tile, and expansive interior spaces with a large staircase and mezzanine.
WA 29	U.S. National Bank Building	601–603 Main Street, Vancouver	The U.S. National Bank Building was constructed in 1912 in downtown Vancouver. It is a five-story, steel-framed commercial building with Renaissance and Classical Revival style ornamentation.
WA 61	Porter House	3000 K Street, Vancouver	The Porter House is a circa 1912 Craftsman bungalow in the Rose Village neighborhood of Vancouver. The building has a T-shaped plan and a concrete foundation with a partial basement. The wood-framed exterior walls rise one and a half stories to a low-pitched, side-gabled roof with wide, overhanging eaves with exposed purlins and a wide fascia under the gable.

State ID	Name	Location	Description
WA 62	Hall House	903 E 31st Street, Vancouver	The Charles W. and Margaret B. Hall House is a Craftsman bungalow in the Shumway neighborhood of Vancouver. Constructed in 1912, the building has a rectangular plan and a full concrete basement. Its wood-framed exterior walls rise two stories in height to a front-gabled roof with a deep overhang, wide wood bargeboards, and wood knee braces.
WA 149	Normandy Apartments	318 E 7th Street, Vancouver	The Normandy Apartments building is a Tudor Revival style, multifamily housing complex. The building was originally constructed in 1928 and modified in 1960.
WA 150	House of Providence (Providence Academy)	400 E Evergreen Boulevard, Vancouver	The House of Providence (Providence Academy) is an institutional property. The property, constructed between 1873 and 1874, contains an ornate, three-story building that is clad in brick and shows the influence of the Georgian/Federal and French Colonial architectural styles.
WA 191	William H. and Myrtle Hood Residence	3405 K Street, Vancouver	The Hood Residence is a circa 1919 Craftsman bungalow in the Rose Village neighborhood of Vancouver. The building has a rectangular plan with a concrete foundation and a full basement. Its wood-framed exterior walls are clad in lapped wood siding and rise one story in height to a front-gabled roof with unenclosed eave overhangs and decorative knee brackets
WA 368, 369, 918, 109	VNHR	The district was listed in the NRHP in 2007 under Criteria A, C, and D with a period of significance beginning in 2,500 BP and ending in CE 1966.	The VNHR is an NRHP-listed historic district that encompasses 397.7 acres and includes a total of five historic properties—four listed or determined eligible historic districts and one historic site. Of the 397.7 acres within the VNHR boundary, 49.74 acres were WSDOT highway right of way at the time of listing of the reserve and do not contribute to eligibility. The Fort Vancouver site was first established as a national historic site in 1966 to preserve and interpret historically significant and exceptionally complex overlapping areas associated with Native American, Hudson's Bay Company, U.S. military, and NPS uses of land that have occurred over time.
WA 381a	Northbound Interstate Bridge		See description under OR 50.
WA 382	Radio Transmission Building	1601 E Fourth Plain Boulevard, Vancouver	The Radio Transmission Building at 1601 E Fourth Plain Boulevard is a Stripped Classical style building constructed in 1940. Within the city, the building is situated along the eastern edge of I-5 inside the campus of the Vancouver Veteran's Affairs Medical Center. The Radio Transmission Building has an L-shaped footprint constructed atop a concrete slab foundation that measures approximately 40 feet from north to south and 60 feet from east to west.
WA 900	Covington House	4201 Main Street, Vancouver	The Covington House at 4201 Main Street is an 1846 hall-and-parlor-pioneer log style, side-gabled single dwelling that presently functions as an events space. The building's T-shaped footprint is constructed atop a modern concrete masonry unit foundation.

State ID	Name	Location	Description
WA 1138	Who Song & Larry's	111 SE Columbia Way, Vancouver	The Who Song & Larry's Restaurant is a roadside style commercial building constructed in 1981. The building has a highly irregular plan and is constructed atop a concrete foundation. The walls of the building are clad in wood clapboard siding with corner boards and rise one to three stories in height.
WA 1144	Office Building	1514 E Street, Vancouver	The office building at 1514 E Street is a Postmodern/Northwest Regional–style office building constructed in 1977. The building is rectangular in plan with a reinforced concrete foundation and wood-framed walls that rise one story in height to a distinctive, steeply pitched roof that is hipped on three sides and gabled on one side.
WA 1148	Washington State Patrol District Five Headquarters	605 E Evergreen Boulevard, Vancouver	The Washington State Patrol District Five Headquarters (now the Vancouver Police Headquarters) is a two-story, Late Modern-style building constructed in 1975.
WA 1168	Duplex Residences	2901 K Street, Vancouver	The buildings at 2901–03 and 2905–07 K Street are single-story, Contemporary-style duplexes constructed in 1968 and located on a single tax lot in the Rose Village neighborhood of Vancouver.
WA 1182	Rudy Luepke Center for Senior Citizens	1009 E McLoughlin Boulevard, Vancouver	The Rudy Luepke Center for Senior Citizens at 1009 E McLoughlin Boulevard is a Northwest Regional–style building located in the Central Park neighborhood of Vancouver constructed in 1979. The building possesses an irregular footprint constructed atop a concrete foundation that measures approximately 93 feet from north to south and 164 feet from east to west.
WA 1192	Bridge Substation	100 SE Columbia Street, Vancouver	The Bridge Substation is a utilitarian electrical substation building. The building was originally constructed circa 1918.
WA 1233	Earls House	815 E 22nd Street, Vancouver	The Earls House is a World War II-Era cottage constructed in 1938 in the Arnada neighborhood of Vancouver. The building has a T-shaped footprint, a hipped roof with no eaves, and wood-framed walls with wood drop siding and fenestration including fixed corner windows.
WA 1258	Mickler House	901 E 29th Street, Vancouver	The Mickler House is a Workingman's Foursquare single-family dwelling located in Vancouver. The residence was constructed in 1907.
WA 1319	Vancouver Barracks National Cemetery	1200 E Fourth Plain Boulevard, Vancouver	The Vancouver Barracks National Cemetery, also referred to as the Army Post Cemetery, is a cemetery located near the southwestern corner of the Rose Village neighborhood in Vancouver. The property was established in 1882 as a permanent cemetery for the Vancouver Barracks, the earliest U.S. Army post in the American Pacific Northwest.
WA 1320	St. James Acres Cemetery	1401 E 29th Street, Vancouver	The St. James Acres Cemetery is a cemetery located at the southern edge of the Rose Village neighborhood in Vancouver.

AD = Anno Domini; BP = before present; I-5 = Interstate 5; NHS = National Historic Site; NPS = National Park Service; ODOT = Oregon Department of Transportation; OR = Oregon; USACE = U.S. Army Corps of Engineers; VNHR = Vancouver National Historic Reserve; VPR&C = City of Vancouver Parks, Recreation, and Cultural Services; WA = Washington; WSDOT = Washington State Department of Transportation

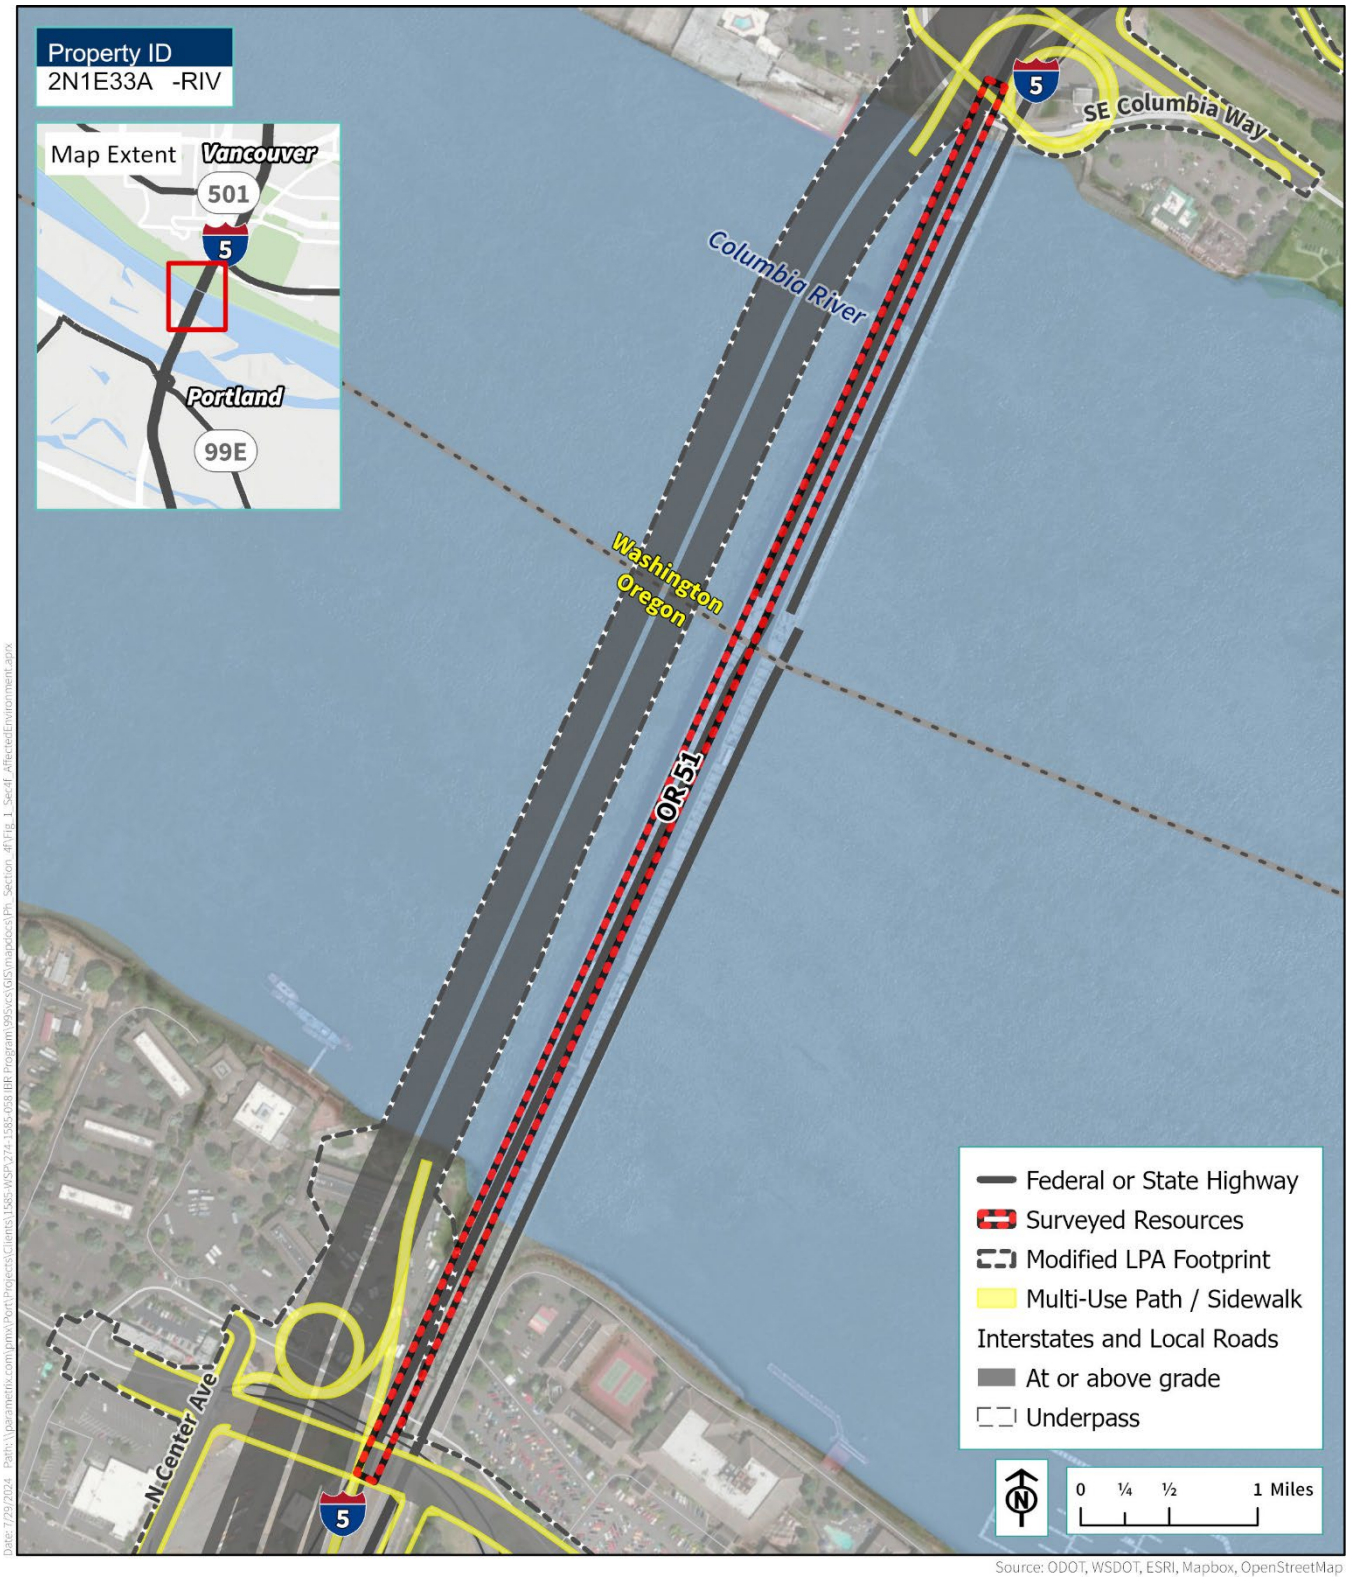
Southbound Interstate Bridge (Map ID – OR 51 and WA 381b)

The southbound Interstate Bridge is a steel truss bridge that crosses the Columbia River between Portland, Multnomah County, Oregon, and Vancouver, Clark County Washington (see Figure 4-10). Completed in 1958, the bridge spans the Columbia River and measures 3,538 feet in length. The bridge consists of 16 spans, 12 piers, and five bents, and it has a distinctive "humpback" raised form in the middle to allow for an alternate shipping channel in addition to the channel through the lift spans.

The southbound Interstate Bridge was determined eligible for the NRHP under Criteria A and C at the state level of significance in the areas of transportation and architecture. The bridge is significant under Criterion A because it is the second bridge to cross the Columbia River at this location between Vancouver and Portland. The bridge is also significant under Criterion C as a notable example of the bridge builder's art. It maintains its integrity of location, design, materials, workmanship, setting, feeling, and association, and its boundary is the entirety of the southbound bridge structure and also includes approach spans, sidewalks, and other appurtenances related to the transportation use of the bridge.

The Finding of Effect (FOE) documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the Modified LPA and its design options. This finding received concurrence from the Washington Department of Archaeology and Historic Preservation (DAHP) and Oregon State Historic Preservation Office (SHPO) on October 13, 2023, and March 19, 2024, respectively.

Figure 4-10. IBR Program Improvements and Area of Permanent Incorporation for the Southbound Interstate Bridge



The Section 106 FOE for the southbound Interstate Bridge documented that the Modified LPA with all design options would result in a finding of "Adverse Effect." This finding received concurrence from the Washington DAHP on October 13, 2023, and from the Oregon SHPO on March 19, 2024. While the bridge has been determined eligible for listing on the NRHP as part of the Section 106 process, pursuant to 23 USC 103(c)(5) and 70 Federal Register (FR) 11,928 (March 10, 2005), the southbound Interstate Bridge is exempt from Section 4(f) review because the bridge was constructed without federal funding and incorporated into the Interstate Highway System after it was constructed and does not otherwise meet the exception to the exemption under 23 USC 103(c)(5). Because the southbound Interstate Bridge is exempt from Section 4(f) review, it is not evaluated for use.

4.3 Evaluation of Use of Section 4(f) Properties

4.3.1 Section Organization

This section evaluates the use of each property protected under Section 4(f). The use evaluation begins by addressing potential uses of Section 4(f) properties that would result from the IBR Program's Modified LPA and the design options with a brief summary of use in tabular format (see Table 4-3). Following the summary of use under Section 4(f) are detailed descriptions of each property and how it could be used, including permanent incorporation, temporary occupancy, and the potential for constructive use for properties that could experience proximity impacts. The evaluation for each property concludes with a Section 4(f) preliminary use determination.

No Section 4(f) properties are located in the vicinity of the Ruby Junction Maintenance Facility expansion.

This section is organized geographically from south to north and discusses uses of Section 4(f) properties located in the following areas:

- Properties in Oregon
- Properties in Washington

4.3.2 Summary of Use of Park, Recreational Areas, Waterfowl Refuges by the IBR Program Modified LPA with All Design Options

Table 4-3 summarizes the use of Section 4(f) properties for the design options of the Modified LPA. Of the 11 park and recreational facilities located in the study area that are subject to protection under Section 4(f), one would have a use with greater than *de minimis* impact, three would experience *de minimis* impacts and seven would experience no use of Section 4(f) properties under the Modified LPA or the design options.

Following the table are detailed descriptions of each Section 4(f) property, an evaluation of its use, and a preliminary determination. The use evaluation includes figures depicting areas of temporary occupancy and permanent use for each park and recreation property (to). The figures are at different scales, as noted.

All design options of the Modified LPA would result in use under Section 4(f) and, with the exception of small differences for the Fort Vancouver NHS, would result in the same area of use for the park and recreation facilities evaluated. Table 4-3 summarizes the area used and preliminary Section 4(f) evaluation for the park and recreation facilities evaluated under the Modified LPA and each design option.

At the Fort Vancouver NHS, the Modified LPA with all design options would result in slightly different levels of acquisition and temporary occupancy of the park as shown in Table 4-3. The different design options would permanently acquire area ranging from 17,000 to 20,000 square feet and would temporarily use area up to 50,000 square feet.

The Modified LPA park-and-ride design options would not use any additional Section 4(f) park and recreation properties beyond those identified for the Modified LPA and, therefore, is not discussed further.

Construction noise impacts for the Modified LPA with all design options would occur at various times throughout the approximately 9-year construction period. The construction measures discussed in Section 3.11.7 of this Draft SEIS would be applied to avoid, minimize, and mitigate temporary adverse noise impacts.

Noise and vibration effects on individual properties are discussed under the use evaluations, below. FHWA guidance (FHWA-HEP-10-025) states that all Section 4(f) properties should be analyzed as noise abatement activity category C, whether or not the underlying use is noise sensitive. Overall, many of the park and recreation properties do not rely on a quiet setting to convey their significance, and the Program's introduction of new atmospheric and audible intrusions would not diminish or impact the use and enjoyment of the property.

Table 4-3. Summary of Section 4(f) Evaluation for IBR Program Modified LPA Design Options for Park and Recreational Properties

Property, Property Size	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, and Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, without C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, and I-5 Shifted West	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, and Centered I-5	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5
Marine Drive Trail 5 miles, including sections with both transportation and recreational primary purposes	• No permanent incorporation. Temporary occupancy of approximately 122 linear feet of recreational trail on levee. Based on 23 CFR 774.13(d), temporary occupancy of the trail would meet the exception criteria. • **Preliminary Determination**: No Section 4(f) use per 23 CFR 774.13(d).					
East Delta Park 3,811,500 square feet	• Acquires approximately 9,300 square feet of park land, including approximately 2,700 square feet of land from the western edge of the main park parcel and 6,700 square feet of vacant land for construction of the eastbound Martin Luther King Jr. Boulevard to North Union Court ramp and new shared-use path. Temporary occupancy of approximately 8,200 square feet for construction access to build a fill wall. • **Preliminary Determination**: Section 4(f) use. Based on CFR 774.17, this would be a *de minimis* impact because the project will not adversely affect the features, attributes, or activities qualifying the property for protection under Section 4(f).					
Vancouver Landing at Terminal 1 Approximately 38,000 square feet	• No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the park. • **Preliminary Determination**: No Section 4(f) use.					
Vancouver Waterfront Park 317,988 square feet	• No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the park. • **Preliminary Determination**: No Section 4(f) use.					
Fort Vancouver NHS 8,886,240 square feet	• Acquires approximately 12,500 square feet of narrow strips of park land along the park's southern and western edges associated with modifications to the I-5/SR 14 interchange and the widening of I-5. Temporary occupancy of approximately 43,400 square feet for construction of a retaining wall. • Visual quality changes to five contributing historic resources that are part of the available recreational opportunities. • **Preliminary Determination:** Section 4(f) use because of permanent incorporation.	• Permanent Incorporation: Approximately 13,800 square feet • Temporary Occupancy: 33,900 square feet • Visual quality changes same as for the Modified LPA **Preliminary Determination:** Section 4(f) use because of permanent incorporation.	• Permanent Incorporation: Approximately 13,600 square feet • Temporary Occupancy: 34,200 square feet • Visual quality changes same as for the Modified LPA **Preliminary Determination**: Section 4(f) use because of permanent incorporation.	• Permanent Incorporation: Approximately 12,500 square feet • Temporary Occupancy: 35,200 square feet • Visual quality changes same as for the Modified LPA, but single-level configuration would be less prominent and less adverse to contributing historic resources and recreational opportunities. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.	• Permanent Incorporation: Approximately 13,100 square feet • Temporary Occupancy: 34,700square feet • Visual quality changes same as for the Modified LPA, but single-level configuration would be less prominent and less adverse to contributing historic resources and recreational opportunities. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.	• Permanent Incorporation: Approximately 13,100 square feet • Temporary Occupancy: 34,700square feet • Visual quality changes same as for the Modified LPA **Preliminary Determination**: Section 4(f) use because of permanent incorporation.
Old Apple Tree Park 56,628 square feet	• Acquires approximately 3,500 square feet of park land to construct a new shared-use path. A permanent airspace easement would also be required, of approximately 4,400 square feet, for the maintenance of the I-5 northbound to SR 14 elevated ramp. Temporary occupancy of approximately 7,200 square feet for construction access for the elevated ramp. • **Preliminary Determination**: Section 4(f) use. Based on CFR 774.17, this would be a *de minimis* impact because the project will not adversely affect the features, attributes, or activities qualifying the property for protection under Section 4(f).					
Marshall Community Center, Luepke Senior Center, and Marshall Park 827,640 square feet	• Acquires approximately 25,200 square feet for placement of a fill wall. Displaces up to four horseshoe pits, as well as trees located in state right of way and within park boundary. Temporary occupancy of approximately 19,100 square feet along the western boundaries of the park parcel. • **Preliminary Determination**: Section 4(f) use. Based on CFR 774.17, this would be a *de minimis* impact because the project will not adversely affect the features, attributes, or activities qualifying the property for protection under Section 4(f).					
Clark College Recreational Fields 566,280 square feet	• No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the park. • **Preliminary Determination**: No Section 4(f) use.					
Leverich Community Park 696,960 square feet	• No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the park. • **Preliminary Determination:** No Section 4(f) use.					

Property, Property Size	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, and Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, without C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, and I-5 Shifted West	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, and Centered I-5	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5
Arnada Neighborhood Park 130,680 square feet	• Temporary occupancy of approximately 2,800 square feet at the north boundary of the park (land would be restored following construction). Based on 23 CFR 774.13(d), temporary occupancy of the park would meet the exception criteria. • **Preliminary Determination**: No Section 4(f) use per 23 CFR 774.13(d).					
Burnt Bridge Creek Trail 42,240 linear feet	• No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the trail. • **Preliminary Determination**: No Section 4(f) use.					

Note: The square footages presented in this table were rounded to the nearest hundred.
I-5 = Interstate 5; LPA = Locally Preferred Alternative; NHS = National Historic Site; SR = State Route

4.3.3 Use of Section 4(f) Park and Recreation Properties (Oregon)

Marine Drive Trail

Description

The Marine Drive Trail is a 5-mile trail located along North Portland Harbor, connecting I-5 and the Marine Drive interchange with Kelley Point Park. The Marine Drive Trail extends from the North Portland Harbor bridge through the Marine Drive interchange, then merges with a public sidewalk on the north side of Marine Drive before veering slightly north onto a levee located on private property. The portion of the Marine Drive Trail closest to the study area is a sidewalk located on Metro-owned property through an easement held by the City of Portland running from the east side of the study area to the western edge of the Red Shores LLC property.

Based on available parcel ownership information from the Multnomah County Assessor, the majority of the length of the trail is located within ODOT right of way or City of Portland right of way and is a sidewalk adjacent to Marine Drive and the Marine Drive interchange from the eastern edge of the study area until the trail turns north onto the levee. In addition, Metro, the Portland area's regional government, designates the Marine Drive Trail a regional trail. Metro's regional trails web page emphasizes the trails purpose as connecting origins and destinations. The web page states that regional trails "connect pedestrians and cyclists to their favorite places across the region" and that "trails are designed to serve a variety of functions." (Metro n.d.). Metro describes the 40-Mile Loop Trail, of which the Marine Drive Trail is a part, as connecting more than 30 parks in Multnomah County along the Columbia, Sandy, and Willamette Rivers; Johnson Creek; and the Tualatin Mountains. The web page also emphasizes linking recreation areas to local communities (e.g., a transportation purpose).

The majority of the length of the trail within the IBR Program study area is located on a public sidewalk adjacent to Marine Drive and meets the exception in 23 CFR 774.13(f)(4) as part of the local transportation system. The FHWA *Section 4(f) Policy Paper* Question 1A provides further guidance on this issue, stating that the primary purpose of a park or recreation area is related to the property's primary function: "Incidental, secondary, occasional or dispersed activities…do not constitute a primary purpose within the context of Section 4(f)" (FHWA 2012). The Marine Drive Trail's emphasis on connecting origins and destinations in the region identify it primarily for active transportation purposes and secondarily for recreation. Therefore, the trail serves a function that is primarily the movement of people through active transportation modes (walking, biking, running, etc.) while also serving a recreational purpose and a purpose secondarily for recreation. All Marine Drive Trail segments that are located in public roadway right of way or are sidewalks, are part of local transportation system, and function primarily for transportation meet the exception under 23 CFR 774.13(f)(4) and are not a Section 4(f) recreational property.

PP&R maintains the trail segment on the levee and considers it to be a recreational facility and is therefore subject to protection under Section 4(f).

Use Evaluation for the Modified LPA

The Modified LPA with all design options would realign and reconstruct Marine Drive which would require approximately 3,000 linear feet of the 5-mile Marine Drive Trail to be closed, detoured, and demolished during bridge construction, then rebuilt in a similar location to current regional trail standards.

Under the Modified LPA with all design options, this realignment and reconstruction would occur east of the recreational trail segment on the levee. However, the recreational trail segment on the levee would be temporarily occupied for the construction of a stormwater pond. A 122 linear-foot segment of trail would be temporarily closed and occupied in this area during the stormwater facility construction.

Temporary Occupancy

The temporary occupancy (see Section) of the trail segment on the levee would meet the exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f) as described below:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

The construction of the Marine Drive recreation trail segment is anticipated to take up to 6 years which is less than the 9-year construction of the Columbia River bridges. The portion of the trail that would be temporarily occupied is owned by Metro and maintained by PP&R and would continue to be owned by Metro following construction.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal

The Marine Drive Trail is 5 miles long. The temporarily occupied and reconstructed trail segment is less than 1% of the entire trail length. During construction, bicycles, pedestrians, and other trail users would be detoured to the other side of Marine Drive and, at times, along the south side of the Portland Expo Center, for approximately 2,000 to 4,000 feet, depending on the stage of construction. Trail users would connect back to the existing alignment of the Marine Drive Trail at the signalized intersection with Force Avenue west of the construction area. The detour of 2,000 to 4,000 linear feet would be 8% to 15% of the total trail length. The trail detour would provide similar functionality as the portion that would be reconstructed on the north side of the road. For portions not affected by construction east and west of the IBR Program footprint, trail users would continue to be able to use the trail during construction with no additional effects. Therefore, the work would be minor and the nature and the magnitude of the changes to the trail would be minimal.

There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis

The temporary detour would maintain continuous trail access during construction and would not diminish or interfere with the protected activities, features, or attributes of the trail on permanent or temporary basis.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and

Following construction, the IBR Program would reconstruct the trail to a condition similar to that which existed prior to construction.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Agreement from the official with jurisdiction, the City of Portland, is pending.

The temporary effects on the Marine Drive Trail meet the requirements of 23 CFR 774.13(d) for an exception from Section 4(f) use.

Preliminary Determination

The IBR Program Modified LPA with all design options would temporarily occupy 122 linear feet of the trail; the temporary occupancy would meet the temporary occupancy exception criteria in 23 CFR 774.13 and therefore would not be a use under Section 4(f). Based on the analysis described above, preliminary determination is that neither the Modified LPA nor design options would result in a use under Section 4(f).

East Delta Park

Description

East Delta Park (Figure 4-11) is a 3,811,500-square-foot neighborhood/regional park located adjacent to I-5 between Martin Luther King Jr. Boulevard and N Denver Avenue. Facilities at East Delta Park include a sports complex with seven lighted softball fields, five grass soccer fields, four synthetic soccer fields, six sand volleyball courts, a playground, picnic tables, restrooms, a parking lot, support buildings, and nature trails. The park has received Section 6(f) funds (Section 3.21, Section 6[f] and Federal Lands to Parks).

Figure 4-11. East Delta Park

Immediately to the north of the 3,811,500-square-foot main park parcel located south of North Union Court, the City of Portland owns a 63,000-square-foot parcel between North Union Court and Martin Luther King Jr. Boulevard that sits vacant and serves no recreational purpose, 43,560 square feet of which was transferred to PP&R under the Federal Lands to Parks (FLP) Program (Section 3.21, Section 6[f] and Federal Lands to Parks). Immediately east of the 63,000 square-foot City-owned parcel was an off-leash dog park installed within ODOT's Martin Luther King Jr. right of way; the dog park is temporarily closed for maintenance. While the dog park is closed, PP&R intends to reopen it once they can restore and maintain it. Because the former off-leash dog park location is ODOT right of way, no agreement exists between ODOT and the City of Portland for its recreational use, and it has never been designated as recreational by the property owner, it is not park or recreational land subject to protection under Section 4(f).

The Owen Softball Complex within the park is the location of the Delta Park Powwow and Encampment, an annual celebration of Native American culture. The Powwow celebrated its 50th year in 2023.

Use Evaluation for the Modified LPA

Permanent Incorporation

The Modified LPA, inclusive of all design options, would acquire approximately 2,600 square feet of land from the western edge of the main park parcel, which is a vegetated slope adjacent to I-5 and serves no recreational purpose. The Modified LPA would also permanently incorporate an approximately 6,700-square-foot portion of the 63,000-square-foot vacant parcel between North Union Court and Martin Luther King Jr. Boulevard for the eastbound Martin Luther King Jr. Boulevard to North Union Court ramp to construct a new shared-use path. The total permanent incorporation of East Delta Park would be approximately 9,300 square feet of the 3,811,500-square-foot park, or less than 1%. The use of 6,700 square feet of vacant land north of the main park parcel and 2,600 square feet along the western edge of the park neither serves nor is planned for a recreational purpose.

The vacant parcel is not used by PP&R and neither it nor the acquired areas on the western edge of the main park parcel provides a recreational function. The equivalent land area, which was converted to transportation use, would be replaced (see Section 3.21.6 for more information); therefore, the Modified LPA would not adversely affect the activities, features, or attributes that qualify East Delta Park for Section 4(f) protection.

Temporary Occupancy

The Modified LPA would also temporarily occupy approximately 8,200 square feet from the northern corner of East Delta Park (Table 4-3) to gain construction access to the I-5 right of way to build a fill wall. The temporarily affected area of the park contains grass that is periodically mowed, as well as trees and shrubby vegetation. As part of Program construction activities, approximately 10 trees along the western edge of the park may require removal or their root systems impacted. The IBR Program will obtain a Tree Removal Permit from the City of Portland and removed trees would be replaced. Construction of the retaining wall on the western edge of the park would take six months or less, and construction in the 63,000-square-foot vacant park land north of Union Court may take up to 5 years.

The park and its recreational features would remain open during construction, including the sports fields, nature trail, play structure, and picnic tables. Following construction, the vegetated slope would be revegetated and restored to equivalent prior conditions. There would be No Adverse Effect on the activities, features, or attributes of the park from the temporary occupancy.

Preliminary Determination

The IBR Program Modified LPA with all design options would permanently incorporate 9,300 square feet from Delta Park. The permanent incorporation would constitute a use of Delta Park under Section 4(f). Temporary occupancy under the Modified LPA with all design options would be an additional 8,200 square feet. Based on the analysis described in this section, neither the Modified LPA nor the design options would adversely affect the activities, features, or attributes that qualify East Delta Park for Section 4(f) protection, pending concurrence of the official with jurisdiction.

The Modified LPA with all design options would result in temporary and permanent Section 4(f) *de minimis* impact to East Delta Park consistent with the definition in 23 CFR Part 774.17.

Based on the analysis described in this section, the preliminary determination is that neither the Modified LPA nor the design options would adversely affect the activities, features, or attributes that qualify East Delta Park for Section 4(f) protection, pending concurrence of the official with jurisdiction.

4.3.4 Use of Section 4(f) Park and Recreation Properties (Washington)

Park and Recreation Properties Evaluated to Have No Use under Section 4(f)

Vancouver Landing at Terminal 1

Description

Vancouver Landing at Terminal 1 (Landing) is a public dock and park located on the Columbia River to the west of I-5. The Landing is owned and maintained by the Port of Vancouver. In 2022, the Port completed an upgrade to the Landing, which included removing the old amphitheater, rebuilding the landing, linking the existing Renaissance Trail to the Landing, and adding a walkway called Rotary Way. The park occupies a portion of the overall Landing and includes landscaped gardens, benches, interpretive signage, walkways, views of the Columbia River, and space for large events or concerts in its upper portion. The Landing also includes a lower portion that consists of a small boat dock and serves river cruise vessels. The Port of Vancouver recently deconstructed and removed the old Red Lion Hotel and Quay Restaurant and will remove the 100+ year-old dock that remains. A new dock will eventually be built in its place to support a new public market. Figure 4-12 depicts Vancouver Landing.

Figure 4-12. Vancouver Landing at Terminal 1

Note: Boundary is based on input from the Port of Vancouver and is approximate.

Use Evaluation for the Modified LPA

No permanent incorporation of Vancouver Landing is proposed as a result of construction of the Modified LPA, inclusive of all design options.

There would be no temporary occupancy of the Vancouver Landing as a result of the Modified LPA, inclusive of all design options.

Constructive Use

The thresholds for constructive use are described in Section 4.1.4 of this evaluation. Because there would be no permanent incorporation or temporary occupancy that rises to the level of use under Section 4(f), the following analysis evaluates the IBR Program Modified LPA with all design options for constructive use on Vancouver Landing consistent with the criteria in 23 CFR 774.15(e) as listed in Section 4.1.4 of this evaluation.

Noise Level Increase

FHWA applies the noise abatement criteria of 67 A-weighted decibels (dBA) Leq(h) for activity category C to Section 4(f) properties. The Modified LPA would not result in operational noise exceedances of these criteria (see Figure 3.11-7 in Section 3.11, Noise and Vibration). Construction noise would be temporary. As such, noise levels would not substantially diminish the use and enjoyment of the park. Noise levels for the Modified LPA with I-5 shifted west design option are expected to be slightly greater than for the Modified LPA because this design option would be located closer to Vancouver Landing, but would continue to be under the noise abatement criteria.

Impairment of Aesthetic Features

Users of Vancouver Landing enjoy views of the Columbia River to the west and south. Eastward views are of the river and the existing Interstate Bridge. The number of in-water piers for the existing Interstate Bridge limits eastward views along the river from Vancouver Landing. The visual analysis in Section 3.9, Visual Quality, discusses effects for the Modified LPA at one key viewpoint (KVP) in Vancouver Waterfront Park, designated as KVP 20, located approximately 1,500 feet west of Vancouver Landing. Table 3.9-6 documents the visual impact as "adverse" at that location due to the higher bridge deck and obstructions of eastward views changing project coherence.

The new bridges, under the Modified LPA and the design options, would be located immediately east of Vancouver Landing, changing southward views of the river, but would open up eastward views under the bridge because the bridge deck would be higher and there would be fewer in-water piers. Westward views would remain unchanged. Eastward views would change under the Modified LPA and the design options by having the bridge located closer, while opening up views under the bridge along the river. These changes in views, while identified as adverse because they would affect project coherence, would not substantially impair the aesthetic enjoyment of Vancouver Landing because views would remain unchanged to the west and south, while views to the east would replace the existing bridges with the new bridges in the viewshed. Aesthetic impacts would vary by bridge configuration. Neither the movable nor fixed-span configurations would substantially impair views from Vancouver Landing.

Restricted Access

The Modified LPA would not directly impact vehicular, pedestrian, or bicycle access to Vancouver Landing. Vehicles access the park from SE Columbia Way through the Vancouver Waterfront Development and would continue to do so after construction of the new Columbia River bridges. SE Columbia Way would be realigned and reconstructed east of Vancouver Landing and underneath the new Columbia River bridges. The reconstructed SE Columbia Way would contain sidewalks, bicycle lanes, and vehicular lanes, and Main Street would also be extended south from downtown to connect to SE Columbia Way, providing overall access enhancements in the vicinity of Vancouver Landing.

During construction of the Modified LPA and associated improvements to the local street network, there could be temporary street closures and increases in traffic due to rerouting from I-5 to local streets that may result in temporary access restrictions to Vancouver Landing, but local street connections to the park would remain open and the park would be accessible.

Therefore, changes to access in the vicinity of Vancouver Landing would not substantially impair its activities, features and attributes.

Vibration Impacts

As described in the *IBR Program Noise and Vibration Technical Report,* Vancouver Landing is not a vibration-sensitive facility; vibration would not damage or substantially impair use of the park.

Ecological Intrusion

Vancouver Landing is not a wildlife or waterfowl refuge. This criterion does not apply.

For these reasons, a constructive use would not occur for the Vancouver Landing park.

Preliminary Determination

The Modified LPA and the design options would not result in long-term direct effects on the Vancouver Landing at Terminal 1 Park, other than changes in eastern and southern views toward the new Columbia River bridges. These changes in views are not expected to adversely affect the function or enjoyment of Vancouver Landing. Land from Vancouver Landing would not be permanently incorporated or temporarily occupied under the Modified LPA or design options. Nor would there be constructive use of the park due to proximity impacts resulting from the Modified LPA or the design options. Neither construction of the Modified LPA nor the design options would result in a Section 4(f) use of Vancouver Landing park.

Vancouver Waterfront Park

Description

Completed in 2018, Vancouver Waterfront Park is one of the newest parks in the city located at the north end of the Interstate Bridge (Figure 4-13). It covers 317,988 square feet that is part of the 1,524,600-square-foot Vancouver Waterfront Development, which is under ongoing development. The park is open from 5 a.m. to 10 p.m. and includes public open spaces overlooking the Columbia River with expansive views east, south, and west along the river. The park includes benches, walking paths, a fountain, landscaped open areas, and a 0.5-mile trail extension connecting to the Columbia River Renaissance Trail farther east.

Use Evaluation for the Modified LPA

No permanent incorporation of Vancouver Waterfront Park would result from the Modified LPA, inclusive of all design options.

The Modified LPA, inclusive of all design options, would not result in a temporary occupancy of Vancouver Waterfront Park.

Constructive Use

The thresholds for constructive use are described in Section 4.1.4 of this evaluation. Because there would be no permanent incorporation or temporary occupancy that rises to the level of use under Section 4(f), the following analysis evaluates the IBR Program Modified LPA with all design options for constructive use of the Vancouver Waterfront Park consistent with the criteria in 23 CFR 774.15(e) as listed in Section 4.1.4 of this evaluation.

Noise Level Increase

> The Modified LPA would not result in noise exceedances of the FHWA noise abatement criteria of 67 dBA (see Figure 3.11-7 in Section 3.11, Noise and Vibration). Construction noise would be temporary. The projected noise levels would not interfere with the use and enjoyment of the park. Therefore, noise levels would not substantially impair the use and enjoyment of the park. Noise levels for the Modified LPA with I-5 shifted west design option are expected to be slightly greater than for the Modified LPA because this design option would be located closer to Vancouver Waterfront Park, but would be under the threshold of 67 dBA.

Impairment of Aesthetic Features

> Vancouver Waterfront Park is located farther west than Vancouver Landing at Terminal 1; however, the effects discussed for Vancouver Landing at Terminal 1 would also apply at Vancouver Waterfront Park, only to a lesser magnitude because the visual changes would be at a greater distance. Aesthetic impacts would vary by bridge configuration. Neither the movable nor fixed-span configurations would substantially impair the activities, features, or attributes of the Vancouver Waterfront Park.

Restricted Access

Neither the Modified LPA nor the design options would directly impact vehicular, pedestrian, or bicycle access to Vancouver Waterfront Park.

During construction of the Modified LPA and local street network, there could be temporary street closures and increases in traffic due to rerouting from I-5 to local streets, but local street connections to the park would remain open and the park would be accessible.

Vibration Impacts

As described in the *IBR Program Noise and Vibration Technical Report*, Vancouver Waterfront Park is not a vibration-sensitive facility; vibration would not damage or substantially impair use of the park.

Ecological Intrusion

Vancouver Waterfront Park is not a wildlife or waterfowl refuge. This criterion does not apply.

For these reasons, a constructive use would not occur for the Vancouver Waterfront Park from the Modified LPA or design options.

Preliminary Determination

Land from Vancouver Waterfront Park would not be permanently incorporated or temporarily occupied. Nor would there be a constructive use of the park due to proximity impacts. Construction of the Modified LPA or the design options would not result in a Section 4(f) use of Vancouver Waterfront Park.

Figure 4-13. Vancouver Waterfront Park

Clark College Recreation Fields

Description

The Clark College Recreation Fields depicted in Figure 4-14, located north of McLoughlin Boulevard and west of Fort Vancouver Way, are a 566,280-square-foot facility owned and maintained by Clark College and open to students and staff. The softball field, tennis courts, and open fields are open to the public and are subject to protection under Section 4(f). The baseball and soccer field are not open to the public and are excluded from protection under Section 4(f). Immediately to the west of the Clark College Recreation Fields is another parcel of land, approximately 4.5 acres, consisting of landscaped areas (grass and trees), and buildings, that was formerly a rest stop and is owned by the State of Washington but used by Clark College for non-recreational purposes and not open to the public. The 4.5-acre parcel does not qualify as a park and recreational facility and is not subject to protection under Section 4(f).

Figure 4-14. Clark College Recreation Fields Modified LPA with All Design Options

Use Evaluation for the Modified LPA

There would be no permanent incorporation of land by the Modified LPA, inclusive of all design options, from the Clark College Recreation Fields.

There would be no temporary occupancy of land under the Modified LPA, inclusive of all design options, from the Clark College Recreation Fields. Although it would be used for staging, the 4.5-acre parcel used for athletic offices, storage, and parking is not designated for recreational use and would not be subject to approval under Section 4(f) under the exception specified in 23 CFR 774.11(d) for use of non-recreational land in a facility used for multiple purposes.

Constructive Use

A constructive use may occur when a transportation project does not incorporate land from a Section 4(f) property, but the proximity impacts are so severe after incorporation of impact mitigation, they result in a substantial impairment of the property's protected activities, features, or attributes. Because there would be no permanent incorporation or temporary occupancy that rises to the level of use under Section 4(f), the following analysis evaluates the IBR Program Modified LPA with all design options for constructive use on the Clark College Recreation Fields consistent with the criteria in 23 CFR 774.15(e) as listed in Section 4.1.4 of this evaluation.

Noise Level Increase

The Modified LPA would not result in noise exceedances of the FHWA noise abatement criteria of 67 dBA (see Figure 3.11-9 in Section 3.11, Noise and Vibration). Construction noise would be temporary. Therefore, noise levels would not substantially impair the activities, features, and attributes of the Clark College Recreation Fields.

Impairment of Aesthetic Features

Aesthetic features or attributes are not important contributing elements to the value of the Clark College Recreation Fields. No substantial impairment of visual or aesthetic qualities would result from the location of the Modified LPA.

Restricted Access

Neither the Modified LPA nor the design options would result in either temporary or permanent access changes to Clark College Recreation Fields. The recreation fields are accessed from Fort Vancouver Way, and parking is provided in a lot adjacent to this road. Users of the recreation fields may experience delays from additional traffic resulting from I-5 freeway reconstruction under the Modified LPA and the design alternatives, but the delays would not diminish the utility of the facility.

Vibration Impacts

As described in the *IBR Program Noise and Vibration Technical Report*, the Clark College Recreation Fields are not a vibration-sensitive facility; vibration would not damage or substantially impair use of the park.

Ecological Intrusion

Clark College Recreation Fields are not a wildlife and waterfowl refuge. This criterion does not apply.

For these reasons, a constructive use would not occur for Clark College Recreation Fields.

Preliminary Determination

Construction of the Modified LPA, including all design options, would not result in permanent incorporation or temporary occupancy of land at the Clark College Recreation Fields. There would be no constructive use of the park. The Modified LPA, including all design options, would result in no use under Section 4(f) for the Clark College Recreation Fields.

Leverich Community Park

Description

Leverich Community Park is a 696,960-square-foot community park located on the east side of I-5 in the northeast corner of the I-5/SR 500 interchange. The park is owned and maintained by the City of Vancouver Parks, Recreation, and Cultural Services (VPR&C) and is open to the public between 5 a.m. and 10 p.m. Site facilities include a disc golf course, picnic tables, paved walkways, a picnic shelter, restrooms, and play equipment.

Use Evaluation for the Modified LPA

No permanent incorporation of land in Leverich Park would result from the Modified LPA, inclusive of all design options.

No temporary occupancy of land in Leverich Park would result from the Modified LPA, inclusive of all design options.

Constructive Use

The thresholds for constructive use are described in Section 4.1.4 of this evaluation. Because there would be no permanent incorporation or temporary occupancy that rises to the level of use under Section 4(f), the following analysis evaluates the IBR Program Modified LPA, including all design options, for constructive use on the Leverich Community Park consistent with the criteria in 23 CFR 774.15(e) as listed in Section 4.1.4 of this evaluation.

Noise Level Increase

> The IBR Program Noise and Vibration Technical Report modeled noise levels in Leverich Park below the 67 dBA FHWA criteria (see Figure 3.11-10 in Section 3.11, Noise and Vibration of this SEIS and Figure 4-6 in the Noise and Vibration Technical Report). Construction noise would be temporary. The Modified LPA and the design options would result in barely perceptible differences in noise levels of up to 3 dBA within Leverich Park. Because noise levels would be less than those listed in the FHWA noise abatement criteria, no substantial impairment of the activities, features, or attributes of Leverich Park would occur as a result of noise from the Modified LPA or any of the design options.

Impairment of Aesthetic Features

> Aesthetic features or attributes are not important contributing elements to the value of Leverich Community Park. The visual character of Leverich Community Park consists of adjacent residential development, busy roads, open space, and other natural environmental elements such as water, riparian vegetation, and natural banks and hillsides. Views of I-5 to the west include the freeway and tall trees in WSDOT's right of way. The visual analysis in Section 3.9, Visual Quality, discusses effects for the Modified LPA at one key viewpoint (KVP 41) in Leverich Park. Table 3.9-9 documents the visual impact as "neutral" at this location. There would be no substantial impairment to the aesthetic features or attributes from construction of the Modified LPA. In the vicinity of Leverich Community Park, Program

improvements for the other design options would be the same as for the Modified LPA and not substantially impair the aesthetic qualities of Leverich Community Park.

Restricted Access

Neither the Modified LPA nor the design options would result in temporary or permanent changes to vehicular, pedestrian, or bicycle access to Leverich Community Park. Vehicular access is currently available from three parking lots in the park (Figure 4-15), which can be accessed from NE Leverich Park Way connecting to 39th Street. Park access points also exist for cyclists and pedestrians along adjacent roadways surrounding the park. Cyclists and pedestrians can access the Burnt Bridge Creek Trail, which parallels the northern boundary of the park from access points at NE 15th Avenue or NE Leverich Park Way.

Vibration Impacts

As described in the *IBR Program Noise and Vibration Technical Report*, Leverich Park is not a vibration-sensitive facility. Vibration would not substantially impair the use of Leverich Park.

Ecological Intrusion

Leverich Park is not a wildlife or waterfowl refuge. This criterion does not apply.

For these reasons, a constructive use would not occur for Leverich Community Park.

Preliminary Determination

Construction of the Modified LPA and the design options would not result in a Section 4(f) use of Leverich Community Park. The Modified LPA, including all design options, would not permanently incorporate or temporarily occupy land within Leverich Community Park and would not substantially impair the activities, features, and attributes that qualify the park for protection under Section 4(f) or result in a constructive use of the park.

Figure 4-15. Leverich Community Park and Burnt Bridge Creek Trail

Arnada Neighborhood Park

Description

Arnada Neighborhood Park is a 130,680-square-foot public park located on the west side of I-5 and south of W Fourth Plain Boulevard. The park is open from 5 a.m. to 10 p.m. The site facilities include a gazebo, picnic shelter, play equipment, a sports court, benches, a paved walkway, and open, grassy areas. As depicted in Figure 4-16, the park is accessible from pedestrian connections to adjacent residential areas to the west and south and from the sidewalk on E Fourth Plain Boulevard.

Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would not result in permanent incorporation of land in Arnada Neighborhood Park.

Temporary Occupancy

Construction of the Modified LPA, inclusive of all design options, would result in temporary occupancy of 2,800 square feet of land in Arnada Neighborhood Park associated with the reconstruction of E Fourth Plain Boulevard and freeway ramps immediately north of the park. The temporarily occupied area would be needed for a temporary construction easement to provide room for construction activities associated with the reconstruction of E Fourth Plain. Landscaping consisting of grass and small trees may be removed within this area but would be replaced upon completion of construction. Temporary occupancy of land within Arnada Neighborhood Park would meet the conditions required for exceptions (23 CFR 774.13(d)), including:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

> Construction of improvements to E Fourth Plain Boulevard and freeway ramps proposed as part of the Modified LPA may last up to 5 years, less than the total 5- to 7-year duration of construction for the Columbia River bridges. Arnada Neighborhood Park is owned and maintained by VPR&C and would remain so after construction.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal.

> During construction, trees that are close to the construction limits would be protected in accordance with the City of Vancouver's standards in its municipal code (Vancouver Municipal Code 20.770.090, Tree Vegetation, and Soil Protection During Construction). A small amount of vegetation at the park's northern boundary adjacent to Fourth Plain Boulevard would be temporarily affected for the reconstruction of the roadway and sidewalk and would be replaced upon completion of construction. The park's recreation features, including the gazebo, picnic shelter, play equipment, a sports court, benches, and a paved walkway, and open, grassy areas, would continue to be available during construction. The scope of the work within the park would be minor, and there would be no permanent changes to the property.

Figure 4-16. Arnada Neighborhood Park

There are no anticipated permanent adverse physical impacts, nor would there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis.

The park's protected activities, features, and attributes would continue to be publicly available during construction, including the gazebo, picnic shelter, play equipment, sports court, benches, and a paved walkway. Landscaping would be replaced upon construction completion, if affected. There would be no adverse physical impacts or interference with the protected activities, features, or attributes of the property on either a temporary or permanent basis.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project.

Upon completion of construction, landscaping would be restored to its original condition.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Agreement from the official with jurisdiction, VPR&C, is pending.

The temporary effects on Armada Neighborhood Park meet the requirements of 23 CFR 774.13(d) for an exception from Section 4(f) use; therefore, temporary occupancy of the park during construction of the Modified LPA would not constitute a Section 4(f) use.

Constructive Use

The thresholds for constructive use are described in Section 4.1.4 of this evaluation. Because there would be no permanent incorporation or temporary occupancy that rises to the level of use under Section 4(f), the following analysis evaluates the IBR Program Modified LPA, including all design options, for constructive use on the Arnada Community Park consistent with the criteria in 23 CFR 774.15(e) as listed in Section 4.1.4 of this evaluation.

Noise Level Increase

Arnada Neighborhood Park is an active recreational facility located within 200 feet of I-5, and freeway noise is prevalent. Both the existing and projected noise levels meet FHWA noise abatement criteria for highway projects (see Figure 3.11-9 in Section 3.11, Noise and Vibration). Construction noise would be temporary. Noise levels for the design options would be similar to those of the Modified LPA.

Arnada Neighborhood Park is approximately 0.75 miles north of the proposed terminus of the transit line that would be located at Evergreen Boulevard and therefore would not experience increases in transit noise. This would be the same for all design options.

The projected noise levels would not substantially interfere with the use and enjoyment of the park.

Impairment of Aesthetic Features

Aesthetic features or attributes are not important contributing elements to the value of Arnada Neighborhood Park. Arnada Neighborhood Park is a small neighborhood park surrounded by residential developments to the west and south and E Fourth Plain Boulevard to the north and east. Views from the park toward surrounding areas are generally blocked by existing vegetation and land cover. The visual analysis in Section 3.9, Visual Quality, discusses effects for the Modified LPA at one key viewpoint (KVP 34) in Arnada Park. Table 3.9-7 documents the visual impact as "neutral" at this location from the Modified LPA. The Modified LPA would not substantially impair the aesthetic features or attributes of the park.

Impacts from the Modified LPA design options are anticipated to be the same as or similar to those of the Modified LPA.

Restricted Access

Existing pedestrian access to Arnada Neighborhood Park is available from various access points surrounding the park. Pedestrians can access the park via the sidewalk along E Fourth Plain Boulevard, as well as from E 25th Street and G Street. Interchange upgrades for the Modified LPA with all design options at E Fourth Plain Boulevard may result in temporary impacts to pedestrian access to Arnada Neighborhood Park from sidewalks along E Fourth Plain Boulevard, but access from surrounding neighborhood streets to the park would remain unaffected by the proposal. Pedestrian access along E Fourth Plain Boulevard would be restored upon construction completion.

There is no vehicular access to the park. As a neighborhood park, the park is intended for access by pedestrians, with no vehicular access areas provided.

Because pedestrian access to the park would be temporarily impacted, but restored upon completion of construction, the Program effects on access would not substantially diminish the utility of the park.

Vibration Impacts

As described in the *IBR Program Noise and Vibration Technical Report*, Arnada Park is not a vibration-sensitive facility; vibration would not damage or substantially impair use of the park.

Ecological Intrusion

Arnada Neighborhood Park is not a wildlife or waterfowl refuge. This criterion does not apply.

For these reasons, a constructive use would not occur for Arnada Neighborhood Park from the Modified LPA and the design options.

Preliminary Determination

Based on the analysis above, there would be no Section 4(f) use of Arnada Neighborhood Park by the Modified LPA or the design options. The Modified LPA with all design options would temporarily occupy 2,800 square feet of land in the park; the temporary occupancy would meet the exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f). Neither the Modified LPA nor the design options would result in permanent incorporation of park land, nor would they lead to a constructive use of the park.

Burnt Bridge Creek Trail

Description

The Burnt Bridge Creek Trail is an 8-mile paved multiuse trail that passes through the Burnt Bridge Creek Greenway located on the east and west sides of I-5, north of the I-5/SR 500 interchange. The trail passes over I-5 on a pedestrian and bicycle-only overcrossing south of the I-5/Main Street interchange.

Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would not result in permanent incorporation of any portion of the Burnt Bridge Creek Trail.

No temporary occupancy of the Burnt Bridge Creek Trail would result from construction of the Modified LPA, inclusive of all design options.

Constructive Use

The thresholds for constructive use are described in Section 4.1.4 of this evaluation. Because there would be no permanent incorporation or temporary occupancy that rises to the level of use under Section 4(f), the following analysis evaluates the IBR Program Modified LPA with all design options for constructive use on the Burnt Bridge Creek Trail consistent with the criteria in 23 CFR 774.15(e) as listed in Section 4.1.4 of this evaluation.

Noise Level Increase

The Burnt Bridge Creek Trail runs through an active recreational facility, Leverich Community Park. The trail is located within 250 feet of I-5, and freeway noise is prevalent in this location. The IBR Program Noise and Vibration Technical Report models existing noise levels for the Modified LPA at several locations near the trail, including points VE-005, VE-008, and VE-016. Existing noise levels range from 60 to 65 dBA at these locations. The model projects that noise would rise to a range of 61 to 66 dBA for the No-Build Alternative and the Modified LPA, with no observation point increasing more than 1 dBA, a less than perceptible amount. Both the existing and projected noise levels for the Modified LPA meet FHWA noise abatement criteria for highway projects. Program improvements for each design option would be largely the same near the Burnt Bridge Creek Trail and, therefore, noise levels are expected to be the same as for the Modified LPA. The analysis shows that the Burnt Bridge Creek Trail is not a noise-sensitive facility, and the design options would not substantially interfere with use of the trail.

Impairment of Aesthetic Features

The visual character of the Burnt Bridge Creek Trail consists of adjacent residential development, open space, and natural environmental elements such as water, riparian vegetation, and natural banks and hillsides. Views of I-5 to the west are framed by tall trees, curving roads, and hilly topography. The visual analysis in Section 3.9 discusses effects for the Modified LPA at one key viewpoint (KVP 41) for the Burnt Bridge Creek Trail. Table 3.9-9 documents the visual impact as “neutral” at this location. The proximity of the Modified LPA would not substantially impair the aesthetic features or attributes of the Burnt Bridge Creek Trail. Visual impacts from the design options experienced by users of Burnt Bridge Creek Trail would be largely similar to the Modified LPA.

Restricted Access

Construction of the Modified LPA and the design options would not impair temporary or permanent access to the Burnt Bridge Creek Trail. Current trail access points are located along adjacent roadways surrounding the multiuse trail, which provides access for biking, walking, and running. Trail users can access the trail from access points at NE 15th Avenue or NE Leverich Park Way. Additional paths are also accessible to reach the trail through Leverich Park. These accesses would remain available during and after construction.

Vibration Impacts

The Burnt Bridge Creek Trail is not a vibration-sensitive facility. Vibration from the Modified LPA or any of the design options would not substantially impair the use of the Burnt Bridge Creek Trail.

Ecological Intrusion

The Burnt Bridge Creek Trail is not a wildlife or waterfowl refuge. This criterion does not apply.

For those reasons, a constructive use would not occur for the Burnt Bridge Creek Trail from the Modified LPA and the design options.

Preliminary Determination

Based on analyses described above, construction of the Modified LPA or the design options would not result in a Section 4(f) use of the Burnt Bridge Multiuse Trail. None of the design options would permanently incorporate or temporarily occupy land for Burnt Bridge Creek Trail nor would they result in a constructive use.

Park and Recreation Property Evaluated to have a Use with Greater Than *de minimis* Impact Under Section 4(f)

Fort Vancouver NHS

Description

The Fort Vancouver NHS is a 204-acre park located almost entirely within the VNHR Historic District and is managed by the NPS. Within this area are approximately 0.5 miles of waterfront south of SR 14 and SE Columbia Way, separate from the remainder of Fort Vancouver NHS. This separated section contains passive and active recreation opportunities including grass-landscaped areas, picnic areas, a segment of the Columbia River Renaissance Trail, and views of and access to the Columbia River for swimming.

The Fort Vancouver NHS was designated as a National Monument in 1948 and enlarged with its name changed to "Fort Vancouver National Historic Site" in 1961 concurrent with its designation as a park under the jurisdiction of the NPS. The NHS was listed on the NRHP as a historic site in 1966. The Fort Vancouver NHS meets the criteria for Section 4(f) protection as a public park. The VNHR Historic District, which overlaps the NHS, is a historic district that was listed in the NRHP in 2007. As an NRHP-listed historic district, the VNHR Historic District meets the Section 4(f) definition of a historic site and is evaluated as such under Section 4(f) separately from the Fort Vancouver NHS park property. The VNHR Historic District, which includes all of the historic features of the NHS, is evaluated in Section.

The NPS identifies various recreational activities, features, and attributes within the Fort Vancouver NHS, including bringing dogs to the park, watching sunrises and sunsets, picnicking, birdwatching, bicycling, playing in the playground, becoming a junior ranger, visiting the reconstructed fur trade fort, and interpretive walking trails to the Fort Vancouver Village, Japanese Castaways' Memorial, Fort Vancouver Garden, and the Spruce Mill Trail. These recreational activities, features, and attributes including passive and active recreational opportunities further described below.

Active Recreational Activities and Features

Active recreational features of Fort Vancouver NHS include trails, walking paths, and sidewalks throughout the park, as well as a playground and open spaces. The Discovery Historic Loop Trail is a 2.9-mile trail that extends east on Evergreen Boulevard over I-5 through Fort Vancouver NHS on multiuse paths and local streets, over SR 14 at the Confluence Land Bridge or under SR 14 at the Columbia Way interchange connecting to the Columbia River Renaissance Trail. The Discovery Historic Loop Trail is used for organized walks throughout the year, including the Discovery Walk Festival held in April.

Approximately 0.6 miles of the 5-mile-long Columbia River Renaissance Trail runs parallel to SE Columbia Way through the waterfront area within Fort Vancouver NHS and offers active recreational opportunities such as biking and walking. The segment of the Columbia River Renaissance Trail located on the west side of the waterfront area, is also a portion of the Discovery Historic Loop Trail.

Other active recreational opportunities within Fort Vancouver NHS include various paths and trails connecting areas of the Fort. The City of Vancouver maintains all roads, sidewalks, paths, and landscaped areas along the park borders, which includes 0.2 miles of concrete paths and 0.6 miles of decomposed granite trails, an unpaved path leading from East 5th Street to a maintenance storage area in the Hudson's Bay Company (HBC) Village in the southwest corner of the fort, 0.7 miles of concrete sidewalk along Columbia Way, and 0.3 miles of concrete/asphalt bordering the waterfront area. The paths around the reconstructed HBC Fort connect it to open fields surrounding the Fort, Village House 1 and Village House 2, the garden area immediately north of the central Fort, and the Spruce Mill Trail that connects to the Headquarters Building and the Pearson Air Museum. The gravel paths and trails in the NHS offer biking, walking, and jogging activities, and the paved paths are available for skateboarding and roller skating in addition to biking, walking, and jogging activities.

The "Confluence Land Bridge," a landscaped pedestrian walkway that spans SR 14 and connects Fort Vancouver to the waterfront, was constructed in 2008. The Confluence Land Bridge landing is located southwest of the reconstructed HBC Fort and connects the existing Fort Vancouver NHS facilities through extensions to the existing trail system. On the south side of SR 14, the bridge links to Old Apple Tree Park via a new trail from the bridge landing. The earth-covered and landscaped bridge follows a curving, multimodal path and includes artwork and interpretations of the site's importance in tribal history. The Confluence Land Bridge was created through a partnership of the nonprofit Confluence Project (the NPS, the City of Vancouver, and WSDOT) and was funded through federal, state, and private sources.

The Fort Vancouver NHS Playground is located in the northeastern part of the Fort and offers active recreation for children and includes two play structures.

Passive Recreational Activities and Features

The fort includes numerous historical buildings from different periods associated with Native American, HBC, U.S. military, and NPS uses of the land that occurred over time. Fort Vancouver NHS includes the Vancouver Barracks Historic District determined eligible in 1984. It includes the HBC ("Kanaka") Village, and the East and South Barracks, the Pearson Air Museum, Fort Vancouver Visitors Center, NPS Administration building, Japanese Memorial, a garden immediately north of the HBC Kanaka Village, and other historic and cultural components. The historical buildings, monuments, and cultural landscapes of the Fort Vancouver NHS are not solely valuable for their historic significance, but also serve as the subject of interpretive programs and the junior ranger program offered at the park. The historic and cultural landscape is an integral setting to the recreational attributes, features, and activities of the NHS. While Section 4(f) requires evaluating park and recreational features separately from historic sites, in the case of Fort Vancouver NHS, the historical context is part of the recreational experience and viewing the historic and cultural landscape is a passive recreational activity of the NHS.

Several structures within the NHS support operation of the park and its visitor experience. The administrative area of the Fort Vancouver NHS contains four buildings: the visitor center, administration building, employee residence, and maintenance shop. There are 16 structures at the reconstructed HBC Fort: the Fort Palisade, the Bastion, the Chief Factor's House, the Kitchen, the Bakehouse, the Blacksmith Shop, the Indian Trade Shop, the Fur Store, the Wash House, the Jail, the Carpenter Shop, the Belfry, the Flagpole, House 1, House 2, and the Wellsweep. The Proulx House is planned for future reconstruction as a major interpretive element.

NPS plans to complete a replica historic village (HBC Village) in the western portion of the NPS property. Construction of two of the village houses is complete. Planned extensions to the trail system within the Fort would be tied to the historic village and the Confluence Land Bridge in the southwestern portion of the Fort Vancouver NHS near the I-5/SR 14 interchange. This development would occur on land owned by the NPS.

Although separated from Fort Vancouver NHS by the BNSF Railway tracks and SE Columbia Way, the waterfront area is a 217,800-square-foot portion of the Fort Vancouver offering passive recreational activities such as picnicking and viewing the Columbia River. Waterfront Park includes grass-covered open spaces, picnic tables and portions of the Columbia River Renaissance Trail that offers active recreation such as walking, running, and bicycling. The Columbia River is also accessible to swimmers and nonmotorized watercraft from paths and stairs leading to the water's edge within the waterfront area. Parking areas adjacent to SE Columbia Way serve the waterfront area and Columbia River Renaissance Trail. The waterfront is open from 7:00 a.m. to dusk.

Use Evaluation for the Modified LPA

Use of the Fort Vancouver NHS by the Modified LPA inclusive of all design options would include permanent incorporation for right-of-way acquisition along I-5 and SR 14, temporary occupancy for construction of project components in these same areas, and changes to noise and views that would be experienced by visitors to the Fort Vancouver NHS.

Permanent Incorporation

The Modified LPA with double-deck fixed-span configuration would acquire approximately 12,500 square feet of the entire 204-acre park, representing less than 1% of the park area. The acquisitions would be narrow land strips along the Fort Vancouver NHS's southern and western edges associated with the modifications to the I-5/SR 14 interchange and the widening of I-5. The acquisitions would be located west of the Confluence Land Bridge along SR 14 and adjacent to I-5 near 5th Street (see Figure 4-18). The acquired land adjacent to SR 14 is composed of existing and planned landscaping and would also be near the partial reconstruction of the HBC Village but would not interfere with the NPS's plans for reconstruction of this area. The areas proposed for acquisition do not have specific designated recreational use and are not developed with trails, sports fields, benches, or other recreational features.

There would be changes in views to the south and west from the Confluence Land Bridge and the HBC Village due to changes in the heights of the interchange ramps and the new bridges across the Columbia River.

The Modified LPA without C Street ramps design option would acquire approximately 13,800 square feet of land within the park, while the Modified LPA with I-5 shifted west design option would acquire approximately 13,600 square feet. The Modified LPA (any bridge configuration) with two auxiliary lanes design option would acquire slightly more land than the Modified LPA—13,100 square feet—due to the wider right of way needed to accommodate the additional lanes. The Modified LPA single-level fixed-span or movable-span configuration with one auxiliary lane design option would acquire the same amount of land as the Modified LPA—12,500 square feet. As with the Modified LPA, the areas acquired under the design options would be narrow strips of land adjacent to SR 14 and I-5 for construction of the freeway ramp and widening of I-5.

Visual and Auditory Effects

As identified in the Section 106 process, the Modified LPA would adversely affect five of the contributing resources within the boundaries of the Fort Vancouver NHS. These resources include the Munitions Storehouse (Building 102), Original Pearson Hangar (Building 189), Pearson Field Office (Building 194), Work Shop (Building 786), and the Fort Vancouver NHS Visitor Center. Affects to these resources would include indirect auditory and visual effects.

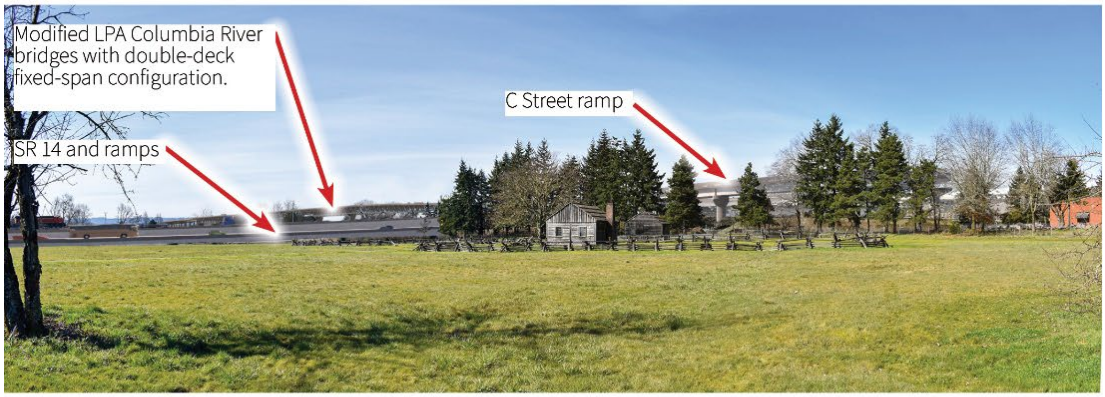
Aesthetic Features

Section 3.9, Visual Quality, notes that there would be visual changes with the construction of the Modified LPA and the SR 14 interchange inclusive of all design options. The visual changes would be most prominent for the Modified LPA with double-deck fixed-span configuration. The upper-roadway deck height of the new double-deck bridge would be 166 feet high (NAVD88), 76 feet taller than the existing bridge deck. The lift span tower of

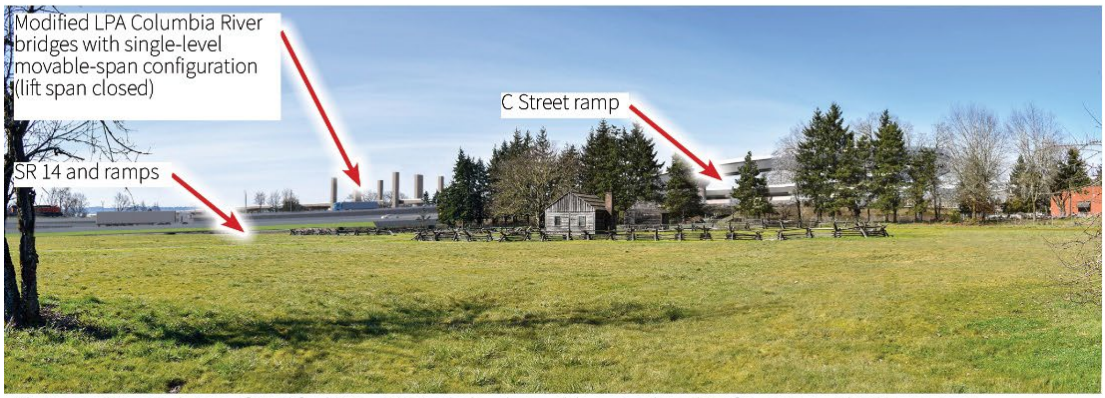
the existing bridge is 247 feet tall. Visual changes would also result from construction of the single-level fixed-span configuration and the single-level movable-span configuration, which have decks of 137 feet and 122 feet high (NAVD88), respectively. The tower height of the single-level movable-span configuration would be approximately 243 feet. Existing views in the Greater Central Park Landscape Unit (the unit that the Fort Vancouver NHS is located within) would include noticeable view changes resulting in changes to visual quality affecting the setting of the Fort Vancouver NHS. The visual character of these resources themselves would remain unchanged. Fort Vancouver NHS contributing historic resources that are part of the cultural landscapes and recreational opportunities and include: (1) Munitions Storehouse (Building 102): Original Pearson Hangar (Building 189); Pearson Field Office (Building 194); Work Shop (Building 786); and Fort Vancouver NHS Visitor Center. The visual impacts associated with the movable-span configuration when closed would be less adverse than those of the Modified with LPA double-deck fixed-span configuration and the single-level fixed-span configuration; however, the towers for the movable-span configuration would be visible. shows the visual changes between existing conditions and the Modified LPA as simulated for Fort Vancouver NHS as documented in the Visual Quality Technical Report.

Figure 4-17. Fort Vancouver National Historic Site - Visual Change Comparison between Existing Conditions and the Modified LPA

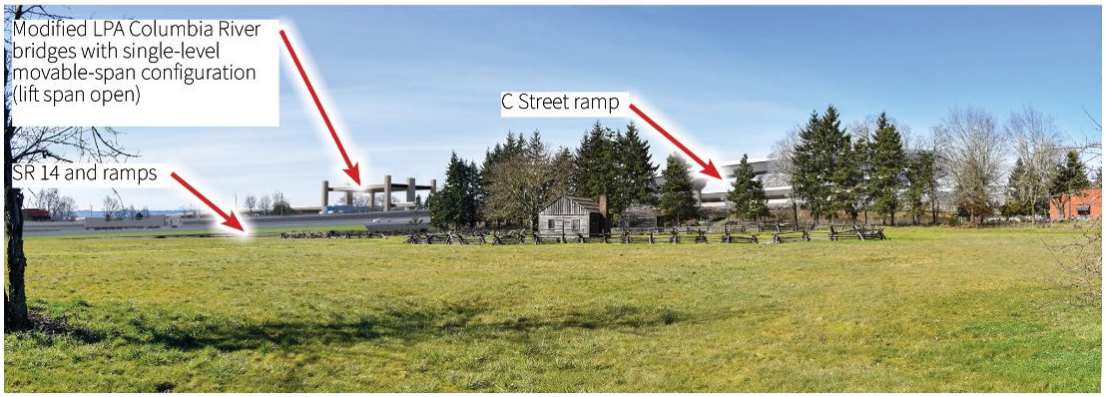
Existing Conditions



Photographic simulation of Modified LPA with double-deck fixed-span configuration with C Street Ramp



Photographic simulation of Modified LPA with single-level movable-span closedconfiguration with C Street ramp



Photographic simulation of Modified LPA with single-level movable-span open configuration with C Street ramp

Noise Level Increase

As documented in Section 3.11, Noise and Vibration, existing modeled traffic noise ranges from 53 to 75 dBA within the Fort Vancouver NHS. The highest noise levels, which are adjacent to I-5 and SR 14, approach or exceed the noise abatement criteria of 67 dBA. These levels would be expected to increase between 0 and 8 dBA under the Modified LPA because of the IBR Program and traffic growth (see Figure 3.11-18 in Section 3.11, Noise and Vibration). Per FHWA *Section 4(f) Policy Paper* Question 7A, constructive use of Section 4(f) property is only possible in the absence of a permanent incorporation of land or a temporary occupancy of the type that constitutes a Section 4(f) use*;* therefore, it would not occur.

Temporary Occupancy

Construction of the Modified LPA would require temporary occupancy of approximately 35,300 square feet of the Fort Vancouver NHS for construction of a retaining wall along I-5 in the western portion of the fort, representing less than 1% of the 204-acre park.

Construction of the Modified LPA design options would temporarily occupy land for construction of a retaining wall along I-5 (and). The occupied land would range from 33,900 square feet under the Modified LPA without C Street ramps design option to 35,200 square feet for the Modified LPA single-level configuration with one auxiliary lane design option. The other design options would temporarily occupy 34,200 square feet (Modified LPA with I-5 shifted west) and 34,700 square feet (Modified LPA with single-level bridge [fixed- or movable-span configuration] with two auxiliary lanes and double-deck fixed-span configuration with two auxiliary lanes). The proposed temporary occupancy would include larger impacts to areas around E 5th Street and the FHWA building parking lot.

Construction would increase noise, vibration, and dust that may temporarily affect recreational activities, but the effect would not be adverse to the extent that it interferes with use of the park.

Fifth Street may be closed or have restricted access, thereby affecting access to the FHWA Western Federal Lands Building, which is outside of the park and not part of the recreational attributes or features of the park. Construction near the SR 14 westbound to I-5 northbound elevated ramp would occur near, but outside of, areas planned for construction of the HBC Village, and would not interfere with NPS's plans for reconstruction of this area. The recreational activities, features, and attributes of the park, including viewing the historic landscape, walking or rolling along recreational trails, picnicking, and attending events at Fort Vancouver, would remain available during construction and would not be substantially affected during construction; therefore, the additional area of temporary occupancy during construction is included in the overall use determination for the park. shows the area of permanent incorporation and temporary occupation for the Modified LPA and each design option.

Table 4-4. Permanent and Temporary Use under the IBR Program Design Options for the Fort Vancouver National Historic Site

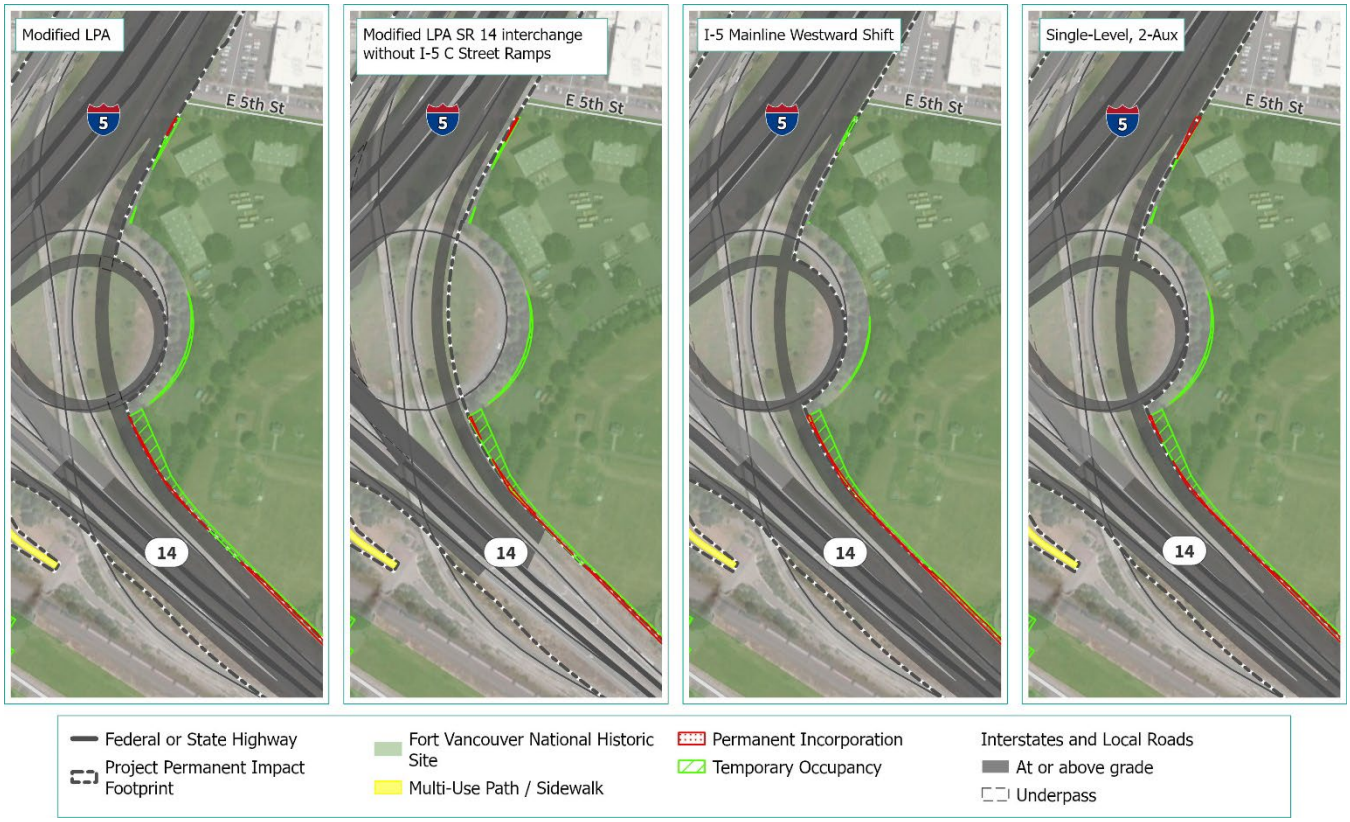
Design Options	Permanent Incorporation	Temporary Occupancy
Modified LPA Double-Deck Fixed-Span Configuration with One Auxiliary Lane, C Street Ramps, and Centered I-5	Approximately 12,500 square feet	Approximately 35,300 square feet
Modified LPA SR 14 Interchange without C Street Ramps	Approximately 13,800 square feet	Approximately 33,900 square feet
Modified LPA I-5 Shifted West	Approximately 13,600 square feet	Approximately 34,200 square feet

Design Options	Permanent Incorporation	Temporary Occupancy
Modified LPA Single-Level Fixed- or Movable-Span Configuration with One Auxiliary Lane	Approximately 12,500 square feet	Approximately 35,200 square feet
Modified LPA Single-Level Fixed- or Movable-Span Configuration with Two Auxiliary Lanes	Approximately 13,100 square feet	Approximately 34,700 square feet
Double-Deck Fixed-Span Configuration with Two Auxiliary Lanes	Approximately 13,100 square feet	Approximately 34,700 square feet

Preliminary Determination

The Modified LPA with all design options would permanently incorporate 12,500 to 13,800 square feet of land and temporarily occupy approximately 33,900 to 35,300 square feet of land in the southern and western reaches of the Fort Vancouver NHS adjacent to SR 14 and I-5. This incorporation would result in a use under Section 4(f). This area is also included in the area calculated for incorporation from the VNHR Historic District.

Figure 4-18. Fort Vancouver National Historic Site – Comparison of Modified LPA Design Options



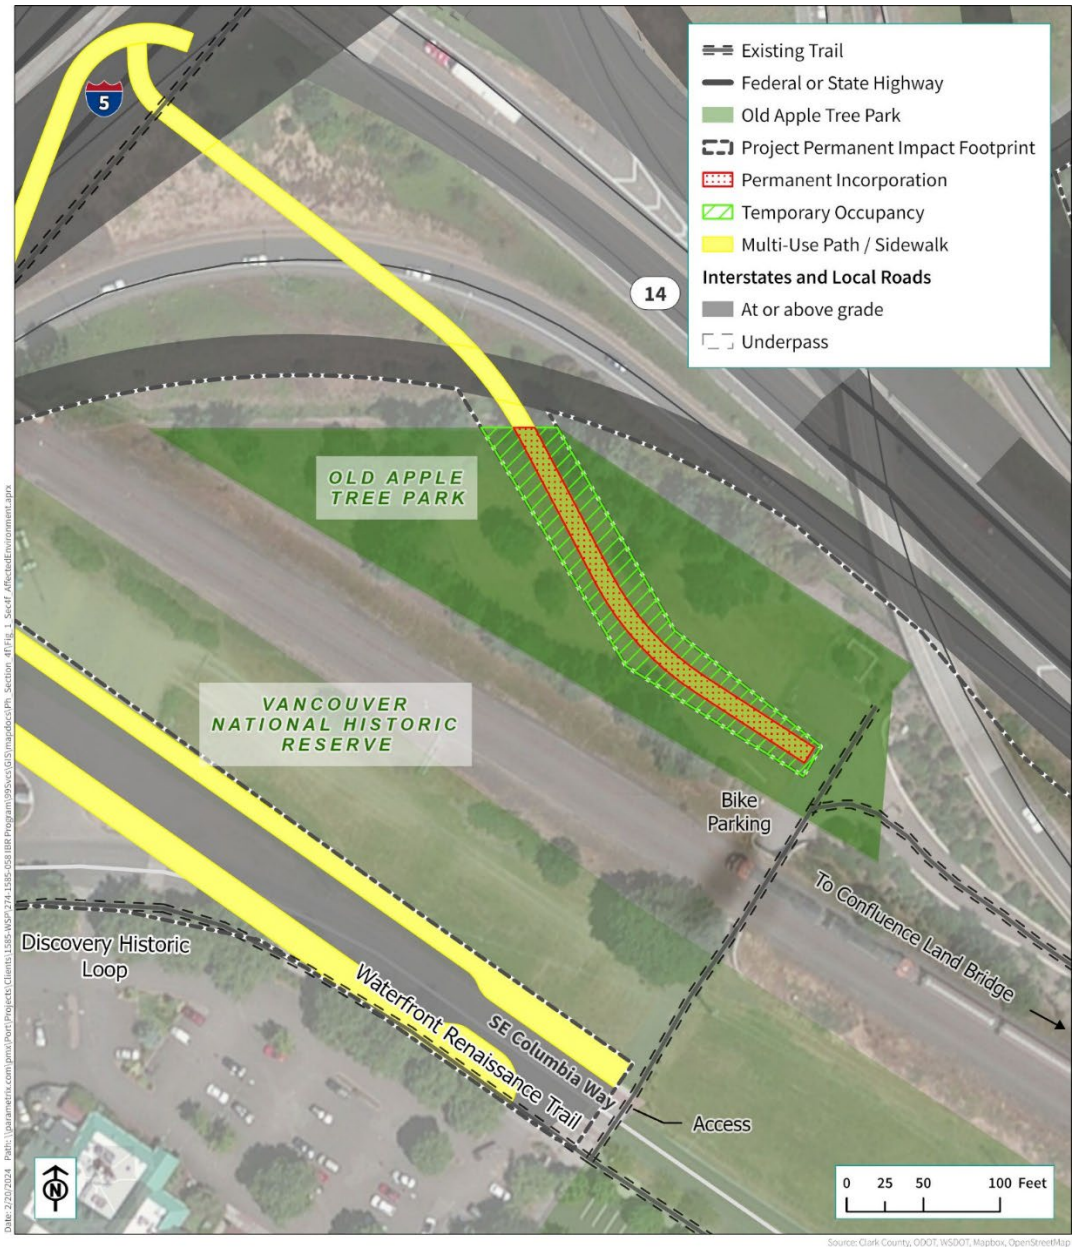
Park and Recreation Properties Evaluated to Have a Use with *de minimis* Impact under Section 4(f)

Old Apple Tree Park

Description

Old Apple Tree Park, depicted in Figure 4-19, is a 56,628-square-foot community park located north of the Columbia River and BNSF Railway and south of SR 14 and within the boundaries of the VNHR. Old Apple Tree Park can be accessed from the Fort Vancouver NHS waterfront beneath the railroad or from the Fort Vancouver NHS using the Confluence Land Bridge over SR 14. The Old Apple Tree from which the park derives its name died in 2020 at the age of 194, but its history lives on through saplings that share its genetic makeup planted in the same location. Old Apple Tree Park still provides passive recreational space, viewing, and bicycle parking for the Confluence Land Bridge.

Figure 4-19. Old Apple Tree Park



Use Evaluation for the Modified LPA

The Modified LPA would construct a new shared-use path through the lawn on the west side of the park, which would require approximately 3,500 square feet of land. The path would link the park to Main Street and downtown Vancouver. Users of the Confluence Land Bridge would travel through Old Apple Tree Park to reach the Fort Vancouver NHS. Under an agreement with WSDOT, VPR&C may own, operate, and maintain the trail and provide WSDOT a construction easement to build the trail as part of the Modified LPA which would enhance recreational activities of the park. The final path alignment in this park is being coordinated with VPR&C and would meet *de minimis* impact requirements.

In addition to the shared-use path connection, the Modified LPA would also require a permanent airspace easement, of approximately 4,400 square feet, over the northwest corner of Old Apple Tree Park for maintenance of the I-5 northbound to SR 14 elevated ramp. This easement would provide WSDOT with the right to enter Old Apple Tree Park with equipment to perform routine inspections of the ramp structure. This easement would not affect landscape on the park and would only be temporarily used for inspection and potentially maintenance of the ramp. It is anticipated that during the ramp inspection when the easement would be in use, access to the park would remain open and would not affect the activities, features, or attributes of the park property. The new I-5 northbound to SR 14 interchange ramp would be located closer to Old Apple Tree Park than the existing ramp, coming within 5 to 10 feet of its northern boundary. The ramp would not adversely impact user experience since the forested buffer along the northern edge of the park would remain, reducing the visual presence of the ramp. The airspace easement would not adversely affect the activities, features, or attributes of Old Apple Tree Park and would result in a *de minimis* impact.

Construction of the elevated ramp would occur immediately north of the park under the Modified LPA and would require access to and temporary occupancy of an approximately 7,200-square-foot portion of, but no permanent acquisition of land from, the park. Construction activities and equipment would be confined to the western and northern portion of the park and immediately adjacent to the new shared-use trail that is a grassed, landscaped, passive recreational area. This portion of the open landscaped area would be unavailable during elevated ramp construction, which would last up to 6 years. The existing shared-use path through the park, which is a segment of the Discovery Historic Loop Trail, and the Old Apple Tree monument, which are the primary recreational features of the park, would remain open and accessible to the public. The temporary occupancy for construction work is included in the *de minimis* impact determination for the park.

Preliminary Determination

The Modified LPA with all design options would enhance 3,500 square feet of land from Old Apple Tree Park for the construction of a shared-use path and require 4,400 square feet for an air space easement. The permanent incorporation would constitute a use of Old Apple Tree Park under Section 4(f). Additionally, the Modified LPA with all design options would temporarily occupy a 7,200-square-foot portion of the park to provide access for elevated ramp construction. Pending consultation with the VPR&C, USDOT has determined that the Program would have a *de minimis* impact to the protected activities, features, and attributes of the park.

Marshall Community Center, Luepke Senior Center, and Marshall Park

Description

The Marshall Community Center and Park is an 827,640-square-foot community park located on the east side of I-5 south of McLoughlin Boulevard. The park, which was renovated in 2006, is owned by the City of Vancouver and maintained by VPR&C and is open from 5:00 a.m. to 10:00 p.m. The park facilities include a large, fully accessible playground with multiple features, community gardens, a loop trail, picnic tables, horseshoe pits, ball fields, the Marshall and Luepke Centers, and the Ruby Luepke Center for Senior Citizens (WA 1182b).

The City completed a playground restoration in 2022. In 2010, a large group picnic shelter was added to Marshall Park. The property was originally transferred to the City of Vancouver in 1986 through the FLP Program, as administered by the NPS. The FLP parcel is described in the original Application for Federal Surplus Property as a grassy area that is used by the public. It is adjacent to a horseshoe pit area and is gently sloping from south to north. The existing parcel also contains a few medium-sized trees that provide a partial vegetative buffer between Marshall Park and I-5.

The Marshall Community Center, open weekdays from 6:00 a.m. to 8:00 p.m., with shortened hours on Fridays and weekends, has a swimming pool, a fitness center, two basketball courts, a commercial kitchen, meeting rooms, administrative offices, an aerobics dance studio, and an arts and crafts studio. The parking lot contains 272 parking spaces, including 26 spaces accessible under the American with Disabilities Act.

The Luepke Senior Center is a full-service senior center with a multipurpose room and meeting rooms.

Use Evaluation for the Modified LPA

The Modified LPA would acquire approximately 25,200 square feet of property from Marshall Park, which includes the Marshall Community Center and Luepke Senior Center. As illustrated in Figure 4-20, the permanent property acquisition would occur along the western edge of the parcel for the fill wall for the I-5 northbound to Fourth Plain Boulevard elevated off-ramp. The permanent acquisition would displace up to four horseshoe pits, as well as trees located in state right of way and within the park boundary that currently serve as a visual buffer between the community center campus and I-5. The fill wall would be located along the border of the parking lot and would be up to 20 feet high.

Trees removed within the park would be subject to the City of Vancouver's replacement requirements during the tree removal permitting process. Landscaping would be restored to its original condition once construction is complete. Under an agreement with the City of Vancouver (VPR&C), the IBR Program would replace the four displaced horseshoe pits within the park. The four new pits would be located near the other horseshoe pits with no loss of recreational function.

The 25,200-square-foot permanent acquisition of land within the park represents a small portion (approximately 3%) of the overall park area. Approximately 6,300 square feet of the 25,200-square-foot acquisition could be replaced with surplus WSDOT right of way. WSDOT would construct a new shared-use path from E Mill Plain Boulevard, providing a southern connection and enhancing pedestrian access to the park. Because the Modified LPA would replace a portion of the acquired land and horseshoe pits and would replant trees that would be removed, it would not adversely impact the activities, features, or attributes qualifying the park for protection under Section 4(f) consistent with 23 CFR 774.17.

The Modified LPA would require the temporary use of approximately 19,100 square feet along the western boundaries of the parcel. Access to and from the Marshall Community Center would be maintained for the duration of construction. It is possible that one of the two access points may need to be closed for short periods to complete construction. During potential access closures, the one-way access between the two main parking lots would likely be signed for two-way traffic to allow for full use of the parking facility; this would likely require flaggers or some other mitigation as this access is currently only one lane. Access closures would be coordinated with the City of Vancouver (VPR&C) and facility users. As discussed in Sections 3.11.4 and 3.9.4, facility users would experience temporary increased levels of noise and construction lighting during the construction of the Fourth Plain off-ramp. However, because access to the facilities would remain open throughout construction, there would be no adverse effects on the activities, features, or attributes of the park that qualify the park for protection under Section 4(f).

Figure 4-20. Marshall Community Center, Luepke Senior Center, and Marshall Park – Modified LPA with All Design Options

As per 23 CFR 774.15, constructive use of Section 4(f) property is only possible in the absence of a permanent incorporation of land or a temporary occupancy of the type that constitutes a Section 4(f) use. The Modified LPA and the design options would permanently incorporate and temporarily occupy land during construction. Therefore, no constructive use would occur.

Preliminary Determination

Construction of the Modified LPA and the design options would result in acquisition and permanent incorporation of approximately 25,200 square feet of land from Marshall Park, which houses the Marshall Community Center and Luepke Senior Center and would also remove trees screening the park from I-5 and up to four horseshoe pits. The permanent incorporation would constitute a use of Marshall Park under Section 4(f). The land, trees, and horseshoe pits would be replaced under the Modified LPA, resulting in both a permanent and a temporary construction-phase *de minimis* impact to the park, community center, and senior center pending concurrence from VPR&C.

4.3.5 Summary of Use of Historic Sites by the IBR Program Modified LPA with All Design Options

This section is organized based on Section 106 determinations of effects to historic sites and discusses uses of Section 4(f) historic sites located in the following areas:

- Sites in Oregon
- Sites in Washington

Historic sites meeting the criteria for protection under Section 4(f), and subject to review under Section 106, are grouped into four categories of use for the historic sites evaluation.

i. **Historic sites within the Section 106 Area of Potential Effect (APE) that would have no Section 4(f) use**. Sites within this category may have a Section 106 determination of "No Effect" or "No Adverse Effect" as well as no permanent or temporary use of the property. This category can also include sites that have a Section 106 determination of "Adverse Effect" but would not have permanent incorporation of land. Therefore, these sites are evaluated for constructive use. There are 15 sites under this category.

ii. **Historic sites for which the temporary occupancy exception applies under Section 4(f), and for which, therefore, there is no Section 4(f) use**. Sites in this category, which is a subcategory of historic sites that would have no Section 4(f) use, have a Section 106 determination of "No Adverse Effect." There are four sites with a preliminary determination of "No Adverse Effect" under Section 106 for which the temporary occupancy exception applies under Section 4(f), with regard to the Modified LPA, including all design options. Additionally, there is one site for which the temporary occupancy exception applies with regard to the Modified LPA, including all design options except for the Modified LPA with I-5 shifted west design option.

iii. **Historic sites evaluated to have a use with greater than *de minimis impact* under Section 4(f)**. Generally, these sites have a Section 106 determination of "Adverse Effect." There are eight sites with an "Adverse Effect" determination and a use with greater than *de minimis* impact under Section 4(f) for the Modified LPA with all design options, including a group of contributing resources that are part of the VNHR Historic District and are evaluated as one historic site.

iv. **Historic sites evaluated to have a *de minimis* impact under Section 4(f)**. As with the previous category, these sites generally have a Section 106 determination of "No Adverse Effect." There are four sites with a preliminary determination of "No Adverse Effect" under Section 106 and an anticipated *de minimis* impact under Section 4(f) for the Modified LPA with all design options; additionally, there is one site with a preliminary determination of "No Adverse Effect" under Section 106 and an anticipated *de minimis* impact under Section 4(f) for the Modified LPA with I-5 shifted west design option only.

The Modified LPA, including all design options, would result in the use of certain historic sites under Section 4(f). Table 4-5 summarizes the preliminary use determination for the historic sites evaluated for the Modified LPA and for each design option. The Modified LPA park-and-ride design option would not use any of the Section 4(f) historic sites and, therefore, is not discussed further.

Of the 32 historic sites within the Section 106 APE identified as Section 4(f) properties, two historic sites in Oregon and 18 in Washington would have no Section 4(f) use for the Modified LPA with all design options (this includes five sites in Washington for which the temporary occupancy exception applies); two historic sites in Oregon, one in Washington, and one in the Columbia River between Oregon and Washington would have a *de minimis* impact for the Modified LPA with all design options; and four historic sites in Oregon, three in Washington, and the northbound Interstate Bridge between the two states would have a Section 4(f) use for the Modified LPA with all design options.

Table 4-5. Summary of Section 4(f) Evaluation for Historic Sites for IBR Program Modified LPA Design Options

State	Historic Site	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Shifted West	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5
Oregon	Columbia Slough Drainage Districts Historic District (OR 2), Portland	Permanent incorporation of approximately 182,300 square feet and temporary occupancy of approximately 140,800 square feet of the more than 150-square-mile historic district. No changes to location of contributing resources or the overall character of the surrounding setting. **Preliminary Determination**: Section 4(f) use. Based on CFR 774.17, this would be a *de minimis* impact because there would be No Adverse Effect under Section 106.					
	Northbound Interstate Bridge (OR 50 / WA 381a)	Permanent incorporation of the entire site (approximately 85,600 square feet) and removal of the NRHP-listed bridge. **Preliminary Determination**: Section 4(f) use because the bridge would be demolished.					
	Portland Assembly Center (OR 56), 2060 N Marine Drive, Portland	Permanent incorporation of approximately 244,800 square feet from the far southern, eastern, and western edges of the site and temporary occupancy of approximately 1,408,700 square feet. No substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: Section 4(f) use. Based on CFR 774.17, this would be a *de minimis* impact because there would be No Adverse Effect under Section 106.					
	Toll Administration Building/ODOT Permit Center (OR 103), 12348 N Center Avenue, Portland	Permanent incorporation of the entire site (approximately 163,700 square feet) and removal of the NRHP-eligible building and landscape features. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.					
	Harbor Shops (OR 107), 11915 N Center Avenue, Portland	Permanent Incorporation of the entire site (approximately 52,200 square feet) and removal of the NRHP-eligible building and landscape features. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.					
	Jantzen Beach Water Tank (OR 109), N Center Avenue, Portland	Permanent incorporation of the entire site (approximately 3,200 square feet) and removal of the NRHP-eligible structures and landscape features. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.					
	Jantzen Beach Moorage (OR 111), 1501 N Jantzen Avenue/1525-2055 N Jantzen Avenue, Portland	Permanent incorporation of approximately 85,900 square feet and removal of a section of dock, at least two finger piers, and approximately 20 floating shelters from the NRHP-eligible moorage. Additionally, temporary occupancy of approximately 19,400 square feet. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.					
	Hayden Island Yacht Club Clubhouse (OR 120), 12050 N Jantzen Drive, Portland	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the historic site. **Preliminary Determination**: No Section 4(f) use.					
	East Vanport Commercial Center (OR 155), 10850 N Denver Avenue, Portland	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the historic site. **Preliminary Determination**: No Section 4(f) use.					
	Lower Columbia River Federal Navigation Historic District (OR 165)	Permanent incorporation of approximately 2,000 square feet from the Upper Vancouver Turning Basin and temporary occupancy of area up to approximately 1,000 feet east of the existing bridge and up to approximately 1,000 feet west of the proposed bridges. Overall, no substantial impairment of the protected activities, features, or attributes of the more than 140-mile-long historic district. **Preliminary Determination**: Section 4(f) use. Based on CFR 774.17, this would be a *de minimis* impact because there would be No Adverse Effect under Section 106.					
Washington	Normandy Apartments (WA 149), 318 E 7th Street, Vancouver	Permanent incorporation of approximately 700 square feet and temporary occupancy of 300 square feet along the eastern boundary of the historic site for construction of noise and retaining walls and elevated LRT alignment. Landscape elements would be removed and new construction would be in proximity to the NRHP-eligible building. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.	Permanent incorporation of the entire site (approximately 14,690 square feet) and removal of the building and landscape features. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.	Permanent incorporation of approximately 700 square feet and temporary occupancy of 300 square feet along the eastern boundary of the historic site for construction of noise and retaining walls and elevated LRT alignment. Landscape elements would be removed and new construction would be in proximity to the NRHP-eligible building. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.			
	Bridge Substation (WA 1192), 100 SE Columbia Street, Vancouver	Permanent incorporation of the entire site (approximately 3,200 square feet) and removal of the NRHP-eligible building. **Preliminary Determination**: Section 4(f) use because of permanent incorporation.					

State	Historic Site	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Shifted West	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5
	Vancouver National Historic Reserve Historic District (WA 368, 369, 918, 109), Vancouver	Permanent Incorporation: Approximately 65,600 square feet Temporary Occupancy: Approximately 110,100 square feet **Preliminary Determination**: Section 4(f) use.	Permanent Incorporation: Approximately 66,900 square feet Temporary Occupancy: Approximately 108,700 square feet **Preliminary Determination**: Section 4(f) use.	Permanent Incorporation: Approximately 53,400 square feet Temporary Occupancy: Approximately 121,600 square feet **Preliminary Determination**: Section 4(f) use.	Permanent Incorporation: Approximately 63,700 square feet Temporary Occupancy: Approximately 111,900 square feet **Preliminary Determination**: Section 4(f) use.	Permanent Incorporation: Approximately 68,400 square feet Temporary Occupancy: Approximately 107,300 square feet **Preliminary Determination**: Section 4(f) use.	Permanent Incorporation: Approximately 68,400 square feet Temporary Occupancy: Approximately 107,300 square feet **Determination**: Section 4(f) use.
	Fendrich's Furniture (WA 7), 209 W 6th Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Evergreen Hotel (WA 21), 500 Main Street, Vancouver	Temporary occupancy of approximately 400 square feet requiring temporary closure of south entrance to the NRHP-eligible building. Based on 23 CFR 774.13(d), temporary occupancy of the park would meet the exception criteria. **Preliminary Determination**: No Section 4(f) use.					
	House of Providence (Providence Academy) (WA 150), 400 E Evergreen Boulevard, Vancouver	Temporary occupancy of approximately 4,700 square feet from the southern boundary of the historic site. Based on 23 CFR 774.13(d), temporary occupancy of the historic site would meet the exception criteria. **Preliminary Determination**: No Section 4(f) use.		Permanent incorporation of approximately 9,800 square feet from the eastern boundary of the historic site and temporary occupancy of approximately 2,100 square feet from the southern boundary. **Preliminary Determination**: Section 4(f) use. *De minimis* impact because there would be No Adverse Effect under Section 106.	Temporary occupancy of approximately 4,700 square feet from the southern boundary of the historic site. Based on 23 CFR 774.13(d), temporary occupancy of the historic site would meet the exception criteria. **Preliminary Determination**: No Section 4(f) use.		
	William H. and Myrtle Hood Residence (WA 191), 3405 K Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Office Building (WA 1144), 1514 E Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Duplex Residences (WA 1168), 2901 K Street, Vancouver	Temporary occupancy of approximately 300 square feet at the southwest corner of the historic site, the possible removal of grass lawn (this would be replaced in-kind following construction), and preservation in place of one ornamental shrub. Based on 23 CFR 774.13(d), temporary occupancy of the historic site would meet the exception criteria. **Preliminary Determination**: No Section 4(f) use.					
	Earls House (WA 1233), 815 E 22nd Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Mickler House (WA 1258), 901 E 29th Street, Vancouver	Temporary occupancy of approximately 48 square feet at the north boundary of the historic site and possibly disturbance of a fence and walkway (these would be restored following construction). Based on 23 CFR 774.13(d), temporary occupancy of the historic site would meet the exception criteria. **Preliminary Determination**: No Section 4(f) use.					
	Vancouver Barracks National Cemetery (WA 1319), 1200 E Fourth Plain Boulevard, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					

State	Historic Site	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Shifted West	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Single-Level Fixed- or Movable-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5
	St. James Acres Cemetery (WA 1320), 1401 E 29th Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Smith Tower (WA 10), 515 Washington Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	U.S. National Bank Building (WA 29), 601-603 Main Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Porter House (WA 61), 3000 K Street, Vancouver	Subsurface easement for installation of subterranean tie-back anchors (per Question 28A of the *Section 4(f) Policy Paper*, Section 4(f) would not apply). No other permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Hall House (WA 62), 903 E 31st Street, Vancouver	Subsurface easement for installation of subterranean tie-back anchors (per Question 28A of the *Section 4(f) Policy Paper*, Section 4(f) would not apply). No other permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Radio Transmission Building (WA 382), 1601 E Fourth Plain Boulevard, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Covington House (WA 900), 4201 Main Street, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					
	Who Song & Larry's (WA 1138), 111 SE Columbia Way, Vancouver	Temporary occupancy of approximately 200 square feet. Based on 23 CFR 774.13(d), temporary occupancy of the historic site would meet the exception criteria. **Preliminary Determination**: No Section 4(f) use.					
	Washington State Patrol District Five Headquarters (WA 1148), 605 E Evergreen Boulevard, Vancouver	Permanent Incorporation of approximately 800 square feet and temporary occupancy of approximately 600 square feet. No substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: Based on CFR 774.17, this would be a *de minimis* impact because there would be No Adverse Effect under Section 106.					
	Rudy Luepke Center for Senior Citizens (WA 1182), 1009 E McLoughlin Boulevard, Vancouver	No permanent incorporation or temporary occupancy, and no substantial impairment of the protected activities, features, or attributes of the site. **Preliminary Determination**: No Section 4(f) use.					

4.3.6 Use of Section 4(f) Historic Sites (Oregon)

Historic Sites Evaluated to Have No Use under Section 4(f)

Permanent Incorporation and Temporary Occupancy (Modified LPA with All Design Options) – No Use

The two historic sites listed in Table 4-6 were evaluated under Section 106 to have a finding of "No Effect" for the Modified LPA, including design options. Neither of these historic sites would be permanently incorporated or temporarily occupied by the Modified LPA or the design options. Therefore, there would be no direct use under Section 4(f) of these sites.

Constructive Use

A constructive use occurs when a transportation project does not incorporate land from a Section 4(f) property, but the project's proximity impacts are so severe that the protected activities, features, or attributes that qualify the property for protection under Section 4(f) are substantially impaired (23 CFR 774.15[a]). A constructive use does not occur when compliance with the requirements of 36 CFR 800.5 (Assessment of adverse effects) for proximity impacts of the proposed action, on a site listed in or eligible for the NRHP, results in an agreement of "No Effect" or "No Adverse Effect" (23 CFR Section 774.15[f][1]). The Section 106 evaluation for the Program determined that there would be "No Effect" to the historic sites listed in Table 4-6. Because the Program would have "No Effect" to the historic sites, it would not substantially impair the protected activities, features, or attributes of the Section 4(f) properties and, therefore, it would not result in a constructive use of either historic site.

Table 4-6. Historic Sites (Portland) – No Use under Section 4(f)

Site ID	Historic Site
OR 120	Hayden Island Yacht Club Clubhouse
OR 155	East Vanport Commercial Center

Historic Sites Evaluated to Have Use with a Greater than *de minimis* Impact under Section 4(f)

Harbor Shops Building (Map ID – OR 107)

Description

The Harbor Shops building is a Postmodern-style strip mall located at 11915 N Center Avenue in Portland. Constructed in 1978, this one-story building features an irregular footprint with an elongated zigzag shape and a flat roof with a high parapet. The Harbor Shops Building is eligible for inclusion in the NRHP under Criterion A, at the local level of significance, in the areas of commerce and community planning and development. The Harbor Shops Building is also eligible, at the local level of significance, under Criterion C in the area of architecture as an intact example of a strip mall property type. Although it has experienced minor alterations to its interior configuration and exterior signage related to tenant turnover, the strip mall generally retains integrity of location, design, setting, materials, workmanship, feeling, and association to this period. The boundary of the historic site coincides with the boundary of the tax lot and includes the Harbor Shops Building as well as the associated parking lot and planted medians.

The Harbor Shops Building was determined eligible for the NRHP in 2023, in an evaluation process carried out as part of the IBR Program. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the IBR

Program Modified LPA and its design options. This finding received concurrence from the Oregon SHPO on March 19, 2024.

Use Evaluation for the Modified LPA

The Modified LPA, including all design options, would acquire and permanently incorporate the Harbor Shops Building into right of way to construct the proposed northbound and southbound Columbia River bridges (see Figure 4-21). Construction of the bridges would require the demolition of extant features on the NRHP-eligible historic site, including the primary commercial building, surface parking lots and circulation, and planted medians. The Modified LPA would remove the features that convey the Harbor Shops Building's significance under NRHP Criteria A and C and would eliminate the site's integrity of location, design, setting, materials, workmanship, feeling, and association; as recommended in the Section 106 FOE, the Modified LPA would have an "Adverse Effect" on the site. The Modified LPA would permanently incorporate the entirety of the approximately 52,200-square-foot Harbor Shops Building site and would constitute a use of the site under Section 4(f).

As the entire site would be permanently incorporated, there would be no temporary occupancy of the Harbor Shops Building site by the Modified LPA, inclusive of all design options.

Preliminary Determination

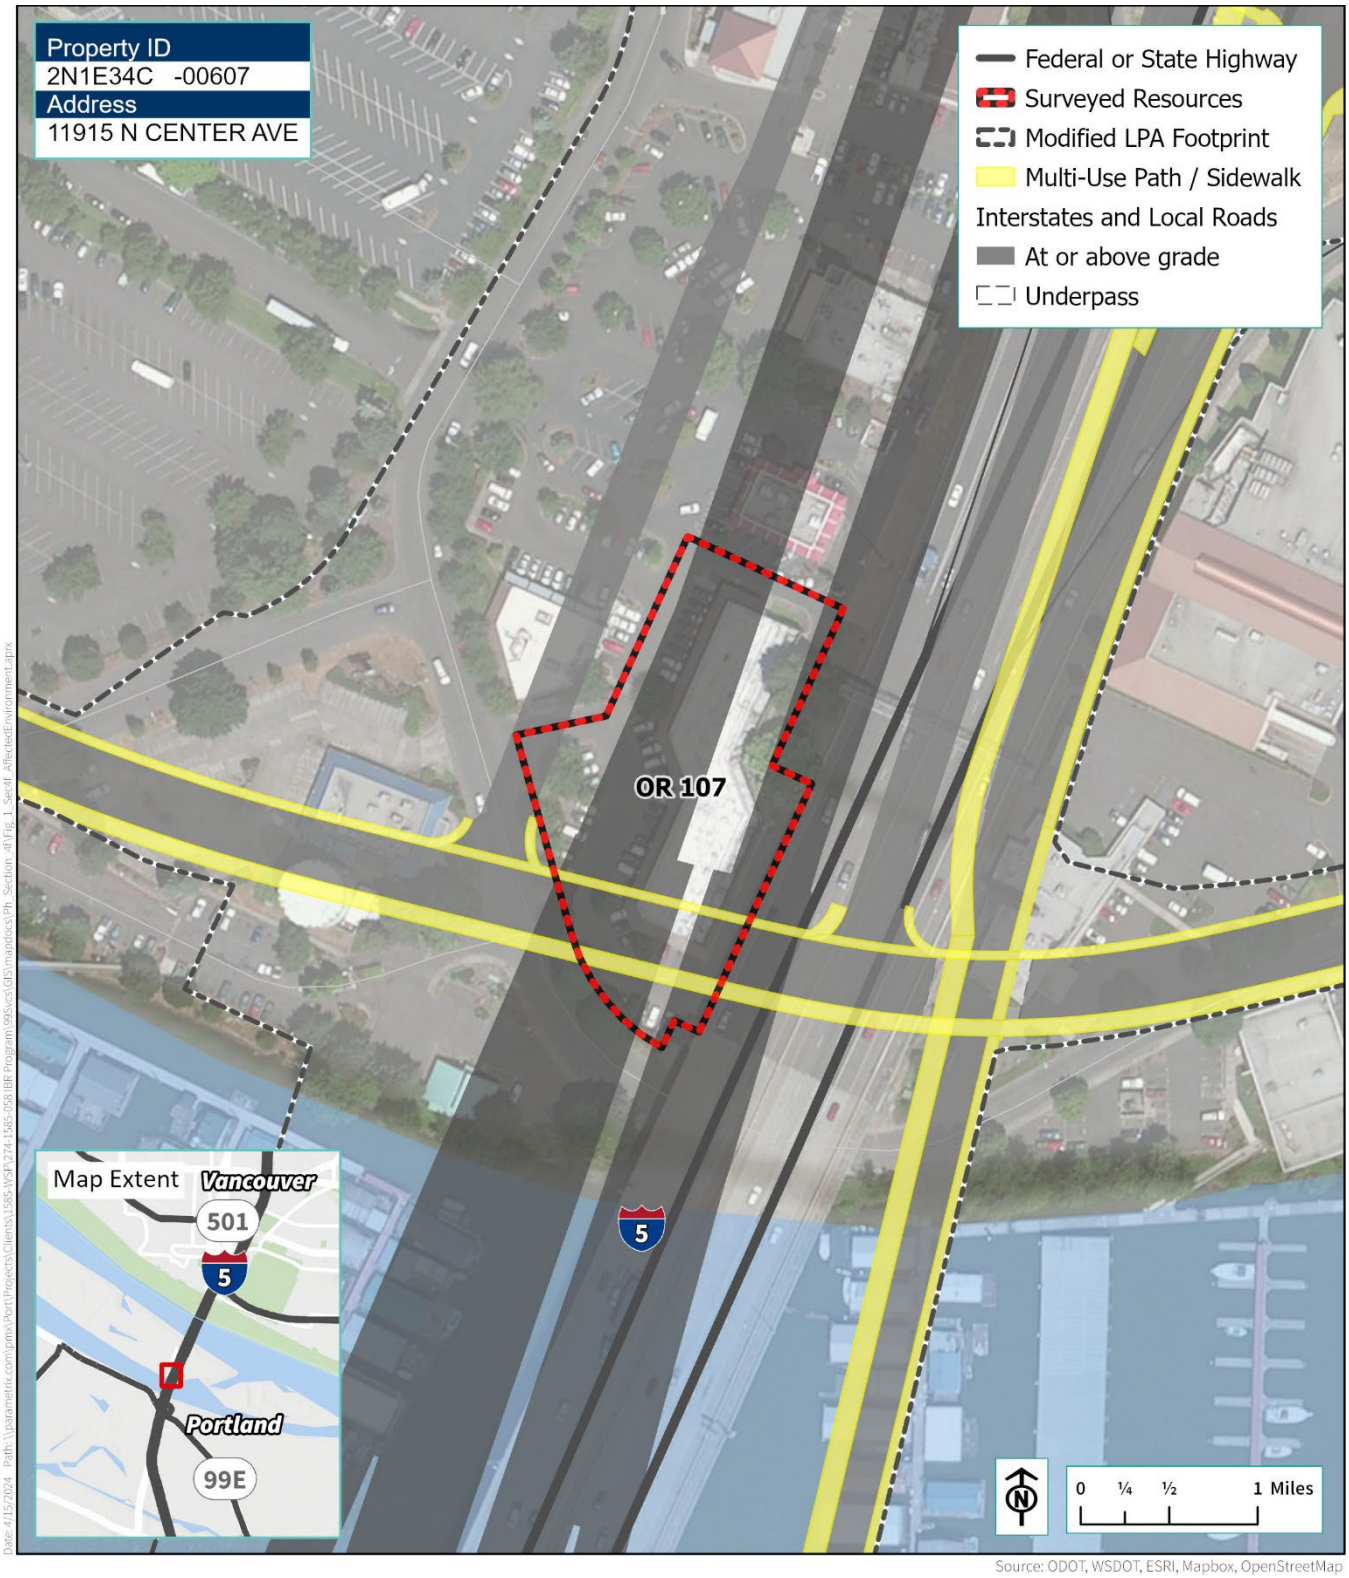
The Modified LPA and its design options would all require the acquisition of the Harbor Shops Building and the subsequent removal of all its extant features, which would render the historic site no longer eligible for the NRHP. Consistent with the definition of use set forth in 23 CFR 774.17, which states that a use of Section 4(f) property occurs "when land is permanently incorporated into a transportation facility," FHWA and FTA have determined that the Modified LPA and its design options would result in a use under Section 4(f) for the Harbor Shops Building.

Jantzen Beach Water Tank and Pump House (Map ID – OR 109)

Description

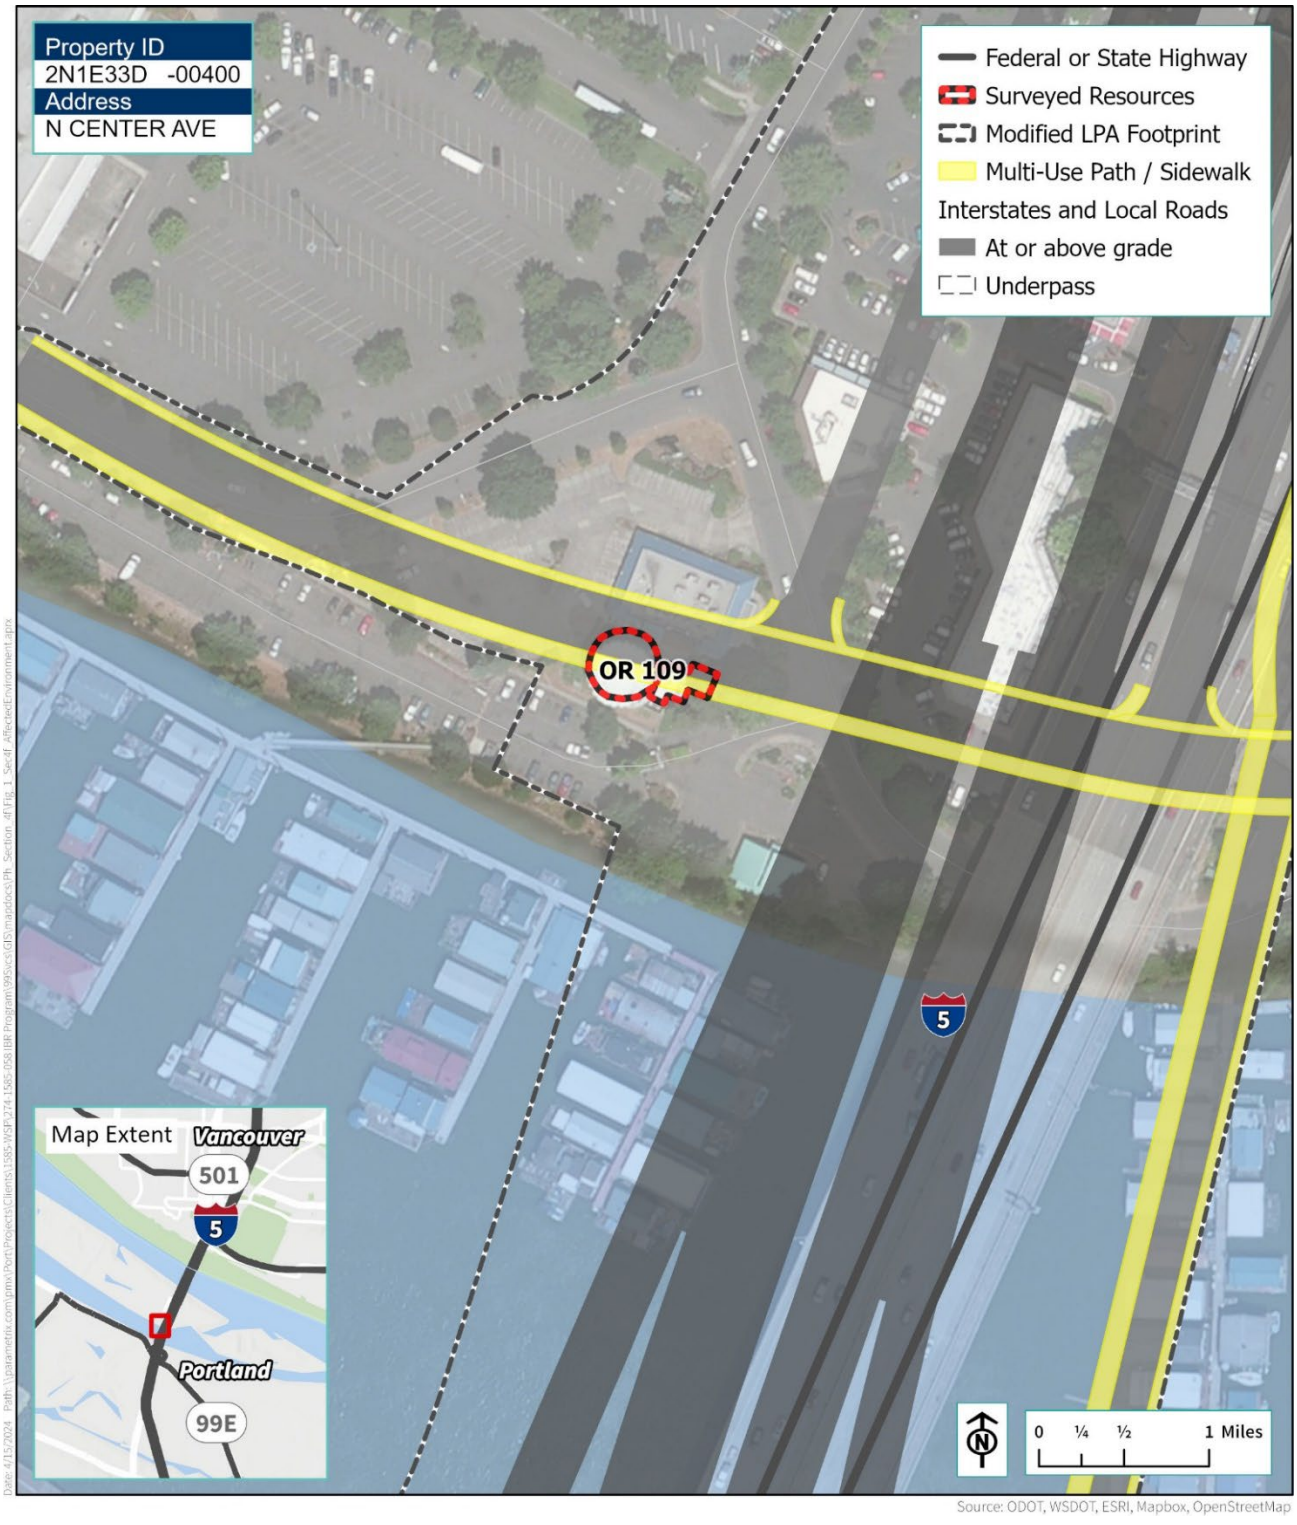
The Jantzen Beach Water Tank and Pump House are utilitarian structures located near the intersection of North Center Street and North Jantzen Avenue on Hayden Island in Portland. Initial construction of the water tank was completed in 1968. The Jantzen Beach Water Tank and Pump House are eligible for inclusion in the NRHP under Criterion A at the local significance level in the area of community planning and development, and under Criterion C at the local significance level in the area of engineering. The historic site is a good example of a welded steel water tank that remains intact and continues to convey its original construction method and materials. Overall, the Jantzen Beach Water Tank and Pump House retain integrity of location, materials, workmanship, feeling, and association; however, the site's integrity of design has been diminished by the changes to the pump house, and its integrity of setting has been diminished by the addition of various site features (fencing, sidewalk, etc.) after the period of significance. Due to the changes to the setting, the historic site's boundary is limited to the extent of the respective footprints of the water tank, pump house, and the associated back-up diesel generator. The Water Tank and Pump House is not currently functioning.

Figure 4-21. IBR Program Improvements and Area of Permanent Incorporation for the Harbor Shops Building



The Jantzen Beach Water Tank and Pump House was determined eligible for the NRHP in 2023, in an evaluation process carried out as part of the IBR Program. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the IBR Program Modified LPA and its design options. The finding received concurrence from the Oregon SHPO on March 19, 2024.

Figure 4-22. IBR Program Improvements and Area of Permanent Incorporation for the Jantzen Beach Water Tower and Pump House



Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would permanently incorporate the entirety of the approximately 3,200-square-foot Jantzen Beach Water Tank and Pump House site as right of way to construct a new road that would join the existing North Jantzen Avenue alignment west of the subject property (see Figure 4-22, above). Construction of the new road would require the demolition of all extant features of the property, including the water tank, pump house, and the associated back-up diesel generator. The Modified LPA would remove the features that convey the property's significance under NRHP Criteria A and C and would eliminate the property's integrity of location, design, setting, materials, workmanship, feeling, and association, resulting in a Section 106 FOE of "Adverse Effect" to the NRHP-eligible property. The Modified LPA would therefore constitute a use of the Jantzen Beach Water Tank and Pump House site under Section 4(f).

As the entire site would be permanently incorporated, there would be no temporary occupancy of the historic site by the Modified LPA, inclusive of all design options.

Preliminary Determination

The Modified LPA and its design options would all require the acquisition of the Jantzen Beach Water Tank and Pump House historic site and the subsequent removal of all its extant features, which would render the historic site no longer eligible for the NRHP. Consistent with the definition of use set forth in 23 CFR 774.17, which notes that a use of Section 4(f) property occurs "when land is permanently incorporated into a transportation facility," FHWA and FTA have determined that the Modified LPA and its design options would result in a use under Section 4(f) for the Jantzen Beach Water Tank and Pump House.

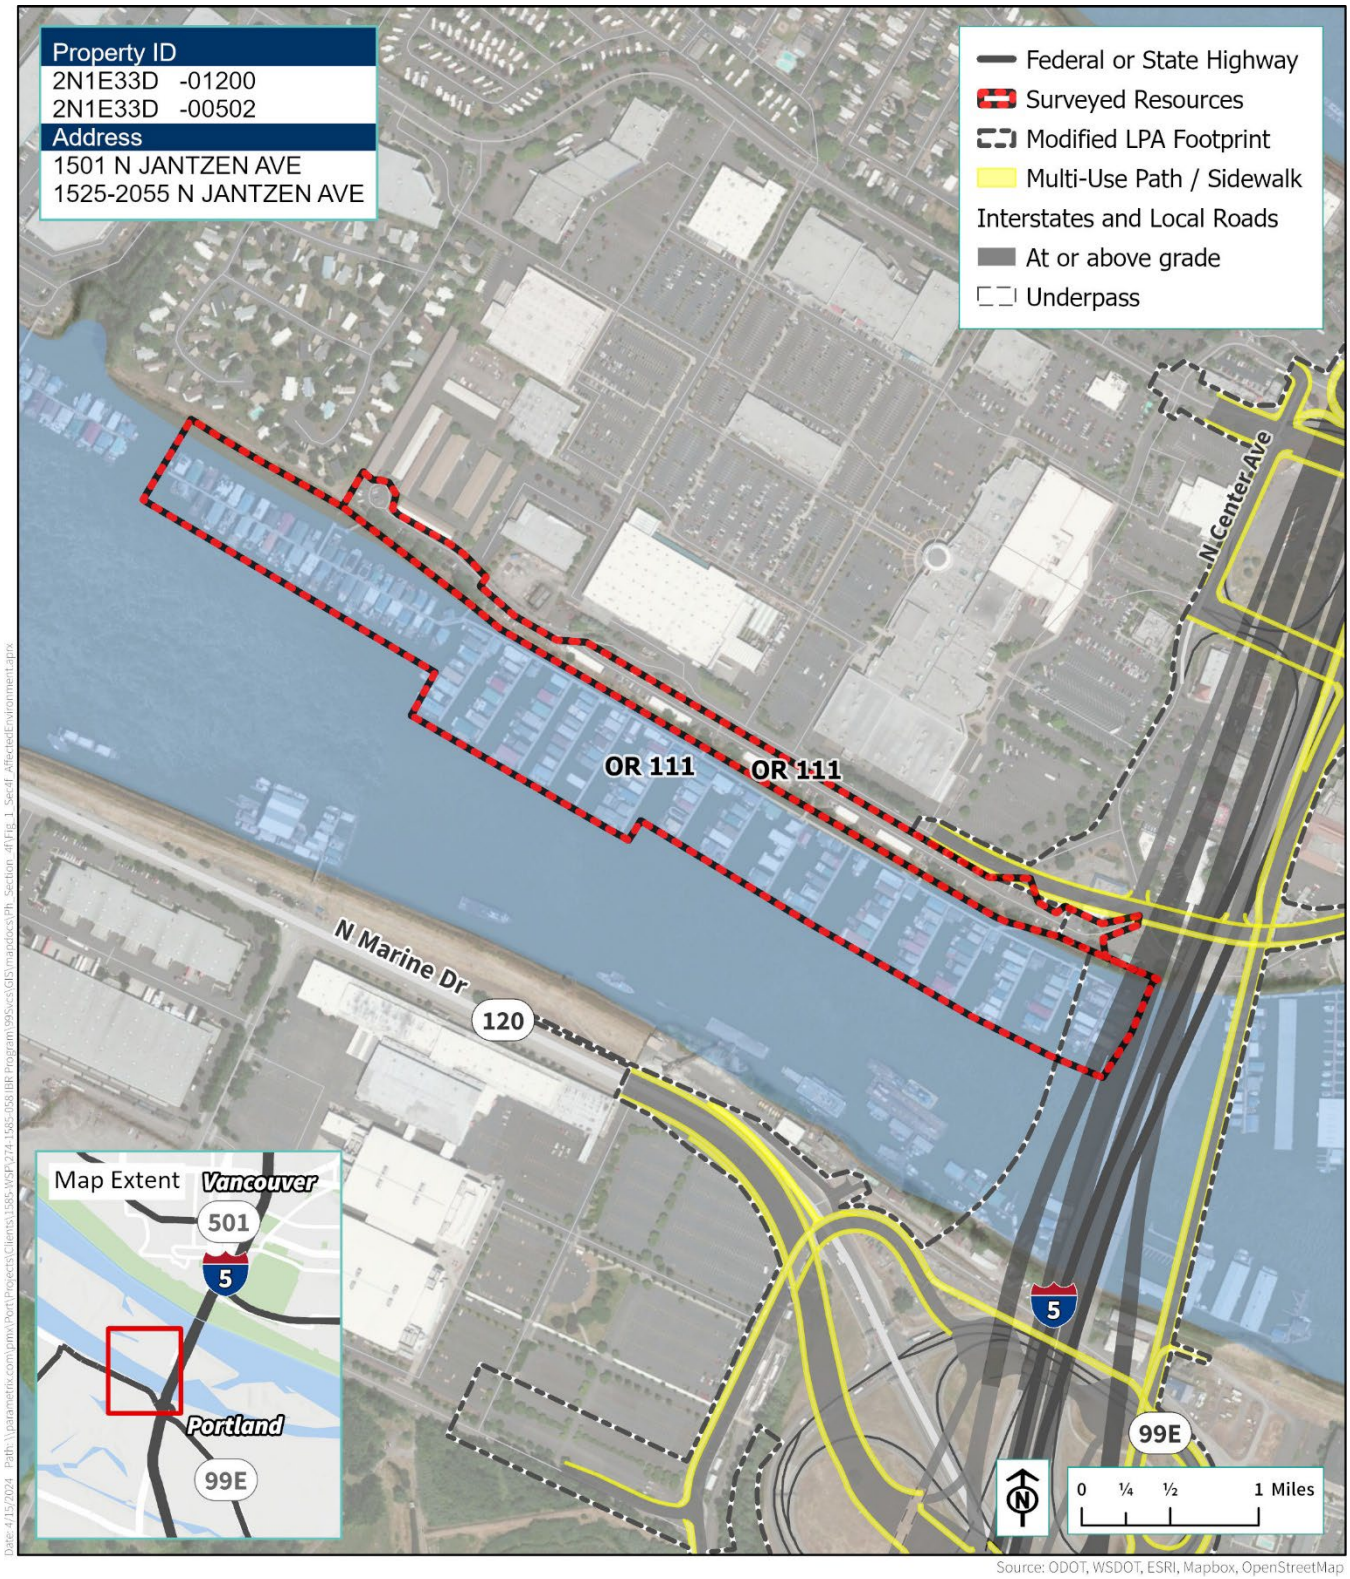
Jantzen Beach Moorage (Map ID – OR 111)

Description

The Jantzen Beach Moorage is located at North Portland Harbor in the Columbia River. Originally built in 1935, the moorage offered leasable and—eventually—privately owned slips for floating homes starting in 1958. The property is 27.3 acres and encompasses a linear dock, multiple finger piers, a parking lot, and associated hardscaping and landscaping. The moorage is host to approximately 175 floating homes located on the water of North Portland Harbor. Figure 4-23 depicts the identified boundary of the historic site. The property is eligible for inclusion in the NRHP under Criterion A for its significance at the local level in the area of community planning and development, and at the local level in the area of maritime history.

The Jantzen Beach Moorage was determined eligible for the NRHP in 2023, in an evaluation process carried out as part of the IBR Program. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Oregon SHPO on March 19, 2024.

Figure 4-23. Aerial Map of Jantzen Beach Moorage (1501, 1525-2055 North Jantzen Avenue), Showing Boundary in Red



Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would replace the existing North Portland Harbor bridge with new bridges. A new LRT bridge would also cross North Portland Harbor to the west of the new North Portland Harbor bridges. Construction of these two structures would permanently incorporate approximately 85,900 square feet of the Jantzen Beach Moorage historic site and result in removal of a section of dock, at least two finger piers, and approximately 20 floating shelters. The Modified LPA, under all design options, would also temporarily occupy 19,400 square feet of the Jantzen Beach Moorage during construction. This occupancy is considered in the "Adverse Effect" determination under Section 106. The temporary occupancy of the site by the Modified LPA is incorporated in the use determination. Figure 4-23, above, depicts how the Modified LPA would intersect with the property. These structures are contributing elements of the NRHP-eligible Jantzen Beach Moorage. Removal of these elements would reduce the resource's integrity of location, design, setting, materials, workmanship, and feeling, resulting in a finding of "Adverse Effect" for the NRHP-eligible Jantzen Beach Moorage under Section 106. Thus, the permanent incorporation would constitute a use of the historic site under Section 4(f).

Preliminary Determination

The Modified LPA and its design options would all permanently incorporate approximately 85,900 square feet of the Jantzen Beach Moorage historic site and the subsequent removal of character-defining features including a section of dock, at least two finger piers, and approximately 20 floating shelters. FHWA and FTA have determined that the Modified LPA and its design options would result in a use under Section 4(f) for the Jantzen Beach Moorage.

Historic Sites Evaluated to Have Use with a *de minimis* Impact under Section 4(f)

Columbia Slough Drainage Districts Historic District (Map ID – OR 2)

Description

The Columbia Slough Drainage Districts Historic District comprises four geographically contiguous drainage districts on the Columbia River floodplain between the Willamette River and the Sandy River, occupying more than 10,000 acres. Within the Columbia Slough Drainage Districts Historic District are elements including levees and cross levees, pump stations, weirs/dams, canals, sloughs, and drainage ditch systems and flood walls. The district is eligible for the NRHP under Criterion A for its association with early drainage district development in Oregon, which reflected the national reclamation movement that began in the 1880s, and under Criterion C as a major engineered drainage system that was initially constructed in the early 20th century. Its boundary is delineated by the levees, major drainages evaluated to be contributing, as well as reasonable immediate areas surrounding pump stations, weirs, and dams; the interior areas within the district's drainage districts are not included within the boundaries.

The Columbia Slough Drainage Districts Historic District was identified as eligible for the NRHP in a draft nomination prepared for the U.S. Army Corps of Engineers (USACE) in 2019. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Oregon SHPO on March 18, 2024.

Figure 4-24. IBR Program Improvements and Area of Permanent Incorporation for the Columbia Slough Drainage Districts Historic District

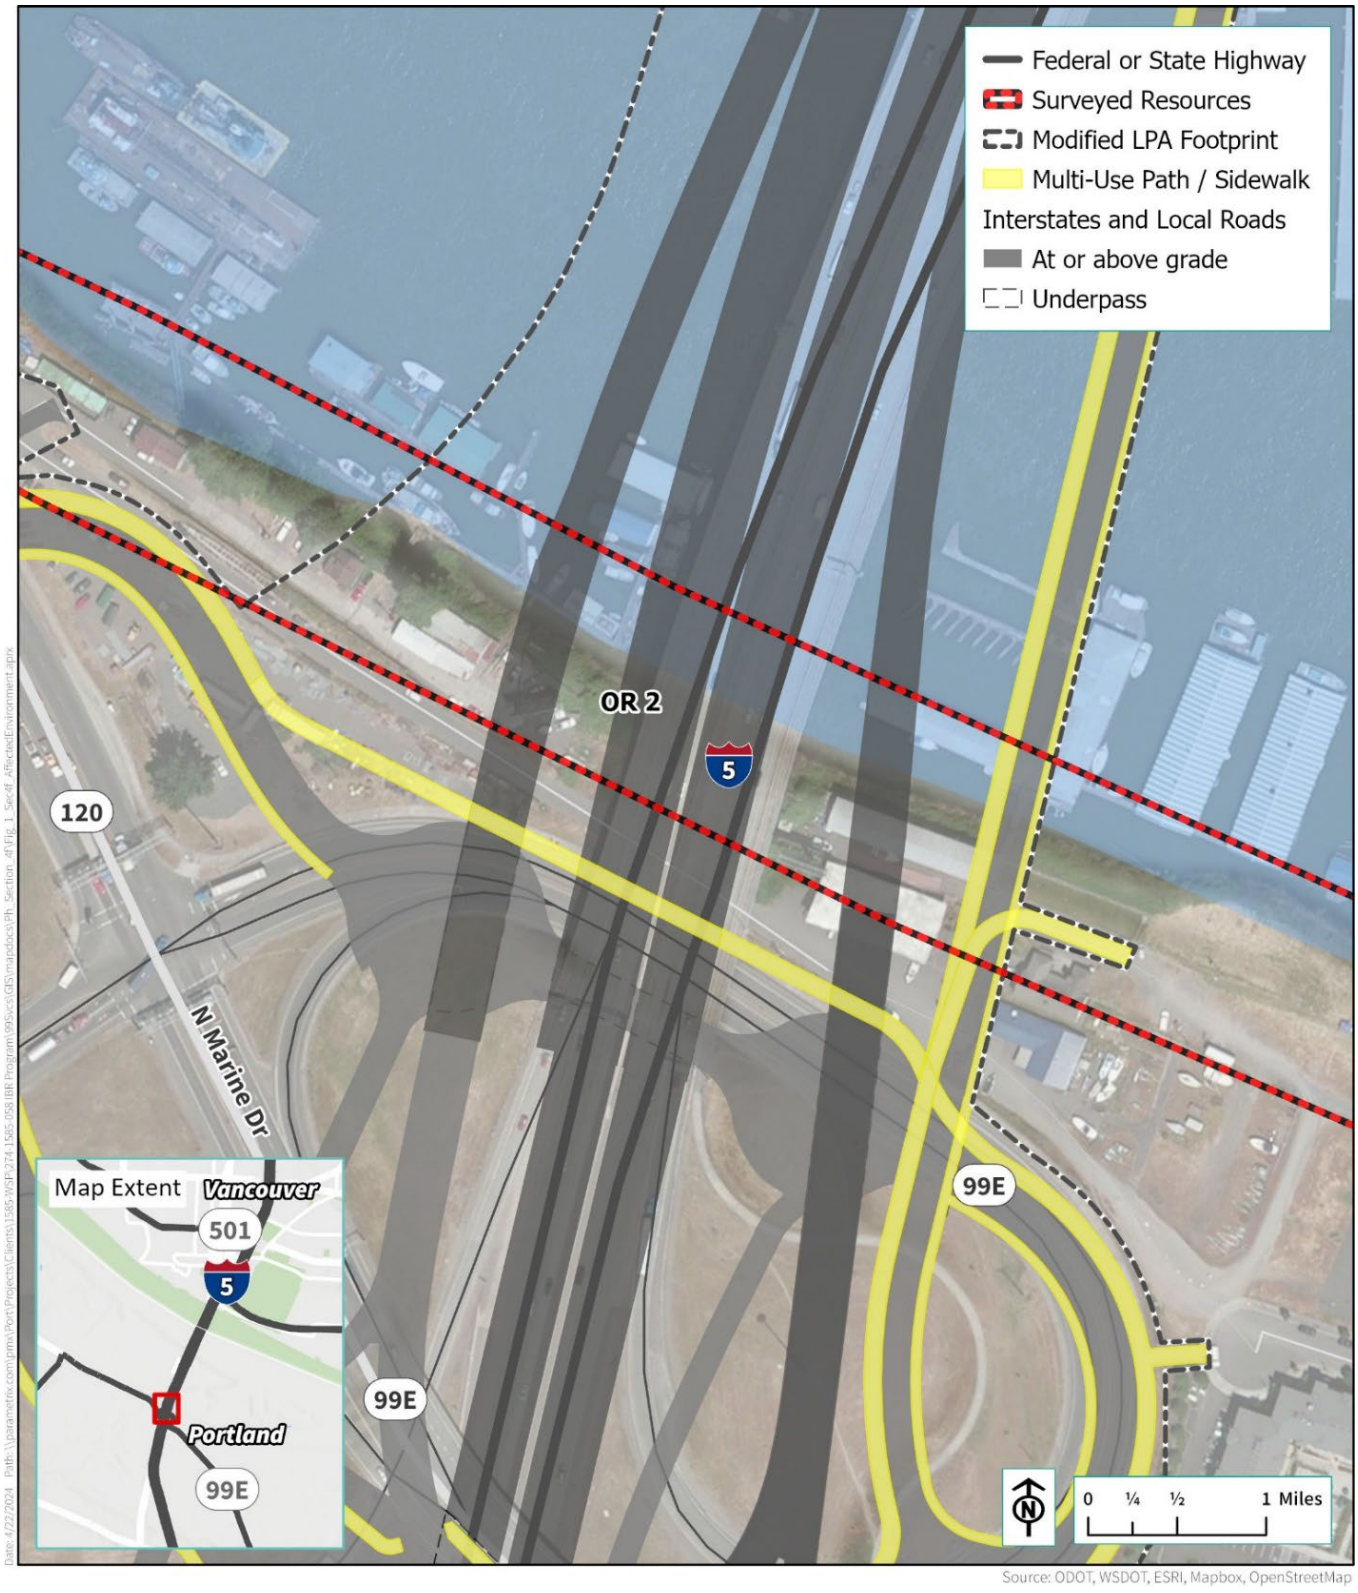


Figure 4-25. IBR Program Improvements and Area of Permanent Incorporation for the Columbia Slough Drainage Districts Historic District

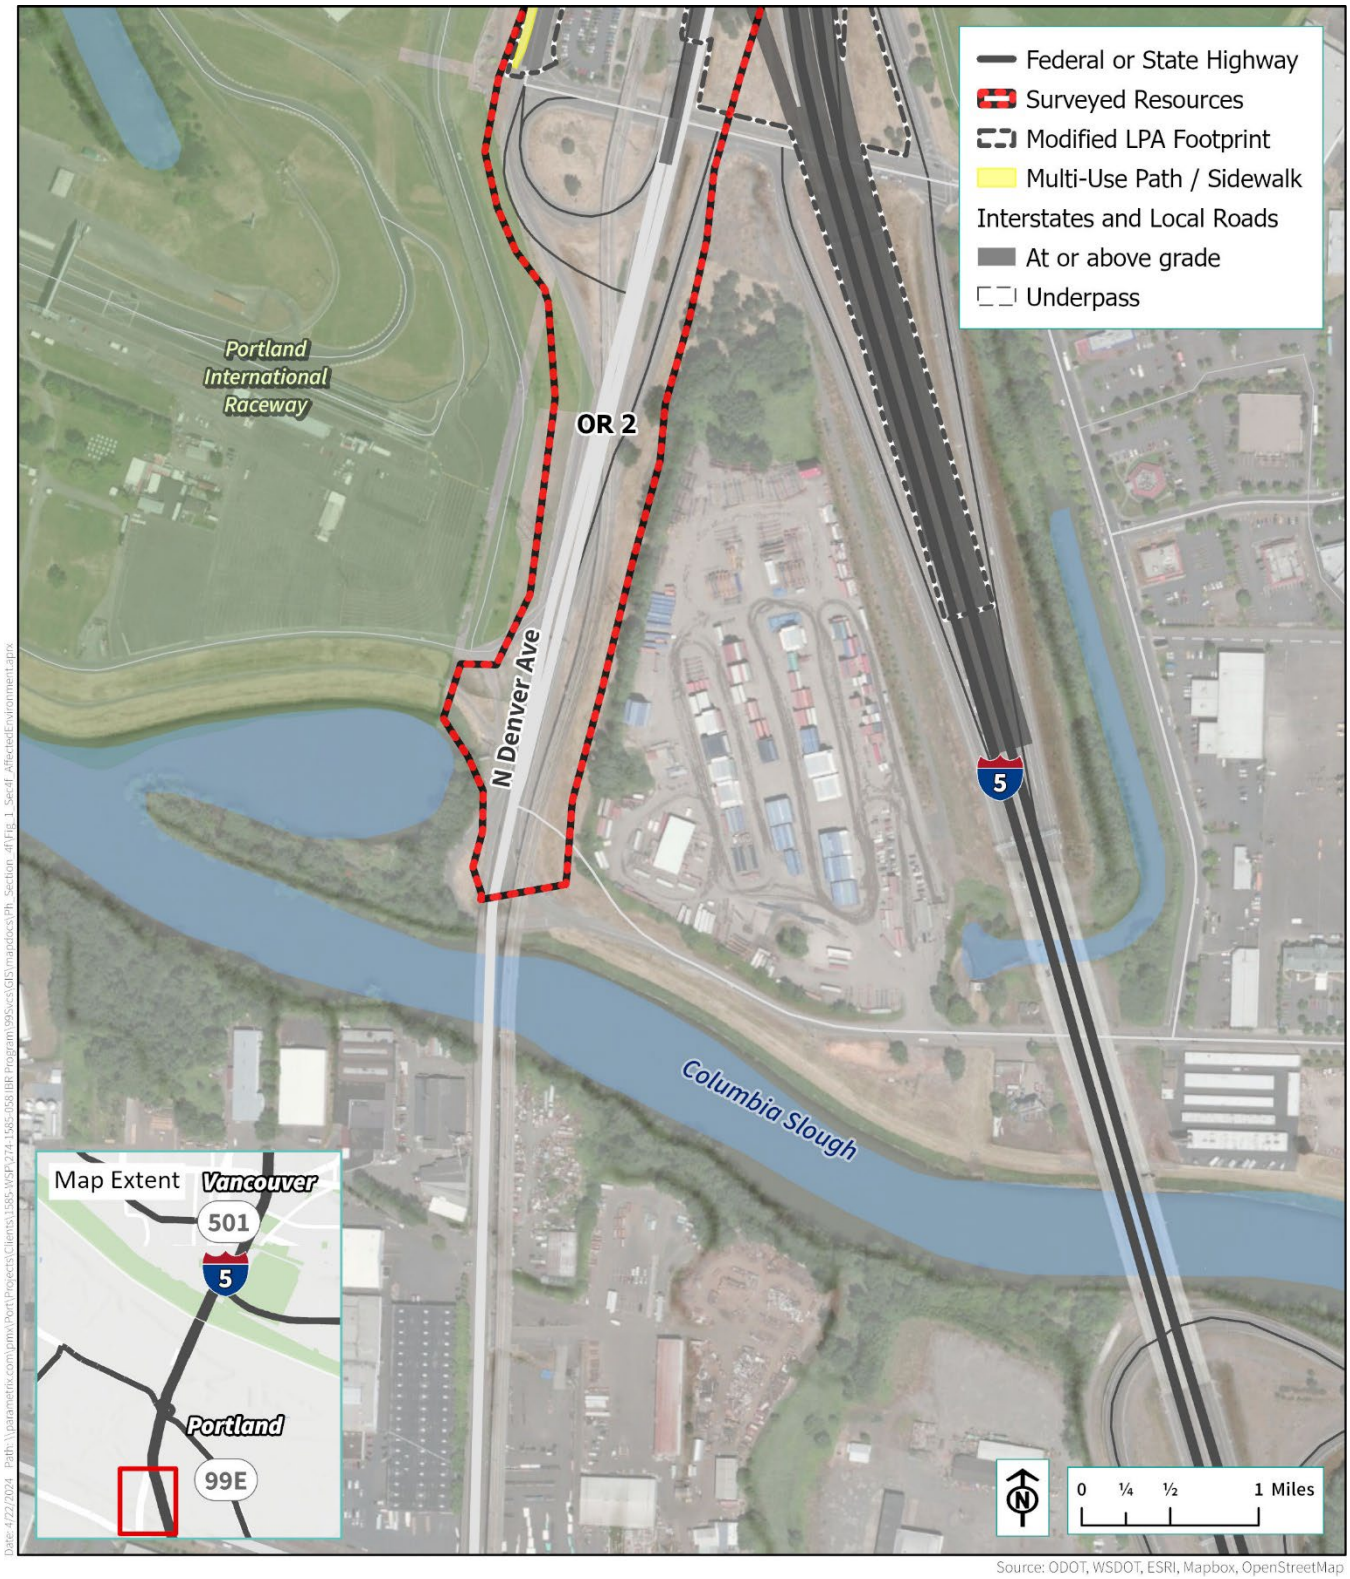


Use Evaluation for the Modified LPA

The Modified LPA straddles the boundary between Peninsula Drainage District No. 1 and Peninsula Drainage District No. 2 and includes portions of four resources that are contributing to the Columbia Slough Drainage Districts Historic District: the Columbia River Levee (Figure 4-24), the Union Avenue/Martin Luther King Jr. Boulevard Cross Levee, the N Denver Avenue Cross Levee, and the Mud Slough Drainage. The Modified LPA, inclusive of all design options, would acquire approximately 182,300 square feet from the historic district, including portions of these four contributing resources. Within the permanent acquisition, the Modified LPA would:

- Reconstruct and widen I-5 between N Victory Boulevard and the Columbia River, on and over portions of the N Denver Avenue Cross Levee, the Mud Slough Drainage, and the Columbia River Levee (Figure 4-25).
- Construct new LRT alignment, new Columbia River bridges, and a new arterial bridge across the North Portland Harbor and over the Columbia River Levee.
- Conduct roadway improvements and create a new shared-use path along N Marine Drive to the west of I-5, on the Columbia River Levee.
- Conduct roadway improvements and create new shared-use paths along N Martin Luther King Jr. Boulevard, NE Union Court, and N Vancouver Way to the east of I-5, on and beside the Union Avenue/Martin Luther King Jr. Boulevard Cross Levee.
- Conduct roadway improvements and create a new shared-use path along N Expo Road, at the west side of the N Denver Avenue Cross Levee.
- Conduct roadway improvements along N Denver Avenue to the north of N Victory Boulevard, on the N Denver Avenue Cross Levee.
- Create new stormwater facilities near N Victory Boulevard and N Denver Avenue and around the I-5 Martin Luther King Jr. Boulevard overpass.

The Modified LPA would not require major changes to the alignments, heights, or widths of the Columbia River Levee, the Union Avenue/Martin Luther King Jr. Boulevard Cross Levee, or the N Denver Avenue Cross Levee, nor would it require infill of the Mud Slough Drainage. As such, the Modified LPA would not substantially impair the character-defining features of the contributing levees and slough, and it would therefore not diminish the Columbia Slough Drainage Districts Historic District's integrity of location, materials, design, or workmanship such that the district could no longer convey its significant development history and engineering merit. While the Modified LPA would alter approximately 182,300 square feet of infrastructure within and around the historic district, it would not change the location of contributing resources or the overall character of the surrounding setting. The Columbia Slough Drainage Districts Historic District would, overall, retain integrity of setting, feeling, and association during construction and after the Program is completed.

Temporary occupancy of other areas within the Columbia Slough Drainage Districts Historic District during construction of the Modified LPA, inclusive of all design options, would include approximately 140,800 square feet for a temporary construction easement to accommodate construction activities, in addition to the area of permanent incorporation. The temporary occupancy area, which was considered in the Section 106 FOE for the historic district, would be a small portion of the overall district and would not adversely affect the qualities of the district that make it eligible for the NRHP.

In conclusion, the Modified LPA would not substantially impair the activities, features, or attributes that contribute to the Columbia Slough Drainage Districts Historic District's NRHP eligibility. The Section 10 FOE for the district therefore includes a finding of "No Adverse Effect" for the Modified LPA. Based on this finding,

and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have found that the Modified LPA would result in a *de minimis* impact for permanent incorporation to this site.

Preliminary Determination

The acquisition of right of way within the Columbia Slough Drainage District Historic District, including from contributing resources, would constitute a use under Section 4(f). The Section 106 FOE for the Columbia Slough Drainage Districts Historic District is "No Adverse Effect" for the Modified LPA, including all design options; the Oregon SHPO concurred with this finding on March 18, 2024. Based on this finding, and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have determined that the Modified LPA and its design options would have a *de minimis* impact on the Columbia Slough Drainage Districts Historic District.

Portland Assembly Center (Map ID – OR 56)

Description

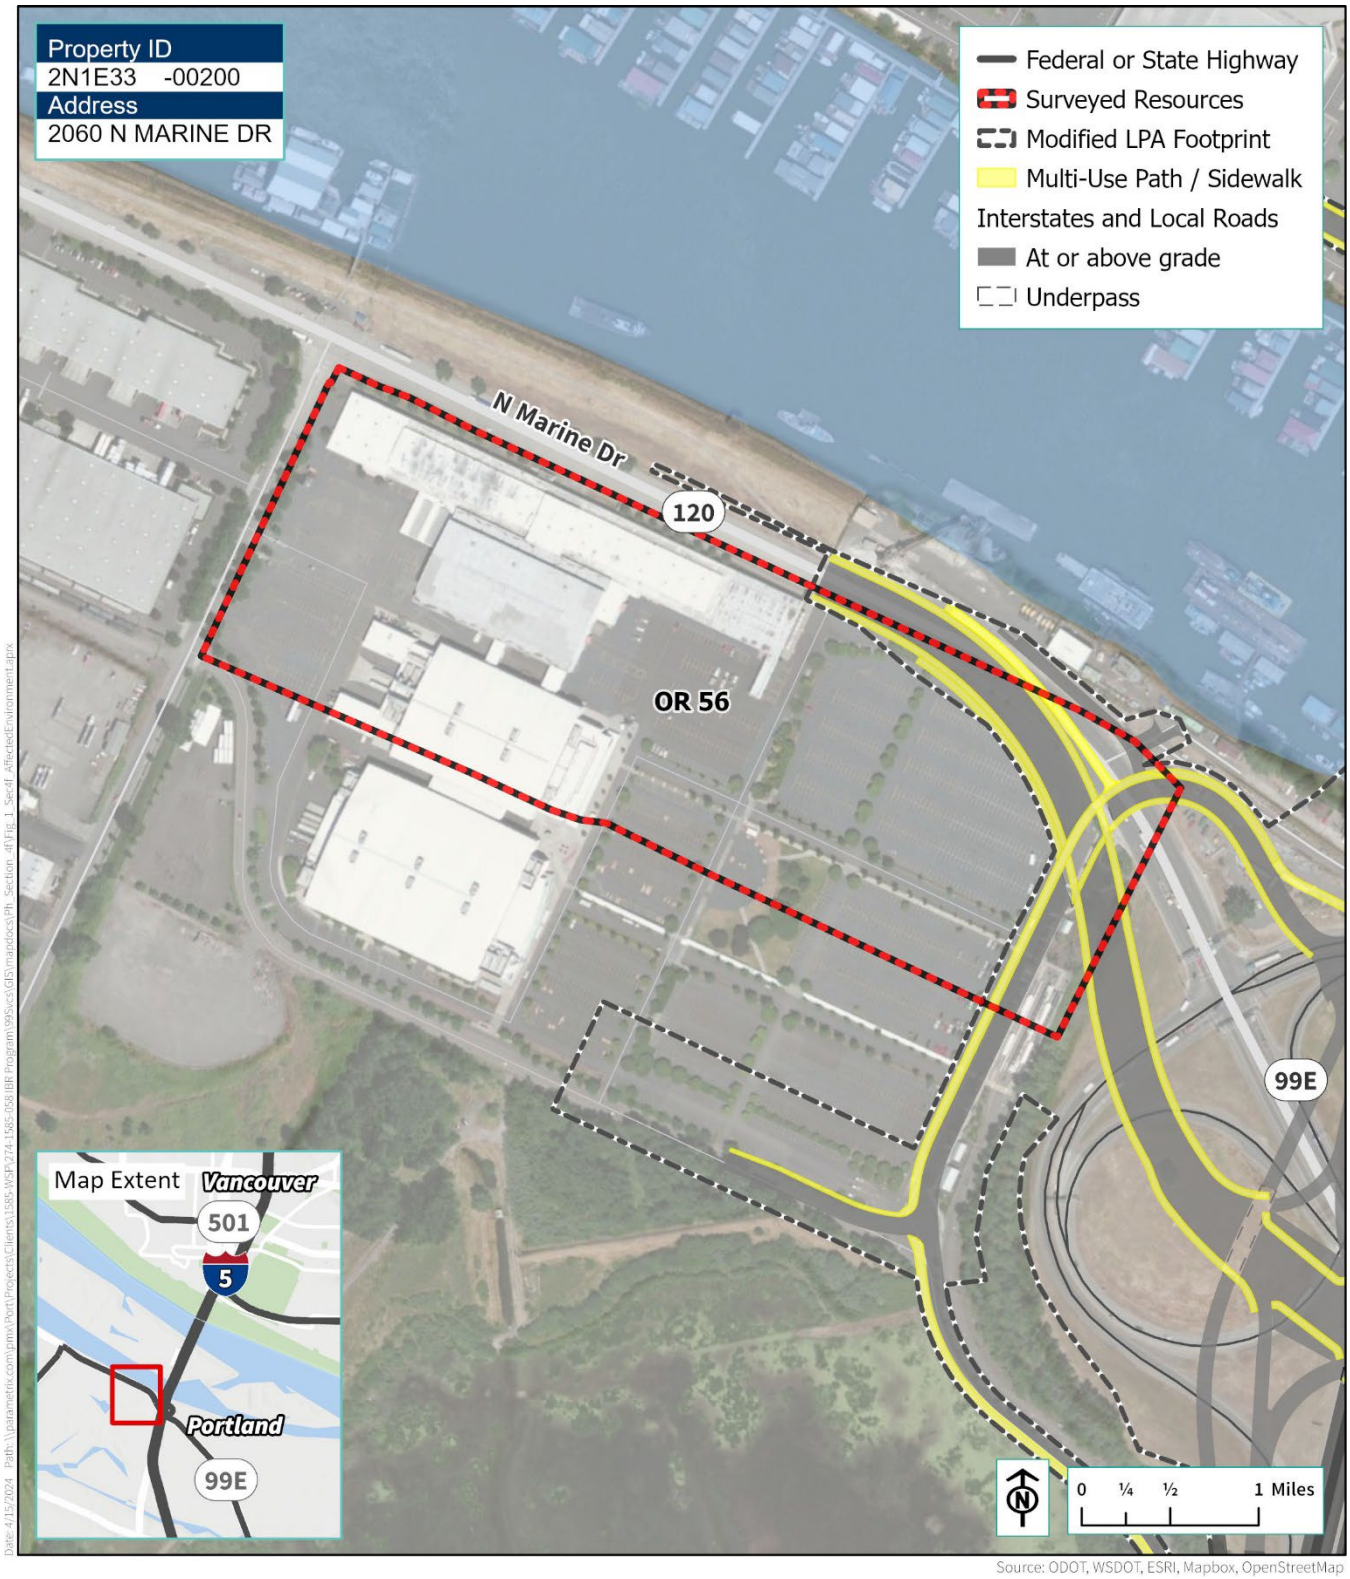
The Portland Assembly Center, located at 2060 North Marine Drive in Portland, is a Georgian Revival and Modern building comprising five interconnected exposition halls built between 1924 and 2001. It is commonly known as the "Portland Expo Center." The Portland Assembly Center is eligible for the NRHP under Criterion A for its association with the World War II Homefront and the events of Japanese American incarceration. The period of significance for the NRHP-eligible Portland Assembly Center is limited to 1942, corresponding to the period of Japanese American incarceration at the site. The historic site is one of only 16 Temporary Assembly Centers originally designated by the Wartime Civil Control Administration and is the only such site in Oregon, making it unique in its association with this period. Its boundary is the area that was contained within the barbed wire fence of the 1942 facility; this is contained within the larger tax lot (R323452). Within the boundary, character-defining features of the site include the essential physical features of Halls A, B, and C that date to the period of significance and those aspects of setting and location that were conducive to its selection as an assembly center: namely the site's flat topography; orientation along the Columbia River; views of North Portland Harbor and the Columbia River Levee; proximity to nearby population centers and transportation infrastructure including the roadway, waterway, and rail lines; its semi-industrial land use, which allowed for immediate availability of energy and water; and its spatial arrangement including the open east half of the site and covered space for shelter and recreation.

The Portland Assembly Center was determined eligible for the NRHP in 2023, in an evaluation process carried out as part of the IBR Program. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Oregon SHPO on March 18, 2024.

Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would permanently acquire 244,800 square feet of property from the far southern, eastern, and western edges of the Portland Assembly Center site within and adjacent to the parking lot. Within the area of permanent acquisition, activities would include modifications to Marine Drive West, along the eastern side of the Portland Assembly Center's historic boundary, and the construction of a new light-rail vehicle overnight facility to the south of the property, outside of its historic boundary (see Figure 4-26).

Figure 4-26. IBR Program Improvements and Area of Permanent Incorporation for the Portland Assembly Center



Both of these areas have been substantially altered since the site's 1942 period of significance by the installation of a surface parking lot and various landscaping features such as sidewalks and vegetated islands. The permanent acquisition and effect of the Modified LPA upon the Portland Assembly Center would not further reduce the site's integrity because the incorporated area has no remaining integrity from the period of significance.

Temporary occupancy of the Portland Assembly Center during construction of the Modified LPA, inclusive of all design options, would include 1,408,700 square feet. Proposed activities would not adversely affect the features of the site that make it eligible for the NRHP. Specifically, these activities would not alter the essential physical features of Halls A, B, and C that date to the 1942 period of significance, nor would they alter the site's spatial arraignment, relatively flat topography, orientation along the Columbia River, views of North Portland Harbor and the Columbia River Levee, proximity to nearby population centers and transportation infrastructure, or semi-industrial land use.

The permanent acquisition and the temporary occupancy of the Portland Assembly Center would result in a Section 106 finding of "No Adverse Effect" for the Modified LPA.

Preliminary Determination

The acquisition of right of way from the Portland Assembly Center would constitute a use under Section 4(f). The Section 106 FOE for the Portland Assembly Center is "No Adverse Effect" for the Modified LPA and its design options; the Oregon SHPO concurred with this finding on March 18, 2024. Based on this finding, and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have determined that the Modified LPA, including all design options, would have temporary and permanent *de minimis* impacts on the Portland Assembly Center.

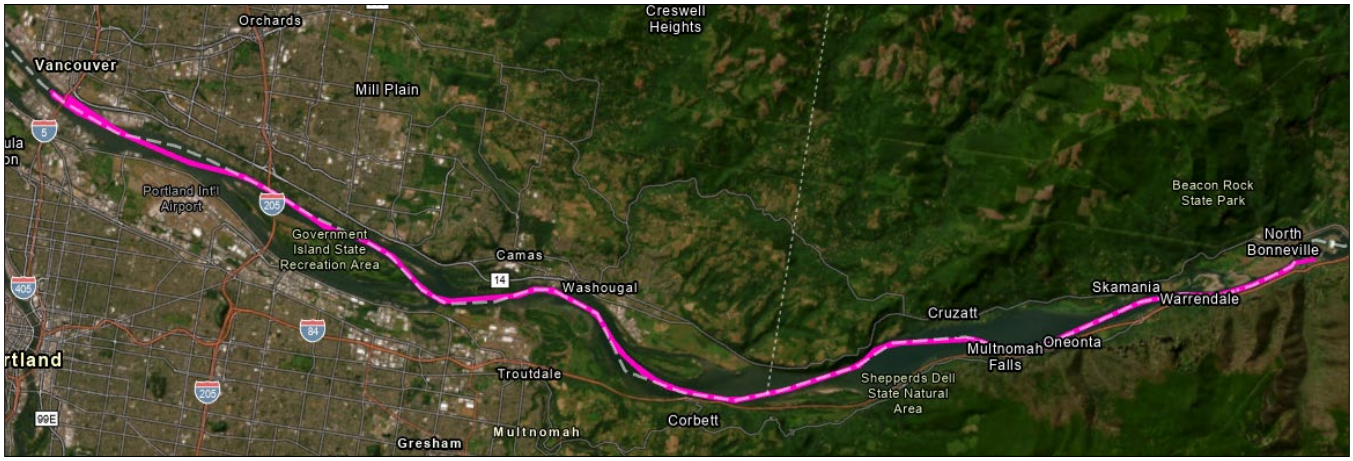
Lower Columbia River Federal Navigation Historic District (Map ID – OR 165)

Description

The Lower Columbia River Federal Navigation Historic District (LCR Nav Historic District), located along the Columbia River from its mouth (River Mile [RM] 3) to the Bonneville Lock and Dam (RM 145), is a series of structures built and maintained by USACE starting in 1873. USACE's federal navigation system along the LCR has helped develop the Pacific Northwest and build its economy by allowing for safe transport of imports and exports, and it also represents a major engineering feat. The boundary for the LCR Nav Historic District encompasses a series of noncontiguous structures, including navigation channels that extend from RM 3 to RM 145, six turning basins, 41 pike dike systems, and nine landforms created from dredge materials. Figure 4-27 depicts the extent of the Lower Columbia River Federal Navigation Channel (LCR FNC), which is one of the district's contributing structures.

The LCR Nav Historic District was determined eligible for the NRHP under Criterion A in the areas of commerce and maritime history and under Criterion C in the area of engineering, in a draft nomination prepared for the USACE in 2023. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the Modified LPA and its design options. The finding received concurrence from the Washington State DAHP on October 13, 2023, and from the Oregon SHPO on March 18, 2024.

Figure 4-27. Aerial Map of the Lower Columbia River Federal Navigation Channel



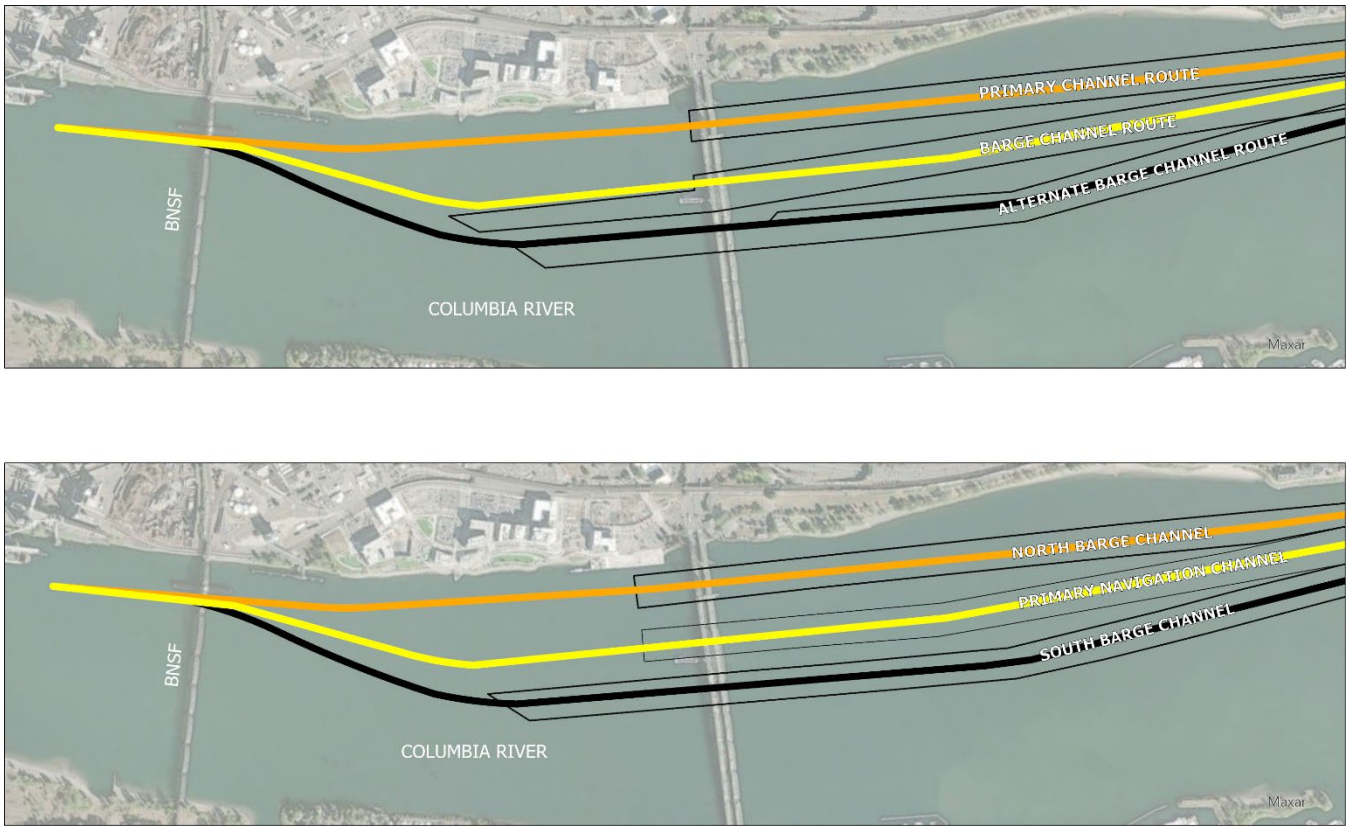
Source: USACE 2023

Use Evaluation for the Modified LPA

The Modified LPA would construct two adjacent bridges carrying I-5 across the Columbia River located immediately downstream (west) of the existing Interstate Bridge, and temporary in-water staging/work areas extending up to approximately 1,000 feet upstream (east) of the existing bridges and up to approximately 1,000 feet downstream (west) of the proposed bridges. These activities would occur over a small portion of two of the district's contributing resources: the LCR FNC from Vancouver to Bonneville Lock and Dam and the Upper Vancouver Turning Basin. The LCR FNC from Vancouver to Bonneville Lock and Dam contains three navigation channel routes (primary, barge, and alternate barge) which would be revised to correspond with the maximum vertical clearance and air draft provided by the proposed bridges. Subject to approval by USACE and U.S. Coast Guard (USCG), the channel routes would be slightly realigned, and the relative locations of the primary navigation channel (currently the northernmost route) and the barge channel (currently the middle route) would be switched so that the north barge channel would become the northernmost route and the primary navigation channel would become the middle route; the relative location of the alternate barge channel (the south barge channel) would remain the same, as would the width of the overall FNC (Figure 4-28). The Upper Vancouver Turning Basin, which marks the west end of the FNC, would shift downstream between approximately 300 and 325 feet to maintain its approximately 2,000 feet of length under the Modified LPA with all design options; its existing width of approximately 800 feet also would be maintained (Figure 4-29).

While these Program-related activities would result in alterations to the district, they would be minor, limited to the margins of two of the contributing structures within the more than 140-mile-long district, and would not reduce the integrity of location, setting, materials, design, workmanship, feeling, and association of either structure or of the district as a whole. Both the contributing structures and the district would retain their integrity and character-defining features under the Modified LPA.

Figure 4-28. Existing and Proposed Channel Routes within the Lower Columbia River Federal Navigation Channel



Note: Top figure shows the Existing Channel Routes within the LCR FNC from Vancouver to Bonneville Lock and Dam. Bottom figure shows the Proposed Channel Routes within the LCR FNC from Vancouver to Bonneville Lock and Dam. The proposed exchange of the relative location of the barge channel route (orange) and the primary channel route (yellow) (IBR, "Navigation Impact Report," rev. May 2022, 2-21) subject to approval by USACE and USCG.

Figure 4-29. Upper Vancouver Turning Basin

NOTE: The red outline denotes the boundary of the Upper Vancouver Turning Basin. The green outlines denote the location of the Lower Columbia River federal navigation channel (including its three channel routes) from Vancouver, Washington (RM 106.5) to Bonneville Lock and Dam (RM 145) (USACE 2023).

Temporary occupancy of the LCR Nav Historic District under the Modified LPA would include temporary in-water staging/work areas extending up to approximately 1,000 feet upstream (east) of the existing bridge and up to approximately 1,000 feet downstream (west) of the proposed bridges. This was considered in the Section 106 FOE for the historic site and was determined to not adversely affect the qualities of the site that make it eligible for the NRHP.

The Section 106 FOE for the historic district includes a finding of "No Adverse Effect" for the Modified LPA.

Preliminary Determination

The acquisition of right of way within the LCR Nav Historic District, including from contributing resources, would constitute a use under Section 4(f). The Section 106 FOE for the LCR Nav Historic District is "No Adverse Effect" for the Modified LPA, including all design options; the Washington DAHP and Oregon SHPO concurred with this finding on October 13, 2023, and March 18, 2024, respectively. Based on this finding, and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have determined that the Modified LPA and its design options would have a *de minimis* impact on the district.

4.3.7 Use of the Interstate Bridge

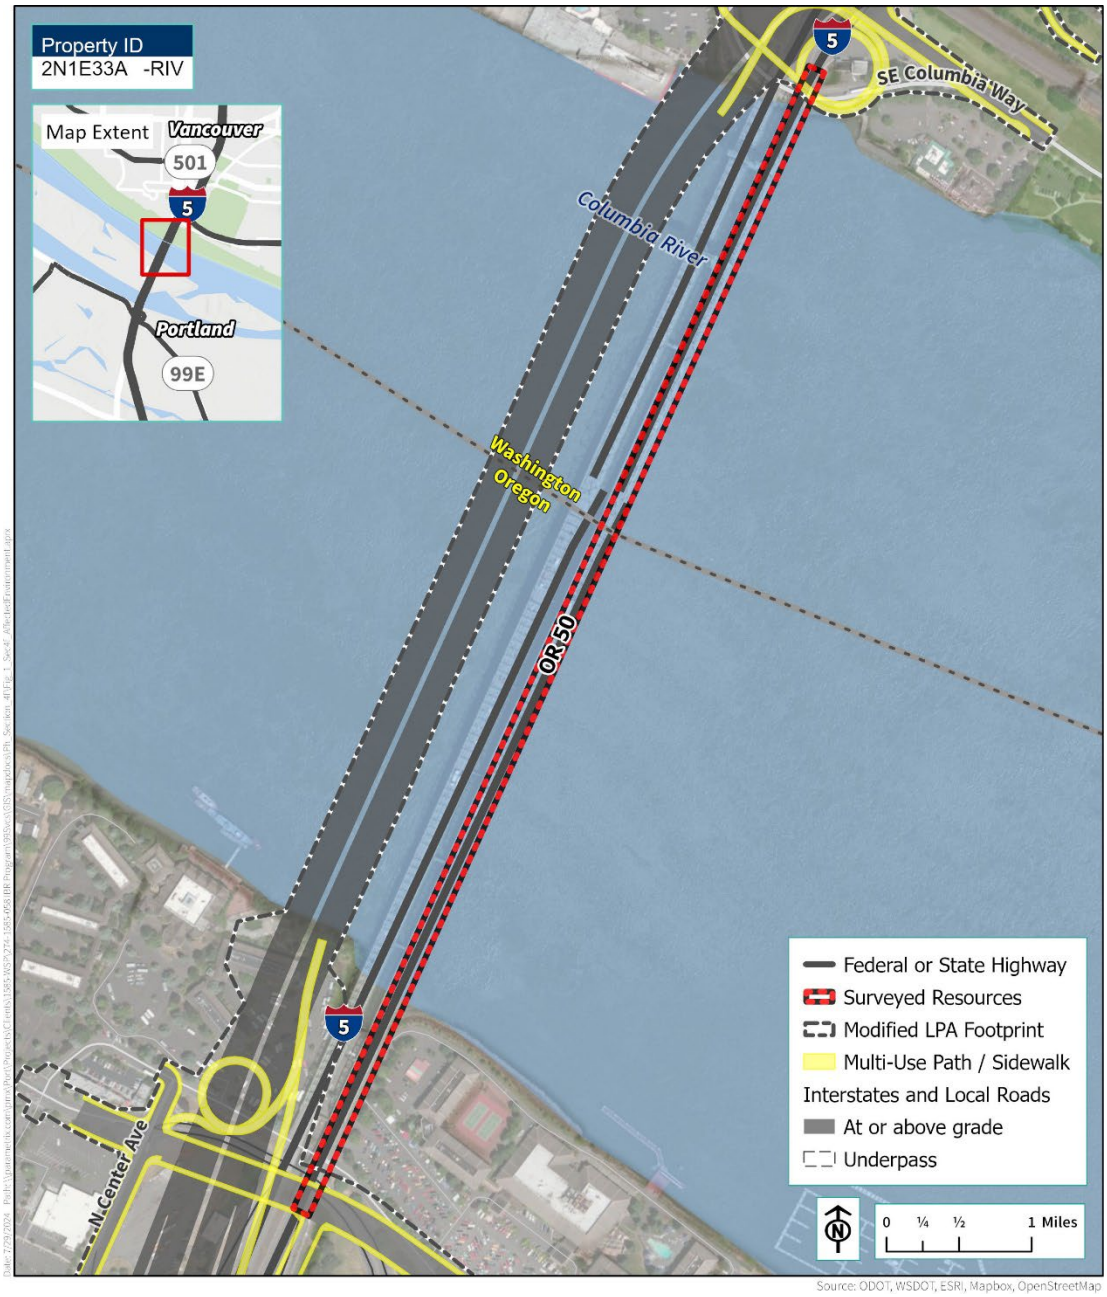
Northbound Interstate Bridge (Map ID – OR 50 and WA 381a)

Description

The northbound Interstate Bridge is a steel truss bridge (see Figure 4-30) that crosses the Columbia River between Portland and Vancouver. Completed in 1917 and modified in 1958, the bridge spans the Columbia River and measures 3,538 feet in length. The main span of the bridge in Vancouver is a steel through truss vertical lift span of the Pennsylvania-Petit type. The vertical lift span, when fully raised, creates a waterway clearance channel that measures 250 feet laterally and 178 feet vertically (above ordinary low water). The bridge is also composed of 10 steel through Pennsylvania truss secondary spans, which range in length from 266 to 531 feet. The bridge was retrofitted in 1958 to mimic the design of the westerly, southbound bridge.

The northbound Interstate Bridge was listed in the NRHP in July 1982 under Criteria A and C. The bridge is listed under Criterion A as a major engineering and financial accomplishment being the first highway bridge across the Columbia River to connect between the states of Oregon and Washington and is listed under Criterion C as an early example of a vertical lift steel bridge and an example of a bridge built by the engineering firm Harrington, Howard and Ash—renowned bridge engineers during the 20th century. The bridge maintains its integrity of location, design, materials, workmanship, and setting, and its boundary is the entirety of the northbound bridge structure and also includes approach spans, sidewalks, and other appurtenances related to the transportation use of the bridge. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Washington DAHP on October 13, 2023, and from the Oregon SHPO on March 19, 2024.

Figure 4-30. IBR Program Improvements and Area of Permanent Incorporation for the Northbound Interstate Bridge



Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would replace the existing Interstate Bridge with new bridges, which would necessitate the removal of the existing northbound Interstate Bridge (see Figure 4-30). The demolition of the existing bridge would destroy the structure's integrity of location, design, setting, materials workmanship, feeling, and association, and would therefore constitute an "Adverse Effect" to this NRHP-listed structure under Section 106. The northbound Interstate Bridge would be permanently incorporated by the demolition, removal, and replacement for the Modified LPA, constituting a use of this historic site under Section 4(f).

As the entire historic site would be permanently incorporated, there would be no temporary occupancy of the northbound Interstate Bridge by the Modified LPA, including all design options.

Preliminary Determination

The Modified LPA and its design options would all require the acquisition of the northbound Interstate Bridge and its subsequent removal, which would render the historic site no longer eligible for the NRHP. Consistent with the definition of use set forth in 23 CFR 774.17, which notes that a use of Section 4(f) property occurs "when land is permanently incorporated into a transportation facility," FHWA and FTA have determined that the Modified LPA and its design options would result in a use under Section 4(f) for the northbound Interstate Bridge. None of the exceptions under 23 CFT 774.13 would apply.

4.3.8 Use of Section 4(f) Historic Sites (Washington)

Historic Sites Evaluated to Have No Section 4(f) Use

Permanent Incorporation and Temporary Occupancy (Modified LPA with All Design Options) - No Use

Sites with No Effect under Section 106

Eleven historic sites listed in Table 4-7 were evaluated under Section 106 to have a finding of "No Effect" in Vancouver. None of these historic sites would be permanently incorporated or temporarily occupied by the Modified LPA or the design options. Therefore, there would be no direct use under Section 4(f) of these resources and the sites are not evaluated further for permanent incorporation or temporary occupancy.

Sites with Subsurface Easements

Two historic sites listed in Table 4-7, the Porter House and Hall House, were evaluated under Section 106 to have a finding of "No Adverse Effect" in Vancouver. These sites would require subsurface easement on portions of the site for installation of subterranean tie-back anchors (see Appendix D of the Historic Built Environment Technical Report for FOEs). No other permanent or temporary use of these properties would occur. Per Question 28A of the *Section 4(f) Policy Paper* (FHWA 2012), Section 4(f) applies to tunneling or other subsurface-only activities if they:

- Disturb archaeological sites that are on or eligible for the NRHP, which warrant preservation in place;
- Cause disruption that would permanently harm the purposes for which the park, recreation, wildlife or waterfowl refuge was established;
- Substantially impair the historic values of a historic site; or
- Otherwise do not meet the exception for temporary occupancy.

Of these, only the third and fourth bullets (historic sites and temporary occupancy) are relevant to analysis of built historic sites such as those in Table 4-7, none of which have associated known archaeological sites or function as public parks. Installation and use of tie-back anchors would neither result in a change to the property's physical, auditory, or visual setting; cause vibration sufficient to damage these sites; or inhibit access to the sites. Therefore, subterranean installation of tie-back anchors would not substantially impair the historic integrity of these sites. Section 4(f) would not apply to the subterranean easements to accommodate tie-back anchors. Surface-level constructive activities would not enter the historic boundary of these sites. Therefore, the Modified LPA or design options would not permanently incorporate or temporarily occupy lands within the boundary of these sites or alter their character-defining features to construct the project.

Constructive Use

A constructive use does not occur when compliance with the requirements of 36 CFR 800.5 (Assessment of adverse effects) for proximity impacts of the proposed action, on a site listed on or eligible for the NRHP, results in an agreement of "No Effect" or "No Adverse Effect" (23 CFR Section 774.15). The Section 106 evaluation for the Program determined that there would be "No Effect" or "No Adverse Effect" on the historic sites listed in Table 4-7. Because the Program would have "No Effect" or "No Adverse Effect" on the historic sites, it would not substantially impair the activities, features, or attributes of the Section 4(f) properties and, therefore, it would not have a constructive use of the historic sites.

Table 4-7. Historic Sites (Vancouver) – No Use under Section 4(f)

Section 106 Determination	Site ID	Historic Site
No Historic Properties Affected ("No Effect")	WA 7	Fendrich's Furniture
	WA 10	Smith Tower
	WA 29	U.S. National Bank Building
	WA 191	William H. and Myrtle Hood Residence
	WA 382	Radio Transmission Building
	WA 900	Covington House
	WA 1144	Office Building
	WA 1182	Rudy Luepke Center for Senior Citizens
	WA 1233	Earls House
	WA 1319	Vancouver Barracks National Cemetery
	WA 1320	St. James Acres Cemetery
No Historic Properties Adversely Affected ("No Adverse Effect") – Historic Sites with Subsurface Easements Only	WA 61	Porter House
	WA 62	Hall House

Historic Sites Evaluated to Have Temporary Occupancy Exception under Section 4(f)

2901 K Street (Map ID – WA 1168)

Description

The buildings at 2901–03 and 2905–07 K Street (collectively referred to as 2901 K Street) are single-story, Contemporary-style duplexes constructed in 1968 and located on a single tax lot in the Rose Village neighborhood of Vancouver, Washington (see Figure 4-31). The dup lexes are eligible for listing in the NRHP under Criterion A at the local level of significance in the area of community planning and development, as well as under Criterion C in in the area of architecture.

Figure 4-31. IBR Program Improvements and Area of Permanent Incorporation for 2901 K Street

The boundary for the historic site is defined by the tax lot boundary and includes both buildings, their shared courtyard, grass lawn, and rear concrete driveways. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Washington DAHP on October 13, 2023.

Use Evaluation for the Modified LPA

The Modified LPA would require widening the I-5 roadway to the west of the 2901 K Street site and the reconstruction of the I-5 overcrossing at E 29th Street. In all design options, the construction of new pedestrian and bicycle facilities at the E 29th Street overcrossing would involve improvements to the K Street and E 29th Street intersection, which is immediately southwest of the 2901 K Street site. The replacement of the overcrossing and improvements to pedestrian and bicycle facilities would result in negligible visual changes and would not alter the residential character of the historic site and its association with development history or Contemporary-style architecture. Furthermore, these activities would not require any permanent right of way from the historic site. As such, there would be no permanent incorporation of the 2901 K Street site.

The Modified LPA would, however, require an approximately 300-square-foot temporary construction easement that extends to the site's southwest corner, which presently contains a portion of the site's grass lawn and a single mature ornamental shrub. The temporary occupancy of the 2901 K Street site for the Modified LPA, inclusive of all design options, would meet the conditions required for exceptions (23 CFR 774.13(d)), including:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

The easement would be needed for a duration less than the construction period for the project.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal

Surface-level construction activities are not anticipated to enter the tax lot of 2901 K Street, which is the boundary for the historic site, nor would any additional structures or elements be constructed within the boundary. Overall, the Modified LPA would not substantially impair the site's character-defining features or reduce its integrity and ability to convey its significance. For these reasons, the temporary occupancy of the 2901 K Street site would result in minimal changes to the property in both nature and magnitude.

There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis

There are no anticipated permanent adverse physical impacts to the 2901 K Street site as a result of construction of the Modified LPA, nor would there be interference with the site's character-defining features. These features include its linear massing, Dutch gable roofs, covered parking, shared courtyard, and landscaping elements, including grass lawns and shrubs growing against the building's walls. While the lawn within the temporary construction easement may be removed for construction, it would be restored following completion of construction. The ornamental shrub located in the temporary construction easement would be preserved in place, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties. The historic site would therefore maintain its ability to convey its significant development history and association with the Contemporary style, for which it is eligible for the NRHP. This is supported by the Section 106 FOE for the historic site, which includes a finding of "No Adverse Effect" for the Modified LPA.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and

The Modified LPA would not construct any additional structures or elements within the boundary of the 2901 K Street site. If construction activities within the temporary construction

easement should require the removal of a portion of the lawn, this landscape feature would be restored to its original state when construction completes. The ornamental shrub located in the temporary construction easement would be preserved in place.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Consultation with the official with jurisdiction, the Washington SHPO, is ongoing.

For these reasons, the temporary occupancy of the 2901 K Street site during construction of the Modified LPA satisfies the temporary occupancy exemption criteria and would not constitute a use under Section 4(f).

Preliminary Determination

Based on the analysis above, there would be no Section 4(f) use of the 2901 K Street site by the Modified LPA, including all design options. The Modified LPA, including all design options, would require a small temporary easement at the southwest corner of the historic site, but this would meet the temporary occupancy exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f). The Modified LPA, including all design options, would not result in permanent incorporation of any portion of the site, nor would they lead to a constructive use of the site.

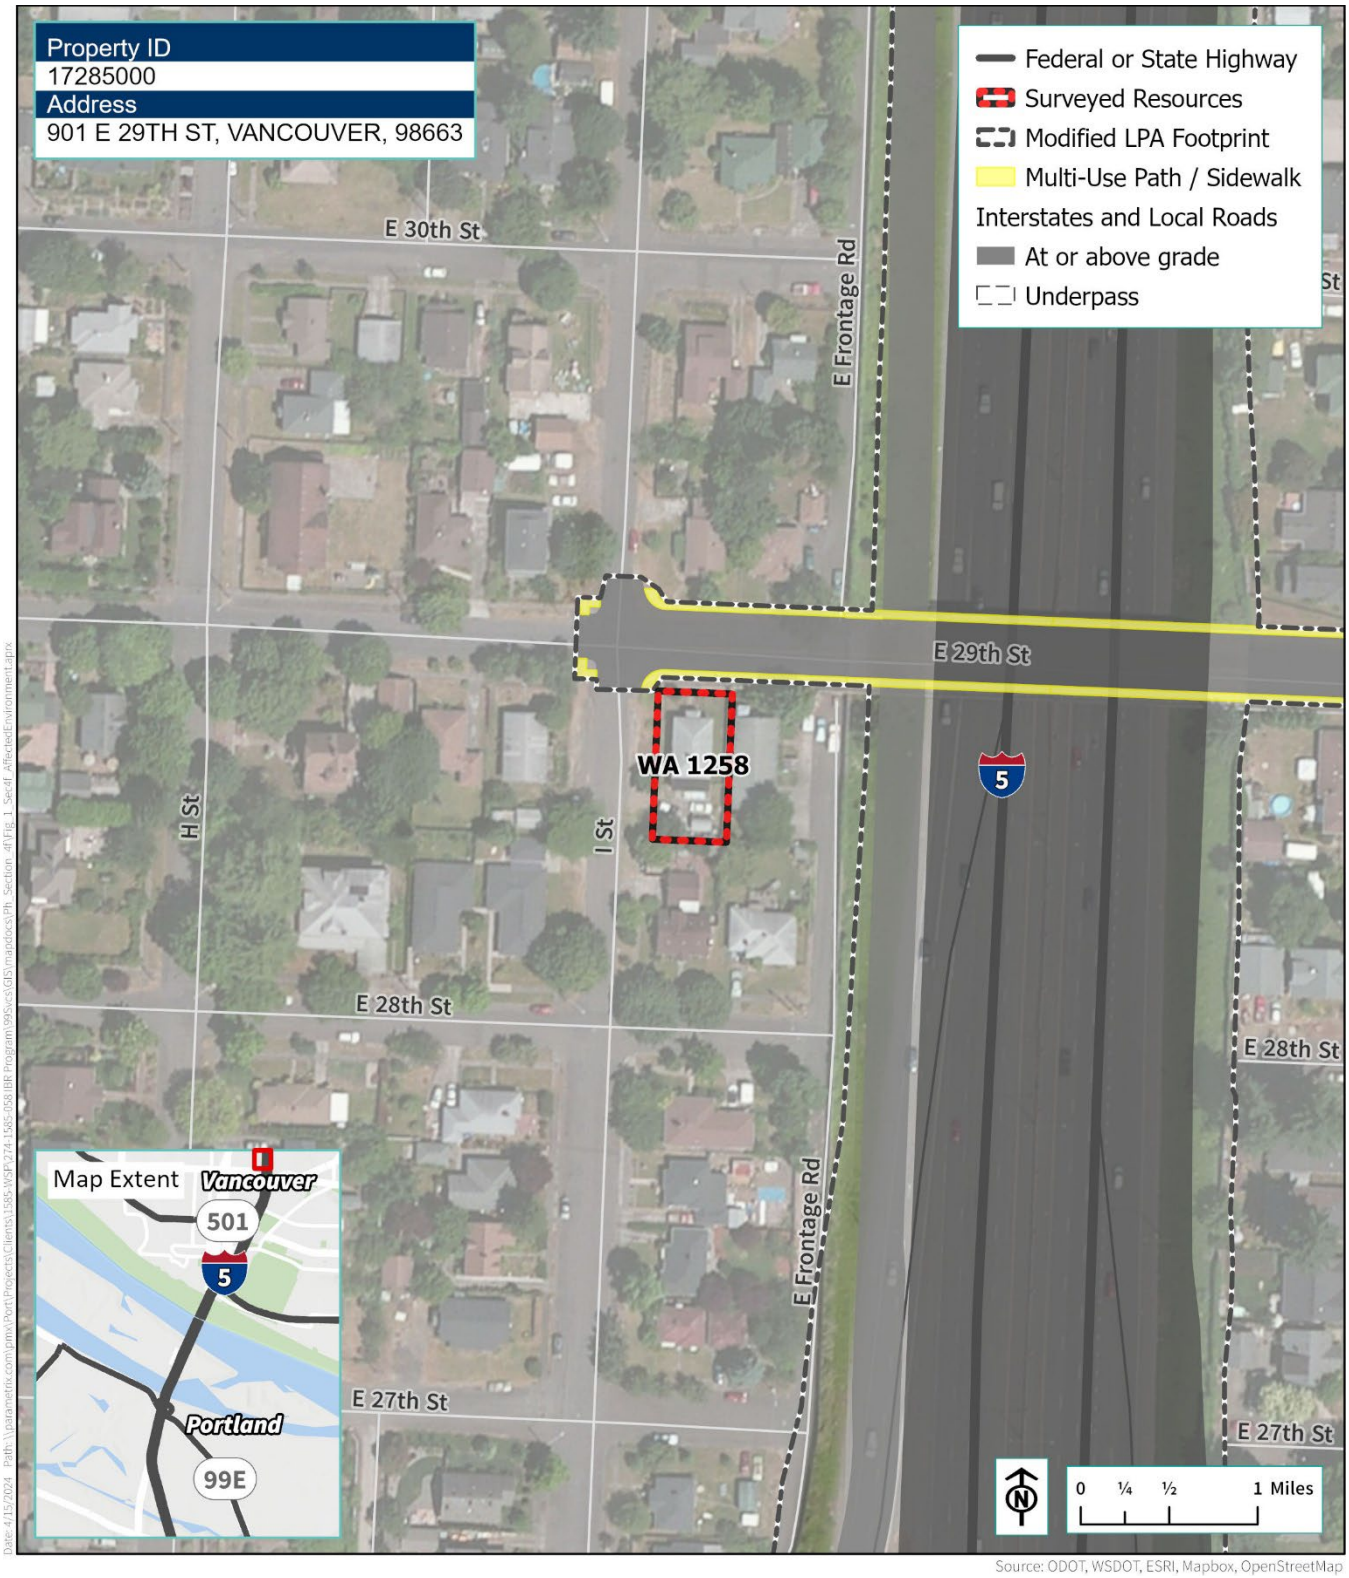
Mickler House (Map ID – WA 1258)

Description

The Mickler House is a Workingman's Foursquare single-family dwelling located at 901 E 29th Street in Vancouver, Washington (see Figure 4-32). Constructed in 1907, the Mickler House is eligible for inclusion in the NRHP under Criterion A at the local level of significance in the area of community planning and development. The dwelling is a particularly early example of development in the area and is also representative of the first wave of urban residents to occupy the Vancouver Heights subdivision, which is now part of the Shumway neighborhood. The building retains its integrity of location, design, workmanship, feeling, and association; however, it has somewhat diminished integrity of setting and materials.

The boundary of the Mickler House site coincides with its tax lot boundaries, which have remained unchanged since the end of the period of significance. Within the boundary, only the residence and the front walkway contribute to the site's significance. All other elements, including the paved driveway, shed, fence, and deck, are noncontributing. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. The finding received concurrence from the Washington DAHP on October 13, 2023.

Figure 4-32. IBR Program Improvements near 901 E 29th Street



Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would reconstruct and widen the I-5 corridor, which is currently separated from the NRHP-eligible Mickler House by one residential parcel, J Street, and a concrete noise wall. Adjacent to the site, the Modified LPA would construct improvements to E 29th Street between the I-5 overcrossing and the I Street intersection. These improvements would potentially include enhancements to pedestrian and traffic access (e.g., sidewalks, curb ramps, signage), but they would not include the reconfiguration of the current roadway or the construction of additional traffic lanes; this section of E 29th Street would remain a two-lane, two-way road. It is anticipated that the Modified LPA would not require any permanent right of way from the Mickler House site. As such, there would be no permanent incorporation of the Mickler House site.

The Modified LPA would, however, require a temporary construction easement of approximately 50 square feet from the northern edge of the Mickler House site. Construction activities within the temporary construction easement could potentially interfere with or require the removal of an existing wood fence that delineates the historic site's tax lot boundary and/or disturb the northern edge of a concrete-paved walkway connecting the north elevation of the Mickler House to the sidewalk along E 29th Street. The temporary occupancy of the site for the Modified LPA, inclusive of all design options, would meet the conditions required for exceptions (23 CFR 774.13(d)), including:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

> The easement would be needed for a duration less than the construction period for the project.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal

> Surface-level construction activities at the Mickler House would be located at the northwest corner of the site. The Modified LPA would not modify any character-defining features of the Mickler House, including its one-story height, hipped roof with boxed eaves, wood tongue and groove siding with flat wood corner boards, double-hung wood windows, or setback from the adjacent streets; nor would it construct additional structures or elements within the boundary of the historic site. Overall, the Modified LPA would not substantially impair the site's character-defining features or reduce its integrity or ability to convey its significance. For these reasons, the temporary occupancy of the Mickler House site would result in minimal changes to the property in both nature and magnitude.

There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis

> There are no anticipated permanent adverse physical impacts to the Mickler House site as a result of construction of the Modified LPA, nor would there be any modification of the site's character-defining features. While the existing wood fence and concrete-paved walkway may be disturbed by construction, the fence does not contribute to the historic site's significance and the fence and walkway would be restored following completion of construction (see below). The historic site would therefore maintain its ability to convey its significant development history, for which it is eligible for the NRHP. This is supported by the Section 106 FOE for the historic site, which includes a finding of "No Adverse Effect" for the Modified LPA.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project.

The Modified LPA would not construct any additional structures or elements within the boundary of the Mickler House site. If construction activities within the temporary construction easement should disturb the northern edge of the concrete-paved walkway or require the removal of the wood fence, these landscape features would be restored to their original state once construction completes.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Consultation with the official with jurisdiction, the Washington SHPO, is ongoing.

For these reasons, the temporary occupancy of the Mickler House site during construction of the Modified LPA would meet the conditions required for exceptions (23 CFR 774.13(d)) and not constitute a use under Section 4(f).

Preliminary Determination

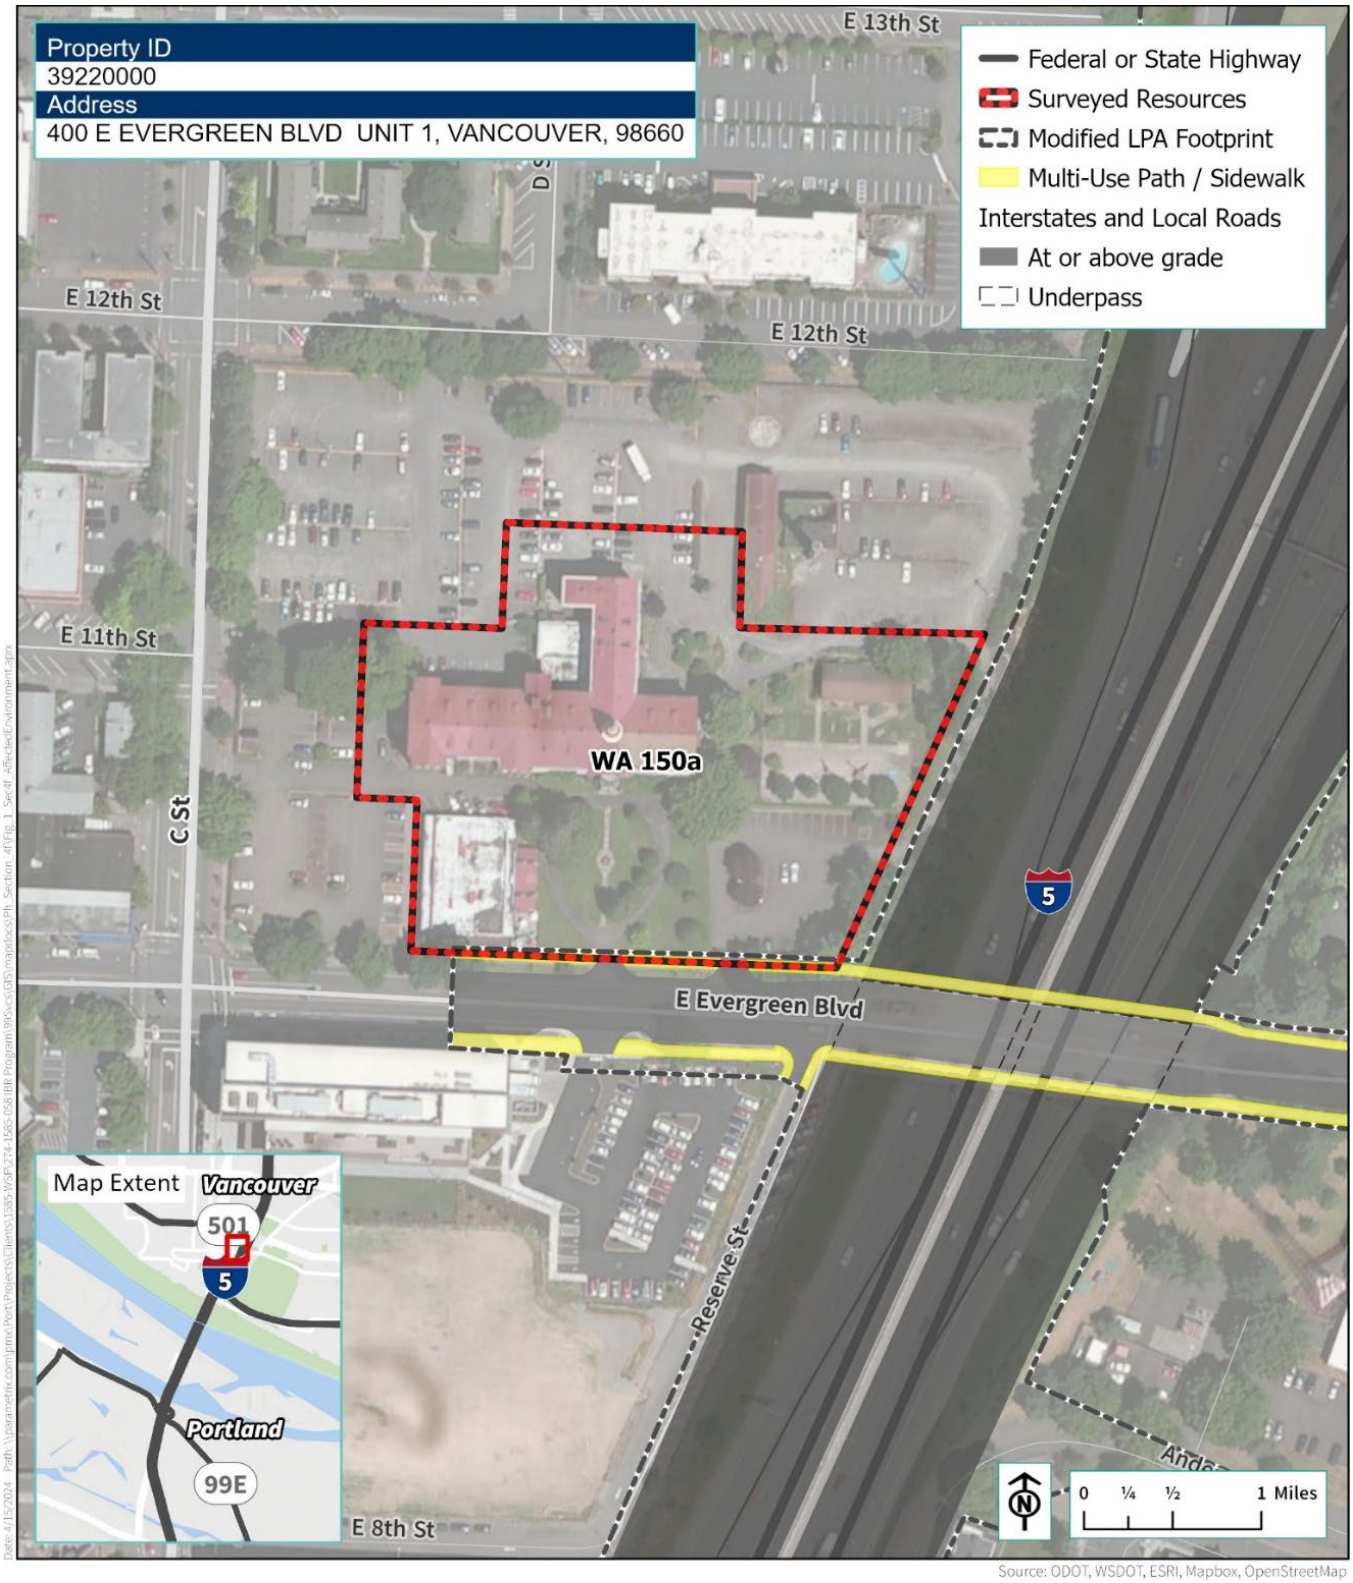
Based on the analysis above, there would be no Section 4(f) use of the Mickler House site by the Modified LPA or its design options. The Modified LPA with all design options would require a small temporary easement at the northern edge of the historic site, but this would meet the temporary occupancy exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f). Neither the Modified LPA nor the design options would result in permanent incorporation of any portion of the site, nor would they lead to a constructive use of the site.

House of Providence (Map ID – WA 150)

Description

The House of Providence (Providence Academy) is an institutional property located at 400 East Evergreen Boulevard in Vancouver, Washington (see Figure 4-33). The property, constructed between 1873 and 1874, contains an ornate, three-story building that is clad in brick and shows the influence of the Georgian/Federal and French Colonial architectural styles. The House of Providence is eligible for listing in the NRHP under Criteria A, B, and C, in recognition of the property's close association with the achievements of Mother Joseph of the Sacred Heart, who was the leader of the Sisters of Providence in the late 19th century and the architect of the House of Providence's primary building.

Figure 4-33. IBR Program Improvements and Area of Permanent Incorporation for House of Providence



The boundary for the House of Providence is defined by the tax lot boundary that contains the NRHP-eligible building and encompasses all extant historic features that convey the institution's original campus-like qualities. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. This received concurrence from the Washington DAHP on February 14, 2024.

Use Evaluation for the Modified LPA

The Modified LPA would reconstruct and widen the I-5 roadway to the east of the House of Providence. Although the widened interstate right of way would not encroach into the boundary of the historic site, the Modified LPA would construct a new retaining wall along the parcel's eastern boundary where no such wall currently exists. This would require one subsurface easement along the eastern edge of the historic site's boundary to accommodate tie-back anchors for the proposed retaining wall along I-5. The subsurface easement would extend approximately 100 feet into the boundary but would remain more than 100 feet from the primary building and its associated landscaping. Per Question 28A of the *Section 4(f) Policy Paper* (FHWA 2012), Section 4(f) applies to tunneling or other subsurface-only activities if they:

- Disturb archaeological sites that are on or eligible for the NRHP, which warrant preservation in place;
- Cause disruption that would permanently harm the purposes for which the park, recreation, wildlife or waterfowl refuge was established;
- Substantially impair the historic values of a historic site; or
- Otherwise do not meet the exception for temporary occupancy.

Of these, only the third (historic sites) and fourth (temporary occupancy) bullets are relevant to analysis of this historic site. At the House of Providence, installation and use of tie-back anchors under the Modified LPA would not result in a change to the site's physical, auditory, or visual setting because they would be entirely underground; cause vibration sufficient to damage the site because they are small diameter anchors drilled into the ground; or inhibit access to the site. Therefore, subterranean installation of tie-back anchors would not substantially impair the historic integrity of the site, and Section 4(f) would not apply to the subterranean easement to accommodate tie-back anchors.

In addition to the subterranean easement at the House of Providence, the Modified LPA would require a 4,700-square-foot temporary construction easement along the site's southern boundary at E Evergreen Boulevard. The easement would extend approximately 10 feet into the House of Providence's boundary, where no character-defining landscape features remain extant. The temporary occupancy of the site for the Modified LPA would meet the conditions required for exceptions (23 CFR 774.13(d)), including:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

The easement would be needed for a duration less than the construction period for the project.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal

The proposed road improvements along E Evergreen Boulevard are limited to the southern edge of the House of Providence Site and would occur more than 100 feet away from the site's primary contributing building. Overall, the improvements would not substantially impair the site's character-defining features or any of the aspects of the site's location or setting that

enable it to convey its significance. For these reasons, the temporary occupancy of the House of Providence would result in minimal changes to the property in both nature and magnitude.

There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis

There are no anticipated permanent adverse physical impacts to the House of Providence as a result of construction of the Modified LPA. Construction would not require the permanent use of this portion of the House of Providence site. The site's character-defining features would remain intact and unaltered, and the Modified LPA would not diminish the site's integrity of location, design, setting, materials, workmanship, feeling, or association despite the proposed temporary construction easement and the adjacent infrastructure improvements. This is supported by the Section 106 FOE for the historic site, which includes a finding of "No Adverse Effect" for the Modified LPA.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and

The Modified LPA would not construct any additional structures or elements within the boundary of the House of Providence site and would restore to pre-construction conditions the hedge and curb within the temporary construction easement.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Consultation with the official with jurisdiction, the Washington SHPO, is ongoing.

For these reasons, the temporary occupancy of the House of Providence site during construction of the Modified LPA would meet the conditions required for exceptions (23 CFR 774.13(d)) and not constitute a use under Section 4(f).

Use Evaluation for the Modified LPA with I-5 Shifted West Design Option

The Modified LPA with I-5 shifted west design option would have a different impact to the House of Providence than the Modified LPA and other design options. The Modified LPA with I-5 shifted west design option would permanently incorporate approximately 9,800 square feet of land from the east side of the House of Providence historic site. Because the east portion of the site has already been heavily altered and does not retain integrity to its period of significance, the permanent acquisition would not impact contributing elements of the site and would not substantially impair the site's ability to convey its significance. This design option would also include approximately 2,000 square feet of temporary occupancy, which was considered in this finding.

Because neither the permanent acquisition nor the temporary occupancy of the House of Providence would substantially impair the activities, features, or attributes that contribute to its NRHP eligibility, the Section 106 FOE for the historic site includes a finding of "No Adverse Effect." Based on this finding, and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have found that the Modified LPA with I-5 shifted west design option's permanent acquisition and temporary occupancy would have a *de minimis* impact to this site

Preliminary Determination

Based on the analysis above, there would be no Section 4(f) use of the House of Providence site by the Modified LPA with or without C Street ramps, with any bridge configuration, with one or two auxiliary lanes, or with centered I-5. The Modified LPA and these design options would each require a temporary easement along the southern boundary of the historic site, but these easements would meet the temporary occupancy

exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f). The Modified LPA and these design options would not result in permanent incorporation of any portion of the site, nor would they lead to a constructive use of the site.

The Modified LPA with I-5 shifted west would require the permanent incorporation of 9,800 square feet from the eastern edge of the House of Providence site, as well as temporary occupancies at the southern edge of the site. The Section FOE for the House of Providence is "No Adverse Effect" for the Modified LPA with I-5 shifted west; the Washington DAHP concurred with this finding on February 14, 2024. Based on this finding, and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have determined that the Modified LPA with I-5 shifted west would result in temporary and permanent *de minimis* impacts under Section 4(f) for the House of Providence site.

Evergreen Hotel (Map ID – WA 21)

Description

The Evergreen Hotel, located at 500 Main Street, is an Italian Renaissance–style hotel located in downtown Vancouver (see Figure 4-34).

The hotel was constructed in 1928. The Evergreen Hotel was listed in the NRHP in 1979 under Criterion A, at the local level or significance, in the area of community planning and development and commerce. The hotel has not undergone any major alterations and retains its character-defining features. These features include the site's central downtown location, two primary entrances with six broad bays (on the south and east elevations), marble balconies, arched motifs, sandstone style finish, projecting roof forms clad in Spanish tile, and expansive interior spaces with a large staircase and mezzanine. Overall, the site retains integrity of location, materials, workmanship, feeling, and association; however, its integrity of design has been slightly diminished by infill to some of the exterior bays, and its integrity of setting has been diminished by the surrounding development of downtown Vancouver after the period of significance. The boundary for the Evergreen Hotel coincides with its tax lot boundary, which is contiguous with the building footprint.

The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. The finding received concurrence from the Washington DAHP on October 13, 2023.

Figure 4-34. IBR Program Improvements in Relation to the Evergreen Hotel

Use Evaluation for the Modified LPA

The Modified LPA activities adjacent to the site would consist of improvements to the intersection of Main Street and E 5th Street, within existing right of way at the southeast corner of the property. Additional activities located near the property would include the construction of a new, elevated on-ramp connecting SR 14 westbound to I-5 southbound and a new bridge supporting LRT; both of these structures would be constructed to the south of the Evergreen Hotel and would be clearly visible from the property. The elevated on-ramp would come within approximately 70 feet of the Evergreen Hotel's boundary but would not require any permanent incorporation of land from the historic site.

A constructive use does not occur when compliance with the requirements of 36 CFR 800.5 (Assessment of adverse effects) for proximity impacts of the proposed action, on a site listed in or eligible for the NRHP, results in an agreement of "No Effect" or "No Adverse Effect" (23 CFR Section 774.15).

The Modified LPA would, however, require a temporary construction easement along the historic site's southern boundary for the improvements to the intersection of Main Street and E 5th Street. Construction activities would not contact the Evergreen Hotel building and would not alter any of its character-defining features, but one of the primary entrances (located on the south elevation) would potentially be inaccessible during construction. However, the building's other primary entrance, located on the east elevation, would remain unobstructed and continue to function as normal. Access signage and instrumentation, such as vibration or noise monitors, may be placed in the hotel during construction.

The temporary occupancy of the Evergreen Hotel for the Modified LPA including design options, would meet the conditions required for exceptions (23 CFR 774.13(d)), including:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

The signage and instrumentation and the south access limitation to the hotel would occur for a duration less than the construction period for the project.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal

Construction activities would not contact the Evergreen Hotel and would not alter any of its character-defining features, but the south entrance would be rendered inaccessible during construction. Any temporary signage or instrumentation would not permanently alter the site and would be removed at the end of construction. The hotel's east primary entrance would remain unobstructed and continue to function as normal. As the east entrance would remain accessible during construction, the building would retain its ability to convey its significance during construction despite the temporary obstruction of the primary entrance on the south elevation.

There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis

There are no anticipated permanent adverse physical impacts to the Evergreen Hotel as a result of construction of the Modified LPA, nor would there be interference with the Evergreen Hotel's character-defining features related to the development history of downtown Vancouver. While the south primary entrance would potentially be inaccessible during construction, the east primary entrance would remain accessible, and the site would maintain its ability to convey its significant development history and role in the development of downtown Vancouver. This is supported by the Section 106 FOE for the historic site, which includes a finding of "No Adverse Effect" for the Modified LPA.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and

Upon completion of construction, the primary entrance on the south elevation would be returned to regular use. Any temporary signage or instrumentation would be removed, and the site would thus be fully restored to its condition prior to the Modified LPA.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Consultation with the official with jurisdiction, the Washington SHPO, is ongoing.

For these reasons, the temporary occupancy of the Evergreen Hotel site would meet the requirements of 23 CFR 774.13(d) for an exception from Section 4(f) use; therefore, temporary occupancy of the site during construction of the Modified LPA or options would not constitute a use under Section 4(f).

Preliminary Determination

Based on the analysis above, there would be no Section 4(f) use of the Evergreen Hotel by the Modified LPA or the design options. The Modified LPA with all design options would temporarily close the southern entrance of the hotel, but the temporary occupancy would meet the exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f). Neither the Modified LPA nor the design options would result in permanent incorporation of any portion of the site, nor would they lead to a constructive use of the site.

Who Song & Larry's Restaurant (Map ID – WA 1138)

Description

Who Song & Larry's Restaurant at 111 SE Columbia Way is a roadside style commercial building constructed in 1981 and located along the north shore of the Columbia River in Vancouver, Washington (see Figure 4-35). Who Song & Larry's Restaurant is eligible for inclusion in the NRHP under Criterion C, at the local level of significance, in the areas of architecture and commerce. It is the best-known example of the roadside style's use within the corporate limits of Vancouver and demonstrates its hallmarks including a distinctive eye-catching design meant to attract and serve customers traveling by car on the adjacent interstate. Character-defining features include the building's general form and massing, its complex roof forms, intricate fenestration and detailing, and its associated parking area. The building's outdoor dining area, river-facing viewsheds, and visibility to I-5 are also important features of its original design and are considered character-defining.

The boundary of the Who Song & Larry's Restaurant site is defined by the southern edge of the outdoor dining deck to the south, the eastern boundaries of the subject parcels (marked on site by a concrete dwarf wall) to the east, the southern edge of the SE Columbia Way sidewalk to the north, and the western boundaries of the subject parcels to the west, excluding the northwest extension. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Washington DAHP on October 13, 2023.

Figure 4-35. IBR Program Improvements in Relation to the Who Song & Larry's Restaurant

Use Evaluation for the Modified LPA

The Modified LPA would involve road improvements along the existing SE Columbia Way to the north, a proposed new shared-use path and bridge to the west, and a construction impact area within the Columbia River waterway to the east. Road improvements along SE Columbia Way would potentially include enhancements to pedestrian and traffic access (e.g., sidewalks, curb ramps, signage), but they would not include the reconfiguration of the current roadway or the construction of additional traffic lanes; this section of SE Columbia Way would remain a two-lane, two-way road. This narrow easement would only be temporary and would be located approximately 150 feet away from the site's primary building. As a result, the Modified LPA, inclusive of all design options, would not require any permanent right of way from the Who Song & Larry's Restaurant.

The Modified LPA, inclusive of all design options, would require a temporary construction easement along the site's northern boundary for improvements to SE Columbia Way. Construction activities would not contact the principal Who Song & Larry's Restaurant building and would not alter any of its character-defining features, but the primary vehicular entrance to the north would potentially be rendered inaccessible during construction. However, the site would still be made accessible from the eastern side of the boundary. Access signage and instrumentation, such as vibration or noise monitors, may be placed in the restaurant during construction.

The temporary occupancy of the Who Song & Larry's site for the Modified LPA would meet the conditions required for exceptions (23 CFR 774.13(d)), including:

Temporary duration, i.e., less than the time needed for construction of the project, and there would be no change in ownership of the land

> The easement would be needed for a duration less than the construction period for the project.

Scope of the work must be minor, i.e., both the nature and the magnitude of the changes to the Section 4(f) property are minimal

> While the proposed road improvements along SE Columbia Way would be partially visible from the north side of the Who Song & Larry's site, activities would occur 150 feet away from the site's primary building. Additionally, there are two rows of mature trees—with a sidewalk in between them—running along SE Columbia Way that would partially visually obscure the proposed road improvements. Overall, the improvements would not substantially impair the site's character-defining features or any of the aspects of the site's location or setting that enable it to convey its significance. For these reasons, the temporary occupancy of the Who Song & Larry's site would result in minimal changes to the property in both nature and magnitude.

There are no anticipated permanent adverse physical impacts, nor will there be interference with the protected activities, features, or attributes of the property, on either a temporary or permanent basis

> There are no anticipated permanent adverse physical impacts to the Who Song & Larry's Restaurant site as a result of construction of the Modified LPA, nor would there be modification of the site's character-defining features. The historic site would therefore maintain its ability to convey its significance as the best-known example of the roadside style's use within the corporate limits of Vancouver, for which it is eligible for the NRHP. This is supported by the Section 106 FOE for the historic site, which includes a finding of "No Adverse Effect" for the Modified LPA.

The land being used must be fully restored, i.e., the property must be returned to a condition which is at least as good as that which existed prior to the project; and

Upon completion of construction, access to the site along the northern boundary would be returned to regular use. Any temporary signage or instrumentation would be removed, and the site would be fully restored to its condition prior to the Modified LPA.

There must be documented agreement of the official(s) with jurisdiction over the Section 4(f) property regarding the above conditions.

Consultation with the official with jurisdiction, the Washington SHPO, is ongoing.

For these reasons, temporary occupancy of the Who Song & Larry Restaurant site during construction of the Modified LPA would meet the conditions required for exceptions (23 CFR 774.13(d)) and not constitute a use under Section 4(f).

Preliminary Determination

Based on the analysis above, there would be no Section 4(f) use of the Who Song & Larry's Restaurant by the Modified LPA or the design options. The Modified LPA with all design options would temporarily close the northern entrance of the restaurant site, but the temporary occupancy would meet the exception criteria in 23 CFR 774.13(d) and would not constitute a use under Section 4(f). Neither the Modified LPA nor the design options would result in permanent incorporation of any portion of the site, nor would they lead to a constructive use of the site.

Historic Sites Evaluated to Have Use with a Greater than *de minimis* Impact under Section 4(f)

Normandy Apartments (Map ID – WA 149)

Description

The Normandy Apartments building is a Tudor Revival style, multifamily housing complex located at 318 E 7th Street in Vancouver (see Figure 4-36). Originally constructed in 1928 and modified in 1960, the historic site is eligible for listing in the NRHP under Criteria A and C, at the local level of significance, in the areas of community planning and development and architecture. The Normandy Apartments building retains integrity of location, materials, workmanship, feeling, and association, and has slightly reduced integrity of design and setting.

The boundary of the historic site is defined by the right of way of I-5 to the east, the sidewalk paving of E 7th Street to the south, and an adjacent parcel to the north. The western portion of the original tax lot has been repaved as part of the surface parking lot; no walkways or other historic features are intact. Because of this, the western boundary of the property is aligned with the western edge of the building footprint. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Washington DAHP on October 13, 2023.

Figure 4-36. IBR Program Modified LPA Improvements in Relation to the Normandy Apartments

Figure 4-37. IBR Program Modified LPA with I-5 Shifted West Design Option in Relation to the Normandy Apartments

Use Evaluation for the Modified LPA

The Modified LPA would reconstruct and widen the I-5 corridor to the east of the Normandy Apartments. Related activities would include the construction of a new, elevated LRT alignment; a ramp connecting I-5 to SR 14; and retaining and noise walls immediately east of the building. These activities would require one narrow, approximately 700-square-foot permanent acquisition paralleling the eastern margin of the boundary of the historic site, as well as one approximately 5,000-square-foot subsurface easement extending under the southern portion of the apartment building's east wing to accommodate for tie-back anchors on the retaining wall.

These tie-back anchors would have no permanent surface disturbance within the boundaries of the historic site. Per Question 28A of the *Section 4(f) Policy Paper* (FHWA 2012), Section 4(f) applies to tunneling or other subsurface-only activities if they:

- Disturb archaeological sites that are on or eligible for the NRHP, which warrant preservation in place;
- Cause disruption that would permanently harm the purposes for which the park, recreation, wildlife or waterfowl refuge was established;
- Substantially impair the historic values of a historic site; or
- Otherwise do not meet the exception for temporary occupancy.

Of these, only the third (historic sites) and fourth (temporary occupancy) bullets are relevant to analysis of the Normandy Apartments. Installation and use of the tie-back anchors would neither result in a change to the property's physical, auditory, or visual setting; cause vibrations sufficient to damage the property; nor inhibit access to the property. Subsurface installation of the tie-back anchors would not substantially impair the historic values of the property. Therefore, Section 4(f) would not apply to the subsurface easements to accommodate tie-back anchors.

Section 4(f) would, however, apply to the permanent acquisition and temporary construction easement paralleling the eastern boundary of the Normandy Apartments (see Figure 4-36). The Modified LPA with or without C Street ramps, with any bridge configuration, one or two auxiliary lanes, and centered I-5 would all have the same acquisition requirements. For the Modified LPA and these design options, the permanent acquisition would measure 705 square feet, while the temporary easement would include an additional 300 square feet. Both would include landscaping elements that currently screen the apartment building from I-5, though neither would include any portion of the apartment building itself. Activities within and around the acquisition and easement, including construction of the proposed noise and retaining walls and elevated LRT alignment, would be located in proximity to the building. The retaining wall would be located approximately 5 feet from its southeast corner; this would considerably reduce the approximately 33-foot-wide buffer that currently separates the building from the western edge of the pavement for the I-5 off-ramp connecting to SR 14. Furthermore, the proposed noise and retaining walls and elevated LRT alignment would be new intrusions, not replacing any preexisting elements of a similar design or function. The proposed elevated LRT alignment, which would rise to the approximate height of the apartment building, would block views of the property from the east. Collectively, the permanent incorporation, temporary occupancy, and effects of the Modified LPA would change the current setting of the historic site and reduce the Normandy Apartments' integrity of setting, feeling, and association to an extent that it would no longer be able to convey its significant association with the interwar development of Vancouver, for which it has been determined NRHP-eligible under Criterion A. The Modified LPA would therefore constitute an "Adverse Effect" to the Normandy Apartments under Section 106.

I-5 shifted west would result in the same use determination, though the effects would be different (see Figure 4-37). The Modified LPA with I-5 shifted west design option would shift the I-5 mainline and ramps approximately 40 feet west of its current location. This option would require the permanent right-of-way acquisition of the Normandy Apartments property and removal of the building and the landscaping elements to the east of the building and in the courtyard. The I-5 shifted west design option would, therefore, permanently incorporate approximately 14,700 square feet of the property. This would be a greater incorporation and greater harm to the historic site than would occur under the other Modified LPA design options.

Preliminary Determination

The Section 106 FOE for the Normandy Apartments includes a finding of "Adverse Effect" for the Modified LPA, including all design options; the Washington DAHP concurred with this finding on October 13, 2023. The Modified LPA with I-5 shifted west design option would require the permanent right-of-way acquisition of the entire Normandy Apartments historic site and the removal of all of its historic features resulting in a use under Section 4(f). The Modified LPA and all other design options (excluding I-5 shifted west design option) would require a permanent incorporation of 705 square feet and a temporary occupancy of 300 feet paralleling the eastern boundary of the historic site. The Modified LPA and all other design options would therefore result in a use under Section 4(f). Therefore, FHWA and FTA have determined that the Modified LPA, including all design options, would result in a Section 4(f) use of this historic site.

Bridge Substation (Map ID – WA 1192)

Description

The Bridge Substation is a utilitarian electrical substation building located at 100 SE Columbia Way in Vancouver, Washington (see Figure 4-38). The two-story portion of the Bridge Substation was originally constructed in 1911 as the Mount Hood Railway and Power Company Vancouver Substation. This substation was located approximately 1 mile to the east of 100 SE Columbia Way and was relocated to its present location in 1913. The Bridge Substation is eligible for inclusion in the NRHP under Criterion C, at the local level in the area of architecture. The building is significant as a relatively rare surviving example of the electrical substation building type constructed between the late 1880s and early 1920s.

The building retains most of its character-defining features indicative of its utilitarian style and electrical substation building type. However, a one-story, west addition was constructed in 1927, and an entrance pavilion was subsequently added to the same part of the building. The primary setting of the building consists of the BNSF Railway embankment to the north and east, SE Columbia Way to the southeast and south, the 1917 Interstate Bridge to the southwest, and I-5 to the west. The setting has changed little from the 1960s and is consistent with the period of significance. As a result, the building retains its integrity of location, setting, workmanship, and feeling, while its integrity of materials, design, and association have been somewhat diminished. The boundary of the site is delineated by the original, eastern portion of the building located at its present site since 1913. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Washington DAHP on October 13, 2023.

Figure 4-38. IBR Program Modified LPA Improvements in Relation to the Columbia Street Bridge Substation

Use Evaluation for the Modified LPA

The Modified LPA, inclusive of all design options, would acquire and permanently incorporate the Bridge Substation site into right of way, to construct a proposed shared-use path and shared-use path bridge. Construction of the path and bridge would include demolition of the Bridge Substation. As a result, no features that allow the site to convey its historic significance as a NRHP-eligible site under Criterion C would remain following the completion of construction. As described in the Section 106 FOE, the Modified LPA would have an "Adverse Effect" on the site. The Modified LPA would permanently incorporate the entirety of the Bridge Substation site.

As the entire site would be permanently incorporated, there would be no temporary occupancy of the Bridge Substation site by the Modified LPA, inclusive of all design options.

Preliminary Determination

The Modified LPA with all design options would require the acquisition of the Bridge Substation and the subsequent removal of all its extant features, rendering the historic site no longer eligible for the NRHP. Consistent with the definition of use set forth in 23 CFR 774.17, which states that a use of Section 4(f) property occurs "when land is permanently incorporated into a transportation facility," FHWA and FTA have determined that the Modified LPA and its design options would result in a use under Section 4(f) for the Bridge Substation.

The use of the Bridge Substation would be a greater than *de minimis* impact, which for historic sites requires a Section 106 finding of "No Adverse Effect" (23 CFR 774.17). Due to the extent of proposed activities at the Bridge Substation, including the demolition of the primary building and its site features, the Section 106 FOE for the historic site includes a finding of "Adverse Effect" for the Modified LPA with all design options; the Washington DAHP concurred with this finding on October 13, 2023.

VNHR Historic District (Multiple)

Description

The VNHR Historic District is an NRHP-listed historic district that encompasses 397.7 acres and includes a total of five historic properties, including four NRHP-listed or determined eligible historic districts and one historic site (see Figure 4-39). Of the 397.7 acres within the VNHR Historic District boundary, 49.7 acres were WSDOT highway right of way at the time the district was listed and do not contribute to eligibility. The Fort Vancouver site was first established as a National Monument in 1948 and redesignated as a national historic site in 1961 to preserve and interpret historically significant and exceptionally complex overlapping areas associated with Native American, HBC, U.S. military, and NPS uses of land that have occurred over time. The originally recognized Fort Vancouver NHS's boundaries have expanded over time, and the original site was encompassed by the NRHP-listing of the VNHR Historic District in 2007.

The VNHR Historic District includes 74 contributing historic built environment resources, as well as an additional 12 contributing archaeological sites and two objects. The district was listed in the NRHP in 2007 under Criteria A, C, and D with a period of significance beginning 2,500 years before present (BP) and ending in 1966 of the common era (CE). Other NRHP individually eligible or listed historic districts encompassed within the boundary, and considered collectively in this Section 4(f) evaluation, of the VNHR Historic District include:

- Pearson Field Historic District (Determined NRHP-Eligible District, 1990)
- Vancouver Barracks Historic District (Determined NRHP-Eligible District, 1984)
- Officers Row Historic District (NRHP District, 1974)
- Fort Vancouver NHS (NRHP Site, 1966)

Figure 4-39. IBR Program Modified LPA Improvements in Relation to the VNHR Historic District

The boundary of the VNHR Historic District is delineated by the alleyway behind Officers Row to the north, I-5 to the west, the north shore of the Columbia River to the south, and a boundary corresponding to the alignment of East Reserve Street to the east. Within these bounds, the site encompasses approximately 207 acres within the VNHR Historic District in three noncontiguous sections. The sections are divided by the alignment of SR 14 and the SE Columbia Way creating a large northern section and two elongated narrow sections to the south. The boundary is generally defined by existing linear features, including roadways or extant property lines; however, its southwest corner runs into the alignment of the I-5 and SR 14 interchange and includes over four acres of noncontributing property that is owned and managed by WSDOT.

The Fort Vancouver NHS is also a unit in the National Park System and qualifies for protection of its recreational activities, features, and attributes under Section 4(f) as a public park in addition to its protection as a historic site. The use of the Fort Vancouver NHS under the provisions of a public park is evaluated in Section 4.3.4

Use Evaluation for the Modified LPA

The Modified LPA would reconstruct and widen the I-5 corridor to the west of the VNHR Historic District. The boundary of the VNHR Historic District includes approximately 50 acres of right of way owned and operated by WSDOT for transportation purposes. Because a portion of the VNHR Historic District was already being used as a transportation facility when the district was listed and does not contribute to the district, the Modified LPA, including all design options, within that boundary does not constitute a Section 4(f) use and is not included in the incorporation areas. Within the VNHR Historic District, the Modified LPA would require the permanent acquisition of a narrow strip of land (less than 1 acre in total) along the district's western edge, small segments (less than 0.05 acres in total) along the alignment of SR 14, as well as additional segments in the district's southwestern corner near the Old Apple Tree (less than 0.3 acres in total) and the embankment of the BNSF Railway alignment. These permanent acquisitions of approximately 65,600 square feet would constitute a use of the VNHR Historic District under Section 4(f).

The Modified LPA with the I-5 shifted west design option would move the I-5 mainline and ramps 40 feet west of its current location.

The Modified LPA also would require a subsurface easement extending approximately 50 feet beneath the site's northwest corner to accommodate tie-back anchors for a new retaining wall within the Historic District's Boundary. These tie-back anchors would have no permanent surface disturbance within the boundaries of the historic district. Per Question 28A of the *Section 4(f) Policy Paper* (FHWA 2012), Section 4(f) applies to tunneling or other subsurface-only activities if they:

- Disturb archaeological sites that are on or eligible for the NRHP, which warrant preservation in place;
- Cause disruption that would permanently harm the purposes for which the park, recreation, wildlife or waterfowl refuge was established;
- Substantially impair the historic values of a historic site; or
- Otherwise do not meet the exception for temporary occupancy.

The tie-back anchors would not disturb archaeological sites within the VNHR Historic District that warrant preservation in place. The tie-backs would not impair the historic value of the site, nor would they require additional temporary occupancy for their installation. For these reasons, the subsurface easements for tie-backs would not constitute additional use of the VNHR Historic District under Section 4(f) beyond the permanent incorporation identified above.

As identified through the Section 106 process, the IBR Program would adversely affect 14 of the contributing resources within the boundaries of the VNHR Historic District. Contributing resources to the NRHP-listed historic district constitute activities, features, or attributes of the district that qualify it for protection under Section 4(f). The 14 resources are:

- House (Building 1)
- House (Building 2)
- Duplex (Building 3)
- Duplex (Building 4)
- Munitions Storehouse (Building 102)
- Original Pearson Hangar (Building 189)
- Pearson Field Office (Building 194)
- Post Hospital (Building 614)
- Non-Commissioned Officer (NCO) Family Quarters (Building 635)
- NCO Family Quarters (Building 644)
- NCO Family Quarters (665)
- Work Shop (Building 786)
- Army Road System
- Fort Vancouver NHS Visitor Center

Adverse effects on these resources include direct effects through incorporation and anticipated construction vibrations, as well as indirect effects, including auditory and visual effects. These effects constitute potential harm to the district.

Permanent Incorporation of Land

The Modified LPA requires the permanent incorporation of approximately 65,600 square feet of the VNHR Historic District, including a small portion of the Army Road System, a contributing feature of the district, at the west end of E 5th Street; small segments along the alignment of SR 14; segments at the southwestern corner of the historic district; and the embankment of the BNSF Railway alignment. Although the site's integrity of setting has already been substantially diminished by the surrounding urban context and construction of I-5 during the early 1950s, the Modified LPA would further diminish its integrity of setting, feeling, and association. The Modified LPA with the I-5 shifted west design option would decrease the incorporation and demolition of a segment of the Army Road System between three and nine feet.

The single VNHR Historic District contributing resource incorporated under the Modified LPA is the Army Road System.

Vibration Effects

As noted in Section 3.11, Noise and Vibration, unmitigated ground-borne vibration could exceed FTA damage risk criteria to resources within the VNHR Historic District. Potential for structural damage was identified to the Post Hospital (Building 614) and NCO Family Quarters (Buildings 635 and 644).

The Modified LPA with I-5 shifted west would reduce the potential risk of vibration damage to both of the NCO Family Quarters Buildings (Building 635 and 644) by moving construction activities more than 100 feet from the building's footprint. Construction would still occur within 100 feet of the Post Hospital building's footprint; therefore, vibration damage risk to the Post Hospital would continue to occur under the Modified LPA with 1-5 shifted west design option.

The Section 106 process, once completed, will result in a Programmatic Agreement on the treatment of historic properties that will identify provisions to reduce and mitigate adverse effects to historic properties. It may include requirements to reduce the potential for harm from vibration during construction, such as condition inspection, monitoring vibration during construction, preemptive maintenance and repair, and limits on certain equipment or activities. Damage caused by construction vibration would be repaired in accordance with the Secretary of the Interior Standards for the Treatment of Historic Properties (36 CFR 68).

Archaeological Resources

Archaeological sites that are NRHP eligible and that meet certain conditions, such as warranting preservation in place, are subject to the provisions and protections of Section 4(f). Archaeological sites are not considered worthy of preservation in place if their primary importance is for the information that can be learned from data recovery.

As referenced above, 12 significant archaeological sites, or archaeological contributing elements to the VNHR Historic District, are located in the APE. Previous construction of I-5 and SR 14 likely affected several sites. The APE also includes an area where a historic military cemetery was located. While graves were exhumed and re-interred at another cemetery during the late 1800s, archaeological research has indicated that not all of the remains were relocated. During the construction of I-5, unmarked graves were reportedly discovered, and other potential grave shafts have been identified in the vicinity of the historic cemetery. The exact location of the cemetery is not included in this document because of the sensitive nature of the resource.

Three of HBC Village archaeological resources within the VNHR Historic District—Kanaka House, Tayenta's House, and House 4—qualify as Section 4(f) properties because they warrant preservation in place, based on consultation with the officials with jurisdiction. None of the other affected archaeological sites in the APE, either inside or outside the VNHR Historic District, were determined to warrant preservation in place under CRC (CRC 2011). Consistent with 23 CFR 774.13(b)(2), as part of the CRC project the officials with jurisdiction over the Section 4(f) properties were consulted and agreed with the Administration finding that each of the other archaeological resources within the VNHR Historic District are "important chiefly because of what can be learned by data recovery and has minimal value for preservation in place." While the Section 106 process for the IBR Program has not yet identified any new information that would change this determination, identification of resources and related consultation is ongoing. Data recovery excavations or other appropriate mitigation would be conducted for these sites in accordance with the Section 106 Programmatic Agreement, once executed.

The Washington DAHP reviewed and concurred with the determinations of Section 4(f) (in)eligibility as part of the CRC project consultation. Concurrence from the Washington DAHP on the findings of effect was obtained in January of 2011. The prior consultation is currently being confirmed as part of the IBR Program and the NPS, a consulting party, has expressed consistent views with the prior consultation regarding these resources. Though the exact extent of the three sites warranted for preservation in place is unknown, they may be adversely affected by the construction of the IBR Program, which would constitute a Section 4(f) use.

Aesthetic Features

The proximity of the Modified LPA would not substantially impair the aesthetic features or attributes of the Section 4(f) property that contribute to its integrity of setting, feeling, and association to the extent that the property's historic value is substantially diminished. Section 3.9, Visual Quality, notes that there would be visual changes with the construction of the Modified LPA elevated structure. Existing views in the Greater

Central Park Landscape Unit (the unit that VNHR Historic District is located within) would include noticeable view changes. As a result, visual quality changes within the VNHR Historic District would affect the setting of the district; however, the visual character of the resources themselves would remain unchanged.

VNHR Historic District contributing resources affected by visual setting include:

- Munitions Storehouse (Building 102)
- Original Pearson Hangar (Building 189)
- Pearson Field Office (Building 194)
- Work Shop (Building 786)
- Fort Vancouver NHS Visitor Center

In comparison to the Modified LPA with double-deck fixed-span configuration, the Modified LPA with single-level fixed-span configuration would be slightly wider and would have a slimmer vertical profile.

The Modified LPA single-level movable-span configuration would include two side-by-side, single-level steel girder bridges with a movable span between Piers 5 and 6. The movable-span configuration would be a vertical lift span with counterweights. Similar to the No-Build Alternative, permanent visual impacts would be associated with the lift towers that would protrude into the skyline for areas in Vancouver and Fort Vancouver (Figure 4-39). Because it would have a lower bridge deck (122 feet [NAVD88]) in the closed position, the single-level movable-span configuration would have fewer visual effects than the fixed-span configurations. Even with the higher lift towers, visual impacts associated with the lower bridge deck of the Modified LPA with movable-span configuration would be less adverse than those of the Modified LPA with double-deck fixed-span and single-level fixed-span configurations.

Noise Level Increase

According to the analysis provided in Section 3.11, Noise and Vibration, existing traffic noise levels modeled at the VNHR Historic District range from 52 to 75 dBA, with the highest levels at unshielded areas along I-5 and SR 14. Existing noise levels approach or exceed the noise abatement criteria of 67 dBA and noise levels would range from 54 to 72 dBA with the Modified LPA. VNHR Historic District contributing resources affected by noise include:

- House (Building 1)
- House (Building 2)
- Duplex (Building 3)
- Duplex (Building 4)
- NCO Family Quarters (Building 665)

Program activities would increase existing noise levels at these contributing resources within the VNHR Historic District boundary from existing levels of between 60 dBA and 65 dBA. The increase in value is dependent on the selected design option but would increase from 65 dBA to 72 or 73 dBA at House (Building 1), from 62 dBA to 72 dBA at House (Building 2), from 60 dBA to 66 dBA at Duplex (Building 3), from 63 dBA to 66 dBA at Duplex (Building 4), and from 61 to 66 dBA at NCO Family Quarters (Building 665).

Temporary Occupancy

Temporary occupancy of the VNHR Historic District during construction would include approximately 110,100 square feet for temporary construction easements adjacent to each permanent acquisition. The temporary occupancy areas include property along a narrow strip of land (less than 2 acres in total) along the district's western edge, small segments (less than 0.1 acres in total) along the alignment of SR 14, as well as additional segments in the district's southwestern corner near the Old Apple Tree (less than 0.6 acres in total) and the embankment of the BNSF Railway alignment.

The temporary occupancy of the VNHR Historic District varies by each of the design options from 107,300 to 121,600 square feet, as shown in Table 4-5.

Preliminary Determination

Based on application of the Criteria of Adverse Effect as defined in 36 CFR 800.5, the permanent incorporations required by the Modified LPA would alter the character-defining features of VNHR Historic District and consequently reduce its eligibility for inclusion in the NRHP. Therefore, the Section 106 FOE for the VNHR Historic District includes a finding of "Adverse Effect" for the Modified LPA, including all design options; the Washington DAHP concurred with this finding on October 13, 2023. Additionally, the Modified LPA would result in permanent incorporation and temporary occupancy use of land within the VNHR Historic District as described above. Therefore, FHWA and FTA have determined that the Modified LPA would result in a Section 4(f) use of the VNHR Historic District. All design options would constitute an "Adverse Effect" to the VNHR Historic District under Section 106. The selection of the Modified LPA with I-5 shifted west design option would reduce harm to contributing elements to the district; however, this design option would still use land from the 4(f) property. The temporary occupancy of the site by the Modified LPA is considered in the "Adverse Effect" determination under Section 106 and incorporated in the use determination under Section 4(f) that is described above.

Historic Sites Evaluated to Have Use with a *de minimis* Impact under Section 4(f)

Washington State Patrol District Five Headquarters (Map ID – WA 1148)

Description

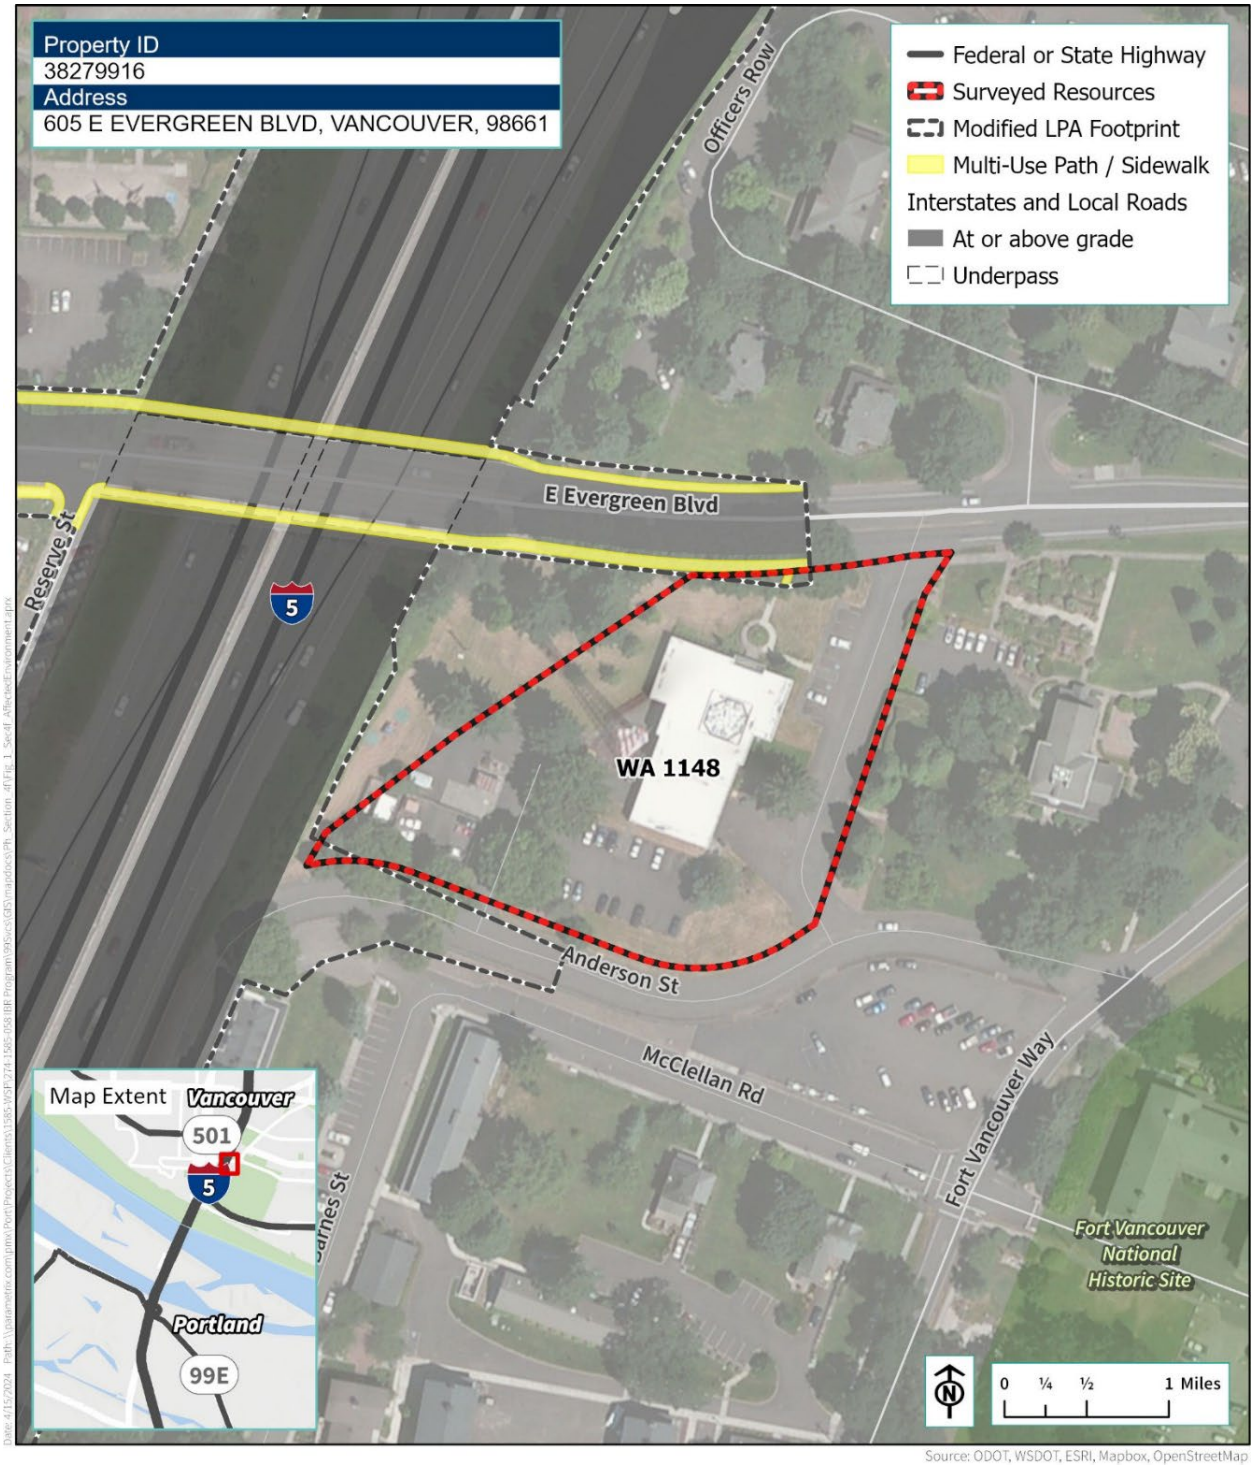
The Washington State Patrol (WSP) District Five Headquarters (now the Vancouver Police Headquarters) is a two-story, Late Modern-style building located at 605 E Evergreen Boulevard on the west edge of the VNHR in Vancouver, Washington (see Figure 4-40). The WSP District Five Headquarters is eligible for inclusion in the NRHP under Criterion A, at the local level of significance, in the areas of community planning and development and politics and government. The site is eligible for inclusion under Criterion A for its association with the transition of the VNHR from military to civilian use, as well as continued development and expansion of the WSP presence in Vancouver and Southwest Washington. The resource is also significant under Criterion C at the local level of significance in the area of architecture as a representative example of the Late Modern style. Overall, the resource retains its integrity of location, design, workmanship, feeling, and association while its integrity of setting and materials has only been slightly diminished. The principal building, walkways, circular planting box, landscaping, parking areas, and communications tower contribute to the site's historic significance. The radio equipment shelter and a new fueling station do not contribute to the site's historic significance.

The boundary of the historic site is defined by the boundary of the tax lot. The FOE documented in the Section 106 Level of Effect form for this site, which is contained in Appendix D of the Historic Built Environment Technical Report, is "No Adverse Effect" for the IBR Program Modified LPA and its design options. This finding received concurrence from the Washington DAHP on October 13, 2023.

Use Evaluation for the Modified LPA

The Modified LPA would construct additional interstate lanes to the west of the WSP District Five Headquarters, as well as improvements along the existing Anderson Street alignment to the south and the E Evergreen Boulevard alignment to the north (see Figure 4-40).

Figure 4-40. IBR Program Improvements and Area of Permanent Incorporation for the Washington State Patrol District Five Headquarters



The various infrastructure improvements proposed by the Modified LPA would alter the current setting of the WSP District Five Headquarters site through the introduction of new visual, atmospheric, and audible elements. However, because the site does not rely upon a quiet setting to convey its significance, the Modified LPA would not reduce any significant atmospheric or audible qualities. The radio equipment shelter and asphalt-paved parking lot, both of which are enclosed by a fence, distance the site from the proposed construction activity on Anderson Street to the south. To the north, the principal building and associated features are deeply set back from the public right of way. The Program would not diminish the site's integrity of location, design, materials, workmanship, feeling, or association in a manner that would diminish its ability to convey its significance. The Modified LPA, inclusive of all design options, would permanently acquire approximately 800 square feet of property from the WSP District Five Headquarters from the southwest corner of the site, adjacent to Anderson Street, and from the northern boundary of the property, adjacent to E Evergreen Boulevard. The permanent acquisition and effect of the Modified LPA upon the WSP District Five Headquarters would occur along the extreme boundary edges at the southwest and northwest corners, and would not substantially impair the site's principal building, walkways, circular planting box, landscape features, parking areas, or communications tower. Thus, the Modified LPA would not remove or alter any character-defining features or contributing elements that allow the site to convey its significance as a Late Modern municipal building associated with the VNHR and WSP.

Temporary occupancy of the WSP District Five Headquarters during construction of the Modified LPA, inclusive of all design options, would include approximately 600 square feet for temporary construction easements adjacent to each permanent acquisition. The temporary occupancy areas are minor and distant from the site's contributing elements and character-defining features, including the principal building, walkways, circular planting box, landscaping, parking areas, and communications tower.

Because neither the permanent acquisition nor the temporary occupancy of the WSP District Five Headquarters would substantially impair the activities, features, or attributes that contribute to its NRHP eligibility, the Section 106 FOE for the historic site includes a finding of "No Adverse Effect" for the Modified LPA.

Preliminary Determination

The acquisition of right of way from the WSP District Five Headquarters would constitute a use under Section 4(f). The Section 106 FOE for the WSP District Five Headquarters is "No Adverse Effect" for the Modified LPA, including all design options; the Washington DAHP concurred with this finding on October 13, 2023. Based on this finding, and consistent with the definition of *de minimis* impact in 23 CFR 774.17, FHWA and FTA have determined that the Modified LPA and its design options would have temporary and permanent *de minimis* impacts under Section 4(f) for the WSP District Five Headquarters.

4.4 Avoidance Alternatives

In accordance with 23 CFR 774.3, FHWA cannot approve the use of Section 4(f) property unless it is determined that there is no feasible or prudent avoidance alternative to the use of the land from a 4(f) property and the action includes all possible planning to minimize harm resulting from such use, or the use of the property will have only a *de minimis* impact. An alternative is not feasible if it cannot be built as a matter of sound engineering judgment. An alternative may not be prudent, according to 23 CFR 774.17(3), for multiple reasons, including if it compromises the project to a degree that it is unreasonable to proceed with the project considering its stated Purpose and Need. In other words, alternatives that do not adequately meet the project's Purpose and Need can be dropped from further Section 4(f) consideration.

A comprehensive alternative analysis was completed during CRC. In early phases of the CRC alternative development and screening process, the project team evaluated a wide range of potential alternative crossing corridors up and downstream of the existing I-5 bridge summarized in Chapter 2 of the CRC project Final EIS (Figure 4-41) and described below:

- A Western Highway crossing 2 to 3 miles west of I-5 that would connect suburban Clark and Multnomah counties.
- A Bi-State Industrial Corridor crossing near the BNSF Railway bridge, 1 mile west of I-5.
- A new crossing at 33rd Avenue in Portland, 2 to 3 miles east of I-5.
- Improvements to I-205 only.
- A new Columbia River crossing 10 to 12 miles east of I-5, that would connect Camas/East Clark County in Washington to Troutdale, Oregon.

Potential avoidance alternatives evaluated during screening also included a package of transportation demand management (TDM) and transportation system management (TSM) measures. The TSM/TDM alternative included very limited capital construction and therefore did not directly result in impacts to Section 4(f) properties, but was determined not to meet fundamental elements of the project's Purpose and Need.

The screening process evaluated how well each alternative crossing corridor would meet the Purpose and Need and determined that, while most of these alternatives could provide transportation benefits, they would do little to address the mobility, transit or safety problems in the I-5 corridor or to serve the proposed action's targeted travel markets. These five alternative crossing corridors failed to meet most or all of the elements of the CRC project's Purpose and Need. Although, these alternatives would have avoided affecting the Section 4(f) properties impacted by the alternatives evaluated in the CRC Draft EIS and Final EIS, because they would be located in other corridors, given the density and distribution of historic and recreational resources within the north Portland and Vancouver areas, these corridors would very likely result in use of different Section 4(f) properties. Alternatives and options that avoid one or more of the Section 4(f) properties (23 CFR 77.17) but have use of other Section 4(f) properties, are not avoidance alternatives. Therefore, the five alternative crossing corridors were not feasible and prudent avoidance alternatives.

Figure 4-41. Alternative Corridors Evaluated during the CRC Initial Screening Process

Source: CRC 2011

After eliminating the alternatives outside the I-5 corridor, the screening process selected a No-Build Alternative (Alternative 1) and four potential build alternatives (Alternatives 2 through 5) located in the immediate vicinity of the existing I-5 bridge summarized in Table 2-1 of Chapter 2, Description of Alternatives, none of which avoided all Section 4(f) resources.

The CRC Section 4(f) analysis concluded with a determination that "there are no alternatives that can simultaneously meet the project's Purpose and Need while also avoiding all Section 4(f) resources" (CRC 2011, page 5-60). Specifically, all alternative corridors evaluated as part of CRC would require substantial out-of-direction travel for transit passengers, bicyclists and pedestrians, and would do nothing to address the identified I-5 safety deficiencies, high crash rates, and seismic vulnerability. The conclusion in the CRC determination that none of the alternative corridors were feasible and prudent avoidance alternatives continues to be applicable because none of the alternatives would meet the Purpose and Need for the IBR Program.

During the early planning phase for the IBR Program, feedback from partner agencies, tribes, organizations, and the public identified changed conditions within the study area that have occurred since the issuance of the CRC project Record of Decision (ROD) in 2011 and the preparation of the two NEPA re-evaluations in 2012 and 2013 (CRC LPA). In response, the IBR Program identified that several components of the CRC LPA required design modifications. Potential options for each of these components went through a multitiered screening process that included input from Program partners, tribes, and community members. The components evaluated were Hayden Island and Marine Drive interchange configurations; the configurations of the replacement bridge over the Columbia River; transit mode, transit alignment, and transit termini; and auxiliary lanes. As the IBR Program conceptual design progressed, additional design options emerged in response to agency and public input and to improve operations or safety or to avoid or reduce impacts, including new interchanges, options for park-and-ride locations, and different bridge configurations.

Within each design area, the IBR Program collaborated with agency partners to develop high-level design options to respond to changes while incorporating current regional values and priorities. These options were subsequently screened for their ability to meet the Program's Purpose and Need statement and to achieve other desired outcomes related to changed conditions, including avoidance and minimization considerations related to the built environment. The design options that performed the best in the screening process were then combined to create the Modified LPA and its design options. The Modified LPA with all design options is fully described in Chapter 2 of this Draft SEIS. The design options include:

- A second auxiliary lane in each direction of I-5 from approximately Marine Drive to Mill Plain Boulevard.
- Different bridge types and configurations across the Columbia River including single-level fixed-span configurations and a single-level movable-span configuration.
- A shift of I-5 up to 40 feet westward in downtown Vancouver near the SR 14 interchange.
- Elimination of the existing C Street ramps in downtown Vancouver.
- Potential site options for park and rides to serve LRT riders in Vancouver include three site options near the Waterfront Station and two near the Evergreen Station (up to one park and ride would be built for each station).

Compared to the CRC LPA, the IBR Modified LPA with all design options reduces the amount of necessary right-of-way acquisitions from the Fort Vancouver NHS and the VNHR Historic District, reduces residential and nonresidential building displacements, reduces the overall bridge and construction footprint, and reduces the visual complexity of the I-5 structures on Hayden Island; however, none of these options fully avoid Section 4(f) properties.

The central findings from CRC's avoidance alternatives evaluation continue to apply to the IBR Program: (1) there are no alternative corridors either up or downstream from the I-5 corridor that can avoid all Section 4(f) properties; (2) there are no alternatives or design options within the I-5 corridor that avoid all Section 4(f) properties; and (3) while a TSM/TDM alternative would avoid all Section 4(f) properties, it would not meet the Purpose and Need. This preliminary 4(f) analysis shows that none of the Modified LPA design options would entirely avoid 4(f) uses either; therefore, there are no feasible and prudent alternatives that can simultaneously meet the IBR Program's Purpose and Need while also avoiding all Section 4(f) properties as required by 23 CFR 774(a)(1) and 774.17(4).

Section 4.5 evaluates measures to minimize harm to Section 4(f) properties from the IBR Program Modified LPA, including all design options, and Section 4.6 analyzes which of the feasible and prudent alternatives and options would have the least overall harm on Section 4(f) properties.

4.5 Measures to Minimize Harm

FHWA and FTA cannot approve the non-*de minimis* use of Section 4(f) properties unless there is no feasible and prudent avoidance alternative and the action includes all possible planning to minimize harm to the property resulting from the use (23 CFR 774.3). Differences in remaining harm between the Modified LPA design options are address in Section 4.6.

In accordance with 23 CFR 774.17, a *de minimis* impact determination subsumes the requirement for all possible planning to minimize harm by reducing the impacts on the Section 4(f) property to a *de minimis* level. All possible planning includes measures to minimize harm. Properties with use that would be greater than *de minimis* under Section 4(f), as documented in Section 4.3, are listed in Table 4-8.

For the historic sites that were evaluated under CRC and are included within the IBR Program cultural resources APE, the avoidance and minimization measures that applied under CRC also generally apply to the IBR Program Modified LPA with minor modifications and are summarized below. Historic sites determined NRHP eligible that would have a use under Section 4(f) for the IBR Program Modified LPA are included in and are discussed in this section. The Section 106 consultation process is ongoing for the IBR Program and will result in a Programmatic Agreement to resolve adverse effects under Section 106. All measures committed to in the Section 106 Programmatic Agreement will become committed measures to minimize harm under Section 4(f). Public parks with a use under Section 4(f) for the IBR Program Modified LPA also are included in and are discussed in this section.

Table 4-8. Section 4(f) Properties with Use with a Greater than *de Minimis* Impact by the IBR Program Modified LPA with All Design Options

Property Type and Location	Historic Site Identifier	Section 4(f) Property
Historic Sites in Portland	OR 103	The Toll Administration Building/ODOT Permit Center
	OR 107	The Harbor Shops
	OR 109	The Jantzen Beach Water Tank and Pump House
	OR 111	The Jantzen Beach Moorage
The Interstate Bridge	OR 50 and WA 381a	The Northbound Interstate Bridge
Historic Sites in Vancouver	WA 149	The Normandy Apartments
	WA 1192	The Bridge Substation
	WA (multiple)	Vancouver National Historic Reserve Historic District
Public Parks	N/A	Fort Vancouver NHS

Avoiding and minimizing adverse impacts to Section 4(f) properties has been an integral part of identifying, developing, and refining the IBR Program design options. These measures include efforts to avoid known historic resources and sensitive cultural areas, to minimize the physical footprint of the Modified LPA, including all design options, and, where possible, to locate the Program within existing transportation right of way. This is illustrated through the properties listed in Table 4-6 and Table 4-7 that are within the Section 106 APE but are avoided by the project design. The following general measures would minimize harm incorporated into the Modified LPA, including all design options:

- Reducing the overall project footprint through use of retaining walls with tie-back anchors rather than fill slopes and acquisition of additional area adjacent to the freeway for all Section 4(f) properties, including the Fort Vancouver NHS and the VNHR Historic District.

- Reducing the footprint of the replacement bridge over land.
- Reducing the construction footprint and visual complexity of I-5 structures over Hayden Island and scaling them to their surroundings.

As outlined in the previous section, there are no alternatives that can meet the project's Purpose and Need and avoid all Section 4(f) properties. However, a variety of design options and refinements avoid at least some of the Section 4(f) properties and minimize harm to others. This section evaluates how well the alternatives, options, and other potential minimization measures could avoid one or more of the Section 4(f) properties, reduce the effects on one or more Section 4(f) properties, or potentially mitigate harm to Section 4(f) properties.

In consultation with PP&R, NPS, Vancouver Parks, Recreation & Cultural Services Vancouver Public Schools, Washington DAHP, Oregon SHPO, and the City of Vancouver, the proposed Modified LPA footprint has been refined and the number and severity of Section 4(f) uses has been reduced, and in many cases only a *de minimis* impact remains. Program planning and design actions to minimize harm to public park and historic Section 4(f) properties in the study area are discussed below. For historic sites, the Section 106 process is ongoing and will culminate in a Programmatic Agreement to resolve adverse effects to historic properties. The stipulations in the Programmatic Agreements will constitute commitments under NEPA and Section 4(f) to implement the identified measures to avoid, minimize, and mitigate harm to historic properties.

As outlined in the definition section at 23 CFR 774.17:

> *All possible planning means that all reasonable measures identified in the Section 4(f) evaluation to minimize harm or mitigate for adverse impacts and effects must be included in the project.*
>
> > *(1) With regard to public parks, recreation areas, and wildlife and waterfowl refuges, the measures may include (but are not limited to): design modifications or design goals; replacement of land or facilities of comparable value and function; or monetary compensation to enhance the remaining property or to mitigate the adverse impacts of the project in other ways.*
> >
> > *(2) With regard to historic sites, the measures normally serve to preserve the historic activities, features, or attributes of the site as agreed by the Administration and the official(s) with jurisdiction over the Section 4(f) resource in accordance with the consultation process under 36 CFR part 800.*
> >
> > *(3) In evaluating the reasonableness of measures to minimize harm under § 774.3(a)(2), the Administration will consider the preservation purpose of the statute and:*
> >
> > > *(i) The views of the official(s) with jurisdiction over the Section 4(f) property;*
> > >
> > > *(ii) Whether the cost of the measures is a reasonable public expenditure in light of the adverse impacts of the project on the Section 4(f) property and the benefits of the measure to the property, in accordance with § 771.105(d) of this chapter; and*
> > >
> > > *(iii) Any impacts or benefits of the measures to communities or environmental resources outside of the Section 4(f) property.*
> >
> > *(4) All possible planning does not require analysis of feasible and prudent avoidance alternatives, since such analysis will have already occurred in the context of searching for feasible and prudent alternatives that avoid Section 4(f) properties altogether under § 774.3(a)(1), or is not necessary in the case of a de minimis impact determination under § 774.3(b).*

For the IBR Program, all measures agreed to by the Administration[1] and the official(s) with jurisdiction to resolve adverse effects to historic properties will be included as stipulations in the Section 106 Programmatic Agreement and be commitments of the Program as measures to reduce harm under Section 4(f) recorded in the Final 4(f) Approval and ROD. A draft of the Section 106 Programmatic Agreement will be distributed for public review prior to the Final SEIS.

This section is organized geographically from the south end to the north end of the I-5 corridor and discusses the options and measures in the context of the Section 4(f) properties located in each geographic area of the project. These resources include the following:

- Resources in Portland
- The northbound Interstate Bridge (located in both Portland and Vancouver)
- Resources in Vancouver

All reasonable minimization measures have been incorporated into project design or mitigation commitments and compose the least harm alternative. The following analysis describes the different options or alternatives that were considered to minimize harm to Section 4(f) properties that would be used by the IBR Program, but may or may not have been implemented depending on whether they are reasonable or met the Purpose and Need. Many of the measures discussed were dismissed as either not reasonable, would not reduce harm, and/or would not meet the Purpose and Need.

4.5.1 Minimizing Harm to Resources in Oregon

There are four historic sites located in Portland that would have use with a greater than *de minimis* impact by the IBR Program Modified LPA with all design options under Section 4(f) which are listed in Table 4-8, above.

Historic Sites in Portland

Four historic sites are located within the right of way for the Modified LPA in Oregon and identified as having a greater than *de minimis* impact from the IBR Program. These historic sites include:

- The Toll Administration Building/ODOT Permit Center (OR 103): The Modified LPA with all design options would require the acquisition of the building and FHWA and FTA have determined that this would result in a use under Section 4(f).
- The Harbor Shops (OR 107): This site would be permanently incorporated under the Modified LPA with all design options, resulting in a use under Section 4(f).
- The Jantzen Beach Water Tank and Pump House (OR 109): The Modified LPA with all design options would permanently incorporate this site as right of way, resulting in a use under Section 4(f).
- The Jantzen Beach Moorage (OR 111). The Modified LPA with all design options would permanently incorporate approximately 85,900 square feet of the site and reduce the resource's integrity, resulting in in a use under Section 4(f).

[1] "Administration" is defined in 23 CFR 774.17 as: "The FHWA, FRA, or FTA, whichever is approving the transportation program or project at issue."

For constructability reasons, the mainline in the area of these Section 4(f) resources would be wider and shifted off the existing I-5 alignment for the Modified LPA, including all design options. The new freeway ramps in a different configuration, the arterial bridge at the Marine Drive interchange, and transit all combine to change where the widest points in the project are situated, leading to new property impacts along the corridor in Portland. The Program improvements under the Modified LPA, including all design options, would connect to roadways and intersections to provide better overall circulation and mobility on and leading to I-5 for automobiles, bicycles and pedestrians. The Modified LPA with I-5 shifted west design option would shift the I-5 mainline approximately 40 feet west of the existing I-5 mainline over Hayden Island and North Portland Harbor to connect to the new Columbia River bridges that would be built west of the existing bridge and more westerly than the existing alignment in part to reduce impacts to Fort Vancouver NHS and the VNHR Historic District north of the river, which are nationally significant park and historic properties.

The wider footprint of the Modified LPA with all design options, in combination with the more westerly location of I-5 on the Oregon side of the Columbia River, will use the four other historic sites that are located immediately to the west of the existing I-5 improvements on Hayden Island and in North Portland Harbor. Measures to minimize harm on Portland historic sites, therefore, include measures to reduce the right-of-way width of I-5, realigning the Modified LPA farther east or west to avoid these sites, or eliminating certain Program elements. The following analysis groups these four historic sites into common measures to minimize harm, because the analysis and findings are the same for each resource.

Reducing the Right-of-Way Width of I-5 under the Modified LPA with All Design Options

Measures to reduce the right of way of I-5 from Hayden Island south to approximately Marine Drive could include reducing or eliminating project elements such as shoulders, travel lanes, or LRT tracks. The Modified LPA, including all design options, must meet federal and state highway design requirements for safety, to avoid substandard roadway design, and maintain or improve traffic operations. The project could potentially reduce the number of through travel lanes from three to two in each direction or eliminate the wider shoulders on I-5 from Marine Drive through Hayden Island that would accommodate bus-on-shoulder service. Another option would include eliminating auxiliary lanes. These measures could reduce, but would not eliminate, impacts to the Jantzen Beach Moorage, would not substantially reduce harm to the other three historic sites in Portland with Section 4(f) use, and they would not meet the Program's Purpose and Need. Each auxiliary lane is 8 feet wide; the one- or two-auxiliary-lane design options would add width to the Program improvements as compared to the existing condition. It is important to note, however, that the existing condition contains entrance and exit ramps over Hayden Island proximate to the historic sites.

The IBR Program purpose is "to improve I-5 corridor mobility by addressing present and future travel demand and mobility needs in the IBR study area." Specific objectives include: "a) improve travel safety and traffic operations on the Interstate Bridge and associated interchanges; b) improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the study area; c) improve highway freight mobility and address interstate travel and commerce needs in the study area; and d) improve the Interstate Bridge's structural integrity (seismic stability)." Eliminating project elements such as travel lanes, auxiliary lanes, shoulders, or LRT tracks would not improve traffic operations; connectivity, reliability, travel times, or operations of public transportation modes, nor would it improve highway freight mobility. Because eliminating these project elements would affect the IBR Program's ability to meet its Purpose and Need, their elimination is not a reasonable measure to minimize harm.

The Modified LPA footprint on Hayden Island is determined by local street improvements and would not be affected by a second auxiliary lane; therefore, the use of historic properties on Hayden Island would not change among the design options. Because reducing or eliminating auxiliary lanes would not reduce harm to the properties, it is not a reasonable measure to minimize harm.

Reducing the width of project elements such as shoulders, and travel lanes would not meet federal and state highway design requirements and could compromise safety. For these reasons, reducing the width of the project is not a reasonable measure to minimize harm.

Realigning Program Elements East or West

The IBR Program Modified LPA with all design options sought to minimize harm to other Section 4(f) properties, as well as non-Section 4(f) resources including businesses and residences in North Portland and on Hayden Island by using the existing I-5 alignment and right of way to the maximum degree possible. Shifting the Modified LPA or design options alignments to the east or west would create large-scale impacts to businesses and residents in North Portland and Hayden Island and to other Section 4(f) properties. A shift to the east would potentially displace East Delta Park. A shift to the west would potentially displace the Smith-Bybee Wetlands, Portland Assembly Center, and a larger area from the Jantzen Beach Moorage.

In addition, an eastward or westward alignment shift would displace non-Section 4(f) resources including existing residences and businesses. A shift to the east would potentially displace Tipp Top Marine, Courtyard by Marriott North Portland, Residence Inn by Marriott Portland North, Red Lion on the River Jantzen Beach, and multiple shopping centers on North Portland and Hayden Island. A shift to the west would potentially displace the Roadway Inn and Suites Portland – Jantzen Beach, Jantzen Beach Center (a regionally important shopping center), and residential areas including Hayden Island Mobile Home Village/Hayden Island Manufactured Home Community, a likely concentration of low-income residents.

For these reasons, an eastward or westward alignment shift is not a reasonable measure to minimize harm to the four historic sites in Portland. Expanding the footprint of the existing alignment to the minimum extent needed to meet Purpose and Need for the project would have the least overall harm to the totality of Section 4(f)-protected properties within Portland.

Eliminating Program Elements

Eliminating project elements such as travel lanes, auxiliary lanes, safety shoulders, connecting roadways, or surface street improvements would narrow the project alignment and could reduce or avoid use of the Toll Administration Building/ODOT Permit Center (OR 103), and the Harbor Shops (OR 107), and the Jantzen Beach Moorage (OR 111), but would not meet the Program's Purpose and Need including: improving mobility along the I-5 corridor by addressing current and future travel demand; improving travel safety and traffic operations on the Interstate Bridge and associated interchanges; improving connectivity, reliability, travel times, and operations of public transportation modal alternatives in the study area; and improving highway freight mobility and addressing interstate travel and commerce needs in the study area. As discussed in Chapter 2, the project elements have been designed to provide mobility and safety improvements as identified in the Purpose and Need. Reducing the number of travel or auxiliary lanes would not improve mobility along the I-5 corridor. Eliminating safety shoulders would not improve travel safety. Eliminating connecting roadways and surface street improvements would not improve connectivity. Eliminating these elements would not be reasonable measures to minimize harm because doing so would be contrary to the Purpose and Need for the Program.

If the realignment of Jantzen Drive were eliminated from the Program, the Jantzen Beach Water Tank could be avoided, but the reconstructed Jantzen Drive would provide connectivity across the island on the south shore that does not currently exist to meet the Program's Purpose and Need related to improving connectivity. The location of Jantzen Drive is driven by the 100-year flood elevation, climate resiliency, roadway geometric design requirements, and structural design considerations for the Interstate Bridge and the North Portland Harbor bridge. Therefore, the roadway cannot be moved or eliminated from the design.

4.5.2 Minimizing Harm to the Northbound Interstate Bridge

The IBR Program Modified LPA would remove the northbound Interstate Bridge. Pursuant to 23 USC 103(c)(5) and 70 FR 11928 (March 10, 2005), the southbound Interstate Bridge is exempt from Section 4(f) review as further explained in Section 4.2.2 of this evaluation. Thus, the southbound bridge is not evaluated for measures to minimize harm.

As discussed in Section 4.4 the CRC project evaluated a range of potential river crossings that would avoid the removal of the northbound Interstate Bridge, none of which met the project's Purpose and Need and were therefore dropped from further consideration. The CRC project team also evaluated a range of I-5 crossing options that would reuse rather than remove the northbound Interstate Bridge. These crossing options were also eliminated from further consideration because they either did not meet the project's Purpose and Need or performed poorly when measured against screening criteria developed for the project (see Section 2.7 of the CRC Final EIS for a discussion of alternative screening [CRC 2011]). Of the alternative river crossings, the Supplemental River Crossing (CRC Alternatives 4 and 5), would have had less harm on the 1917 bridge. However, the supplemental crossing had an accumulation of performance deficiencies, adverse impacts, and other factors that would have made it an unreasonable alternative and, therefore, an unreasonable measure to reduce harm to the northbound Interstate Bridge (see Section 5.5.2 of the CRC Final EIS for a discussion of the supplemental crossing [CRC 2011]). If the 1917 bridge were left in place, it would continue to be at risk of mechanical failure or damage from a seismic event.

The conclusion of the CRC evaluation for measures to minimize harm that none of the alternative river crossings were reasonable remains applicable because all identified reasonable alternatives, including the IBR Program Modified LPA with all design options, would remove the northbound Interstate Bridge.

Consultation under the Section 106 process for the Modified LPA is ongoing and will culminate in a Programmatic Agreement to resolve adverse effects to historic properties. The Programmatic Agreement will stipulate measures to address the removal of the northbound Interstate Bridge. Once agreed upon through the Section 106 consultation process, all measures identified in the Programmatic Agreement will be included as committed measures to minimize harm under Section 4(f).

4.5.3 Minimizing Harm to Resources in Washington

Three historic sites and one park and recreation property are located near the Modified LPA with all design options adjacent to both sides of I-5 in Vancouver. Several additional sites were avoided using retaining walls to limit the width of the improved I-5 (Table 4-7). The Modified LPA or design options would result in a use with greater than *de minimis* impact under Section 4(f) of the following historic sites in Vancouver:

- The Normandy Apartments (WA 149):
- The Modified LPA with all design options (excluding the with I-5 shifted west design option) would require a narrow, 705-foot acquisition paralleling the eastern property boundary and would remove the landscaping screening the building from I-5. The site's setting would also be changed with retaining walls placed 5 feet from the building and the construction of elevated LRT tracks that would rise to the height of the building, blocking views to the east. These Program improvements would result in an adverse effect under Section 106 and a use under Section 4(f).
- Under the Modified LPA with I-5 shifted west shift design option, the building would be demolished, resulting in an adverse effect under Section 106 and a use under Section 4(f) in the Modified LPA with I-5 shifted west design option.
- The Bridge Substation (WA 1192): This site would be permanently incorporated under the Modified LPA with all design options, resulting in a use under Section 4(f).

- The VNHR Historic District and Fort Vancouver NHS (WA Multiple): Land within this historic district and park and recreation property would be permanently incorporated and temporarily occupied under the Modified LPA with all design options, resulting in a use under Section 4(f).

The resources above would be affected by the highway widening, I-5/SR 14 interchange improvements, and the elevated LRT alignment in downtown Vancouver. The following discussion highlights measures to minimize harm by resource.

The Normandy Apartments (WA 149)

The Normandy Apartments are located at 318 7th Street in downtown Vancouver immediately west of the existing I-5 improvements. While the Modified LPA with all design options would incorporate land from the Normandy Apartments, the Modified LPA with I-5 shifted west design option would require demolition of the entire property. Balancing of harm between Section 4(f) properties is discussed in Section 4.6.

Potential measures to minimize harm for the Modified LPA with all design options, including the I-5 shifted west design option, include reducing the dimensions of or eliminating project elements including travel lanes, shoulders, auxiliary lanes, or LRT tracks. For reasons, described below, eliminating Program elements would not meet the Program's Purpose and Need because it would not address present and future travel demand and mobility needs; would not improve traffic operations; would not improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the study area and would not improve highway freight mobility:

- **Eliminating Program Components:** The Modified LPA, including all design options, would have three northbound and three southbound travel lanes in downtown Vancouver, as does the existing interstate. I-5 through the Program study area frequently experiences bottlenecked traffic in which speeds are less than 45 miles per hour for large portions of the day as summarized in Table 3.1-13 in Section 3.1, Transportation. Southbound, the Interstate Bridge experiences a bottleneck from 6:00 a.m. to 9:00 a.m. extending up to 3 miles long northward into downtown Vancouver. The northbound bridge experiences a bottleneck from 11:15 a.m. to 8:00 p.m. for 10+ miles. As discussed in Chapter 2, the project elements have been designed to provide mobility and safety improvements as identified in the Purpose and Need. Reducing the number of travel lanes, shoulders, auxiliary lanes, or LRT tracks would only exacerbate bottlenecks and would not address the Program's Purpose and Need because it would not improve traffic operations or travel times. Eliminating safety shoulders would not improve travel safety. Because eliminating lanes or shoulders would not meet the Program's Purpose and Need, it would not be a reasonable alternative to minimize harm to the Normandy Apartments. Due to its more westerly location and greater impact on the Normandy Apartments, eliminating Program components would be least effective for the Modified LPA with I-5 shifted west design option.
- **Reducing the Width of Program Components:** All components of the Modified LPA with all design options, including travel lanes, auxiliary lanes, shoulders, and LRT tracks, have been designed to meet federal and state highway design requirements. Reducing the width of project components would be contrary to the Program's Purpose and Need because it would compromise safety, traffic, freight, and transit operations depending on the component and is therefore not a reasonable measure. For example, reducing shoulder width would prevent disabled vehicles from pulling out of and away from the travel lanes, reducing the safety benefit of the shoulders.

The Bridge Substation (WA 1192)

The Bridge Substation is located immediately east of the northbound Interstate Bridge and would be demolished under the Modified LPA with all design options to construct a shared-use path and shared-use path bridge. The shared-use path bridge would provide access from the elevated bridge deck immediately north of the Columbia River shoreline to the downtown Vancouver street network at grade level. Potential measures to minimize harm include moving, modifying the design of, or eliminating the shared-use path and shared-use path bridge.

- **Modifying the Design of the Shared-Use Path and Shared-Use Path Bridge:** Potential design modifications to the shared-use path bridge would include elongating or enlarging the circular shared-use path bridge to be more of an oval shape, while leaving the Bridge Substation in place. Enlarging the shared-use path bridge would require the redesign of Columbia Way to follow the current street alignment which would also conflict with on-land structural supports for the bridge and would not be a structurally feasible design for the new Columbia River bridges.
- Elongating the shared-use path bridge would require additional permanent property acquisition from Who Song & Larry's (another Section 4(f) protected historic site) and a viable business. Therefore, modifying the design of the shared-use path and bridge would not be a reasonable measure to minimize harm.
- **Eliminating the Shared-Use Path and Shared-Use Path Bridge:** The Program's Purpose and Need statement includes improving "the I-5 corridor mobility by addressing present and future travel demand and mobility needs in the IBR study area." The mobility of bicycles and pedestrians through the I-5 corridor would not be improved without the shared-use path and shared-use path bridge and, therefore, eliminating these elements from the Program design would not meet the Purpose and Need and would not result in a reasonable alternative. Without the shared-use path, there would be no bicycle and pedestrian connection across the Columbia River in the I-5 corridor.

The Vancouver Barracks National Cemetery (WA 1319)

Initial designs for the Modified LPA, including all design options, would have required removal of historic contributing elements of the Vancouver Barracks National Cemetery. Design refinements explored alignment revision and narrowing of roadway and sidewalk areas to remain outside of this property entirely, which reduced the effects under Section 106 on the historic property to less than adverse resulting in no use under Section 4(f). These refinements were incorporated as measures to minimize harm to a property that would otherwise be used.

VNHR Historic District and Fort Vancouver NHS (WA Multiple)

The Modified LPA with all design options would result in permanent incorporation and temporary occupancy of land within VNHR Historic District and Fort Vancouver NHS as described in Sections 4.3.8 and 4.3.4 of this evaluation. The Modified LPA with I-5 shifted west and Modified LPA without C Street ramps design options were developed to minimize acquisition from the VNHR Historic District and Fort Vancouver NHS. The effects of those design choices on other resources and measures of system performance are discussed in the least overall harm analysis (Section 4.6). The permanent incorporations for the Modified LPA with double-deck fixed-span configuration, Modified LPA without C Street ramps, and Modified LPA with single-level with two auxiliary lanes design options would incorporate approximately 100, 200, or 700 square feet of the Army Road System, which is a contributing feature to the VNHR, respectively, resulting in a use of the VNHR Historic District. The Modified LPA with I-5 shifted west design option would avoid the area of incorporation of a segment of the Army Road System and reduce the area of permanent incorporation from the VNHR Historic District compared to the other design options by between 10,000 and 15,000 square feet to approximately 53,400 square feet (Table 4-5).

In addition to permanent incorporation of land, the IBR Program Modified LPA with all design options would adversely affect 11 of the contributing resources within the VNHR Historic District NHS under Section 106, as discussed in Section 4.3.8. Adverse effects to these resources include:

- Vibration: Within the VNHR Historic District, the Post Hospital and NCO Family Quarters (Buildings 635 and 644) could experience ground-borne vibration exceeding FTA damage risk criteria that could result in the potential for structural damage. The Modified LPA with I-5 shifted west design option would reduce the risk of vibration damage to both of the NCO Family Quarters Buildings by moving construction 100 feet west of the buildings, but vibration risk for the Post Hospital would still occur.
- Three HBC archaeological resources, Kanaka House, Tayenta's House, and House 4, that have been considered worthy of preservation in place are located within this area. Though the exact extent of these three sites is not known, they may be adversely affected by the construction of the Modified LPA, including all design options, which would constitute a Section 4(f) use.
- Aesthetic features: The Munitions Storehouse, Original Pearson Hangar, Pearson Field Office, Work Shop, and Fort Vancouver NHS Visitor Center, all of which are located in both the VNHR Historic District and the Fort Vancouver NHS, would experience affects to their visual setting resulting from the higher bridge heights. In particular, the movable-span configuration would have lift towers that would protrude into the skyline and would have a bridge deck height of 122 feet (NAVD88), whereas the Modified LPA with double-deck fixed-span configuration would have a second deck height of 166 feet (NAVD88). Therefore, the Modified LPA with single-level movable-span configuration would have fewer visual effects than with the double-deck fixed-span configuration.
- Noise level increases: House (Building 1), House (Building 2), Duplex (Building 3), Duplex (Building 4), and NCO Family Quarters (Building 665) would experience noise increases from 60 to 65 dBA to between 66 and 72 dBA, under the Modified LPA. These sound levels would approach or exceed the noise abatement criteria of 67 dBA under the Modified LPA. The Modified LPA with I-5 shifted west would slightly reduce noise by moving I-5 to the west.

Evaluated measures to minimize harm to the VNHR Historic District and Fort Vancouver NHS from the Modified LPA with all design options include eliminating project elements or shifting the Program alignment further west as evaluated under the Modified LPA with I-5 shifted west design option. Measures to minimize harm to the VNHR Historic District and the Fort Vancouver NHS include eliminating project elements, and standard mitigation measures for noise and vibration effects.

Eliminating Program Components

Eliminating project elements such as travel lanes, auxiliary lanes, or safety shoulders may reduce or eliminate permanent incorporation of the VNHR District and Fort Vancouver NHS required under the Modified LPA with all design options, but, in most cases would not meet the project's Purpose and Need as described in the analysis for the Normandy Apartments above. For these reasons, eliminating project elements, including travel lanes, auxiliary lanes, and safety shoulders, is not reasonable for any design options of the Modified LPA.

The Modified LPA without C Street ramps design option eliminates the C Street loop ramp from I-5 northbound into downtown Vancouver that would require approximately 15,000 additional square feet of land acquisition from the VNHR Historic District and the Fort Vancouver NHS as compared to the Modified LPA. While this design option would not provide as high a level of access and connectivity to downtown Vancouver, it would meet the Program's Purpose and Need and is a reasonable measure to minimize harm to the VNHR Historic District and the Fort Vancouver NHS and is further considered in Section 4.6.

Shifting the Program's Alignment Farther West

The Modified LPA with I-5 shifted west design option would shift the Program alignment approximately 40 feet farther west. This design option would reduce permanent incorporation and, therefore, use of the VNHR Historic District and the Fort Vancouver NHS, as well as meet the Program's Purpose and Need. This design option would require permanently incorporating the Normandy Apartments (WA 149), another Section 4(f) resource, as discussed in Section 4.6.6, displacing the residents of 33 apartment units and would not be a reasonable measure to minimize harm.

Standard Minimization Measures for Noise, Vibration, and Visual Effects

House (Building 1),House (Building 2), and NCO Family Quarters (Building 665) would experience noise increases from 61 to 65 dBA to between 66 and 72 dBA under the Modified LPA. This would approach or exceed the noise abatement criteria. As noted in the IBR Program Noise and Vibration Technical Report, for

noise mitigation to be feasible, WSDOT requires that it be physically constructable; reduce noise levels by at least 5 dBA for a minimum of three first-row impacted receivers; and at least one receiver must achieve the design goal of a 7-dBA noise reduction. The Modified LPA with I-5 shifted west design option would cause slightly lower increase in noise for House (Building 1) and House (Building 2) than the other design options, but would require demolition of the Normandy Apartments. Noise mitigation is not reasonable in this area, per WSDOT noise abatement policy as detailed in Section 3.11.6.

The Section 106 process will result in a Programmatic Agreement with mitigation or other commitments to resolve adverse effects to historic properties. For contributing historic resources affected by vibration, such as the Post Hospital, these are expected to include condition inspection; monitoring vibration during construction; pre-emptive stabilization, maintenance, and repair; limits on certain equipment or activities; and repair of construction damage in accordance with the Secretary of the Interior Standards for the Treatment of Historic Properties (36 CFR 68).

For any noted adverse visual effects to the VNHR Historic District and Fort Vancouver NHS, such as to the Munitions Storehouse (Building 102), the Original Pearson Hangar (Building 189), the Pearson Field Office (Building 194), the Work Shop (Building 786), and the Fort Vancouver NHS Visitor Center, the Modified LPA with I-5 shifted west design option would be less prominent as viewed from these resources although effects would still be adverse. Tradeoffs between the remaining harm on various resources between the design options is addressed in Section 4.6.

4.6 Least Overall Harm Analysis

In accordance with 23 CFR 774.3, if there are no prudent and feasible alternatives that avoid the use of all Section 4(f) properties, then FHWA can approve only the alternative that causes the least overall harm. Replacing the existing bridges on the same alignment would not be a prudent and feasible alternative because it would require complete demolition of at least one bridge prior to reconstruction; therefore, traffic could not be maintained during the multiyear construction period. Section 4(f) properties on which the project would have only *de minimis* impacts, or for which the project would result in no use, do not need to be considered in the least overall harm analysis (23 CFR 774.17). The IBR Program would have use with greater than *de minimis* impact of eight historic sites and one park property subject to protection under Section 4(f) and is therefore subject to the requirement to identify the alternative with least overall harm. The single park property, the Fort Vancouver NHS, is located within the VNHR Historic District, which is one of the eight historic sites with use that is greater than *de minimis*. Each of the Modified LPA design options is considered to be an "alternative" solely for purposes of the least overall harm analysis under Section 4(f).

Table 4-9 summarizes the use of Section 4(f) properties by design option. The Modified LPA without C Street ramps design option would have the smallest area of use of Section 4(f) historic sites, with 12.0 acres permanently incorporated. The remaining Modified LPA design options have similar overall use of Section 4(f) properties ranging from approximately 12.4 to 12.5 acres.

The park-and-ride location options would not result in a use of any Section 4(f) property beyond what is already considered for the Modified LPA with all design options and are therefore not considered in the least overall harm analysis.

Table 4-9. Use with Greater than *de Minimis* Impact of Section 4(f) Properties by Alternative

Alternative	Number of Section 4(f)-Protected Properties with Use Greater than *de Minimis*	Section 4(f) Properties with Permanent Use Greater than *de Minimis*	Section 4(f) Properties with Temporary Use Greater than *de Minimis*
Modified LPA with Double-Deck Fixed-Span Configuration with One Auxiliary Lane, C Street Ramps, and Centered I-5	8 historic sites and 1 park	12.4 acres, including 0.3 acres that are both a public park and historic site	3.0 acres
Modified LPA SR 14 Interchange without C Street Ramps	8 historic sites and 1 park	12.5 acres, including 0.3 acres that are both a public park and historic site	3.0 acres
Modified LPA with I-5 Shifted West	8 historic sites and 1 park	12.5 acres, including 0.3 acres that are both a public park and historic site	3.2 acres
Modified LPA Single-Level Fixed- or Movable-Span Configuration with One Auxiliary Lane	8 historic sites and 1 park	12.4 acres, including 0.3 acres that are both a public park and historic site	3.0 acres

Alternative	Number of Section 4(f)-Protected Properties with Use Greater than *de Minimis*	Section 4(f) Properties with Permanent Use Greater than *de Minimis*	Section 4(f) Properties with Temporary Use Greater than *de Minimis*
Modified LPA with Single-Level Fixed- or Movable-Span Configuration with Two Auxiliary Lanes	8 historic sites and 1 park	12.5 acres, including 0.3 acres that are both a public park and historic site	2.9 acres
Modified LPA with Double-Deck Fixed-Span Configuration with Two Auxiliary Lanes	8 historic sites and 1 park	12.5 acres, including 0.3 acres that are both a public park and historic site	2.9 acres

As discussed in Section 4.5, there are no prudent and feasible alternatives that would avoid all Section 4(f) properties. Therefore, it is necessary to analyze which alternative would cause the least overall harm. Section 4.6 identifies all reasonable measures to minimize harm or mitigate adverse impacts. This is an important consideration in determining the least harm alternative. In addition, regulations in 23 CFR 774.3(c) provide the following direction for determining the alternative that would cause the least overall harm:

(c) If the analysis … concludes that there is no feasible and prudent avoidance alternative, then the Administration may approve only the alternative that:

(1) Causes the least overall harm in light of the statute's preservation purpose. The least overall harm is determined by balancing the following factors:

i. The ability to mitigate adverse impacts to each Section 4(f) property (including any measures that result in benefits to the property);

ii. The relative severity of the remaining harm, after mitigation, to the protected activities, attributes, or features that qualify each Section 4(f) property for protection;

iii. The relative significance of each Section 4(f) property;

iv. The views of the official(s) with jurisdiction over each Section 4(f) property;

v. The degree to which each alternative meets the purpose and need for the project;

vi. After reasonable mitigation, the magnitude of any adverse impacts to resources not protected by Section 4(f); and

vii. Substantial differences in costs among the alternatives.

The following section addresses each of the factors in the least overall harm analysis.

4.6.1 Ability to Mitigate Adverse Impacts to Each Section 4(f) Property, Including Any Measures That Result in Benefits

All of the alternatives have a similar ability to mitigate impacts to Section 4(f) properties in Washington, with the exception of the Modified LPA with I-5 shifted west and the Modified LPA without C Street ramps. The Modified LPA design options would have similar impacts on the VNHR Historic District and the Fort Vancouver NHS, requiring relatively small acquisitions ranging from approximately 1.2 to 1.6 acres on the western and southwestern edges of the VNHR Historic District or 0.3 acres for Fort Vancouver NHS adjacent to I-5 and SR 14. The Modified LPA with I-5 shifted west design option would have greater impacts to the Normandy Apartments (WA 149) in downtown Vancouver than any of the other Modified LPA design options and would require complete removal of this historic site with no ability to mitigate this impact. The Modified LPA with I-5 shifted west design option would have less impact on the VNHR Historic District than all other design options, including approximately 0.3 acres less than the Modified LPA with single-level (fixed- or movable-span) configuration with two auxiliary lanes and the double-deck fixed-span configuration with two auxiliary lanes and approximately 0.2 to 0.3 acres less than the other Modified LPA design options. All design options would have approximately 0.3 acres of use of Fort Vancouver NHS. The Modified LPA with I-5 shifted west design option would have severe impacts on the Normandy Apartments (WA 149) and would have no ability to mitigate adverse impacts on this historic site.

For Oregon historic sites, all Modified LPA design options would have the same effect on historic resources, with no ability to mitigate impacts to these sites.

Section 4.5 analyzes the measures that could be used to minimize impacts to Section 4(f) properties and determines which measures would be reasonable.

Modified LPA with all Design Options

The Modified LPA with all design options would provide all of the reasonable measures to minimize harm listed in Section 4.5 of this evaluation. Program-wide, measures to minimize harm primarily include:

- Reducing the overall project footprint through use of retaining walls with tie-back anchors rather than fill slopes and acquisition of additional area adjacent to the freeway.
- Reducing necessary right-of-way acquisitions from the VNHR Historic District and Fort Vancouver NHS.
- Reducing the footprint of the existing Interstate Bridge over land.
- Reducing the construction footprint and visual complexity of I-5 structures over Hayden Island and scaling them to their surroundings.
- Incorporate commitments agreed upon through the Section 106 Programmatic Agreement consultation process to resolve adverse effects to historic properties.

In addition, the Modified LPA with all design options would provide the measures to minimize harm listed for the CRC LPA in Section 4.1.5, except that the Modified LPA mitigations would not include transit access to Marshall Park since transit would not occur along McLoughlin Boulevard. The Columbia River Renaissance Trail is not protected under Section 4(f), as discussed in Section 4.2.1.

Key differences in adverse impacts between the Modified LPA and its design options are that the Modified LPA with I-5 shifted west design option would require complete removal of the Normandy Apartments in downtown Vancouver with no ability to mitigate this impact on this Section 4(f) historic site. The Modified LPA would have less overall impact on historic sites than the other design options due to a smaller footprint within the Fort Vancouver NHS (Table 4-3).

All Modified LPA design options have the ability to mitigate harm to the VNHR Historic District and Fort Vancouver NHS using the measures identified above and the measures identified in the CRC LPA (see Section). In particular, the Modified LPA with I-5 shifted west design option would result in less harm to the VNHR Historic District that the other Modified LPA design options.

However, the Modified LPA with I-5 shifted west design option would also result in severe harm to the Normandy Apartments through demolition of the structure, with no ability to mitigate that harm. The other Modified LPA design options would reduce harm to the Normandy Apartments to a partial acquisition of land, as discussed in the use evaluation in Section 4.3.8.

The Modified LPA with any of the design options would not have the ability to fully mitigate impacts to historic sites in Oregon, as discussed in Section 4.5.1 of this evaluation.

4.6.2 The Relative Severity of the Remaining Harm after Mitigation to the Protected Activities, Attributes, or Features That Qualify Each Section 4(f) Property for Protection

Section of this evaluation discusses measures to minimize harm after including the effects of reasonable mitigation measures. For all design options, the footprint of improvements and the use of Section 4(f) properties is the same south of the Columbia River.

The footprint over the Columbia River would differ across design options based on bridge configuration and the number of auxiliary lanes. The northbound Interstate Bridge would be completely removed by all design options, resulting in severe remaining harm for this Section 4(f) historic site and little ability to mitigate it. The only other Section 4(f) property within the Columbia River is the Lower Columbia River Federal Navigation Channel with a *de minimis* impact, which is not subject to all possible planning to minimize harm under 23 CFR 774.17.

North of the Columbia River, the Modified LPA design options have substantially the same alignment and footprint and would have similar use of Section 4(f) properties, with the exception of the VNHR Historic District, Fort Vancouver NHS, and the Normandy Apartments, which are discussed below.

Normandy Apartments

Except for the Modified LPA with I-5 shifted west design option, the Modified LPA and other design options would have the same use and relative severity of remaining harm to the protected activities, features, and attributes that qualify the Normandy Apartments for protection under Section 4(f) (Figure 4-37). The protected attributes and features of the Normandy Apartments include its eligibility as a historic site under Criteria A and C at the local level of significance in the areas of community planning and development and architecture. The Normandy Apartments building retains integrity of location, materials, workmanship, feeling, and association and has slightly reduced integrity of design and setting due to the original construction of I-5.

The Modified LPA with all design options would result in permanent incorporation of land from the Normandy Apartments site. Except for the Modified LPA I-5 with I-5 shifted west design option, this would include removal of landscaping and placement of a soundwall within 5 feet of the building, which would compromise the site's setting, feeling, and association. In addition, the elevated LRT tracks would be located near the building, affecting views to the east. These Program improvements would result in remaining harm to the Normandy Apartments site.

The Modified LPA with I-5 shifted west design option would shift the I-5 mainline and ramps 40 feet west of its current location. This option would require permanent right-of-way acquisition of the Normandy Apartments property and removal of the building and the landscaping elements to the east of the building and in the courtyard. The Modified LPA with I-5 shifted west design option would permanently incorporate approximately 14,700 square feet of the property and require demolition of the apartment building. This would be a greater incorporation and greater harm to the historic site than would occur under the Modified LPA and all other design options; it would completely remove all protected attributes and features that qualify the site for protection under Section 4(f).

Therefore, removal of the Normandy Apartments under the Modified LPA with I-5 shifted west design option would cause substantially greater harm to this resource than the Modified LPA and all other design options.

The VNHR Historic District and Fort Vancouver NHS

The Modified LPA with all design options would adversely affect 14 contributing resources within the VNHR Historic District under Section 106 (Table 4-5). They would incorporate land from the Fort Vancouver NHS (Table 4-4). Adverse effects on the VNHR Historic District include incorporation of land from the Army Road System, thereby resulting in a use of the district. However, acquisitions within the VNHR Historic District and Fort Vancouver NHS would primarily be of noncontributing resources, including landscaping along SR 14. The Modified LPA without C Street ramps design option would result in less use of the VNHR Historic District than the other Modified LPA design options, including the Modified LPA with I-5 shifted west option. However, changes would occur to the same noncontributing resources and would not change the use of, or harm to, contributing resources discussed in Section 4.3.8. Other potential harm identified for contributing resources includes visual, noise, and vibration effects, as discussed in Section 4.3.4. There would be visual and noise effects on recreational users of the Fort Vancouver NHS.

The single-level movable-span configuration with either one or two auxiliary lanes would be visually less prominent than the fixed-span configurations, but the vertical lift span would introduce vertical lift towers of a height similar to that of the existing bridge. The lift towers would have a greater maximum height than any of the other alternatives.

The Modified LPA with I-5 shifted west design option would result in less use of the VNHR Historic District than the Modified LPA and all other design options, with the exception of the Modified LPA without C Street ramps design option. This option would decrease the incorporation and demolition of a segment of the Army Road System by 3 to 9 feet. The Modified LPA with I-5 shifted west design option would slightly reduce the potential risk of vibration damage to both of the NCO Family Quarters Buildings (Buildings 635 and 644) by moving construction activities to more than 100 feet from the building's footprint. Construction would still occur within 100 feet of the Post Hospital building's footprint; therefore, there would still be a risk of vibration damage to the Post Hospital under the Modified LPA with I-5 shifted west design option. Although this design option would reduce use of and risk to VNHR Historic District contributing resources, use of, and risk to, contributing resources would still occur.

The Modified LPA with I-5 shifted west design option would result in the smallest remaining harm to the protected features and attributes that qualify the VNHR Historic District for protection than the Modified LPA and all other design options. Although total use of the VNHR Historic District would be less under the Modified LPA without C Street ramps design option, severity of remaining harm to contributing resources would be identical to the Modified LPA and greater than with the Modified LPA with I-5 shifted west design option (Figure 4-39).

The Modified LPA with one auxiliary lane design option would result in the least permanent incorporation of Fort Vancouver NHS (Table 4-5). All of the design options would have the same visual and auditory effects on contributing resources in the Fort.

4.6.3 Relative Significance of Each Section 4(f) Property

Modified LPA with All Design Options

The majority of historic sites that would be used by the Modified LPA or design options are NRHP eligible at the local significance level (Table 4-10). As a National Historic District, the VNHR Historic District is of greater significance as a whole than the individually eligible historic properties that would also be affected by the Modified LPA with all design options. The Fort Vancouver NHS is a National Park Unit, making it a nationally significant park property. It is also listed on the NRHP as a nationally significant historic site and is included in the VNHR Historic District.

Table 4-10. Relative Significance of Section 4(f) Properties with Use with a Greater than *de Minimis* Impact

Property	Significance
Northbound Interstate Bridge (OR 50 and WA 381a)	NRHP-listed at the regional significance level
The Toll Administration Building/ODOT Permit Center – 12348 N Center Avenue (OR 103)	NRHP-eligible at the state significance level
Harbor Shops – 11915 N Center Avenue (OR 107)	NRHP-eligible at the local significance level
Jantzen Beach Water Tank – N Center Avenue (OR 109)	NRHP-eligible at the local significance level
Jantzen Beach Moorage – 1501 N Jantzen Avenue/1525-2055 N Jantzen Avenue (OR 111)	NRHP-eligible at the local significance level
Normandy Apartments – 318 E 7th Street (WA 149)	NRHP-eligible at the local significance level
Bridge Substation – 100 SE Columbia Street (WA 1192)	NRHP-eligible at the local significance level
Vancouver National Historic Reserve Historic District (WA Multiple)	NRHP-listed district at the national significance level
Fort Vancouver National Historic Site	National Park Unit

NRHP = National Register of Historic Places; ODOT = Oregon Department of Transportation

4.6.4 Views of Officials with Jurisdiction over Each Section 4(f) Property

Discussions with officials with jurisdiction are ongoing for the IBR Program, as described in Section 4.7, Coordination. Discussions with the NPS, City of Portland, City of Vancouver, and Port of Vancouver confirmed that park properties identified as protected under Section 4(f) are significant. PP&R requested additional details and coordination about trail connections in and around Delta Park. VPR&C expressed general agreement with preliminary *de minimis* and temporary occupancy findings, pending public comment. Consultation under Section 106 identified the historic sites eligible for Section 4(f) protection within the IBR APE. NPS expressed that the portion of the VNHR Historic District that is also within the NRHP-listed boundary of the Fort Vancouver NHS is more significant than other parts of the VNHR Historic District because it was established by an act of Congress. The Oregon SHPO and Washington DAHP concurred with the Section 106 FOE for historic architecture on March 19, 2024, and October 13, 2023, respectively.

4.6.5 Degree to Which Each Alternative Meets the Purpose and Need for the Program

The Purpose and Need for the IBR Program is detailed in Chapter 1 of this Draft SEIS. As summarized below for each element of the Purpose and Need, the Modified LPA, including all design options, would meet the Purpose and Need; however, the degree to which each alternative addresses the Purpose and Need would vary as discussed for each element of the Purpose and Need.

Growing Travel Demand and Congestion and Impaired Freight Movement

The Modified LPA (with any design options) would improve congestion, safety issues, and freight movement. However, there are some differences in their performance, and certain design options would perform better than others. Compared to the No-Build Alternative, the Modified LPA would decrease travel (measured by vehicle miles traveled) by 1% in both the Portland metropolitan region and traffic subarea and travel times (measured by vehicle hours traveled) by 1% in the Portland metropolitan region and up to 3% in the subarea. The subarea is defined as a ring around I-5 and I-205 from where they meet in Vancouver to where they both intersect with I-84 in Portland. The Modified LPA (with either one or two auxiliary lanes) would result in an 11% decrease in delay (measured in vehicle hours of delay) in the Portland region and a 30% (one auxiliary lane) to 32% (two auxiliary lanes) decrease in delay in the subarea, compared to the No-Build Alternative.

The Modified LPA single-level movable-span configuration would involve periodic bridge openings and gate closures that would interrupt traffic operations (including freight and buses), LRT, and active transportation. Daytime bridge openings could impact traffic congestion for an hour or more, while nighttime bridge openings would have less impact to traffic congestion and transit operations (approximately 12 minutes would be needed for the bridge opening/closure, with the remainder of the hour needed for traffic operations to return to pre-opening conditions). The restrictions on when bridge openings would be permitted may change to reduce interruptions to all modes of transportation on the new Columbia River bridges. The fixed-span configurations would reduce congestion, improve vehicular and transit safety, and improve truck freight movement slightly more than the movable-span configuration. However, when open, the movable-span configuration would provide vertical clearance for river navigation than would the other bridge configurations. The higher vertical navigation clearance of the fixed-span bridge options compared to the No-Build Alternative would enable more vessels to pass under the bridges without requiring a bridge opening, resulting in fewer restrictions on the time needed to pass under the fixed-span configuration.

The Modified LPA has 10 intersections that do not meet agency performance standards for level of service (LOS) during either the AM and/or PM peak hours. An additional nine study area intersections would operate below agency standards during the AM and/or PM peak hours for the design option without C Street ramps. Removal of the C Street ramps would redirect trips between downtown Vancouver and I-5 to the Mill Plain Boulevard interchange, resulting in higher volumes compared to the other design options.

Overall, the Modified LPA without C Street ramps design option would perform less well than the other design options in meeting the project need to address growing congestion. The design options with two auxiliary lanes would perform slightly better than the options with one auxiliary lane at addressing growing congestion.

Safety and Vulnerability to Incidents

The Modified LPA under all design options would reduce the number of crashes in the corridor compared to the No-Build Alternative, with some differences among the options. The Modified LPA with double-deck fixed-span configuration, one auxiliary lane, and C Street ramps design option is predicted to experience 23% fewer crashes than the No-Build Alternative.

The Modified LPA with two auxiliary lanes design option is predicted to reduce crashes compared to the one auxiliary lane option by up to 6%. Under the Modified LPA without C Street ramps design option, more traffic would travel through the Mill Plain Boulevard interchange, which may increase the likelihood of crashes on the affected ramps and intersections; however, the removal of the C Street northbound off-ramp and southbound on-ramp is likely to offset these crashes and have a safety performance similar to that of the Modified LPA with C Street ramps design option.

While the impacts of the movable-span configuration cannot be quantified within the predictive analysis, the movable span is associated with a higher likelihood of crashes. It is therefore likely that the single-level movable-span configuration would perform slightly worse (i.e., experience more crashes) than the two fixed-span configurations but better (i.e., experience fewer crashes) than the No-Build Alternative.

Overall, the Modified LPA without C Street ramps design option and the design options with a movable span would perform less well than the other design options in meeting the project need to address safety. The design options with two auxiliary lanes would perform slightly better than the options with one auxiliary lane at addressing safety.

Substandard Bicycle and Pedestrian Facilities

The Modified LPA includes a shared-use path over North Portland Harbor and the Columbia River, as well as various improvements along connecting facilities. The alignment of the shared-use path in the Modified LPA ties into planned active transportation projects in Portland and Vancouver.

The effects of the Modified LPA design options would be similar because they offer either the same or similar improvements for active transportation. The single-level movable-span configuration would involve delays in active transportation due to bridge openings, whereas the other two bridge configurations would not. It is possible that openings could be limited to nighttime hours to reduce conflicts with active transportation, vehicular traffic, and transit; however, changes to bridge opening restrictions have not been determined.

The shared-use path across the Columbia River on all bridge configurations under the Modified LPA would be at a higher elevation over the Columbia River than the No-Build Alternative. In the single-level fixed-span configuration, the shared-use path would be at an elevation of 137 feet, while the single-level movable-span configuration would be 122 feet. The path transition from the I-5 northbound bridge down to Columbia Way would require extensive ramp lengths to span the vertical distance at a grade that meets or exceeds Americans with Disabilities Act requirements. The Modified LPA design incorporates a helix ramp to make this transition, but this design introduces considerable additional path length. While lower than the Modified LPA with double-deck fixed-span configuration, the paths in these configuration options would still be higher than under the No-Build Alternative, requiring all users to climb longer distance to get over the peak. In both options, users would experience a level of security similar to the No-Build Alternative by being separated from traffic. The Modified LPA with double-deck fixed-span configuration would provide active transportation users on the lower deck some shelter from weather conditions while making them not visible to traffic.

Overall, all of the design options would address active transportation needs to a similar degree.

Limited Public Transportation Operation, Connectivity, and Reliability

The Modified LPA with all design options would improve transit operations, connectivity, and reliability. In general, the Modified LPA design options would provide similar improvements to the public transportation system (i.e., extend LRT from Expo Center Station to Evergreen Boulevard, construct an LRT station on Hayden Island, provide bus-on-shoulder service, etc.). The single-level movable-span configuration would require delays to transit operations due to bridge openings. It is possible that openings could be limited to nighttime hours to reduce conflicts with active transportation, vehicular traffic, and transit; however, changes to bridge opening restrictions have not been determined.

There would be small routing changes to access downtown Vancouver in the Modified LPA without C Street ramps design option and travel time improvements for express bus transit in the two-auxiliary-lane design option. The other design options would all have similar effects on transit service.

Overall, all of the design options would address transit needs to a similar degree.

Seismic Vulnerability

The Modified LPA (including all design options) would improve seismic resiliency in the corridor by replacing the Interstate Bridge and North Portland Harbor bridge with a modern, seismically resilient crossing. There are additional structural considerations for a single-level movable-span configuration. While the bridge would be designed for seismic event(s), a movable span with moving parts and machinery is more likely to suffer misalignment and/or damage from a seismic event that would be detrimental to resuming operations without significant cost and down time. While the movable-span design option would meet seismic vulnerability safety requirements, it would be less resilient than the fixed-span options because it would likely require substantially greater time and effort to restore full operation after a substantial seismic event.

Overall, the Modified LPA movable-span design options would perform less well than the other design options in meeting the project need related to seismic resiliency.

4.6.6 After Reasonable Mitigation, the Magnitude of Any Adverse Impacts to Resources Not Protected by Section 4(f)

The Modified LPA was developed in part to reduce impacts to various resources. The primary differences in impacts and benefits to non-Section 4(f) resources between the alternatives are compared below.

Acquisitions and Displacements

The new transportation facilities and their long-term operation and maintenance would require permanent property acquisitions and displacements (Section 3.3, Property Acquisitions and Displacements). The number and location of acquisitions would generally be the same for all Modified LPA design options, except that the Modified LPA with I-5 shifted west design option would require additional acquisitions amounting to 1 acre, and the displacement of a 33-unit apartment complex and three commercial businesses in downtown Vancouver. The proposed locations for park and rides would require a total of 1.6 acres between sites 2 and 3 and displace one business. Two alternative park-and-ride locations are proposed for the Evergreen Station, which would require the full acquisition of an additional 3.16 acres. See Section 3.3, Property Acquisitions and Displacements, for additional information about acquisitions and displacements.

Transportation

The Modified LPA would reduce travel times and congestion along I-5 and improve traffic safety, multimodalism, freight mobility and access, and pedestrian and bicycle infrastructure compared to the No-Build Alternative. The Modified LPA with two auxiliary lanes design option has the potential to further reduce travel times and the duration of congestion by improving the efficiency of traffic flow. Transportation impacts are similar between the Modified LPA and the remaining design options (single-level fixed-span configuration, I-5 shifted west design option, and park-and-ride locations design option), with the exception of a slightly greater reduction to northbound PM peak travel time with the elimination of the C Street ramps and delays to all transportation modes during bridge openings with the single-level movable-span configuration. An additional nine study area intersections would not meet agency LOS performance standards under the Modified LPA without C Street ramps design option. See Section 3.1, Transportation, for additional information about transportation benefits and effects.

Aviation and Navigation Safety and Efficiency

The fixed-span bridge configurations proposed under the Modified LPA would improve aviation safety compared to the No-Build Alternative by reducing intrusion into the Pearson Field protected airspace. The single-level movable-span configuration would penetrate the Pearson Field protected airspace, when in the open and closed position, due to the lift span tower heights. All bridge configurations would reduce the potential for bird nesting and roosting.

The new crossing would also reduce the number of piers across the Columbia River and increase horizontal clearance. The Modified LPA fixed-span configurations (single-level or double-deck) would have a lower vertical navigation clearance than the single-level movable-span configuration, which is the only bridge option that provides a vertical navigation clearance of at least 178 feet (OLW, in the open position) per the USCG's Preliminary Navigation Clearance Determination (USCG 2022). The Modified LPA with either the double-deck or single-level fixed-span configurations (all bridge type options) would reduce the maximum clearance from 178 feet to 116 feet (OLW), requiring adjustments to some vessels or business operations.

The Modified LPA with double-deck fixed-span configuration would shift the 2,000-foot-long Vancouver Upper Turning Basin downstream approximately 300 feet compared to the No-Build Alternative, while the single-level configurations would shift it approximately 325 feet. Likewise, construction of the Modified LPA west of the existing Interstate Bridge would also reduce the distance between the proposed Columbia River bridges and the BNSF Railway bridge by 300 to 325 feet, resulting in a shorter available distance for vessels to align with the openings of the two bridges. See Section 3.2, Navigation, and Section 3.22, Aviation, for additional information about navigation and aviation benefits and effects, respectively.

The Modified LPA would increase the number of piers in North Portland Harbor because it would increase the number of bridges crossing the waterway.

Land Use, Circulation, and Development

The Modified LPA would alleviate capacity and mobility constraints along I-5, improve multimodalism, and address the need for regional high-capacity transit in a manner consistent with state, regional, and local plans. Interchange improvements at Denver/Interstate, Marine Drive, Hayden Island, SR 14/City Center, Mill Plain, Fourth Plain, and SR 500/Main Street would improve access and connectivity within the region.

Land use patterns would remain largely unchanged under the Modified LPA, with some differences in circulation and development between design options. The Modified LPA with two auxiliary lanes design option would require slightly more acquisition of property at Fort Vancouver but would further improve mobility and access for freight and employment compared to the Modified LPA. Approximately 35 businesses and 580 employees

would be displaced under the Modified LPA and most design options. The Modified LPA with I-5 shifted west design option would displace an additional three businesses and approximately 140 employees because the alignment would require more acquisitions in downtown Vancouver.

The reduced highway grade associated with the single-level fixed-span configuration (all bridge type options) would benefit freight vehicle speed and have corresponding economic benefits for the region. The Modified LPA without C Street ramps design option would create additional traffic delay near the Mill Plain Boulevard interchange and in downtown Vancouver, potentially having an economic impact to local businesses. The park-and-ride locations would all have similar effects. See Section 3.4, Land Use and Economic Activity, for additional information about land use benefits and effects.

Neighborhood Access and Mobility

The design options would have neighborhood impacts similar to those of the Modified LPA, with the exception of reduced transportation reliability due to bridge backups under the single-level movable-span configuration. Specifically for Hayden Island, the improvements to a more continuous street system, pedestrian and bicycle facilities, and transit connections could benefit residents and community cohesion. See Section 3.5, Neighborhoods and Equity, for additional information about neighborhood benefits and effects.

Natural Environment Impacts

The Modified LPA with all design options would improve water quality through updates to stormwater management and treatment. The replacement bridges and existing bridge removal would physically change the benthic and overwater footprint over the Columbia River and North Portland Harbor.

All design options would result in similar ecosystem effects but would differ in quantity and intensity. The Modified LPA with two auxiliary lanes design option would require an additional 4.8-acre (2.3%) increase in elevated overwater shading and contributing impervious area compared to one auxiliary lane. The single-level fixed-span configuration requires structural changes that would increase benthic impacts (net loss of 0.03 acres) and shading (additional 4 acres), but without meaningfully different effects on habitat function or water quality. The single-level movable-span configuration would bring similar increases to benthic habitat impacts (net loss of 0.07 acres) and overwater shading (additional 1.58 acres) at a slightly higher level than the fixed span due to a larger number of drilled shafts and shaft caps and a larger bridge deck. The Modified LPA with single-level fixed-span and single-level movable-span configurations would have wetland impacts similar to those of the double-deck fixed-span configuration (0.58 acres). The Modified LPA with I-5 shifted west design option and the Modified LPA without C Street ramps design option would have similar impacts to the natural environment. For additional information about these resources, see Section 3.14, Water Quality and Hydrology, for water quality, Section 3.15, Wetlands and Other Waters, for wetlands and waters, and Section 3.16, Ecosystems, for ecosystems.

Environmental Justice

The Modified LPA with all design options would have both beneficial and adverse effects on environmental justice (EJ) populations. There are no notable differences in effects among the design options, with the exception of increased residential displacements under the Modified LPA with I-5 shifted west design option. Beneficial effects include improved air quality; transit connectivity and service frequency; active transportation connectivity and safety; and vehicle travel reliability. For adverse effects, construction of the Modified LPA and any design option(s) would displace residences and businesses in high-priority and meaningfully greater EJ neighborhoods,[2] impacts from tolling, and noise impacts. The Modified LPA with I-5 shifted west would result in the displacement of an additional 33 residential units (Normandy Apartments) and three businesses. Although the Normandy Apartments are not identified by the U.S. Department of Housing and Urban Development as a low-income housing tax credit property, the 33 displacements would occur within the Esther Short neighborhood, a high-priority EJ area for low-income populations.

[2] See Section 3.20, Environmental Justice, for an explanation of what constitutes a “high-priority” and “meaningfully greater” EJ neighborhood or area.

The mitigation strategies related to acquisition and displacement and noise and vibration include statutory requirements, best management practices, and obligations the IBR Program must comply with under existing law (e.g., a noise wall is currently proposed to mitigate noise impacts). The Program is evaluating including a low-income tolling program as part of IBR implementation. Once fully developed, a low-income tolling program would play a critical role in mitigating disproportionately high and adverse effects of tolling on EJ populations. See Section 3.20, Environmental Justice, for additional information about benefits and effects for EJ populations.

4.6.7 Substantial Differences in Costs Among the Alternatives

The estimated capital cost ranges for the alternatives are provided in Table 4-11. These are high-level conceptual cost estimates that will be further refined by the IBR Program in 2024. Where a comparison is provided, the comparison is to the estimated cost of the Modified LPA with double-deck fixed-span configuration, one auxiliary lane, C Street ramps, and centered I-5. Overall, while there would be substantial differences between alternatives in the cost of the bridge alone, when factored into complete program costs, the differences would be within 10%.

Table 4-11. Cost Estimates

Alternative	Capital Cost
Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, and Centered I-5	Program cost: 5 to 7.5 billion (YOE $) [a] Bridge cost alone: 860 million to 1.3 billion (YOE $) [a]
Modified LPA with Single-Level Fixed-Span Configuration and One Auxiliary Lane	Program cost: Between 3% less and 2% more than the Modified LPA, depending on bridge type (i.e., steel or concrete segmental girder bridge, extradosed bridge, or finback bridge) Bridge cost alone: between 22% less and 13% more than the Modified LPA
Modified LPA with Single-Level Movable-Span Configuration and One Auxiliary Lane	Program cost: Program cost approximately 7% more than the Modified LPA Bridge cost alone: approximately 43% more than the Modified LPA
Modified LPA with all other design options	Program cost: Less than 1% difference from the Modified LPA

a Cost range is a risk-loaded estimate with 80% probability that the cost will be within the range.
I-5 = Interstate 5; LPA = Locally Preferred Alternative; YOE = year of expenditure dollars

4.6.8 Conclusion of Least Overall Harm Analysis

Overall, the difference in harm between the Modified LPA design options would be small, as summarized in Table 4-12, which draws from the information and analysis in this 4(f) evaluation. The locations of that information are cited in the first column of the table. Based on the consideration and balancing of all factors, the least overall harm alternative is the Modified LPA with double-deck fixed-span configuration, as explained further in text after the table.

Table 4-12. Summary of Least Overall Harm Analysis

Factor	1 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	2 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, without C Street Ramps, Centered I-5	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, and I-5 Shifted West	4 Modified LPA with Single-Level Fixed- or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	5 Modified LPA Single-Level Fixed- or Movable-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	6 Modified LPA Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5
Ability to mitigate impacts to 4(f) properties, including any benefits to properties (addressed in Section 4.6.1)	Direct use of VNHR Historic District would fall in the middle of the range of all alternatives (1.5 acres; 0.3 acres for Fort Vancouver NHS) and could not be offset. Use of Oregon historic sites could not be avoided and would be the same as most Modified LPA design options (9.0 acres). No use of the Normandy Apartments.	Same use of and ability to mitigate Section 4(f) properties as Column 1; direct use of the VNHR Historic District would be 1.5 acres; 0.3 acres for Fort Vancouver NHS.	Same use of and ability to mitigate Section 4(f) properties as Column 1, with the exception that direct use of VNHR Historic District would be the smallest of all alternatives (1.2 acres; 0.3 acres for Fort Vancouver NHS) and the Normandy Apartments site would be completely acquired and the building demolished. Impacts to Normandy Apartments would be severe and unavoidable with no ability to mitigate impacts.	Same use of and ability to mitigate Section 4(f) properties as Column 1, and same remaining harm; direct use of VNHR Historic District would be 1.5 acres; 0.3 acres for Fort Vancouver NHS.	Same use of and ability to mitigate Section 4(f) properties as Column 1 and same remaining harm, with the exception that direct use of VNHR would be at the top of the range (1.6 acres; 0.3 acres for Fort Vancouver NHS).	Same use of and ability to mitigate Section 4(f) properties as Column 1, with the exception that direct use of VNHR would be at the top of the range of all alternatives (1.6 acres; 0.3 acres for Fort Vancouver NHS).
Severity of remaining harm after mitigation (addressed in Section 4.6.2)	*De minimis* impact to three parks. Use with greater than *de minimis* impact of 8 historic sites and the Fort Vancouver NHS. Total use of 12.4 acres. The Modified LPA area of incorporation would fall in the middle of the range of all alternatives for the VNHR Historic District (1.5 acres). Adverse effects to 14 contributing resources in the VNHR Historic District; acquisitions primarily from noncontributing resources. Severe remaining harm to the northbound Interstate Bridge and Oregon-side resources, which would be demolished.	*De minimis* impact to three parks. Use with greater than *de minimis* impact of 8 historic sites and the Fort Vancouver NHS. Total use of 12.5 acres, falling in the middle of the range of all alternatives. More incorporation of the VNHR Historic District than the Modified LPA with C Street ramps design option (difference of 0.03 acres); Fort Vancouver NHS would have an additional 0.03 acres of incorporation. No change to the use or harm to contributing resources within VNHR Historic District. Same remaining harm to the northbound Interstate Bridge and Oregon-side resources as Column 1, which would be severe.	*De minimis* impact to three parks. Use with greater than *de minimis* impact of 8 historic sites and the Fort Vancouver NHS. Total use of 12.5 acres, falling in the middle of the range of all alternatives. Less harm to the VNHR Historic District than Column 1 due to decreased demolition of Army Road System and reduced vibration risk to NCO Family Quarters Buildings. Less use of the VNHR Historic District than the Modified LPA with C Street ramps design option (difference of 0.28 acres). Same remaining harm to the northbound Interstate Bridge and Oregon-side resources as the Modified LPA, which would be severe. Severe harm to the Normandy Apartments, which would be demolished.	*De minimis* impact to three parks. Use with greater than *de minimis* impact of 8 historic sites and the Fort Vancouver NHS. Total use of 12.4 acres, the least of all alternatives. Less incorporation of the VNHR Historic District than Column 1 (difference of 0.05 acres). Same remaining harm to the northbound Interstate Bridge and Oregon-side resources as Column 1, which would be severe.	*De minimis* impact to three parks. Use with greater than *de minimis* impact of 8 historic sites and the Fort Vancouver NHS. Total use of 12.5 acres, falling near the top of the range of all alternatives. More incorporation of the VNHR Historic than Column 1 (difference of 0.1 acres). Same remaining harm to the northbound Interstate Bridge and Oregon-side resources as Column 1, which would be severe.	*De minimis* impact to three parks. Use with greater than *de minimis* impact of 8 historic sites and the Fort Vancouver NHS. Total use of 12.5 acres, falling near the top of the range of all alternatives. More incorporation of the VNHR Historic District than Column 1 (difference of 0.1 acres). Same remaining harm to the northbound Interstate Bridge and Oregon-side resources as Column 1, which would be severe.
Relative significance of each 4(f) property (addressed in Section 4.6.3)	The VNHR Historic District and Fort Vancouver NHS are nationally significant and are the most significant properties affected. The northbound Interstate Bridge is a regionally significant property. All other properties are locally significant.	Same significance of Section 4(f) properties Column 1.	Same significance of Section 4(f) properties as Column 1. The Normandy Apartments, which is a locally significant resource, would be severely harmed, while harm to the VNHR Historic District, which is nationally significant, would be reduced.	Same significance of Section 4(f) properties as Column 1.	Same significance of Section 4(f) properties as Column 1.	Same significance of Section 4(f) properties as Column 1.

	1	2	3	4	5	6
Views of officials with jurisdiction (addressed in Sections 4.7 and 4.6.4)	At the time of this Draft Section 4(f) Evaluation, discussions with officials with jurisdiction are ongoing. NPS has expressed that the Fort Vancouver NHS has the greatest significance.	Same status as Column 1.	Same status as Column 1.	Same status as Column 1.	Same status as Column 1.	Same status as Column 1.
Degree to which alternative meets the Purpose and Need for the project (addressed in Section 4.6.5)	**Congestion, Safety, and Freight Movement**: Improved mobility and safety and reduces congestion due to design modifications that tie in to recent and planned improvements. Would have 23% fewer total crashes than the No-Build Alternative. **Transit:** Improved connectivity to existing and planned transit facilities **Bicycle and Pedestrian Facilities:** Improved connectivity to local street network **Seismic Vulnerability:** Decreased vulnerability due to replacement of the Interstate Bridge and North Portland Harbor bridge.	**Congestion, Safety, and Freight Movement:** Nine additional study area intersections would operate below LOS agency standards during the AM and/or PM peak hours, negatively affecting congestion and freight movement as compared with all other Modified LPA design options. Similar safety performance. **Transit:** Same as Column 1. **Bicycle and Pedestrian Facilities:** Same as Column 1. **Seismic Vulnerability:** Same as Column 1.	Same status as Column 1.	**Congestion, Safety, and Freight Movement:** Movable-span configuration would require periodic disruptions to all modes using the river crossing during bridge openings. May result in more crashes than fixed-span configurations because of the higher likelihood of crashes associated with bridge openings.	**Congestion, Safety, and Freight Movement:** Would reduce travel demand slightly more than Column 1 with shorter travel times for vehicles (including personal, freight, and bus). Would reduce crashes by up to 6% over the Column 1. A movable span would require periodic disruptions to all modes using the river crossing during bridge openings. **Seismic Vulnerability:** A movable span could be less resilient in returning to full operation after a seismic event.	**Congestion, Safety, and Freight Movement:** Similar to Column 1, except would reduce crashes by up to 6%. **Seismic Vulnerability:** A movable span could be less resilient in returning to full operation after a seismic event.
Magnitude of impacts to non-Section 4(f) resources after mitigation (see Section 4.6.6)	Reduced travel times and congestion, as well as improved traffic safety, multimodalism, freight mobility and access, and pedestrian and bicycle infrastructure. Improved aviation safety. Reduced vertical navigation clearance and relocated Vancouver Upper Turning Basin. Improved water quality through stormwater management. Physical changes in benthic habitat and overwater footprint. Full acquisition of 46 residential and commercial properties, 42 residential and 34 commercial displacements, including some in meaningfully greater and high-priority environmental justice (EJ) areas. New toll would require a higher proportion of income of low-income drivers (ODOT and WSDOT are evaluating a low-income toll program). The Modified LPA would bring new high-capacity transit service to meaningfully greater and high-priority	Similar to Column 1. Removal of C Street ramps would affect local traffic circulation patterns resulting in an additional nine study area intersections that would not meet agency level of service performance standards. It would also increase traffic delay near the Mill Plain Boulevard interchange.	Similar to Column 1, but would result in displacement of an additional 33 residential units (Normandy Apartments). Although the Normandy Apartments are not identified by the U.S. Department of Housing and Urban Development as a low-income housing tax credit property, the 33 displacements would occur within the Esther Short neighborhood, a high-priority EJ area for low-income populations. Also, additional displacement of three businesses (approximately 540) jobs in downtown Vancouver.	Similar to Column 1. A single-level fixed-span configuration would require 0.3 acres additional right-of-way acquisition in Portland and Vancouver and increase overwater shading by 4 acres and impacts to benthic habitat by 0.03 acres. A single-level movable-span configuration would require 0.3 acres additional right-of-way acquisition in Portland and Vancouver and increase overwater shading by 5.6 acres and impacts to benthic habitat by 0.07 acres. The increased width of the single-level configurations would relocate the Vancouver Upper Turning Basin. A single-level movable-span configuration would have a higher vertical navigation clearance for river users but would intrude into protected airspace.	Similar to Column 1. Overwater shading and impervious surfaces increased by 0.8 acres compared to the Modified LPA with single-level, one auxiliary lane design option.	Similar to Column 1. Increased overwater shading and impervious surfaces compared to Column 1. Would require 0.1 acres additional right-of-way acquisition compared to the Modified LPA with double-deck, one auxiliary lane design option.

	1	2	3	4	5	6
	EJ areas such as Esther Short in Vancouver.					
Substantial cost difference among alternatives (see Section 4.6.7)	Program cost: 5 to 7.5 billion (YOE $)	Program cost less than 1% difference from Column 1.	Program cost less than 1% difference from Column 1.	Between 3% less and 7% more than Column 1, depending on bridge type.	Program cost less than 1% difference from Column 1 for the fixed-span. Program cost approximately 7% greater than Column 1 for movable-span configuration.	Program cost less than 1% difference from Column 1.

EJ = environmental justice; I-5 = Interstate 5; LPA = Locally Preferred Alternative; NCO = non-commissioned officer; ODOT = Oregon Department of Transportation; SR = State Route; VNHR = Vancouver National Historic Reserve; WSDOT = Washington State Department of Transportation; YOE = Year of Expenditure

The Modified LPA with all design options would result in remaining harm after mitigation to Section 4(f) historic sites in Oregon and Washington. In Oregon, remaining harm would be the same for all of the Modified LPA design options. In Washington, the remaining harm after mitigation would be the same for all of the Modified LPA design options to all resources except the Normandy Apartments, VNHR Historic District, and Fort Vancouver NHS, which would differ for the Modified LPA without C Street ramps design option and the Modified LPA with I-5 shifted west design option.

Impacts to non-Section 4(f) resources would also generally be similar (Table 4-12) for all Modified LPA design options, with some differences for the Modified LPA with I-5 shifted west design option, the Modified LPA without C Street ramps design option, the Modified LPA single-level fixed-span or movable-span configuration with one or two auxiliary lanes design options, and the Modified LPA with double-deck fixed-span configuration due to displacement impacts. At a Program level, differences in costs would not be substantial.

Key distinguishing factors of the least overall harm analysis between the alternatives include the following:

- Ability to mitigate impacts to 4(f) properties, including any benefits to properties: All design options of the Modified LPA have about the same ability to mitigate impacts, with the exception of the Modified LPA with I-5 shifted west design option, which would remove the NRHP-eligible Normandy Apartments. However, the Modified LPA with I-5 shifted west design option would reduce impacts to the VNHR Historic District relative to other design options, including 0.2 to 0.3 acres less area used from the district than the other design options and less harm to contributing resources, such as the Army Road System, and decreased vibration damage risk to the Post Hospital and NCO Family Quarters Building. The Modified LPA with all design options could mitigate vibration risk by repairing any damage in accordance with the Secretary of the Interior Standards but could not mitigate incorporation of the Army Road System. Overall, the Modified LPA with I-5 shifted west design option has the least ability to mitigate impacts to Section 4(f) properties due to its impact on the Normandy Apartments.
- Severity of remaining harm after mitigation: The Modified LPA with I-5 shifted west design option would acquire and demolish the Normandy Apartments resulting in severe remaining harm, while the other design options would have less severe remaining harm. All alternatives would have similar effects on contributing elements of the VNHR Historic District except for the Modified LPA with I-5 shifted west design option, which would slightly reduce harm to the Army Road System and potential for vibration effects to other contributing elements. The Modified LPA without C Street ramps design option would use less land in the Fort Vancouver NHS and the VNHR Historic District than the other design options, with the exception of the Modified LPA with I-5 shifted west design option, but in an area of the park and historic district that does not contribute to the historic site's significance.
- Degree to which alternative meets the Purpose and Need: The Modified LPA with all design options all meet the Program's Purpose and Need, but some design options meet it better than others. All of the Modified LPA design options would improve congestion, safety, freight movement, transit, bicycle and pedestrian facilities, and seismic vulnerabilities over existing conditions. The Modified LPA with single-level movable-span configuration would require periodic disruptions of all modes during bridge openings. Design options with two auxiliary lanes would reduce travel demand more than one auxiliary lane and would result in marginally shorter travel times.
- Magnitude of impacts to non-Section 4(f) resources after mitigation:
  - The Modified LPA without C Street ramps design option would have the most substantial effects on arterial traffic operations of all of the design options because it would result in LOS standards not being met for an additional nine intersections. There would be delays to all modes during bridge openings for the Modified LPA with single-level movable-span configuration.

  - The fixed-span configurations proposed under the Modified LPA would improve aviation safety by reducing intrusion into the Pearson Field protected airspace.
  - Fixed-span configurations would have greater impacts on river navigation by reducing the vertical clearance under the bridge, requiring adjustments to some vessels or business operations. The Modified LPA with single-level configurations (movable or fixed span) would relocate the Vancouver Upper Turning Basin by an additional 25 feet compared with the double-deck fixed-span configuration.
  - The Modified LPA with I-5 shifted west design option would result in additional impacts to an EJ population from residential displacements. The single-level configurations are wider and would result in more navigation impacts due to reduced vertical clearance, while a single-level movable-span configuration would retain the existing clearance but intrude into protected airspace. Design options with two auxiliary lanes would result in more overwater shading.

- Substantial Cost Difference Among the Alternatives: The most substantial difference in cost would be for the Modified LPA with single-level movable-span configuration, which would increase Program costs by approximately 7% (between 370 and 560 million YOE $) compared to the Modified LPA with double-deck fixed-span configuration.

Balancing the small differences in harm, the Modified LPA with double-deck fixed-span configuration has preliminarily been identified as the alternative with least overall harm, as supported by the comparison of the seven factors considered in Table 4-12 and the discussion above. Overall, the difference in harm across the design options would be small, with the exception of demolition of the Normandy Apartments and additional residential displacements for the Modified LPA with I-5 shifted west design option. FHWA and FTA will consider public comment on this Draft Section 4(f) Evaluation prior to making a final determination on the alternative with least overall harm in the Final Section 4(f) Evaluation.

As the IBR Program continues into final design, the Program team will continue to consider ways to further reduce impacts on Section 4(f) properties, ensuring that the action will include all possible planning to minimize harm.

4.7 Coordination

The IBR Program sponsors and/or the federal co-lead agencies have coordinated with 11 Native American tribes, the Washington DAHP, the Oregon SHPO, the NPS, the City of Vancouver, the Vancouver Public School District, Clark College, the City of Portland, and other interested parties in identifying Section 4(f) properties, evaluating the use of Section 4(f) properties, and identifying measures to minimize harm to these properties. Coordination is in process and will continue with officials with jurisdiction over the park and recreation properties and historic sites regarding *de minimis* impact and temporary occupancy determinations. FHWA and FTA will obtain written concurrence from officials with jurisdiction over park and recreation properties where they intend to make a *de minimis* impact determination subsequent to a 45-day public comment period as required by 23 CFR 774.5(b). For properties where temporary occupancy exceptions are sought, FHWA and FTA will obtain written agreement that the conditions of 23 CFR 774.13(d) are met. Concurrence for *de minimis* impact determinations and agreement for temporary occupancy exceptions will be obtained prior to issuance of the Final SEIS.

During October 2023, the Draft Section 4(f) evaluation was provided to the lead agencies, the Cities of Portland and Vancouver, the Ports of Portland and Vancouver, and consulting parties for review and comment regarding the identification and significance of properties subject to Section 4(f) and evaluation of use of those properties. The IBR Program sponsors met with NPS, PP&R, VPR&C, and the Port of Vancouver regarding parks within their jurisdictions. The analysis in this chapter reflects comments received from these agencies.

The agencies confirmed that they have jurisdiction over the respective park properties identified in this chapter and that the properties are significant public parks. NPS clarified that it manages Waterfront Park as part of the Fort Vancouver NHS, clarified resource and boundary definitions between the park and historic district, and expressed that recreational experience is not separate from that of the historic site. The City of Portland provided comment on project features at East Delta Park regarding active transportation facilities within the city. The IBR Program's features and effect on Old Apple Tree Park and Marshall Park were discussed with the City of Vancouver, including ongoing need for coordination on right-of-way ownership. The City of Vancouver identified a location preference for the trail within Old Apple Tree Park; the Program is continuing to evaluate trail alignment in coordination with VPR&C. The Port of Vancouver confirmed the boundary of the public park area at their recently constructed Vancouver Landing and committed to ongoing coordinated planning of future park development in coordination with the IBR Program to reduce potential for conflicts between the two.

Consultation regarding the identification, significance, and effects on historic sites has occurred through the Section 106 process and documented in the Archaeology Technical Report and the Historic Built Environment Technical Report.

Additional coordination will occur after the Draft SEIS comment period to inform refinement of the Modified LPA during the preparation of the Final SEIS. The U.S. Department of the Interior (DOI) will formally review and comment on the Section 4(f) Evaluation during the Draft SEIS public comment period in 2024 (pending), and the DOI and other agencies will be given an opportunity to review the revised Section 4(f) Evaluation prior to publishing the Final SEIS. The U.S. Department of Transportation will make its Section 4(f) approval, under 23 CFR 774.3(a), as part of the Final SEIS or ROD.

Please see the FOE Concurrence Forms included in the appendices of the IBR Program Historic Built Environment Technical Report for further information regarding coordination with the Oregon SHPO and Washington DAHP.

4.8 Preliminary Section 4(f) Findings

The USDOT has made the preliminary determination that:

- The IBR Program would have:
  - Use with greater than *de minimis* impact of eight Section 4(f) protected historic sites and one public park (Table 4-8),
  - Use with *de minimis* impact on three public parks and four historic sites except for the Modified LPA with I-5 shifted west design option, which would have five (Table 4-3 and Table 4-5), and
  - The temporary occupancy exception would apply to five historic sites (Table 4-5).
- There is no feasible and prudent alternative that completely avoids all Section 4(f) properties;
- The Modified LPA is the alternative that causes the least overall harm; and
- The Modified LPA includes all possible planning to minimize harm.

Appendix A

AGENCY AND TRIBAL COORDINATION

This appendix documents how the Interstate Bridge Replacement (IBR) Program has collaborated with regulatory agencies and tribes as part of the National Environmental Policy Act (NEPA) process. Additionally, the following discussion summarizes the collaboration and coordination implemented to date and how these efforts will continue throughout the duration of the NEPA process. Roles and responsibilities of each agency or tribe, and the coordination that has occurred with each, are included as well.

Agency Coordination

Agency coordination has played a significant role throughout the IBR Program NEPA process, from defining the Purpose and Need to development of the Supplemental Environmental Impact Statement (SEIS). Because the project is located in two states, cities, and counties, it requires coordination and outreach with numerous federal, state, and local agencies. In addition, the project is composed of three major structural components: a bridge, light-rail transit, and a highway. Thus, various agencies have a wide range of expertise and jurisdictional authority.

For the purpose of the following discussion, *regulatory agency* refers to any federal, state, or local agency from which a permit is anticipated or approval is needed for the Modified Locally Preferred Alternative (LPA). The IBR Program team has and continues to communicate with regulatory agencies throughout the NEPA process to identify permits and approvals needed for construction. Previously, during the environmental review stage for the Columbia River Crossing (CRC) project, the project team engaged with regulatory agencies on a regular and ongoing basis. Agency engagement extended throughout the NEPA process for the CRC project, from defining the Purpose and Need to development of the Draft Environmental Impact Statement and Final Environmental Impact Statement (EIS), and it is described in detail in Appendix A of the CRC Final EIS. This effort continues under the IBR Program. The IBR Program team works extensively with regulatory agencies and local jurisdictions, which are organized into the following designated agency groups: lead agencies, cooperating agencies, and participating agencies.

Lead Agencies

A lead agency is the agency carrying out the federal action and is responsible for complying with the requirements of NEPA. In some cases, such as the IBR Program, more than one federal agency is designated as a federal lead agency. Federal agencies, together with state agencies, local agencies, and/or tribes, may act as joint lead agencies. Lead agencies prepare the environmental documentation for a project and oversee the NEPA process.

The federal lead agencies for the IBR Program include the Federal Highway Administration (FHWA) and the Federal Transit Administration (FTA). The federal lead agencies for the IBR Program are responsible for:

- Overseeing the coordination process (as codified in 23 USC § 139).
- Determining the level of NEPA documentation required to complete the NEPA process for the IBR Program.
- Providing guidance on the NEPA process, including resolving differences in agency procedures.
- Confirming the sufficiency of NEPA documentation.
- Providing legal sufficiency review of project documents.
- Participating in discussions involving other federal agencies.

- Coordinating with FHWA and FTA headquarters to obtain "prior concurrence" on key NEPA decisions made by the FTA regional and FHWA division office.
- Leading consultation with other federal agencies for compliance with federal statutes (e.g., Endangered Species Act [ESA], National Historic Preservation Act [NHPA]).
- Overseeing tribal consultation.
- Making the final NEPA decision.

The federal lead agencies undertake additional responsibilities in conjunction with other nonfederal joint lead agencies for the IBR Program. Nonfederal joint lead agencies include the Oregon Department of Transportation (ODOT); Washington State Department of Transportation (WSDOT); local transit agencies Tri-County Metropolitan Transportation District (TriMet) and Clark County Public Transportation Benefit Area (C-TRAN); and regional metropolitan planning organizations Oregon Metro (Metro) and the Southwest Washington Regional Transportation Council (RTC). In conjunction with the federal lead agencies, the nonfederal joint lead agencies are responsible for:

- Providing timely, technical review and comments on the impact assessment methodologies, technical analyses, and environmental review documentation.
- Supporting the preparation and distribution of a NEPA coordination plan (including schedule), Draft SEIS, Final SEIS, and Record of Decision in compliance with the requirements of all applicable environmental laws, executive orders, and other related requirements.
- Supporting identification of a preferred alternative to be evaluated in the Final SEIS to the extent practicable.
- Supporting the public involvement activities, notifications of availability and distribution of environmental review documents, and posting of decisions related to the environmental review documents.
- Identifying any issues of concern regarding the Program's environmental impacts and mitigation measures.
- Providing timely input on unresolved issues.
- Coordinating with Program staff to develop and maintain an administrative record for relevant Program decisions.
- Providing timely review of permit applications and authorizations that fall under the agency's jurisdiction.

Lead agencies and their roles and responsibilities for the IBR Program are listed in Table A-1 and Table A-2.

Additional lead agency responsibilities are to be determined.

Table A-1. Federal Lead Agencies

Agency	Permits and Approvals
FHWA FTA	• Federal approval. • Compliance with federal laws and regulations. • Right-of-way permit (interstate) (FHWA).

Table A-2. Joint Lead Agencies

Agency	Permits and Approvals
ODOT WSDOT	• State approval. • Washington State Environmental Policy Act (SEPA) (WSDOT). • Program delivery via funding from the two state legislatures and potential federal funding sources. • Potential grant recipients for FTA (WSDOT) (to be determined). • Design, construction, and operation and maintenance of state and interstate highways according to respective Stewardship and Oversight Agreements. • Right-of-way encroachment permits.
Metro RTC	• Regional approval. • Maintenance of the regional and metropolitan transportation plans that include the IBR Program. • Program funding in Transportation Improvement Program. • Coordination, planning, and approval of investments in the transportation system.
TriMet C-TRAN	• Local approval of transit. • Design, construction, and operation and maintenance of the transit facility. • Potential grant recipients for FTA (TriMet) (to be determined).

Cooperating Agencies

A cooperating agency is any federal agency, other than a lead agency, that has jurisdiction by law (with permitting or land transfer authority) or special expertise with respect to any environmental impact involved in a proposed project or project alternative. A state or local agency of similar qualifications may also become a cooperating agency by agreement with the lead agencies, as may a Native American tribe when the effects are on lands of tribal interest. Lead agencies specially request cooperating agencies to participate during the environmental evaluation process for a project. All cooperating agencies are also considered participating agencies.

Cooperating agencies are specifically requested by the lead agencies to participate during the environmental evaluation process for a project. Cooperating agencies have an elevated status in the NEPA process due to the independent actions these agencies may take that depend on the Program's NEPA analysis; this includes an opportunity to contribute expertise in the development of methodology and analysis of impacts. In addition, it is anticipated that cooperating agencies will use the Final SEIS to support their respective permit or approval decision-making. Cooperating agencies are also invited to be participating agencies.

Each cooperating agency will have the opportunity to participate in Program meetings, open houses, and workshops in addition to reviewing and providing comments on the following Program milestones and activities:

- Consult and concur with the lead agencies concerning the schedule in the *IBR NEPA Coordination Plan*.
- Participate in agency coordination meetings.

- Provide input on the EIS analysis methodology memoranda within the areas of the cooperating agency's expertise during the review period.
- Provide input on the administrative Draft SEIS, Final SEIS, and relevant EIS technical documentation.
- Provide adequate information for the cooperating agency to discharge its NEPA responsibilities and any other requirements regarding jurisdictional approvals, permits, licenses, and/or clearances.

Cooperating agencies for the IBR Program, along with their roles and responsibilities, are summarized in Table A-3.

Table A-3. Cooperating Agencies

Agency Name	Role	Permit and Approval Responsibilities
National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NOAA Fisheries)	Federal permitting; agency with jurisdiction and special expertise on fish and wildlife.	• Endangered Species Act (ESA) Section 7 Consultation • Magnuson-Stevens Fishery Conservation and Management Act • Marine Mammal Protection Act • Biological Opinion
National Park Service (NPS)	Property owner; Agency with jurisdiction and special expertise on historic resources.	• National Historic Preservation Act (NHPA) Section 106 Consultation • Archaeological Resources Protection Act Permit • Fort Vancouver National Historic Site • U.S. Department of Transportation Act Section 4(f) Consultation • Section 6(f) of the Land and Water Conservation Fund Act Consultation • Federal Lands to Parks Concurrence
U.S. Army Corps of Engineers (USACE)	Federal permitting; agency with jurisdiction and special expertise on the Clean Water Act, water quality, and the levee and navigation channel.	• Section 401 of the Clean Water Act Water Quality Certification • Section 404 of the Clean Water Act Permit • Section 408 Authorization for Modification/Alteration of USACE Civil Works Projects (levee and navigation channel)
U.S. Coast Guard (USCG)	Federal permitting; Agency with jurisdiction and special expertise on navigable waterways.	• General Bridge Act of 1946 Permit
U.S. Environmental Protection Agency (EPA)	Federal permitting; Special expertise on the adequacy and the acceptability of the environmental impacts analysis.	• Sole Source Aquifer Protection Act • Clean Air Act
Washington State Department of Archaeology and Historic Preservation (DAHP)	State permitting; Special expertise on archaeology and historic resources.	• NHPA Section 106 Consultation • U.S. Department of Transportation Act Section 4(f) Consultation

Beginning in 2005 as part of the CRC project, the CRC project team met with each of the cooperating agencies to gather information and seek advice on project development and potential build concepts. Each cooperating agency played a key role in developing the build alternatives analyzed in the CRC Final EIS. The IBR Program's approach has been similar in that the Program has either met, or will meet, one-on-one with each of the cooperating agencies prior to publication of the Draft SEIS. Each cooperating agency has the opportunity to provide input on the Modified LPA as it relates to the respective agency's expertise, interest, and mandates.

Participating Agencies

Participating agencies are agencies that have a specific interest in a project. Non-governmental organizations and private entities cannot serve as participating agencies. Pursuant to 23 USC § 139, participating agencies are responsible for identifying, as early as practicable, any issues of concern regarding the IBR Program's potential environmental, social, or economic impacts that could substantially delay or prevent an agency from granting a permit or other approval that is needed for the Program.

Designation as a participating agency does not imply Program support, and if applicable, does not provide an agency with increased oversight or approval authority beyond its statutory limits. Each participating agency will have the opportunity to participate in Program meetings, open houses, and workshops in addition to reviewing and providing comments on the following NEPA milestones and activities:

- Participate in the NEPA process starting at the earliest possible time. Participation includes providing comments and responses on NEPA documents, reviewing studies or methodologies on the areas within the special expertise or jurisdiction of the agency and advising on the level of detail for the analysis of impacts.
- Identify, as early as practicable, environmental issues of concern regarding the IBR Program.
- Provide meaningful and timely input on unresolved issues.
- Comment on the schedule in the *IBR NEPA Coordination Plan*.

Participating agencies may also contribute to other environmental compliance processes (e.g., NHPA Section 106, ESA) that are pertinent to agency interests or area(s) of expertise. Participating agencies and their roles and responsibilities are summarized in Table A-4.

Table A-4. Participating Agencies

Agency	Role	Permits and Approvals
Federal Aviation Administration (FAA)	Agency with jurisdiction, special expertise on aviation impacts.	• 7460-1 Permit for Permanent Obstruction • 7460-1 Permit for Construction Obstruction
U.S. Fish and Wildlife Service (USFWS)	Special expertise on fish and wildlife.	• Endangered Species Act Section 7 Consultation • Letter of Concurrence
U.S. General Services Administration (GSA)	Special expertise on federal lands.	• Federal Lands to Parks Concurrence

Agency	Role	Permits and Approvals
City of Portland	Agency with jurisdiction, property owner, special expertise on city facilities and operations.	• Land Use Review (environmental, adjustment, design) • Historic Demolition Review • Noise Variance • Improvements in Right-of-way • Building Permit – Site Development • Sign Permit • Trade Permits – Electrical; Mechanical; Plumbing • Features on Park Lands • Tree removal permits (12-inches or larger)
City of Vancouver	Agency with jurisdiction, property owner, special expertise on city facilities and operations.	• Regional and local transportation, local land use, and local permits • Public Facilities Master Plan (Hybrid Approach) • Transportation Development Review • Traffic Impact Analysis • Shoreline permit or exemption approval • Critical Areas permit or exemption approval • Noise Permit • Building Permit • Trade Permit – Electrical; Mechanical; Plumbing • Temporary Use Permit • Access Closure • Sign Permit (Temporary) • Features on Park Lands • Tree removal permits
City of Gresham	Agency with jurisdiction	• Right-of-way Permits • Tree Permit • Design Review
Oregon Department of Environmental Quality (DEQ)	Agency with jurisdiction, special expertise on multiple environmental resources (air quality, water quality).	• Clean Water Act Section 401 Water Quality Certification • 1200-C construction stormwater permit • Air Quality Permit • Stationary Source Permit • Voluntary Cleanup Pathway approval
Oregon Department of Fish and Wildlife (ODFW)	Agency with jurisdiction, special expertise on fish and wildlife.	• Fish Passage Act Fish Passage Permit • Habitat Mitigation Policy

Agency	Role	Permits and Approvals
Oregon Department of Land Conservation and Development (DLCD)	Special expertise on statewide planning	• Oregon's Statewide Land Use Planning Goals Compliance
Oregon Department of State Lands (DSL)	Agency with jurisdiction, special expertise on bridge easement and fish passage.	• Removal-Fill Permit • Lease/Bridge Easement Permit • Oregon Fish Passage Act Approval
Oregon State Historic Preservation Office (SHPO)	Special expertise on archaeology and historic resources.	• NHPA Section 106 Consultation • U.S. Department of Transportation Act Section 4(f) Consultation
Port of Portland	Special expertise on freight movement.	• Regional and local transportation, traffic impact analysis, local land use
Port of Vancouver USA	Special expertise on freight movement.	• Regional and local transportation, traffic impact analysis, local land use
Washington State Department of Ecology	Agency with jurisdiction, special expertise on multiple environmental resources (air quality, water quality, wetlands, contaminated sites).	• Clean Water Act Section 401 Water Quality Certification • Construction Stormwater General Permit • Air Quality Permit • Stationary Source Permit • Shoreline Management Act Approval
Washington State Department of Fish and Wildlife (WDFW)	Agency with jurisdiction, special expertise on waters under the state's jurisdiction.	• Hydraulic Project Approval • Mitigation Policy (POL-M5002)
Washington State Department of Natural Resources	Agency with jurisdiction, special expertise on natural resources.	• Aquatic Lands Lease/Easement • Aquatic Use Authorization
Multnomah County Drainage District	Responsible for reducing flood risk by maintaining levee systems, managing drainage, and responding to emergencies.	• Development Review permit • Letter/Statement of No Objection Letter for the Section 408 Process

Note: Two agencies (the Washington State Recreation and Conservation Office and the Oregon Parks and Recreation Department) declined to serve as participating agencies.

The participating agencies identified in Table A-4 may also participate in other environmental compliance processes (e.g., NHPA Section 106, ESA) that are respective to agency interests (or area of expertise).

Ten federally recognized tribes with jurisdiction or other interests in the IBR Program study area will be involved in the IBR Program NEPA process. Each participating tribe will have a participating agency role in the

development of the Program, including the following as it relates to each tribe's area of expertise or environmental issues of concern to their jurisdiction:

1. Provide meaningful and early input on methodologies and level of detail required in the alternatives analysis.
2. Participate in coordination meetings and joint field reviews as appropriate.
3. Provide timely review and comment on the technical reports to reflect the views and concerns of each respective tribe on the adequacy of the document, alternatives considered, and the anticipated impacts and mitigation.

Participating federally recognized tribes in the IBR Program NEPA process include:

- Confederated Tribes and Bands of the Yakama Nation
- Confederated Tribes of Siletz Indians of Oregon
- Confederated Tribes of the Colville Reservation
- Confederated Tribes of the Grand Ronde Community of Oregon
- Confederated Tribes of the Umatilla Indian Reservation
- Confederated Tribes of the Warm Springs Reservation of Oregon
- Cowlitz Indian Tribe
- Nez Perce Tribe
- Nisqually Indian Tribe
- Spokane Tribe of the Spokane Reservation Indians (Spokane Tribe of Indians)

In addition to the above, the Program is coordinating with the Chinook Indian Nation, which is not currently a federally recognized tribe. A tribe's designation as a participating agency does not replace formal government-to-government or Section 106 tribal consultation with federally recognized tribes. The approach to formal tribal consultation and tribal consultation activities to date are discussed below in the Tribal Consultation section of this appendix.

Agency Coordination Points and Responsibilities

Table A-5 identifies the key NEPA coordination points, as well as agency responsibilities, information provided, and anticipated timeframe. The lead agencies will provide reasonable advance notification to cooperating and participating agencies for expected review dates.

The IBR Program will routinely update the schedule and inform agencies and tribes of the timeframes identified below. Timeframes for review and/or comment will be established. Reviewers shall compile comments from their respective agencies and tribes and send a single set of comments to the IBR Program team when more than one staff member reviews a document. Federal permitting agencies will be able to track federal permits and timelines via the federal Permitting Dashboard.

Table A-5. Agency Coordination Points and Responsibilities

Coordination Point	Information or Activity Provided	Agency Responsible for Commenting	Comments Provided or Activity Conducted	Anticipated Timeframe
Cooperating and Participating Invitation Letters	Distribute invitation letters	Cooperating/ Participating	Review and respond	October 2022
NEPA Coordination Plan	Distribute Draft Coordination Plan	Cooperating/ Participating	Review and comment	October 2022
Issue Notice to Supplement (NTS)	Publish NTS in Federal Register	Cooperating	Review and comment	April 2023
Impact assessment methodologies	Distribute draft impact assessment methodologies	Cooperating/ Participating	Review and comment	October–December 2022
Draft SEIS (Administrative Draft)	Distribute Administrative Draft SEIS	Cooperating	Review and comment	July - October 2023
Biological Opinion for Endangered Species Act/Section 7	Distribute Final Biological Assessment	NOAA Fisheries, USFWS	Review and issue biological opinion or letter of concurrence	September 2023–September 2024
Draft SEIS	Distribute Draft SEIS	Participating	Review and comment	August 2024
Mitigation Plan	Included in the SEIS	Cooperating/ Participating	Review and comment	August 2024
Final Supplemental Environmental Impact Statement (Final SEIS) (Administrative Draft)	Distribute Administrative Draft Final SEIS	Cooperating	Review and comment	March 2025
Signing of the Programmatic Agreement for Section 106	Distribute Programmatic Agreement	FHWA, FTA, USACE, Oregon SHPO, Washington State DAHP, WSDOT, ODOT, NPS	Review, comment, and sign	March – April 2025
Concurring Signatures on Programmatic Agreement for Section 106	Distribute Programmatic Agreement	*To be determined*	Review, comment, and sign if concurring party	March – April 2025
Final EIS	Distribute Final EIS	Participating	N/A	July 2025
Record of Decision (ROD)	Publish ROD	Federal Lead	Review and comment	September 2025

DAHP = Department of Archaeology and Historic Preservation; ESA = Endangered Species Act; FHWA= Federal Highway Administration; FTA = Federal Transit Administration; N/A = not applicable; NOAA Fisheries = National Oceanic and Atmospheric Administration National Marine Fisheries Service; NPS = National Park Service; SEIS = Supplemental Environmental Impact Statement; SHPO = State Historic Preservation Office; USACE = U.S. Army Corps of Engineers; USFWS = U.S. Fish and Wildlife

Technical Coordination with Agencies in Development of the Modified LPA

The IBR Program has worked in tandem with partner agency technical staff through focused technical working groups to develop, evaluate, refine, and identify design concepts, transit investments, and modeling and analytical approaches in development of the Modified LPA. Descriptions of these efforts with partner agencies follow.

Executive Steering Group

The IBR Program's design team collaborated with executive leadership and technical staff from local partner planning and transportation agencies to develop, evaluate, refine, and identify design concepts and transit investments for consideration by advisory groups and the community. These meetings served as a venue for developing a shared understanding of local conditions, needs, and planned transportation improvements. The Executive Steering Group identified design options for screening, contributed to desired outcomes, developed screening criteria, considered tradeoffs, and was engaged in the process of developing the Modified LPA.

The Executive Steering Group included executive leadership from the IBR Program and the following 10 partner agencies:

- ODOT
- WSDOT
- Local transit agencies C-TRAN and TriMet
- Regional metropolitan planning organizations Metro and RTC
- Cities of Portland and Vancouver
- Ports of Portland and Vancouver

Travel Demand Modeling Working Group

Representatives from the IBR Program, ODOT, WSDOT, C-TRAN, TriMet, the Cities of Vancouver and Portland, the Ports of Vancouver and Portland, Metro, and RTC met to review and discuss methods and assumptions related to travel demand modeling being used in support of analysis for the IBR Program. This group met approximately monthly starting in June 2021 to discuss many aspects of the demand model process including data collection, land use, travel markets, regional data analysis, tolling (for the IBR Program, as well as modeling assumptions made by the Oregon Toll Program), definition of model assumptions for screening of highway and transit options, and post-processing for traffic analysis. The group also reviewed screening criteria and analysis related to transportation modeling to support the evaluation of design options.

Transit Options Technical Session

Representatives from the IBR Program, C-TRAN, TriMet, the Cities of Vancouver and Portland, Ports of Vancouver and Portland, Metro, and RTC developed and refined an array of transit scenarios (including mode, alignment, stations, and operations) and their varying performance and operating measures. This technical team was convened under the name of the Transit Options Technical Session and met eight times between October 2021 and February 2022.

Climate Technical Working Group

The IBR Program invited climate and planning staff from each of the partner agencies to join ODOT and WSDOT climate specialists for discussions on strategies to support shared climate goals. The climate technical working group meetings are held monthly and cover topics such as methods to assess greenhouse gas emissions associated with the Program, greenhouse gas reduction goals and targets, and the need for mutually supportive policies and programs to support shared climate goals. Future meetings will address design refinements, the environmental study, and construction means and methods, as well as investigate potential mitigation or offsets.

Tribal Consultation

Below is a summary of the IBR Government-to-Government tribal consultation activities. The summary details how this Program team is coordinating with tribal governments.

WSDOT, ODOT, FHWA, and FTA are committed to government-to-government consultation with tribes on projects that may affect tribal rights and resources. The IBR tribal consultation process is designed to encourage early and continued feedback from, and involvement by, tribes potentially affected by the IBR Program and to ensure that their input is incorporated into the decision-making process. Although tribal coordination and government-to-government tribal consultation is being undertaken as a distinct outreach effort, tribal involvement is also occurring concurrently with agency coordination and public involvement.

Goals for Tribal Consultation

The primary goal of tribal consultation within the IBR Program is to achieve meaningful engagement with tribes concerning the IBR Program, and it is supported by numerous federal and state agreements and executive orders, including but not limited to, the following:

- Executive Order 13175, Consultation and Coordination with Indian Tribal Governments
- President Biden's Memorandum on Tribal Consultation and Strengthening Nation-to-Nation Relationships
- Washington State Centennial Accord
- WSDOT Executive Order 1025, Tribal Consultation
- Oregon Revised Statutes 182.162 to 182.168, Relationship of State Agencies with Indian Tribes
- NEPA
- Section 106 of the NHPA

In addition to the federal and state executive orders, memorandums, and mandates for tribal consultation, it is FHWA and FTA's goal to fulfill its Trust responsibilities to tribes. The best and most appropriate manner to learn of these concerns and obligations is through consultation and coordination with federally recognized tribes.

Consultation is an ongoing process that develops a richer and lasting understanding of the area while strengthening the relationship among FHWA, FTA, WSDOT, ODOT, and the consulting tribes. Lessons learned from the CRC project will be incorporated into the IBR Program. FHWA, FTA, and the IBR Program will, to the extent possible, seek to avoid and minimize the effects the IBR Program may have on tribal resources and to mitigate actions for all unavoidable impacts.

Tribal Consultation Approach

The IBR Program has a designated tribal liaison who will facilitate all communications with the consulting tribes. Other WSDOT and ODOT team members may participate in the ongoing government-to-government dialogue. FHWA and FTA have designated a federal tribal liaison who will oversee and participate in all activities and coordination undertaken by the IBR tribal liaison. The federal tribal liaison will review all requests for consultation, be invited to and attend all tribal and intertribal meetings, and coordinate review of consultation and coordination materials with other representatives from FHWA and FTA. At any time, tribes may request government-to-government consultation separately with the federal agencies.

Consultants will assist in preparing for meetings with the tribes, but all contact will be through the IBR tribal liaison, federal tribal liaison, and WSDOT and ODOT staff on the Program. All communication with tribes is coordinated through the IBR tribal liaison and federal tribal liaison to ensure that information is managed internally and integrated into the government-to-government dialogue with the tribes. Tribal consultation activities are documented in the Program's administrative record unless noted as sensitive or confidential.

The general approach to government-to-government consultation for the IBR Program is as follows:

- Meet with representatives of consulting tribes to review broad issues.
- Consult and coordinate with tribal leadership and staff per each tribe's preference. At the request of the tribes, FHWA, FTA, and the IBR Program team will meet with respective tribal representative or entities including, but not limited to, cultural and natural resource staff.
- Incorporate tribal input into Program planning and permitting activities. FHWA, FTA and the IBR Program team will keep the consulting tribes fully informed throughout the Program planning, permitting, and development process. The FHWA, FTA and the IBR Program team recognize and respect that consulting tribes, as sovereign entities, are afforded opportunities for engagement in the planning and permitting process, independent and separate from public outreach and other engagements with the public. FHWA, FTA, and the IBR Program team understand that input, feedback, and comment may be received through a variety of methods, including working groups, on-on-one technical meetings, formal consultation, and via written comment.

The following summarizes the tribal consultation in which the IBR Program has engaged through May 2024. The IBR Program team has conducted extensive consultation with interested tribes since September 2020. The ODOT Tribal Liaison led the consultation effort until the Program arranged to have a tribal liaison dedicated to the project in October 2022 . FHWA and FTA designated a federal tribal liaison in September 2023.

Who are we consulting with and why?

During the environmental review stage for the CRC project, the project team consulted with both the natural and cultural resource offices of each affected tribe. CRC staff periodically met with tribal councils and committees as appropriate. This effort continues under the IBR Program.

In September 2020, government-government consultation was reinitiated when FHWA and FTA extended letters to the 21 tribes and Native Hawaiian Organizations that were contacted originally on the CRC project, four of which have adjudicated treaty fishing access rights along the Columbia River. In February 2022, as a result of consultation with the National Park Service (NPS), outreach was extended to an additional 17 tribes. Through that effort, 10 federally recognized tribes expressed an interest in consultation on the IBR Program.

The IBR Program team initiated formal consultation with the following federally recognized tribes:

- Confederated Tribes of Grand Ronde Community of Oregon

- Confederated Tribes of the Colville Reservation
- Confederated Tribes of the Umatilla Indian Reservation
- Confederated Tribes of Warm Springs Reservation of Oregon
- Cowlitz Indian Tribe
- Nez Perce Tribe
- Confederated Tribes of Siletz Indians of Oregon
- Spokane Tribe of the Spokane Reservation Indians (Spokane Tribe of Indians)
- Confederated Tribes and Bands of the Yakama Nation
- Nisqually Indian Tribe

The Program team is also consulting with the Chinook Indian Nation, which is currently not a federally recognized tribe. The Program team is consulting with technical staff in various departments from each consulting tribe. The IBR Program periodically presents to/meets with tribal councils and committees when requested.

Consulting tribes will have the opportunity to identify issues of concern regarding the IBR Program's potential environmental or socioeconomic impacts; to participate in project meetings, open houses, and workshops; and will have the opportunity to review and provide comments on the project milestones and activities, including but not limited to:

- Design options development and screening report
- Tribal consultation plan
- Draft SEIS methods, data reports, and technical reports
- Section 106 documentation
- Section 4(f) analysis
- Biological assessment

Consultation Activities to Date

- Reinitiated consultation with the tribes in September 2020.
- Conducted face-to-face and virtual meetings with each tribe as well as intertribal meetings.
- Sent invitations to be participating tribes for the NEPA compliance process to 10 federally recognized tribes in November 2022.
- The consulting tribes were given the opportunity to review the following products:
  - Methods and data reports
  - Design options development and screening report
  - Area of Potential Effects for Section 106
  - Tribal consultation plan
  - All Draft SEIS technical reports
  - Draft research designs for archaeological discovery field investigations
  - Historic built environment baseline surveys

- Historic built environment determinations of eligibility
- Historic built environment findings of effects
- IBR programmatic agreement
- Section 4(f) analysis
- Biological assessment

Appendix B

PUBLIC INVOLVEMENT

This appendix describes the overall public involvement activities for the Interstate Bridge Replacement (IBR) Program. It includes a general description of public involvement activities and specific public outreach efforts conducted during preparation of the Draft Supplemental Environmental Impact Statement (SEIS) from January 2021 through September 2023. Extensive public involvement efforts were undertaken as part of the Columbia River Crossing (CRC) Environmental Impact Statement (EIS) process from publication of the Notice of Intent to prepare an EIS in September 2005 through publication of the Final EIS in 2011 (CRC 2011). Public comments on the Draft EIS for the CRC project are described in Chapter 6 of the CRC Final EIS, and the overall public involvement program for the CRC project is summarized in Appendix B of the Final EIS. The IBR public involvement efforts build on the work done during CRC by incorporating the feedback, best practices, and lessons learned from past work with new tools and opportunities. This appendix documents the public involvement conducted for the IBR Program and includes the IBR Program's goals for public involvement, a description of the primary audiences identified for outreach, and the tools used to communicate with these interested parties.

The IBR Program has engaged with partner agencies, tribal governments, and community-based organizations (CBOs) since late 2020 and has been conducting more formal intentional community engagement since January 2021. This engagement has shaped the communications strategy and implementation, the environmental review process, the Modified Locally Preferred Alternative (LPA), and the design options that are part of the Modified LPA.

The IBR Program strives to minimize barriers to engagement and frequently offers ongoing opportunities for input. Engagement includes a range of online, hybrid, and in-person options, as detailed in the Public Involvement Tools section.

The IBR Program is complying with and exceeding National Environmental Policy Act (NEPA) requirements for public involvement and is fully complying with Executive Order (EO) 12898 (as amended by EO 12948), which requires each federal agency to make achieving environmental justice (EJ) part of its mission "by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations" (White House 1995). In compliance with EO 12948, the IBR Program has identified Black, Indigenous, and People of Color (BIPOC), people whose incomes are below the federal poverty threshold, and limited English proficiency (LEP) populations within the study area to inform the outreach and engagement approach. In addition to these groups, the IBR Program has identified people with disabilities, people experiencing houselessness, immigrants and refugees, young people (25 and under) and older adults (65 and older) as equity priority communities. The IBR Program has also established an Equity Advisory Group (EAG) to better solicit feedback and center equity. For more information on the IBR Program's Equity Commitment, see the IBR website.[1]

In 2023, EO 14096, Revitalizing Our Nation's Commitment to Environmental Justice for All, was signed by the Biden administration. EO 14096 directs the federal government to strengthen its commitment to deliver EJ through an updated definition of EJ, a change in the standard for what constitutes as an EJ effect, and an expansion of EJ communities. Although formal guidance on how to apply EO 14096 to NEPA projects has yet to be published, the IBR Program has sought to meet the intent of the rule through a robust EJ analysis, coordinated with an equity analysis completed as part of the Equity Technical Report.

[1] https://www.interstatebridge.org/equity

Outreach efforts have resulted in approximately 40,000 engagements with community members since 2021. Additionally, the IBR Program has significant interaction through a dedicated website and is active on multiple social media channels. The IBR Program has been featured in over 900 media stories, op-eds, and reader stories through the third quarter of 2023. This engagement provides important input that the IBR Program will continue to consider and integrate throughout the planning and design process. Appendix D, Design Option Development and Screening Report, details how feedback shaped the development of the Purpose and Need, Desired Outcomes, and the Modified LPA.

Goals for Public Involvement

Community engagement efforts provide extensive, inclusive, and ongoing opportunities for meaningful communication with community members that prioritize equity, diversity, accessibility, transparency, and inclusion. The goals for public involvement are as follows:

- Seek feedback from a diverse range of partners.
- Engage equity priority communities.
- Embrace innovation.
- Uplift all voices.
- Demonstrate accountability through transparency and feedback.
- Achieve trust among partner agencies and the community.

Primary Audiences

The following groups and organizations have been identified as interested parties in the IBR Program. These parties are the primary focus of outreach:

- Program-defined equity priority communities: people whose incomes are below the federal poverty threshold, individuals and families experiencing houselessness, people with LEP, BIPOC, immigrants and refugees, people with disabilities, young people, and older adults.
- Residents of Clark County, Washington, and Multnomah County, Oregon.
- Property and business owners within and adjacent to the Program area.
- People who drive, use transit, and active transportation users in the Program area.
- Future potential users of the Program area.
- The commuter, business, and freight communities.
- Media.
- Neighborhoods in and adjacent to the Program area.
- CBOs.
- Tribal members.[2]
- Local, state, and federal elected officials in both Oregon and Washington.
- Community leaders.

[2] The IBR Program acknowledges that tribes are sovereign nations. The Program consults with federally recognized tribes through a government-to-government consultation process separate and distinct from public and community outreach and comment. Appendix A to this SEIS details the IBR Program's Tribal Consultation.

Public Involvement Tools

Public involvement tools and methods used by the IBR Program team are summarized below.

Website

An IBR Program website has been created and is regularly updated (https://www.interstatebridge.org/). The website provides Program information, newsletters, fact sheets, advisory group meeting schedules and materials, and schedules of public events. It also gives the public a means to provide the IBR Program team with feedback. The website has been used to offer web-based surveys and online open house efforts at key Program milestones. The website also provides links to videos that have been produced for the IBR Program, including "Bridge Stories," described below.

Accountability Dashboard

The IBR Program's accountability dashboard is a transparency tool designed to share key community engagement metrics, holding the IBR Program accountable to the public. This is a space where the public can learn about what the IBR Program has heard from the community and how the Program is responding. Funding sources, expenditures, and disadvantaged business enterprise (DBE) participation goals are reported within the accountability dashboard. The accountability dashboard is available on the Program website and updated quarterly.

Bridge Stories

"Bridge Stories" is a campaign designed to spotlight diverse community members who live, work, and congregate in the greater Portland-Vancouver region. The campaign consists of a series of short videos showcasing real stories of people who use the Interstate Bridge. Participants share what the bridge means to them, how they use the bridge, and how the bridge replacement impacts them. Links to the videos are provided on the Program's website and are shared on social media.

Monthly Newsletter Monthly emails provide regular Program status updates to all those on the IBR Program email list. The IBR Program's email list, used to encourage participation in public events and involve the broader community, has grown to more than 7,500 contacts. This includes 7,082 subscribers who have signed up to receive monthly newsletters. Interested parties can sign up for monthly email updates through the website (https://www.interstatebridge.org/contact).

Social Media

The IBR Program maintains active accounts across multiple social media platforms to provide Program updates and engage the broader community in a more informal setting. In particular, social media is an important tool to support outreach to young people.

Office Hours

Office hours provide the opportunity for community members to sign up for an appointment to speak directly to IBR Program team members to ask questions and share their feedback. Office hours timeslots are offered at various times and days of the week and include both in-person and virtual options to make them as inclusive and accessible as possible.

Neighborhood Forums and Open House Events

In-person open house style events provide an opportunity for community members and businesses within the Program area to drop in and speak directly with IBR Program staff. Neighborhood forums were held in May and June 2023 to provide an opportunity for the public to learn about the Program's environmental review process, including what is being analyzed in the study area, the financial plan, design work, and community engagement opportunities. Additional events will be considered to support outreach during key Program milestones.

Presentations to Community-Based Organizations, Neighborhood Associations, and Conferences

The IBR Program proactively reaches out to neighborhood associations and CBOs to offer updates on Program activities and respond to requests to provide briefings. The Program also searches for speaking opportunities to engage a broad range of audiences at the national, regional, and local levels to share the Program's story, inform audiences of the Program's progress, and address any questions.

Outreach to Equity Priority Communities

An important component of the public involvement strategy for the IBR Program is outreach and engagement with equity priority communities. To this end, the Program coordinates with local community leaders, liaisons, groups, and CBOs to develop appropriate strategies for outreach to these populations. The EAG and the Community Advisory Group (CAG) have also provided valuable feedback on outreach to equity priority communities. The Program has used an assortment of virtual outlets, including social media, a website translation tool, resources to reach LEP communities, events, and newsletters. The Program has also networked with community leaders, college students, school parent groups, churches and religious institutions, and other organizations.

The Program conducts intentional outreach to equity priority communities and uses a number of tools to improve accessibility and inclusion. Examples of outreach efforts the Program has implemented to minimize barriers to engagement and reach equity priority communities include:

- Providing American Sign Language interpreters and closed-captioning in English and Spanish at advisory group meetings, listening sessions, and upon request.
- Providing accessible materials, website, and meetings and anticipating the needs of equity priority community members so they can fully participate in meaningful engagement and make informed decisions. The website allows translation into eight languages and documents and graphics posted on the website are remediated to Americans with Disabilities Act standards to ensure compatibility with screen reader software.
- Producing three-dimensional physical models to assist blind and low-vision community members.
- Partnering with CBOs serving equity priority communities, including small-scale, low-barrier grants to extend the Program's engagement outreach.
- Providing incentives for participation to equity priority participants.
- Working with multilingual community engagement liaisons who are fluent in languages other than English and deeply connected within their local communities to help spread the word about the Program and connect with those with LEP, immigrants, and refugees.

- Translating selected Program documents to support outreach listening sessions and events into Arabic, Chinese, Chuukese, Korean, Somali, Spanish, Russian, Vietnamese, Thai, and Ukrainian. These translated documents were posted on the Program website and were distributed in hard copy form at strategic community locations.
- Providing verbal language interpreters upon request for affinity listening sessions.
- Hosting youth press conferences for high school and college news/media outlets to give them space to ask questions in an affinity setting.

Written Materials

One of the main components of the communications effort for the IBR Program is a range of written materials that are easily identifiable as IBR Program materials and that can be accessed either in print form or electronically via the website. Individuals who require reasonable accommodations can request written material in alternative formats or sign language interpreters by contacting the Program team. All documents on the IBR Program website are also remediated for accessibility for individuals with visual impairments to comply with Section 508 of the Rehabilitation Act of 1973. Under Section 508, agencies must give disabled employees and members of the public access to information comparable to the access available to others.

The following are examples of the written materials produced:

- **Newsletters**. Monthly newsletters are sent via email and published on the IBR Program website to describe plans and timelines, opportunities for public input, options and alternatives under consideration, and progress. They also serve as part of the notification system for public meetings and other milestones.
- **Fact Sheets**. Fact sheets have been developed that can be used individually or in packets for specialized audiences. A general background document was created that describes Program need, process, timelines, and benefits and is updated as needed. Additional fact sheets provide information about other topics of public interest, such as the Modified LPA, how the Program centers equity, cost and funding information, and tolling.
- **Display Boards**. Display boards are created for open houses, booths at fairs and festivals, and miscellaneous presentations.
- **Postcards**. Postcards are mailed to relevant addresses to notify neighbors and other interested parties of upcoming opportunities to review the Program team's work and provide input.
- **Presentation Materials**. Presentation materials are prepared to support open houses; briefings with neighborhood associations, business groups, and community organizations; and meetings with media and elected officials. Materials are tailored to each group and may consist of a combination of slides, illustrations, display boards, and presentation handouts.

Online Public Meetings, Surveys, Listening Sessions, and Roundtables

Due to the 2019 coronavirus (COVID-19) pandemic, most of the events held during 2021 and in 2022 were conducted online. As the IBR Program begins to offer more in-person events, these in-person events will be held in both Vancouver and Portland for the convenience of the public. The Program will continue to provide virtual and hybrid engagements to provide communities members with several options to connect.

Online public meetings, listening sessions, surveys, and roundtables have been held to share Program information and gather feedback in coordination with key Program milestones. The Program team has provided accessible meeting materials upon request for individuals who require reasonable accommodations, including written materials in alternative formats or sign language interpreters.

Fairs, Festivals, and Community Events

To connect with a broader range of people, the IBR Program focuses on reaching people where they are, on their terms and schedules. These efforts include participation in local and regional community events such as fairs, festivals, and farmers' markets. These outreach opportunities are designed to provide the general public with an informal opportunity to engage with the team, view Program information, and learn about upcoming milestones and public involvement opportunities. This type of outreach provides the public with increased knowledge of the Program, a broad-based understanding of its goals and schedules, and a convenient means of providing feedback directly to Program staff. Team participation in community events typically involves staffing informational tables and booths.

Media Support

A media strategy is used to reach a broad audience with accurate and timely information, increase public awareness of the Program, and encourage participation in public events. It includes methods for gaining media coverage at Program milestones and methods to keep the Program in the public eye between milestones, including the following:

- **News releases**. The Program sends news releases to the media distribution list to alert reporters and blog writers about major milestones and public meetings. News releases are also posted on the Program website.
- **Media outreach**. The Program proactively contacts media outlets to offer briefings at key milestones and updates.
- **Media responses**. The Program strives to provide timely and accurate responses to inquiries received from media outlets.
- **Authored content**. The Program identifies opportunities to provide topic-specific columns and opinion pieces to highlight milestones or key messages.
- **BIPOC and small press**. Minority-owned and neighborhood-based media are included in the distribution of press materials. The Program team has provided translated versions of press releases.
- **Media distribution list**. The Program maintains a media list and distribution systems to ensure that materials are distributed to all relevant and interested news outlets. Neighborhood publications and transportation-related blogs are included on this list.
- **Community calendars**. Dates, times, and locations of community open houses and other public events are submitted to a wide variety of community calendar sections of publications (both inside and outside the Program corridor) to reach a broad regional audience.
- **Media tracking**. All print media stories are collected for reference, distributed via email to key Program team members on a daily basis, and archived.
- **Email messages**. The Program communications team keeps the media informed with monthly emails about the Program.

Comments, Responses, and Tracking

The public can provide the Program team with comments through a variety of methods, including email, the Program website, voicemail, and public meetings. Public and agency comments gathered over the course of the Program are shared with selected Program staff based on phase, issue, and area of responsibility. By attending outreach events, Program staff (including technical staff) also receive comments directly from members of the public.

Each written comment (form, letter, or email), outreach summary, record of telephone conversation with a member of the public, and transcript of testimony at a public hearing is logged into the public comment system so that it may be made available to decision-makers.

After receiving a comment, Program staff determine whether a question or comment requires a response. If a response is required, staff research the answer and respond within approximately one week; complex questions may take additional time to research and respond to. All comments and questions are then categorized by topic. Each comment can address numerous topics. At regular intervals, comments are summarized, along with information about recent outreach events and media coverage, and are distributed internally to help ensure awareness across Program disciplines.

Communications Coordination

The communications team periodically convenes communications staff from the partner agencies for Program progress updates, to introduce and review communications plans and messages, and track the distribution of Program materials. Meetings are typically held around major Program milestones or as needed.

Summary of Public Engagement Events

The IBR Program seeks to provide ongoing, accessible, and inclusive engagement opportunities using a variety of methods to meet people where they are. The Program also conducts additional outreach efforts to gather public feedback to inform Program work around key milestones. Below is a high-level summary of engagement efforts broken out by timeframe.

Public Involvement Efforts

From November 2020 to September 2023, Program staff engaged in over 400 public outreach meetings and events. Table B-1 at the end of this document presents a chronological list of these events. A summary of outreach efforts by timeframe is also included below. Additional public involvement events are currently planned for 2023 and 2024 prior to publication of the Draft SEIS.

Winter and Spring 2021 Public Engagement Efforts

In the first quarter of 2021, the IBR Program conducted intentional community engagement to gather specific public feedback regarding the transportation problems travelers experience with the current Interstate Bridge and to understand the community priorities and values that should shape the Program. This feedback helped the Program to confirm that the previously identified Purpose and Need and Vision and Values for replacing the Interstate Bridge remain valid and identified equity and climate change as key community priorities. A comprehensive Community Engagement Report was prepared that details the feedback received (IBR 2021a).

Engagement activities included the following:

- Launching Program website, social media accounts, and e-newsletter.
- Launching three Program advisory groups and began regularly scheduled public meetings (initial kick-off meetings for Executive Steering Group [ESG] held in November 2020).
- Holding four online public briefings in February 2021, including one conducted in Spanish, to introduce the community to the Program purpose, workplan, ways to get involved
- Holding an online open house and interactive survey from February 16 to 28, 2021 on the IBR website to provide the public with Program information and gather public input to help define priority issues and key

problems in the study area. Materials were translated into eight languages and printed for distribution through multilingual community liaisons.

- Reviewing completed community surveys from over 9,100 individuals with over 14,400 comments submitted.
- Hosting four listening sessions for youth and equity priority communities, including BIPOC, people experiencing houselessness, and people with disabilities in an effort to elevate historically excluded voices and address demographic gaps in survey responses.

Key takeaways included:

- Widespread agreement that the transportation problems previously identified by the CRC project still exist: congestion and travel reliability, safety, earthquake vulnerability, impaired freight movement, inadequate bicycle and pedestrian pathways, and limited public transportation.
- Desire for solutions that consider climate change, minimize impacts to neighboring communities, impacts to equity priority communities.
- Congestion and travel reliability were consistently ranked or expressed as the highest concerns, with safety and earthquake vulnerability both ranked second and mentioned frequently.
- Concerns about transportation safety, including earthquake vulnerability and interstate design.
- Support for an improved public transit connection between Portland and Vancouver.
- Concerns regarding tolling and potential impacts on equity priority communities and distribution of the cost burden.
- Value of a cost-effective Program with funding support that builds on previous work.
- Desire for low-barrier engagement options and the opportunity to have meaningful conversations with the Program.

Summer 2021 Public Engagement Efforts

Community engagement efforts from April through August 2021 were focused on gathering feedback and input to help inform the development of initial design elements and priorities to shape the process.

Engagement opportunities included the following:

- equity-focused communities, with Key Takeaways
- Spring 2021 community engagement demonstrated widespread agreement that the previously identified transportation problems still exist with congestion, seismic resiliency, and safety as top community concerns.
- Equity and climate change considerations were clearly identified as important community priorities.
- The community values low-barrier engagement options and the opportunity to have meaningful conversations with the Program.
- Listening session participants shared their desire to see more investment into the local economy, increased opportunities for equity priority communities to get involved, and continued transparent communication from the Program.
- Significant interest in discussing details of a solution, including the design process. Two video storytelling series launched, “Bridge Stories” and “The Case for IBR,” showcasing how community members use the Interstate Bridge and the benefits a replacement bridge will provide.

- IBR Program summer interns help launch the Program's TikTok account and bolster other digital content efforts to better engage with youth.
- Four community working groups (Active Transportation, Multimodal Commuter, Downtown Vancouver, and Hayden Island/Marine Drive) formed to act as Program focus groups with over 90 community participants involved.
- The EAG adopted a definition of equity specific to the IBR Program, inclusive of both process and outcome equity, and began development of the Equity Framework.
- Advisory groups provided input on the Program's Climate Framework and how climate change goals will be applied to various components of the Program.
- The CAG developed a summary of community values and priorities to inform Program work.
- Eleven CBOs in both Oregon and Washington were awarded small-scale, low-barrier grants to help reach equity priority communities in partnership with the IBR Program.
- Hosted six listening sessions for specific user groups (active transportation, multimodal commuter, freight movement), potential impact concerns (downtown Vancouver, Hayden Island/Marine Drive, and sustainability and climate change), and eight equity-focused communities:
  - Multimodal commuter listening session to gather feedback on issues that are important to automobile, transit, and bicycle commuters who use the Interstate Bridge.
  - Active transportation listening session for community members who bicycle, walk, roll, or use other forms of active transportation to move through the study area (or would like to do so in the future).
  - Downtown Vancouver listening session to gather insights from community members who live, work, play, or represent organizations within downtown Vancouver.
  - Listening session regarding sustainability and climate considerations to gather insights from community members regarding climate change concerns.
  - Listening sessions with people living with disabilities to gather insights from community members with disabilities, whose views have historically been excluded from large transportation programs and projects.
  - BIPOC listening sessions to gather insights BIPOC communities, whose views have historically been excluded from large transportation programs and projects.
  - A listening session with people and families experiencing houselessness and CBOs that work with people experiencing houselessness to gather insights from this community, whose views have historically been excluded from large transportation programs and projects.
  - Listening sessions with older adults, whose views have historically been excluded from large transportation programs and projects.
  - Multilingual listening sessions with individuals with LEP in their respective native languages to provide information and gather insights from those whose views have been historically excluded from large transportation projects and programs.

Key takeaways included:

- Feedback demonstrated widespread agreement that the previously identified transportation problems still exist with congestion, seismic resiliency, and safety as top community concerns.
- Equity and climate change considerations were clearly identified as important community priorities.

- The community values low-barrier engagement options and the opportunity to have meaningful conversations with the Program.
- Listening session participants shared their desire to see more investment into the local economy, increased opportunities for equity priority communities to get involved, and continued transparent communication from the Program.
- Significant interest in discussing details of a solution, including the design process.

Fall and Winter 2021Public Engagement Efforts

From September to December 2021, the IBR Program held a second period of intentional community engagement, including surveys, community briefings, listening sessions, advisory groups, community working groups to gather feedback and input on the design options and weigh in on the priorities that informed elements of the Modified LPA. In addition to public comments provided during briefings, listening sessions, and other events, more than 9,600 survey responses and 1,700 survey comments were received as a result of these efforts. A comprehensive Community Engagement Report for fall and winter of 2021 details feedback received (IBR 2021b).

Engagement opportunities included the following:

- An online open house with detailed information about previous planning efforts, preliminary design options, equity and climate frameworks, the environmental compliance process, and steps to identifying an IBR solution.
- Community input survey with 9,600 participants to gather feedback on preferences and priorities associated with the user experience and design options.
- Two youth press conferences hosted by the Program administrator.
- Four community working groups (Active Transportation, Multimodal Commuter, Downtown Vancouver, and Hayden Island/Marine Drive).
- Four community-specific listening sessions were held in November 2021 in partnership with 10 CBOs that have established deep connections within equity priority communities. CBO partners act as a trusted facilitator, encouraging participation and spreading awareness of listening sessions among their networks through email blasts, social media posts, texts, posters, phone calls, and authored newsletter articles. The purpose of these sessions was for Program staff to share information on design options with equity priority communities and solicit feedback in an affinity space. More than 300 community members participated in this series of listening sessions (see Table B-2), many of whom reported it as being their first time engaging with the Program.
- Four online community briefings were held to provide an update on the IBR Program's progress. Participants were provided with information on preliminary design options, draft equity and climate frameworks, steps to develop a recommended Modified LPA, and ways to stay informed and get involved along the way. Event participants had the opportunity to ask questions and engage with Program staff.

Key takeaways included:

- Design options and Program elements that improve travel times, relieve congestion, improve safety, and mitigate negative impacts to people and the environment are preferred.
- Equity priority communities rely on transit for a diverse range of needs.
- Trip time is the most influential factor when choosing what form of transportation to take. Ease of trip and avoiding a toll were the second and third most influential factors, respectively.

- While preferences for how to access Hayden Island and Marine Drive are heavily influenced by a respondent's geographic location, when asked to identify the priority for a Hayden Island Interchange design, nearly 70% of all survey respondents agreed that congestion relief on I-5 near Hayden Island is most important.
- Washington residents prefer direct access to Hayden Island from I-5, while Oregon residents prefer to access Hayden Island via Marine Drive and a new arterial bridge.
- The top three preferences for transit station locations are (1) the Vancouver waterfront, (2) near Clark College, and (3) the Expo Center.

2022 Public Engagement Efforts

Outreach efforts in 2022 focused on continued engagement to inform the development of the Modified LPA, communicate the elements being recommended by the Program, and seek regional consensus on the Modified LPA and next steps to further analyze it through the SEIS process. Following screening and evaluation of the design options and transit investments, the IBR Program developed recommendations for the key components of the Modified LPA, informed by technical and screening work along with Program partners and community feedback. Together, these key components form a comprehensive multimodal solution that addresses the Program's Purpose and Need, meets equity and climate change objectives, and supports regional and local priorities and desired outcomes. From September through December of 2022, the IBR Program shared updates on the NEPA compliance process and path toward publishing a Draft SEIS.

Highlight of 2022 community engagement efforts:

- Regional consensus to move the Modified LPA into the federal environmental review process in summer 2022. This included endorsement by the board, council or commission of all eight local partner agencies, unanimous consensus from the Program's ESG, and acknowledgment by the Bi-State Legislative Committee to move the Program forward into the next phase of work.
- The Program tabled at six in-person community events, including farmers' markets and festivals, and had direct conversations with nearly 500 people through this engagement effort.
- Direct outreach to over 200 neighborhood associations and CBOs resulted in discussions with a wide variety of community members about the Modified LPA, next steps in the environmental review process, and how to provide meaningful input once the Draft SEIS is released.
- Provided informational presentations to approximately 60 organizations, including local partner agency boards, councils, and commissions, neighborhood associations, and CBOs.
- Participated in over 20 speaking opportunities at the national, regional, and local level to engage various members of the public to share the Program's story, inform audiences of the Program's progress, and address any concerns.
- Hosted three equity roundtable discussions: "Black Communities and their Relationships with Infrastructure," "Why Equity Matters in Infrastructure," and "Accessibility through Infrastructure."
- Hosted 29 public steering and advisory group meetings, including the ESG, EAG, and CAG.
- Coordinated and hosted Program area tours for Program advisory group members

Key public comment themes during this effort included:

- Interest in elements of the Modified LPA and the river crossing design.
- Interest in information about upcoming opportunities for engagement.

- Comments on replacement bridge alternatives (tunnel, third bridge crossing, and retrofitting the current bridge).

2023 Engagement Efforts

The Program's outreach in 2023 was primarily focused on an extended effort to conduct both broad and mindful community engagement prior to the release of the Draft SEIS. The purpose of the engagement during this timeframe was to continue raising awareness about the Program and key milestones, inform community members of the Modified LPA and the elements that are being analyzed in the Draft SEIS, and prepare community members to effectively provide input during the public comment period.

Highlight of community engagement efforts from January to September 2023:

- Held 18 public steering and advisory group meetings.
- Provided Program updates and presentations to over 60 organizations.
- Held two in-person neighborhood forums.
- Hosted a DBE meet-and-greet event.
- Tabled at 17 community events, split between Oregon and Washington, approximately 50% of which were centered on equity priority communities. The Program was able to engage with more than 1,250 individuals at a diverse range of events.
- Participated in 16 regional and national conferences.
- Coordinated and conducted over 16 bridge or Program area tours.
- Completed a cultural resources open house.
- Conducted three equity roundtables: "Women Paving the Way," "The Intersection of Multimodal Transportation and Equity," and "Road to Prosperity: A Conversation About Workforce Diversity and Disadvantaged Business Enterprises."
- Launched office hours beginning in August 2023, offering the opportunity for community members to sign up for an appointment (in person or virtual) to speak directly to IBR Program team members to ask questions and share their feedback.
- Formed the Community Benefits Advisory Group (CBAG) in September to develop recommendations to leverage the Program's work to achieve the greatest positive benefit to the communities in the Program area and broader region, in alignment with the Program's equity framework and community priorities.
- Offered a second round of small-scale, low-barrier grants to CBOs serving equity priority communities to extend the outreach of the Program.

Technical Coordination with Partner Agencies

In developing the Modified LPA, the IBR Program worked with partner agency technical staff through focused technical working groups to develop, evaluate, refine, and identify design concepts and transit investments for consideration by community, steering, and advisory groups. These efforts with partner agencies are briefly described below and are discussed in greater detail in Appendix A, Agency and Tribal Engagement.

Partner Agency Working Groups and Technical Sessions

The IBR Program's design team worked with technical staff from local agency partners through focused working groups and technical sessions. These meetings served as a venue for developing a shared

understanding of local conditions, needs, and planned transportation improvements that could then be used to engage with interested parties in the community. The technical working groups identified design options for screening, contributed to desired outcomes, developed screening criteria, considered tradeoffs, and were engaged in the process of developing the Modified LPA.

The working groups and technical sessions included technical staff from the IBR Program and the following agencies:

- Oregon Department of Transportation (ODOT).
- Washington State Department of Transportation (WSDOT).
- Local transit agencies: Clark County Public Transportation Benefit Area (C-TRAN) and Tri-County Metropolitan Transportation District (TriMet).
- Regional metropolitan planning organizations Oregon Metro (Metro) and Southwest Washington Regional Transportation Council (RTC).
- Cities of Portland and Vancouver.
- Ports of Portland and Vancouver.

During development of the Modified LPA, the IBR Program convened several issue-specific working groups with members from the above local partner agencies. These included a Travel Demand Modeling Working Group, a Transit Options Technical Session, and a Climate Technical Working Group. The Agency Working Group and technical session activities are discussed further in Appendix A, Agency and Tribal Engagement.

Executive Steering Group

The ESG directly supports the IBR Program's progress. ODOT and WSDOT convened the 12-member group to provide regional leadership support and consensus on key Program issues of importance to the community. The ESG provides recommendations on planning, design, operational approach, and funding of the IBR Program.

The following members of the ESG include representatives from the 10 bi-state partner agencies with direct delivery or operational roles in the integrated, multimodal transportation system around the Interstate Bridge, as well as a community representative from each state. The two community representatives serve as co-chairs of the CAG.

- CAG Co-chair (Washington): Lynn Valenter
- CAG Co-chair (Oregon): Ed Washington
- ODOT: Kris Strickler, Director
- WSDOT: Roger Millar, Secretary
- TriMet: Sam Desue, Jr., General Manager
- C-TRAN: Shawn Donaghy, CEO
- Oregon Metro: Lynn Peterson, Council President
- RTC: Matt Ransom, Executive Director
- City of Portland: Mingus Mapps, Commissioner
- City of Vancouver: Anne McEnerny-Ogle, Mayor
- Port of Portland: Curtis Robinhold, Executive Director

- Port of Vancouver USA: Julianna Marler, CEO

Advisory Groups

The Program's advisory groups were created to ensure ongoing engagement with a broad range of community leaders/groups representing a variety of constituencies and priorities throughout the Program development and design process. The EAG and CAG are direct pathways to the community to help ensure that the IBR Program remains centered on equity and that the Program outcomes reflect community needs, issues, and concerns. The Program uses both advisory groups to provide community-informed insight to inform Program work. This includes soliciting input on outreach strategies and regularly providing updates on concerns voiced by the community.

Community Advisory Group

The CAG is composed of community members from both Oregon and Washington. The IBR Program shares information with CAG, which then discusses and provides input in a public forum to help ensure that Program outcomes reflect community needs, issues, and concerns. CAG members and the Program team engage in dialogue with a commitment to meaningful, two-way feedback. The CAG generally meets monthly. Two co-chairs, one representing each state, lead the group's diverse and inclusive membership. These co-chairs also sit on the ESG. For more information on the CAG, see the Program website.[3]

Co-Chairs as of September 2023:

- Lynn Valenter, Vice President of Finance, Reed College (former Vice Chancellor, Washington State University, Vancouver)
- Ed Washington, Director of Outreach and Community Engagement in Global Diversity and Inclusion, Portland State University

Members as of September 2023:

- Jay Clark, Director of Government Affairs, Portland Metro Chamber
- Bill Prows, Director of Business Development / Events, Oregon Association of Minority Entrepreneurs
- Darcy Hoffman, Workforce Southwest Washington
- Dena Horton, Governmental Relations Manager, Pacific Northwest Waterways Association
- Irina Phillips, Community member
- Jana Jarvis, President / CEO, Oregon Trucking Association
- Javier Navarro, Owner, State Farm Insurance; President, League of United Latin American Citizens (LULAC) Southwest Washington
- Jeffery Temple, Director of Corporate Affairs, Fred Meyer
- Julie Doumbia, Community member
- Dr. Karin Edwards, President, Clark College
- Marcus Mundy, Executive Director, Coalition of Communities of Color
- Mark Riker, Executive Secretary, Washington State Building and Construction Trades Council

[3] https://www.interstatebridge.org/advisory-groups/community-advisory-group/.

- Martha Wiley, Public transit representative, Washington
- Michael Kelly, Director of Transportation, Human Services Council
- Michelle Brewer, Vice President, Human Resources + Facilities, Zoominfo, Columbia River Economic Development Council
- Mikaela Williams, Community member
- Randali Desantos-Benromdhane, Community member
- Robert Camarillo, Oregon State Building and Construction Trades Council
- Robin Jay Richardson, Community member
- Ryan Webb, Project Manager, The Confederated Tribes of Grand Ronde
- Sam Kim, Community member
- Sheri Call, Executive Vice President, Washington Trucking Association
- TBD, Tribal Council Representative, Cowlitz Indian Tribe
- Tom Hickey, Bridgeton Neighborhood Association
- Victor Caesar, Public Transit Representative, Oregon
- Yolanda Frazier, President, NAACP – Vancouver
- Zachary Lauritzen, Oregon Walks

Equity Advisory Group

The EAG helps ensure that the IBR Program remains centered on equity. The EAG has been responsible for defining equity and equity priority communities and developing an equity framework to deliver on this commitment. The group refined equity-focused screening criteria and has made recommendations to IBR Program leadership regarding the components of the Modified LPA, evaluating options through an equity lens to advance the Program's equity objectives. They are currently in the process of developing equity key performance indicators for the IBR Program to track its advancement of equitable processes and outcomes. The EAG meets monthly. For more information on the EAG, see the Program website.[4] The members as of September 2023 are listed below:

- Aidan Gronauer, WSDOT
- Albert Lee, NAACP – Portland
- Alicia Sojourner, City of Vancouver
- Barbara Alexander, Port of Portland
- Bianca Kolle, Washington State Department of Services for the Blind
- Erika McCalpine, ODOT
- Hai That Ho Ton, Community member
- Jennifer Campos, RTC
- John Gardner, TriMet

[4] https://www.interstatebridge.org/advisory-groups/equity-advisory-group/

- Jonathan Eder, Port of Vancouver USA
- Karyn Kameroff, Community member
- Megan Marie Johnson, Community member
- Miriam Halliday, Workforce Southwest Washington
- Obie Ford III, Washington State University Vancouver
- Pat Daniels, Constructing Hope
- Sebrina Owens-Wilson, Metro
- Shane Valle, Portland Bureau of Transportation
- Shona Carter, Community member
- Sokho Eath – IRCO
- Vicki Nakashima, Community member

Community Benefits Advisory Group

The CBAG will develop recommendations for community benefit efforts to achieve the greatest positive benefit to the communities in the Program area and broader region from the Program's work, in alignment with the Program's equity framework and community priorities. For more information on the CBAG, see the Program Website.[5] The members as of September 2023 are listed below:

- Greg Johnson, IBR Program Administrator
- Commissioner Mapps, City of Portland
- Mayor McEnerny-Ogle, City of Vancouver
- Darcy Hoffman, Workforce SW Washington
- Kelly Haines, Worksystems, Inc.
- Victor Caesar, Vancouver Housing Authority
- Nate McCoy, National Association of Minority Contractors Oregon
- Marcus Mundy, Coalition for Communities of Color
- Nicole Davison Leon, Hispanic Metropolitan Chamber
- Javier Navarro, President, LULAC, Southwest Washington
- Scott McCallum, Superintendent, Washington School for the Blind
- Peter Fels, Alliance for Community Engagement
- Jessica Green, Portland Parks Foundation
- Holly Williams, Vancouver resident
- Michael Strahs, Kimco Realty
- Corky Collier, Columbia Corridor Association
- Jasmin Tolbert, YWCA Clark County

[5] https://www.interstatebridge.org/get-involved-folder/advisory-groups/community-benefits-advisory-group/

- Farleigh Winters, LSW Architects
- Rian Windsheimer, ODOT
- Carley Francis, Washington Department of Transportation
- Ben Jacobsen, Jane's Forum
- Ernesto Fonseca, Hacienda Community Development Corporation

Engagement with Freight Partners

Freight Movement Public Listening Session

On May 27, 2021, the IBR Program hosted a freight movement listening session with members of the public. There were 46 participants, including representatives of marine and highway freight interests, ports, industry associations, and the Oregon and Washington legislatures. This engagement provided information regarding the IBR Program and the opportunity to hear the freight community's concerns about the bridge. The key themes and takeaways included the following:

- Inability to use the Interstate Bridge due to height and weight limitations.
- Concerns regarding congestion negatively impacting freight operations around Marine Drive.
- Concerns regarding unreliability, narrow turns, safety, and bridge lifts.
- Desire for more freight capacity on and around the bridge.
- Challenges regarding travel path and turning radius.

Freight Leadership Meetings

In partnership with the Ports of Vancouver and Portland, the IBR Program hosted two freight engagement sessions in the fall and winter of 2021 with leaders of the regional freight community and IBR Program leadership. Attendees from the freight community included representatives from regional ports, industry associations, freight retail, and the Oregon and Washington legislatures. The key themes and takeaways included the following:

- Unimpaired freight movement is important to the local, regional, national, and international economies.
- Congestion through the I-5 corridor increases freight operational costs and negatively impacts the ability to attract and retain employees.
- Trucks avoid peak travel times if possible (6 a.m. to 9 a.m. and 3 p.m. to 9 p.m.).
- Suggestions for improvement include:
- Install truck-only lanes.
- Reduce the number of on/off-ramps.
- Remove current height restrictions and bridge lifts.
- It is desirable that road and pathway alignment be designed with consideration for optimal freight movement.
- High, wide, and heavy freight movement, including bridge and overpass heights, should be considered.
- Interest in learning about impacts to freight connectivity, including on/off-ramp locations and east/west access to Terminal 6 in North Portland.

- Interest in future engagement regarding the alignment and number of lanes through the study area.
- Concern that current exponential freight volume growth may increase congestion connected with Interstate 205.

Engagement with Affected Users of the River

For the Navigation Impact Report, the IBR Program conducted outreach with known Columbia River users who travel under the existing Interstate Bridge, fishery management groups, and others with an interest in mitigation discussions. Information on the vessels, such as navigation and dimensional features, was collected through an online survey, marina contacts, and individual vessel owners. In addition, the IBR Program sought information from other river users through the placement of notices and advertisements in the U.S. Coast Guard (USCG) Local Notice to Mariners, in local newspapers and specialty maritime publications, and on the Program website and social media accounts. Presentations were also conducted with industry associations, including the Pacific Northwest Waterways Association and the Lower Columbia River Harbor Safety Committee.

Users included commercial tugs, tows, and barges; marine contractors; federal/emergency/maintenance vessels; passenger cruise vessels; and recreational boats. Forty commercial, marine contractor, fabricator, shipyard owner, federal, and passenger cruise users were contacted, of which approximately half responded confirming the vessel data obtained from prior reports and/or providing updated vessel information. Information on recreational users was obtained from recreational marinas in the project vicinity, as well as through responses to the online river user survey. The online survey received 39 responses: 5 surveys were received for commercial vessels, 3 for cruise vessels, 7 for recreational motor vessels, 23 for sailboats, and 1 for a kayak.

The USCG reviewed and conducted further validation of the Navigation Impact Report by publishing USCG Navigation Only Public Notice (NOPN) 02-22, dated March 23, 2022, seeking comments exclusively related to navigation from maritime partners. The primary goal of the NOPN was to receive comments regarding current or future vertical navigation clearance requirements greater than 116 feet to inform the USCG's issuance of a Preliminary Navigation Clearance Determination. The comment period ended on April 25, 2022, and the USCG received 13 comments. Since the end of the comment period, both the USCG and the IBR Program have continued to coordinate with potentially affected river users.

On July 31, 2023, the IBR Program hosted a Navigation Simulation Workshop in Vancouver, Washington. River pilots and tug captains were invited to provide their thoughts and experiences navigating along the Columbia River. Attendees included pilots and captains from Shaver Transportation, Columbia River Pilots, Foss Maritime Company, Tidewater company, and Combined Forestry and Marine Services, as well as representatives from federal partners and regulatory agencies, such as the USCG and the U.S. Army Corps of Engineers. The workshop included discussions around current navigation conditions and use, such as impacts of the existing bridge on river navigation, and new considerations for navigation with the proposed Columbia River bridges. The feedback provided by the river captains and pilots contributed to the IBR Program's navigation simulation efforts, such as adjusting the simulation inputs including wind factors, visibility, vessel types and characteristics, and possible river system changes.

Incorporating Community Feedback

The IBR Program strives to offer ongoing opportunities to connect with the Program, proactively share updates and information on Program work, and intentionally hold more intensive engagement efforts to seek feedback on specific topics to inform key Program work. Highlighted below are examples of how community

engagement feedback has informed specific elements of Program work. Community feedback described in this appendix was used to:

- Identify themes related to transportation problems and community priorities and values.
  - The IBR Program conducted intentional community engagement to gather specific public feedback regarding the transportation problems travelers experience with the current Interstate Bridge and to understand the community priorities and values that should shape the Program. This feedback helped the Program to confirm that the previously identified Purpose and Need and Vision and Values for replacing the Interstate Bridge remain valid: congestion and travel reliability, safety, earthquake vulnerability, impaired freight movement, inadequate bicycle and pedestrian pathways, and limited public transportation. Community feedback also identified equity and climate change as key community priorities.
- Ensure current community priorities and changes since the previous planning efforts are reflected as Program decisions are made.
  - Planning work has built upon previous planning efforts accomplished as part of the CRC project. Early planning work defined the physical and contextual changes that have occurred in the Program area since 2013. To address these changes, the IBR Program, in coordination with Program partners and the community, developed design options, desired outcomes, and transit investments, to identify a Modified LPA to be further studied through a Draft SEIS in compliance with NEPA.
- Help inform the IBR Program's Modified LPA recommendation.
  - The Modified LPA recommendation is based on work completed since 2019, including climate and equity frameworks; screening results and modeling data; and input and feedback from partner agencies, Program advisory groups, and the broader community. The Modified LPA recommendation identified key components for further evaluation as part of the multimodal Program corridor investments: transit investments, interchange configuration for Hayden Island/Marine Drive, and the number of auxiliary lanes across the bridge. Community engagement efforts to gather feedback on design options to help inform the recommendation included an online survey with over 9,600 responses, 300+ listening session participants across multiple sessions, four community working groups, over two dozen public meetings and a community opinion survey. Details on the community feedback that informed the Modified LPA is available at: https://www.interstatebridge.org/media/0rjf5bda/ibr_lpa_memo_final.pdf.
  - Transit: Connect existing transit systems by extending light-rail from Portland to Vancouver to integrate the transit investments in the region, including C-TRAN's bus rapid transit network and express bus service. Priorities expressed in community feedback included a desire for transit options that improve connectivity across the river and to the regional transit system, ease of access for a variety of users, and transit travel time/reliability. Specific feedback included support for High Capacity Transit options, with many preferring light-rail or a combined light-rail/bus rapid transit option; interest in accessible and dependable transit options expressed by equity priority communities, including a desire for multiple transportation options that are efficient, reliable, and user-friendly; and preferences for transit stations located at (or near) Expo Center, Hayden Island, Vancouver Waterfront, Vancouver Library (Evergreen) and Clark College.
  - Hayden Island/Marine Drive Configuration: Partial interchange at Hayden Island and a full interchange at Marine Drive. A partial interchange on Hayden Island recognizes the desire to balance vehicle and freight access, with a preference expressed by the community to minimize the footprint over Hayden Island. Other community feedback taken into consideration is the need to accommodate active transportation safety and access; the desire to prioritize congestion relief on I-5 near Hayden Island,

  - safe intersections and road improvements, and convenient access to services, shopping, and restaurants; the preference expressed by Washington residents for direct access to Hayden Island; and the preference expressed by Oregon residents for island access via Marine Drive and a local access bridge.
  - Auxiliary lanes: Include one auxiliary lane northbound and one auxiliary lane southbound between Marine Drive and Mill Plain Boulevard. Community engagement feedback has consistently expressed support for the addition of auxiliary lanes, with both travel time and environmental impacts expressed as important considerations. Feedback received from advisory groups and surveys was mixed on the preference for the number of auxiliary lanes.
- Develop the equity and climate frameworks, as well as establishing community values that will be used along with the climate and equity lens.
  - As part of the IBR Program's commitment to centering equity, the EAG helped to develop a definition of equity specific to the Program, inclusive of both process and outcome equity. The EAG also informed the development of an equity framework—the lens through which the Program is grounded in historical context and includes a core set of values focused on diversity, equity, and inclusion.
  - The CAG informed the development of a summary of community values and priorities to help shape design options and guide decision-making. The values and priorities reflect feedback gathered from intentional community engagement efforts.
  - Both advisory groups provided input on the Program's climate framework and how climate change goals will be applied to various components of the Program.
- Inform community engagement efforts and help improve future outreach.
  - Community engagement feedback clearly identified the desire for low-barrier engagement options and the opportunity to have meaningful conversations with the Program.
  - Both the CAG and EAG have provided feedback on community engagement efforts, including suggestions on events to attend, groups to reach out to, and tools to consider. Regular updates and feedback from these groups will continue to help shape outreach efforts.

Public Involvement Efforts: November 2020 through July 2024

Table B-1 presents a chronological list of public involvement efforts from November 2020 through September 2023.

Table B-1. Public Involvement Events Conducted from November 2020 through September 2023

Date	Activity/Organization	Location	State	Number of Public Participants
11/6/2020	ESG Kick-Off Meeting Part 1	Virtual	Both	*

- EXISTING LEVEE ALIGNMENT
- PROPOSED LEVEE WORK FROM ARMY CORPS
- LRT ALIGNMENT

FOOTPRINT DEFINITIONS:

INFRASTRUCTURE FOOTPRINT - Brown dashed line generated from the 3D corridor model of the IBR project. Outlines cut and fill limits, areas of existing infrastructure to be demolished as part of IBR construction. This line represents the ultimate footprint of the built IBR project infrastructure.

CONSTRUCTION IMPACT AREA - Purple solid line encompasses areas of existing public right-of-way or private property in which work will be done or temporary construction activities (i.e. staging, access) will take place, on land and in water. This line does not differentiate between permanent and temporary uses or full or partial acquisitions, and is not intended to indicate displacements of residences or businesses. These determinations will be made on a parcel-by-parcel basis in collaboration with the NEPA disciplines which require this information for their analysis.

NOTES:

- None of the lines shown are intended to represent the Bridge Influence Area (BIA) or Area of Potential Effect (APE).

- Stormwater facility sizes and shapes are conceptual

FOOTPRINT DEFINITIONS:

INFRASTRUCTURE FOOTPRINT - Brown dashed line generated from the 3D corridor model of the IBR project. Outlines cut and fill limits, areas of existing infrastructure to be demolished as part of IBR construction. This line represents the ultimate footprint of the built IBR project infrastructure.

CONSTRUCTION IMPACT AREA - Purple solid line encompasses areas of existing public right-of-way or private property in which work will be done or temporary construction activities (i.e. staging, access) will take place, on land and in water. This line does not differentiate between permanent and temporary uses or full or partial acquisitions, and is not intended to indicate displacements of residences or businesses. These determinations will be made on a parcel-by-parcel basis in collaboration with the NEPA disciplines which require this information for their analysis.

NOTES:

- None of the lines shown are intended to represent the Bridge Influence Area (BIA) or Area of Potential Effect (APE).

- Stormwater facility sizes and shapes are conceptual

FOOTPRINT DEFINITIONS:

INFRASTRUCTURE FOOTPRINT - Brown dashed line generated from the 3D corridor model of the IBR project. Outlines cut and fill limits, areas of existing infrastructure to be demolished as part of IBR construction. This line represents the ultimate footprint of the built IBR project infrastructure.

CONSTRUCTION IMPACT AREA - Purple solid line encompasses areas of existing public right-of-way or private property in which work will be done or temporary construction activities (i.e. staging, access) will take place, on land and in water. This line does not differentiate between permanent and temporary uses or full or partial acquisitions, and is not intended to indicate displacements of residences or businesses. These determinations will be made on a parcel-by-parcel basis in collaboration with the NEPA disciplines which require this information for their analysis.

NOTES:

- None of the lines shown are intended to represent the Bridge Influence Area (BIA) or Area of Potential Effect (APE).

- Stormwater facility sizes and shapes are conceptual

ACRONYMS, ABBREVIATIONS, AND TERMS

Item	Definition
2013 LPA	Columbia River Crossing Locally Preferred Alternative
AC	Advisory Circular
Active transportation	Human-powered modes of transportation, such as walking, biking, or using a wheelchair.
Auxiliary lanes	Ramp-to-ramp connections adjoining through lanes that allow for better access to and from on-/off-ramps. This improves speed changes, turning, weaving, and truck climbing, resulting in better safety and congestion relief.
BIPOC	Black, Indigenous, and People of Color
BRT	Bus rapid transit - a term for bus-based transit systems that deliver fast and efficient service that may include dedicated lanes, busways, traffic signal priority, off-board fare collection, elevated platforms and enhanced stations. They are usually larger and can carry more riders per vehicles than standard busses. BRT currently runs in several corridors throughout Clark County and is operated by C-TRAN.
CAG	Community Advisory Group
CFR	Code of Federal Regulations
CIG	Capital Investment Grant – The FTA discretionary funding program for funding transit capital investments, including heavy rail, commuter rail, light rail, streetcars and bus rapid transit.
CRC	Columbia River Crossing
C-TRAN	Clark County Public Transportation Benefit Area Authority
Diamond interchange	A type of interchange that is used where a controlled-access highway crosses a local road. The highway is grade-separated from the local road, with one route crossing over the other on a bridge.
EAG	Equity Advisory Group
EIS	Environmental Impact Statement
ESA	Endangered Species Act
ESG	Executive Steering Group

Item	Definition
FAA	Federal Aviation Administration
FHWA	Federal Highway Administration
Folded diamond interchange	A type of diamond interchange, with two entrance ramps and two exit ramps, where one or more of the ramps are "folded" into a loop.
FRA	Federal Railroad Administration
FTA	Federal Transit Administration
Half diamond interchange	A type of diamond interchange, where one travel direction does not extend past the interchange, limiting access to three directions.
HCT	High-capacity transit – HCT encompasses different transit options, such as bus rapid transit and light rail transit.
I-205	Interstate 205
I-5	Interstate 5
IAMP	Interchange Area Management Plan
IBR	Interstate Bridge Replacement
Interchange	An interchange is a roadway junction that uses grade separations to accommodate the movement of traffic between two or more routes, allowing some of the traffic to pass through the junction without interruption. Common types of interchanges include diamond and cloverleaf interchanges. A full interchange uses four left and right exits and on-ramps, and a partial interchange uses less than four.
LPA	Locally Preferred Alternative
LRT	Light rail transit – LRT is a form of high-capacity transit that operates in its own fixed guideway and is powered by overhead electrical current. Currently, light rail connects Portland City Center with Beaverton, Clackamas, Gresham, Hillsboro, Milwaukie, North/Northeast Portland and Portland International Airport and is operated by TriMet.
MCDD	Multnomah County Drainage District
Metro	Oregon Metro
MLK	Martin Luther King, Jr.
Modified LPA	A subset of three components in the preliminary preferred alternative that are considered foundational to the Program and were vetted and approved

Item	Definition
	by partner agencies. The Modified LPA components include interchange configuration for Hayden Island/Marine Drive, transit investments, and the number of auxiliary lanes across the bridge.
MPO	Metropolitan Planning Organization
NEPA	National Environmental Policy Act
NOAA Fisheries	National Oceanic and Atmospheric Administration, National Marine Fisheries Service
NOI	Notice of Intent
ODOT	Oregon Department of Transportation
ORS	Oregon Revised Statutes
Preliminary preferred alternative	The proposed solution that will be studied in the NEPA document for the IBR Program. The preliminary preferred alternative consists of a replacement bridge over the Columbia River as well as other components such as transit improvements, the types of interchanges at various locations throughout the corridor, and active transportation improvements.
RCW	Revised Code of Washington
ROD	Record of Decision
RTC	Southwest Washington Regional Transportation Council
SEIS	Supplemental Environmental Impact Statement
SPUI	Single-point urban interchange - a type of diamond interchange which has a large overpass or underpass that provides space for a signalized intersection for the ramps and the cross streets.
SR	State Route
TAZ	Transportation Analysis Zones
Tight diamond interchange	A type of diamond interchange, where the highway ramps are split between two crossroads, with an entry ramp and an exit ramp serving each of the crossroads.
TOTS	Transit Options Technical Session
TriMet	Tri-County Metropolitan Transportation District of Oregon
USACE	U.S. Army Corps of Engineers

Item	Definition
USC	U.S. Code
USCG	U.S. Coast Guard
USFWS	U.S. Fish and Wildlife Service
WSDOT	Washington State Department of Transportation

1. INTRODUCTION

The Interstate Bridge Replacement (IBR) Program is a continuation of the Columbia River Crossing (CRC) Project and will replace the aging Interstate Bridge across the Columbia River with a modern, seismically resilient, multimodal structure. During early efforts for the IBR Program, feedback from partner agencies, tribes, organizations and the public identified changes within the Program area that had occurred since the selection of the Locally Preferred Alternative (LPA) studied in the CRC project's Environmental Impact Statement (EIS), selected in the 2011 Record of Decision (ROD), and updated in two National Environmental Policy Act (NEPA) re-evaluations prepared in 2012-2013. To respond to these changes and provide a bridge replacement solution that better fits the current and future needs of the region, the IBR Program identified several components of the CRC LPA that would benefit from design modifications.

The purpose of this report is to document the screening and evaluation process used to select the modifications that were included in the preliminary preferred alternative for the IBR Program. The screening process took place prior to issuance of a Notice to Supplement to prepare a Supplemental EIS (SEIS) for the IBR Program in order to address changes that have occurred since the ROD. The Notice to Supplement will formally reopen the NEPA process that was closed with the ROD and re-evaluations, and the preliminary preferred alternative will be studied in the SEIS. The following components were selected through the screening process:

- The type(s) of interchanges for Hayden Island and Marine Drive
- The main river crossing (the structure and alignment of the replacement bridges over the Columbia River)
- Transit mode, general alignment and termini
- Auxiliary lanes

The modifications were selected through the development of high-level design options, which were then screened to identify tradeoffs and benefits among the options. In conjunction with Program partners and the community, these design options and transit investments were then screened against criteria to evaluate their ability to meet the Program's Purpose and Need statement and achieve other desired outcomes, including equity and climate objectives. The highest performing

design options were then combined to create the preliminary preferred alternative for the IBR Program.

This report identifies how design options were developed for these components, the screening process, and how the most promising design options were selected and advanced for further study.

2. GETTING TO THE PRELIMINARY PREFERRED ALTERNATIVE

This section provides an overview of how the IBR Program arrived at the preliminary preferred alternative and identifies the components that comprise the preliminary preferred alternative.

2.1 CRC Project Alternatives Analysis and Screening

Because the IBR Program is a continuation of the CRC project, the Program builds on much of the previous project's NEPA documentation while conducting additional analysis and environmental review, as needed, to comply with NEPA. Based on a re-evaluation signed in December 2021, the Federal Highway Administration (FHWA) and Federal Transit Administration (FTA) (the federal leads for this NEPA process) determined that the IBR Program requires a SEIS due to the potential for new adverse environmental impacts.

Under the CRC project, multiple alternatives were developed and screened based on their ability to meet the six needs in the Purpose and Need statement and accomplish the performance measures in the Vision and Values statement. For any project going through the NEPA process, an alternative must meet all aspects of the Purpose and Need statement to advance to more detailed screening.

Throughout the CRC's development, the project team worked in tandem with the CRC Task Force, which was a 39-member group composed of leaders representing a broad cross section of Washington and Oregon communities.[1] The Task Force met regularly to advise the CRC project team and provide guidance and recommendations at key decision points.

During the initial component screening process, the CRC Task Force and project team reviewed various types of river crossing components and transit components to narrow the range of alternatives. The initial Step A screening effort in April 2006 evaluated a wide variety of river crossing and transit components using a pass/fail test designed to eliminate ideas well outside the scope of the project and/or that clearly could not address the relevant elements of the project's Purpose and Need.

River crossing and transit components that passed the Step A screening process were recommended to advance to Step B screening for further consideration and screening, while components that failed were recommended to be dropped from further consideration. During Step B, components were

[1] Public agencies, businesses, civic organizations, neighborhoods, and freight, commuter, and environmental groups were represented on the Task Force.

scored on project values, which were developed and formalized by the CRC Task Force in October 2005.[2] Additional screening efforts took place during and after the Step B screening, with the subsequent dismissal or revision of various components. Later in the screening process, the river crossing and transit options were combined into multimodal alternatives that represented a reasonable range of combinations to be advanced to the Draft EIS for detailed evaluation. Additional details on the CRC project screening process are available on the Washington Department of Transportation's (WSDOT's) Alternative Development webpage for the CRC project.[3] Through these screenings and other planning work, the CRC project LPA was selected in 2011, evaluated in the 2011 Final EIS, and documented in the 2011 ROD. Figure 1 shows the CRC project LPA.

In 2012, the LPA was modified to raise the maximum vertical clearance of the bridge from 95 feet to 116 feet. The LPA was modified again in 2013 to evaluate building the project in a phased approach. Both of these modifications were approved under NEPA and became the CRC project LPA (also referred to as the "2013 LPA" or "2013 Design"). The 2013 LPA was used as a starting point for the IBR Program's identification and development of design options.

[2] The adopted values are Community livability and human resources; Mobility, reliability, accessibility, congestion reduction, and efficiency; Safety; Regional economy, freight mobility; Stewardship of natural resources; Distribution of benefits and impacts.

Figure 1. 2013 Locally Preferred Alternative

Source: CRC 2011

2.2 IBR Program Design Option Screening and Evaluation

As previously noted, the IBR Program identified several components of the 2013 LPA that would benefit from design modifications. The IBR team used a five-step process, identified below, to identify changes, develop design options, and screen design options, resulting in the development of the preliminary preferred alternative. Throughout these steps, the IBR Program worked in tandem with partner agency technical staff, the Program's advisory groups, tribes, the public, and other partners. These engagement avenues are highlighted in Section 3.

1. **Review and Validate the Purpose and Need statement and Vision and Values.** First, the IBR Program worked with partner agencies and the public to review the Purpose and Need statement and Vision and Values that were adopted during the CRC project. In early to mid-2021, the IBR

Program brought the Purpose and Need statement and Vision and Values to partner agencies and the advisory groups to discuss the identified transportation problems (the "needs"). These foundational statements were also brought to the public for comment during an open house. The outcome of these efforts was the confirmation that the six transportation problems identified in the statement still exist today, and the values identified in the Vision and Values document remain community values. Feedback from agencies and the public led to the elevation of equity and climate resiliency as key Program values, and these were elevated and incorporated into the subsequent steps of the screening process.

2. **Identify Desired Outcomes.** Following confirmation of the Purpose and Need and Vision and Values, the IBR Program worked with the three advisory groups (the Community Advisory Group (CAG), Equity Advisory Group (EAG), and the Executive Steering Group (ESG)) to develop "desired outcomes" for the Program. Desired outcomes are observable and measurable accomplishments that the IBR Program aspires to achieve at a Program level. In addition to desired outcomes tied to the Purpose and Need statement, the IBR Program developed desired outcomes for equity and climate resiliency, to reflect the input received during step 1. The desired outcomes are detailed in Section 4.
3. **Identify and Document Changes.** The IBR Program worked with Program partners to identify physical and contextual changes that have occurred in the Program area since 2013. The purpose of identifying changes was to determine which, if any, components of the Program would need to be modified in response to the changes. The key changes identified are detailed in Section 5.
4. **Develop Screening and Evaluation Methods and Metrics:** The IBR Program worked with agency partners and the advisory groups to develop methodologies and metrics to evaluate the extent to which a design option achieves the Program's desired outcomes. The metrics were used in step 5 to help identify the differentiators among design options. Screening metric development is detailed in Section 6.
5. **Develop, Screen and Evaluate Design Options:** The IBR Program worked with agency partners to identify potential high-level design options for the four foundational components affected by the changes since 2013 (identified in step 3): Hayden Island/Marine Drive, the main river crossing, transit (mode, general alignment, and terminus), and auxiliary lanes. The IBR Program then worked with agency partners to screen and evaluate the design options using the methods and metrics developed in step 4. The screening and evaluation process is detailed in Section 6. Design option development and the results of the screening and evaluation are detailed in Section 7.

2.3 Description of the Preliminary Preferred Alternative

The list below identifies all of the components that constitute the preliminary preferred alternative for the IBR Program, which includes the four components that went through the design option evaluation and screening process. The "Modified LPA" is a term used by the IBR Program for a subset of the components listed below that are considered foundational to the Program and were vetted and approved by partner agencies. Components with an asterisk below denote that the component is part of the Modified LPA.

Preliminary Preferred Alternative Components:

- River Crossing Structures:
  - Main River Crossing (over the Columbia River)
    - Replaced with seismically sound structure*
    - Bridge Type
  - North Portland Harbor Bridge*
- Highway, Interchanges, and Local Streets:
  - Auxiliary Lanes*
  - Victory Boulevard Interchange
  - Marine Drive Interchange*
  - Hayden Island Interchange*
  - State Route (SR) 14 Interchange
  - Fourth Plain Interchange
  - SR 500 Interchange
- Transit:
  - Operating Characteristics:
    - Mode*
    - Termini*
    - Headways
  - Portland Alignment and Station Locations*
  - Vancouver Alignment and Station Locations*
  - Park & Rides
  - Operations and Maintenance Facility
  - Potential off-site improvements
- Active Transportation Improvements
- Tolling

3. COMMUNITY AND AGENCY ENGAGEMENT

The IBR Program has been engaging with partner agencies, tribal governments, and the community. This engagement has helped shape communications strategy and implementation, the environmental review process, and the development of design options—all of which are critical to identifying a multimodal bridge replacement solution that meets the needs and priorities of the region. The IBR Program has solicited input and exchanged information with the public, as agency and tribal representatives. This section briefly lists the different groups that have been engaged and have contributed to the advancement of the IBR Program, as well as the substantial community engagement efforts that have ensured that public voices are heard and incorporated into the Program.

3.1 Technical Coordination with Partner Agencies

The IBR Program worked in tandem with partner agency technical staff through focused technical working groups to develop, evaluate, refine, and identify design concepts, transit investments, and modeling and analytical approaches. Descriptions of these efforts with partner agencies follow.

3.1.1 Task Forces

The IBR Program's design team worked in tandem with partner agency technical staff through focused technical task forces to develop, evaluate, refine, and identify design concepts and transit investments for consideration by community, steering and advisory groups. These meetings served as a venue for developing a shared understanding of local conditions, needs, and planned transportation improvements. The task forces identified design options for screening, contributed to desired outcomes, developed screening criteria, considered tradeoffs, and were engaged in the process of developing the Modified LPA.

The task forces included technical staff from the IBR Program and the following agencies:

- Oregon Department of Transportation (ODOT).
- Washington Department of Transportation (WSDOT).
- Local transit agencies: Clark County Public Transportation Benefit Area (C-TRAN) and Tri-County Metropolitan Transportation District (TriMet).
- Regional metropolitan planning organizations Oregon Metro (Metro) and Southwest Washington Regional Transportation Council (RTC).
- Cities of Portland and Vancouver.
- Ports of Portland and Vancouver.

3.1.2 Travel Demand Modeling Working Group

Representatives from the IBR Program, ODOT, WSDOT, C-TRAN, TriMet, the Cities of Vancouver and Portland, the Ports of Vancouver and Portland, Metro, and RTC met to review and discuss methods

and assumptions related to travel demand modeling being used in support of analysis for the IBR Program. This group met approximately monthly starting in June 2021 to discuss many aspects of the demand model process, including data collection, land use, travel markets, big data analysis, tolling (for the IBR Program, as well as modeling coordination with the Oregon Toll Program), definition of model assumptions for screening of highway and transit options, and post-processing for traffic analysis. The group also reviewed screening criteria and analysis related to modeling to support the evaluation of options.

3.1.3 Transit Options Technical Session

Representatives from the IBR Program, C-TRAN, TriMet, the Cities of Vancouver and Portland, Ports of Vancovuer and Portland, Metro, and RTC developed and refined an array of transit scenarios (including mode, alignment, stations, and operations) and their varying performance and operating measures. This technical team was convened under the name of the Transit Options Technical Session (TOTS) and met eight times between October 2021 and February 2022.

3.1.4 Climate Technical Working Group

The IBR Program invited climate and planning staff from each of the partner agencies to join ODOT and WSDOT climate specialists to convene for discussions and strategies to support shared climate goals. The climate technical work group meetings are held monthly and cover topics such as methods to assess greenhouse gas emissions associated with the Program, greenhouse gas reduction goals and targets, and the need for mutually supportive policies and programs to support shared climate goals. Future meetings will address design refinements, the environmental study, and construction means and methods, and investigate potential mitigation or offsets.

3.2 Community and Equity Advisory Groups

The CAG is composed of community members from both Oregon and Washington. The IBR Program shares information with the CAG, which then discusses and provides input in a public forum to help ensure that Program outcomes reflect community needs, issues, and concerns. CAG members and the Program team engage in dialogue with a commitment to meaningful, two-way feedback. The CAG generally meets monthly. Two co-chairs, one representing each state, lead the group's diverse and inclusive membership. These co-chairs also sit on the ESG. For more information on the CAG, see https://www.interstatebridge.org/advisory-groups/community-advisory-group/.

The EAG helps ensure that the IBR Program remains centered on equity. The group refined equity-focused screening criteria and has made recommendations to IBR Program leadership on the components of the Modified LPA, evaluating options through an equity lens to advance the Program's equity objectives. The EAG developed multiple screening criteria for the different design components (see Section 6). The EAG meets monthly. For more information on the EAG, see https://www.interstatebridge.org/advisory-groups/equity-advisory-group/.

3.3 Executive Steering Group

The ESG directly supports IBR Program progress. ODOT and WSDOT convened the 12-member group to provide regional leadership support on key Program issues. Members of the ESG include representatives from the 10 bi-state partner agencies with direct delivery or operational roles in the integrated, multimodal transportation system around the Interstate Bridge, as well as a community representative from each state. The two community representatives serve as the co-chairs of the CAG.

3.4 Federal Agencies

Coordination between the IBR Program and federal agencies is formalized through the environmental review process. Federal statute 23 United States Code (USC) 139 requires that agencies that have jurisdiction by law or a special interest in a project are provided an opportunity to formally participate in a program's environmental review process. The NEPA Coordination Plan is in development and will outline the roles and responsibilities of federal and other agency partners for the duration of the NEPA process.

3.5 Tribes

The IBR tribal consultation process is designed to encourage early and continuous feedback from, and involvement by, tribes potentially affected by the IBR Program, and to ensure that their input is incorporated into the decision-making process. Although tribal coordination and government-to-government tribal consultation is being undertaken as a distinct outreach effort, tribal involvement is also occurring during agency coordination. A tribal consultation plan is currently in development and will outline consultation milestones and strategy. To date, tribal concerns are similar to those expressed on the CRC project—impacts to natural and cultural resources, in particular fisheries and habitat loss and mitigation, as well cultural sites in and around the Fort Vancouver area. Tribes have asked to be deeply engaged throughout the Program lifecycle, and the IBR Program is committed to that engagement.

3.6 Community Engagement

The IBR Program offers continual opportunities for the community at large to provide input and feedback. Methods used to share information and solicit feedback include online open houses, digital surveys, equity priority listening sessions, community briefings, community working groups, and public comment submission via email and phone. These opportunities are advertised via the Program website, social media, mailed postcards, media advisories, in-person canvassing, multilingual community liaison outreach, Program newsletters, and partnerships with local community-based organizations. Engagement efforts have resulted in nearly 30,000 touch points with the community in 2021 alone, including receiving more than 18,000 online survey responses and 16,000 comments. The Program's spring 2021 community engagement efforts were recognized with a national TransComm 2021 Skills Award for Public Involvement Approach (with a consultant).

Between early February and mid-March 2021, the IBR Program held a targeted period of community engagement to gather specific feedback from the public regarding the transportation problems they experience with the current Interstate Bridge and to understand the community priorities and values that should help shape the Program. A comprehensive community engagement report details all feedback received. Key takeaways included:

- Widespread agreement that the six previously identified transportation problems still exist: congestion and travel reliability, safety, earthquake vulnerability, impaired freight movement, inadequate bicycle and pedestrian pathways, and limited public transportation.
- Solutions that address climate change, minimize impacts on neighboring communities, and address transportation needs of low-income travelers, people with disabilities, and non-drivers are valued.
- Congestion and travel reliability consistently ranked or expressed as the highest concern, with safety and earthquake vulnerability both ranked second and mentioned frequently.
- Concerns about transportation safety, including earthquake vulnerability and the impacts of substandard interstate design on drivers.
- Strong desire for an improved public transit connection between Portland and Vancouver.
- Concerns regarding tolling, including potential impacts on equity priority communities and the distribution of the cost burden.
- Value of a cost-effective Program with funding support that builds on previous work.

In the fall and winter of 2021–2022, the IBR Program held a second period of targeted community engagement to gather feedback and input on the design options and weigh in on the priorities that inform elements of the Modified LPA. A comprehensive community engagement report details all feedback. Key takeaways included:

- Design options and Program elements that improve travel times, relieve congestion, improve safety, and mitigate negative impacts to people and the environment are preferred.
- Equity priority communities rely on transit for a diverse range of needs.
- Trip time is the most influential factor when choosing how to make trips in the future. Ease of trip and avoiding a toll were the second and third most influential factors, respectively.
- While preferences for how to access Hayden Island and Marine Drive is heavily influenced by a respondent's geographic location, when asked to identify the priority for any Hayden Island Interchange design, nearly 70 percent of all survey respondents agreed that congestion relief on I-5 near Hayden Island is most important.
- Survey results indicate Washington residents prefer direct access to Hayden Island from I-5, while Oregon residents prefer to access Hayden Island via Marine Drive and new arterial bridges.
- The top three preferences for transit station locations are: (1) Vancouver waterfront, (2) near Clark College, and (3) Expo Center.

The IBR Program offers real-time engagement in online and in-person community meetings to address specific geographic areas, issues of concern, and Program priorities. Since February 2022, the

Program has hosted or attended more than a dozen community engagement events, including an online Black History Month Roundtable, multiple virtual and in-person meetings with the freight community, and presentations to and discussions with Program area neighborhood associations, including Bridgeton, Shumway, Hi-Noon, Arnada, and Rose Village, among others.

This feedback is important input that the IBR Program will continue to consider and integrate throughout the planning and design process.

3.7 Engagement with Freight Community

3.7.1 Freight Movement Public Listening Session

On May 27, 2021, the IBR Program hosted a Freight Movement Listening Session with members of the public. There were 46 participants, including representatives of marine and freight interests, ports, industry associations, and the Oregon and Washington legislatures. The purpose of this engagement was to provide information regarding the IBR Program and to hear from the freight community regarding their issues and concerns regarding the bridge. The key themes and takeaways included the following:

- Inability to use the Interstate Bridge due to height and weight limitations
- Concerns regarding congestion negatively impacting freight operations around Marine Drive
- Concerns regarding unreliability, narrow turns, safety, and bridge lifts
- Desire for more freight capacity on and around the bridge
- Challenges regarding travel path and turning radius

3.7.2 Freight Leadership Meetings

In partnership with the Ports of Vancouver and Portland, the IBR Program hosted two freight engagement sessions in the fall of 2021 and winter of 2021 with leaders of the regional freight community and IBR Program leadership. Attendees from the freight community included representatives from regional ports, industry associations, freight retail, and the Oregon and Washington legislatures. The key themes and takeaways included the following:

- Unimpaired freight movement is important to the local, regional, national, and international economies.
- Congestion through the I-5 corridor increases freight operational costs and negatively impacts the ability to attract and retain employees.
- Trucks avoid peak travel times if possible (6 to 9 AM and 3 to 9 PM).
- Suggestions for improvement include:
  - Install truck-only lanes
  - Reduce the number of on/off-ramps
  - Remove current height restrictions and bridge lifts

- It is desirable that road and pathway alignment be designed with consideration for optimal freight movement.
- High, wide, and heavy freight movement, including bridge and overpass heights should be considered.
- There is interest in learning about impacts to freight connectivity, including on/off-ramp locations and east/west access to Terminal 6 in North Portland.
- There is interest in future engagement regarding alignment and number of lanes through the Program area.
- There is concern that current exponential freight volume growth may increase congestion connected with Interstate 205 (I-205).

4. DESIRED OUTCOMES

Desired outcomes are observable and measurable accomplishments that the IBR Program aspires to achieve at a Program level. Input from partners,[4] the public, and the CAG and EAG was used to identify the Program's desired outcomes. The desired outcomes align with the Program's Purpose and Need statement, as well as with the community priorities and values adopted by the CAG, the equity objectives adopted by the EAG, and the IBR Program's climate objectives.

Table 1 identifies desired outcomes that are associated with the Program's Purpose and Need statement, and Table 2 identifies additional desired outcomes in alignment with the Program values, including desired outcomes specific to equity and climate resiliency. Desired outcomes were only developed for Program values that are applicable to the screening of high-level design options, (e.g., "foster leadership and cooperation" does not apply).

Table 1. Desired Outcomes Associated with the Purpose and Need Statement

Purpose and Need for the Program	Desired Outcomes
Growing travel demand and congestion	More people can move through the Program area.
	People of all ages, abilities, and incomes have access to move through the Program area, regardless of mode.
	Regional trips stay on I-5.
	Travel times through the Program area are faster and more predictable.
	Increase transportation choices and efficient travel patterns through coordinated land use and transportation planning.
Impaired freight movement	Freight travel through the Program area is more reliable.
	Freight travel times through the Program area are faster.
	Accommodate high, wide, and heavy cargo in existing and future routes.

[4] ODOT's and WSDOT's local partner agencies include Metro, the RTC, TriMet, C-TRAN, the City of Portland, the City of Vancouver, the Port of Portland, and the Port of Vancouver.

Purpose and Need for the Program	Desired Outcomes
Limited public transportation operations, connectivity, and reliability	More people have access to high-quality, affordable, and reliable transit.
	Transit connects people to their origins and destinations.
	Travel by transit is competitive with other modes.
	More people use transit.
	Travel by transit is predictable, reliable, and consistent.
Safety and vulnerability to accidents	Reduce overall crashes on I-5, including severe injury and fatal crashes.
	Reduce overall crashes, including severe injury and fatal crashes, on I-5 ramps, local streets, and active transportation networks in the Program area.
	Safety is reflected in the design of all modes.
	Fewer diverted trips from I-5 to local streets.
Substandard bicycle and pedestrian facilities	Active transportation is an attractive mode, and more people walk and cycle, both to access transit and instead of traveling by autos.
	More people have access to high-quality active transportation facilities.
	Traveling by walking, biking, and rolling feels safe because facilities are separated from moving vehicles and the shared-use path environment is visible and connected.
	The high-quality networks for walking/biking/rolling are convenient and connect destinations that are important for most trips.
Seismic	Bridges will be designed and constructed so that they will not collapse and will remain operable in a Cascadia subduction zone earthquake.

Table 2. Additional Desired Outcomes

Additional Desired Outcome Category	Desired Outcomes
Climate change and resiliency	Reduce greenhouse gas emissions in support of state climate goals.
	Minimize operational and embodied carbon during construction.
	All structures are resilient to and operable following anticipated climate disruptions (e.g., heat events, flooding, sea level rise).
	Program limits other environmental impacts that exacerbate effects of climate change (e.g., heat island, runoff).
Equity	Improved mobility, accessibility, and connectivity, especially for lower income travelers, people with disabilities, and communities who experience transportation barriers.
	Fewer identity-based disparities in travel time, access, transportation costs, and exposure to air pollution, road noise, and traffic crashes.
	Local community improvements are implemented in addition to required mitigations.
	Economic opportunities generated by the Program benefit minority- and women-owned firms, BIPOC workers, workers with disabilities, and young people.
	Equity priority communities have access, influence, and decision-making power throughout the Program in establishing objectives, design, implementation, and evaluation of success.
	Disproportionate impacts on equity priority communities are avoided rather than simply mitigated.
Cost effectiveness and financial resources	Pursue and leverage any and all federal, state, and other funding sources that support all modes and address long-term needs.
	Identify equitable tolling and pricing strategies supporting multimodal construction costs and improved operations and access, in coordination with statewide tolling program and in support of each state's climate goals.
	Ensure fiscal responsibility across the Program and into the future, including new technology to solve future problems.

The draft desired outcomes were presented to the ESG on October 21, 2021, and to the Bi-State Legislative Committee on October 27, 2021. The list above reflects the suggestions and discussion from those groups. The ESG concurred on the process for developing desired outcomes.

5. CHANGES SINCE THE CRC PROJECT

The existing conditions, regulatory and policy context, and community priorities have changed since the CRC project. These changes required revision of specific components of the 2013 LPA and the corresponding modification of design options. Section 5 summarizes the broader changes that apply to the entire IBR Program area, including equity and climate considerations. Section 7 identifies changes specific to a Program component (e.g., the river crossing).

Since the issuance of the CRC ROD and subsequent re-evaluations, there have been changes in existing environmental conditions ranging from physical changes in the environment within the Program footprint to regulatory changes to societal changes in community priorities and interests. The IBR Program prepared a NEPA re-evaluation in 2021 that identified some of those changes, which are summarized below.

- **Demographic changes.** The Portland-Vancouver metropolitan area added more than a quarter of a million residents between 2010 and 2020, with the majority being Black, Indigenous or People of Color (BIPOC) and/or Hispanic/Latino (U.S. Census Bureau 2010, 2020).
- **Housing costs.** The cost of housing has increased significantly, forcing many households with lower incomes to move to neighborhoods where housing is more affordable but that may be farther from job and activity centers (Metro 2015). The combination of longer distances traveled and limited public transit service in these areas places an added transportation cost burden on these community members, including many who moved from Portland to Clark County but still need to travel to Portland for work, medical appointments, family, or other needs (Metro 2018). Related to rising housing costs is a growing houseless population throughout the region (Clark County Council for the Homeless 2022; Multnomah County Joint Office of Homeless Services 2022). The number of encampments has increased, including in the highway right of way and throughout the study area.
- **Climate change.** In the past decade, there has been growing awareness and acceptance of the implications and impacts of climate change. Many communities, agencies, and businesses are reassessing their behavior and operations to identify how they might be contributing to global warming and resultant climate change, and they are examining how their environment is changing due to climate change. Both Washington and Oregon, as well as local governments in the study area, have established new climate policies since 2011. Additionally, recent exceptional weather events are driving changes in considerations and assumptions about climatic conditions and related community needs.
- **Traffic.** Changes have occurred since 2013 in traffic volumes and activities (RTC n.d.). The IBR Program has updated traffic models to extend the forecast to 2045 (CRC used 2035).
- **Transit service.** Changes in existing transit services and activities include C-TRAN's Fourth Plain Vine bus rapid transit route, which began service in 2017, and bus-on-shoulder operations on I-5

north of the Interstate Bridge, which began in 2020. TriMet has also expanded operations and planning for additional bus rapid transit service in the region.

- **Tolling.** Tolling programs are being studied and planned in Oregon (ODOT n.d.). Tolling on the Interstate Bbridge was included in the CRC analysis and is included in the IBR analysis.
- **Land use.** Localized development includes limited construction and buildings developed since issuance of the CRC ROD or building permit applications.
- **Historic resources.** A new group of historic-aged structures potentially eligible for listing on the National Register of Historic Places has been identified since the previous historic period survey, which considered structures dating back to 1967. Assuming that construction of the Modified LPA will begin in 2025, the historic resources period has been extended 15 years to consider buildings built in or prior to 1982.
- **Endangered Species Act.** ESA listings and critical habitat designations have changed since the 2013 consultations with the National Oceanic and Atmospheric Administration National Marine Fisheries Service (NOAA Fisheries) and the U.S. Fish and Wildlife Service (USFWS) (NOAA n.d.; USFWS 2021). The IBR Program has consulted with NOAA Fisheries and USFWS to determine the Section 7 consultation approach and bring the consultations up to date with current species listings and critical habitat designations and to reflect changes in best available science.
- **Changes in other regulations.** Many environmental regulations, procedures, and permits, including the U.S. Coast Guard's Section 9 Bridge Permit process, have changed or been updated since the issuance of the CRC ROD and re-evaluations. The technical reports prepared to support this Draft SEIS include additional detail on regulations specific to each technical discipline that have changed since 2013.

As noted above, to evaluate the effect of changes in conditions and regulations since 2013, as well as potential design changes, the IBR Program prepared a NEPA re-evaluation in 2021. Based on the information presented in the re-evaluation, FHWA and FTA concluded that the IBR Program could include project design changes or refinements to the CRC Selected Alternative that would result in new or changed significant adverse impacts that were not evaluated in the CRC Final EIS and ROD. In addition, they concluded that new information or circumstances (due to changes in the physical environment, community priorities, and regulations) since the CRC ROD could result in new or changed significant adverse impacts not previously evaluated. Therefore, in compliance with 23 CFR 771.130(a), FHWA and FTA determined that an SEIS would be necessary to identify and disclose new adverse impacts and mitigation associated with the IBR Program.

6. SCREENING AND EVALUATION PROCESS

The proposed design modifications were selected through the five-step process described in Section 2.2, which began with (1) validating the Purpose and Need, (2) identifying desired outcomes, and (3) documenting changes in the Program area. The last two steps were to develop screening methods and metrics, and to screen and evaluate the design options. The methods and metrics were tailored for each component to provide a meaningful evaluation that reflected the key considerations for each component (i.e., the screening methods and metrics for the main river crossing were not the same as those for the auxiliary lanes). The following sections describe the screening and evaluation processes for each component.

6.1 Screening and Evaluation Process for Hayden Island/Marine Drive Interchanges and Main River Crossing

The following sections summarize the screening process used to arrive at recommendations for the interchange configurations on Hayden Island and Marine Drive, and for the general design of the replacement bridges across the Columbia River.

6.1.1 Process Overview

Screening metrics that reflect the Program's Purpose and Need and other desired outcomes were developed in fall 2021. Screening metrics are specific, measurable metrics that provide differentiating data between the design options for a given Program component (e.g., the river crossing). The metrics were used during screening to identify the benefits and tradeoffs between the design options and ultimately assessed how well a design option met the desired outcomes (see Table 1 and Table 2 in Section 4).

Working in collaboration with partners and the task forces, the IBR design and environmental teams developed a menu of potential screening metrics for design components through an iterative process, including input from the EAG, who reviewed and identified screening metrics that could be used to advance the Program's equity objectives. See Section 6.1.2 for a description of how equity and climate were embedded in the screening process.

To align with the desired outcomes tied to the Purpose and Need, the metrics were organized into the following categories:

- Active Transportation
- Transit Access
- Vehicles
- Freight
- Seismic issues

The following categories were also included to reflect other desired outcomes:

- Climate Impacts/Adaptation
- Natural Environment
- Built Environment
- Cost

As screening metrics were developed, IBR staff, partner agencies, and the EAG identified whether a metric was representative of a desired outcome; in many cases, a metric was representative of more than one desired outcome or objective. Additional metrics were identified to help assess a design option's effects on the natural and built environment. Metrics were modified during the evaluation process if it became apparent that additional differentiators were needed or if the selected metrics were not highlighting differences among the options.

During screening, the task force for each component used a three-point Harvey balls system (○ = good, ◑= better, ● = best) to score each metric in the matrix for a given design option. Some metrics were considered for informational purposes only and did not receive a score. The task forces reviewed the data and the scoring to understand a design option's ability to meet the Purpose and Need statement and desired outcomes, its benefits and tradeoffs, and its success in meeting the equity and climate objectives.

Detailed screening summaries were developed for each of the design options that the task force ultimately recommended to advance. For the screening summaries, the original three-point Harvey balls system was converted to a five-point Harvey balls system (five scores from good to best: ○◔◑◕●) to help further differentiate each of the design options. A single Harvey balls score summarized all of the data for a given category.

The screening results were also considered through an equity lens and a climate lens (described below). A design option's performance in meeting the equity objectives and climate objectives was determined by evaluating the option's performance under all metrics identified as upholding an equity and/or climate objective. Each design option was then scored from low to high for equity and climate.

6.1.2 Incorporating Equity and Climate

During screening, each design option received a rating under the "equity lens" and "climate lens." These ratings range from low to high and are based on how a design option scored on all metrics that support an equity objective or climate objective. The task forces and EAG developed the equity and

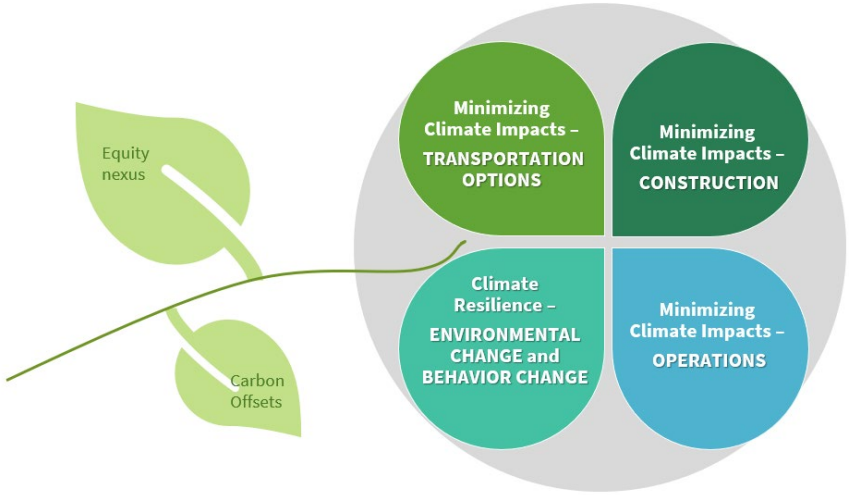
climate objectives and provided input on which metrics could be used to measure the extent to which a design option met an objective.

The equity objectives were developed by the EAG and adopted as part of the IBR Program's Equity Framework. The following equity objectives apply to the screening of high-level design options and were subsequently included in the screening process:

- **Avoid further harm.** Avoid rather than simply mitigate disproportionate impacts on equity priority groups.
- **Community benefits.** Find opportunities for and implement local community improvements in addition to required mitigations.
- **Economic opportunity.** Ensure that economic opportunities generated by the Program benefit minority- and women-owned firms, BIPOC workers, workers with disabilities, and young people.
- **Mobility and accessibility.** Improve mobility, accessibility, and connectivity, especially for lower income travelers, people with disabilities, and communities that experience transportation barriers.
- **Physical design.** Integrate equity, area history, and culture into the physical design elements of the Program, including bridge aesthetics, artwork, amenities, and impacts on adjacent land uses.

The IBR Program's climate objectives were developed in collaboration with agency partners, advisory groups, and the community. Attachment A provides a summary of the climate planning, policies and goals of agency partners and shows where and how the IBR Program climate framework and desired outcomes (as well as other Program initiatives, efforts and goals – such as equity and public engagement) are aligned. The IBR Program's climate framework consists of a four-pillar approach, as illustrated on Figure 2, that focuses on improving climate resilience through changes in the environment and behavior, and minimizing climate impacts through transportation options, construction methods, and long-term operations. Given the equity focus of the Program, climate considerations will also be evaluated for disproportionate impacts to communities of concern and equity priority groups (as defined by the EAG); this is referred to as the "equity nexus". Offsets, while not part of the framework, are acknowledged as a potential tool in further achieving climate objectives.

Figure 2. IBR Program Climate Framework



The following climate objectives were included in the screening process for consideration of design options:

- Supports complete communities.
- Compatible with low carbon construction.
- Supports intelligent transportation systems.
- Supports multimodal environmental factors.
- Supports low emission operations and maintenance.
- Improves **resilience** to uncertain climatic conditions.
- **Reduces idling** of vehicles (freight, single-occupancy vehicles, transit).

6.2 Screening and Evaluation Process for Transit Options

6.2.1 Process Overview

An initial range of potential transit investments was developed by the IBR Program and the partner agency transit technical teams to better understand how different combinations of mode (bus rapid transit [BRT], light rail transit [LRT]), alignment, station locations, termini (end points), and park-and-ride locations could perform relative to each other. To arrive at forecasts for the year 2045, each of the representative transit investments was modeled through the Metro/RTC regional travel demand model. Through TOTS, partners and the IBR team developed measures to better understand how the

representative transit investments would perform relative to each other (see Attachment D). The measures included:

- Multiple measures of ridership demand in 2045
  - River crossings by mode
  - Ridership by time of day
  - Mode of access
    - Walk
    - Transfer from other transit (bus/rail)
    - Park and ride
- Access for equity priority communities
- Relative costs
  - Capital cost
  - Operations and maintenance cost
- Potential impacts

6.2.2 Incorporating Equity and Climate

The equity and climate objectives identified in Section 6.1.2 were used to evaluate transit options. Input from the EAG was collected to identify specific considerations that should be taken into account during the evaluation of transit options. To evaluate the transit investments through an equity lens, the IBR Program Equity Team applied a methodology to estimate access to jobs - and, by proxy, services - by transit for different demographics. To evaluate the transit investments through a climate lens, the IBR Climate Team evaluated how the design options could support climate initiatives and local and regional policies to reduce greenhouse gas emissions. For example, one metric looked at how a design option could improve transit demand, thereby supporting a mode shift away from personal vehicles. Additional details on equity and climate considerations for the transit evaluation are identified in Section 7.3.3.

6.3 Screening and Evaluation Process for Auxiliary Lanes

6.3.1 Process Overview

Based on the desired outcomes, a series of metrics were developed with input from technical partner agency staff. These metrics included anticipated travel time during morning and evening peak travel periods, the anticipated congestion index (a measure of vehicle density and congestion levels), and the estimated daily mode share (i.e., what percentage of travelers would be personal vehicles, freight vehicles, transit, and active transportation). The analysis was completed by modeling 2045 forecast traffic volumes in order to obtain estimates for the identified metrics. The analysis also included close coordination with partner agencies in order to balance regional needs and priorities, including safe, efficient, and reliable travel, as well as equity and climate goals.

6.3.2 Incorporating Equity and Climate

The equity and climate objectives identified in Section 6.1.2 were used to evaluate auxiliary lanes. The EAG provided input on specific considerations that the Program should take into account when evaluating auxiliary lanes and selecting a design option. To evaluate the auxiliary lanes through an equity and climate lens, metrics were identified that could help address equity objectives (e.g., improve travel times) and support goals and policies to reduce greenhouse gas emissions (e.g., encourage a mode shift to transit or active transportation). Additional details on equity and climate considerations for the transit evaluation are identified in Section 7.4.3.

7. DESIGN OPTION DEVELOPMENT AND SCREENING

This section identifies the Program components proposed for refinement through design options, the changes that have occurred since 2013, and provides an overview of agency input and public feedback to date for each Program component proposed for refinement through design options. To address the changes identified in Section 5, and to evaluate the components through an equity lens and a climate lens, the IBR Program collaborated with agency partners to develop high-level design options to respond to changes while incorporating current regional values and priorities. There are four components, or design areas, for which the IBR Program, partners, and community identified the need for design changes:

- Hayden Island and Marine Drive
- Main river crossing
- Transit mode, general alignment and termini
- Auxiliary lanes

7.1 Hayden Island and Marine Drive

The primary design considerations for Hayden Island and Marine Drive were the interchange type on Hayden Island and resulting multimodal connections with Marine Drive and I-5. The IBR Program evaluated multiple concepts, ultimately advancing full, partial, and no-interchange options for Hayden Island into the screening process. All design options included a full interchange at I-5/Marine Drive; an arterial bridge across North Portland Harbor to serve local traffic; a shared-use path for active transportation connecting North Portland, Hayden Island and the 40-Mile Loop Trail; and the realignment of N Tomahawk Island Drive[5] to provide an additional east-west local street connection on Hayden Island.

Supporting materials for the Hayden Island and Marine Drive design options are provided in Attachment B, including the screening matrices and screening summaries. The IBR Program will ensure that information in the SEIS is consistent with and supports the Interchange Access Modification Request process, as it collaborates with and seeks approval from FHWA for the Program's proposed access revisions.

7.1.1 Changes since 2013

The IBR Program identified the following changes in conditions since 2013 related to Marine Drive and Hayden Island through advisory group input, community feedback, and input from agency partners serving on the Hayden Island/Marine Drive task force. These changes necessitated the development of design options for the Marine Drive and Hayden Island interchanges.

[5] In response to a government-to-government request, the IBR Program is pursuing conversations with the City of Portland for consideration of a street name change to N Tomahawk Island Drive.

- **Land use.** Planned land uses at the west end of Hayden Island have changed (e.g., a marine terminal is no longer planned).
- **Freight.** Freight movements have changed, with less freight anticipated on Hayden Island but increased freight in the North Portland area. The Port of Portland is no longer planning to develop West Hayden Island into a port facility. Meanwhile, freight-related development in North Portland industrial areas has grown.
- **Traffic.** Auto and freight volumes in the Program area have increased, and the design year for the Program has been updated from 2030 to 2045.
- **North Portland Harbor Bridge.** Over the past decade, the need to replace this seismically deficient structure has increased. The IBR Program will replace the North Portland Harbor bridge to improve seismic resiliency in the corridor.
- **Project Footprint.** During the CRC project's public engagement, community feedback suggested that the project's footprint on Hayden Island was too large under the 2013 Design.
- **Portland Transportation Hierarchy.** The City of Portland uses a transportation hierarchy to prioritize modes when making transportation investment and design decisions. Variations of this hierarchy existed during the CRC project, but it was last updated with the City of Portland's 2035 Comprehensive Plan (policy 9.6). The prioritization of modes has changed since the CRC project, including the elevation of transit to the third priority, following walking and biking.
- **Levee.** The USACE, in partnership with the Multnomah County Drainage District (MCDD), is planning improvements to the existing levee along the south side of the harbor (the Levee Ready Project). It is anticipated that the new levee design will require any improvements associated with the IBR Program to stay above a 38-foot elevation (North American Vertical Datum of 1988). Alterations to I-5 will require review by the USACE, MCDD, and the City of Portland for compliance with levee requirements associated with the Levee Ready Project.

7.1.2 Community Input

Community input on the Hayden Island/Marine Drive interchanges came from a variety of events and sources. An online survey in the winter of 2021 was held to understand the community's values and priorities around various improvements, including interchange options for Hayden Island/Marine Drive. Survey participants identified congestion relief on I-5 near Hayden Island as the top priority for interchange design. Additional input on the interchanges was collected from the Hayden Island/Marine Drive Community Working Group (meetings were held in September and December 2021), CAG meetings (Hayden Island/Marine Drive discussions were held in March 2022 to May 2022), and other outreach efforts detailed in the community engagement report (see Section 3.6). Feedback from the community on the Hayden Island and Marine Drive interchange area included:

- Congestion relief and safety are priorities.
- There is a community desire for a local connection between North Portland and Hayden Island.
- There is a need for active transportation facilities and multimodal connections in the Program area between North Portland and Hayden Island and the I-5 bridge over the Columbia River.
- There is a community desire to maintain and/or improve east-west connectivity across Hayden Island.
- The Program should address the bottlenecks that affect access to Hayden Island.
- Prioritize the option with smallest footprint over Hayden Island.
- Consider freight needs, as well as active transportation safety and access.
- Prioritize congestion relief on I-5 near Hayden Island, safe intersections and road improvements, and convenient access to services, shopping, and restaurants.
- Washington residents preferred direct access to Hayden Island and Oregon residents preferred island access via Marine Drive and local access bridge.

7.1.3 Equity and Climate Considerations

See Section 6.1.2 for a discussion on how equity and climate were incorporated into the screening process. Equity considerations for the interchanges screening were identified through coordination with the EAG (discussions on the Hayden Island/Marine Drive interchanges were held winter 2021 – spring 2022), two equity-focused listening sessions (held in March 2021), the winter 2021 community survey, and input from partner agencies on their equity programs and policies. To evaluate the IBR Program through an equity lens, the following considerations, applicable to the Hayden Island/Marine Drive interchanges, were incorporated during development of the design options:

- There is a need to provide access to the significant number of retail and service industry jobs located in the area.
- There are a high proportion of older adults and people with disabilities living on Hayden Island.
- The Program should consider the relationship between the Program's footprint and opportunities for ancillary development.
- Minimize impacts to property, including displacement of businesses and residences.

Climate considerations for the interchanges screening were identified through input from the CAG and partner agencies on their climate initiatives and policies. See Section 6.1.2 for a discussion of these planning policies and goals. To evaluate the IBR Program through a climate lens, the following considerations were incorporated during development of the design options:

- The design options should raise the I-5 mainline and local streets above the 100-year flood elevation to protect them from sea-level and water rise associated with climate change.
- The North Portland Harbor bridge has aged beyond the point that seismic retrofitting is feasible, as was proposed in the 2013 Design. Replacing this bridge would improve the community's resiliency to sea level rise.
- The design options should improve multimodal connectivity to, from, and through Hayden Island and encourage a shift from vehicle trips to low or no emissions travel (e.g., transit, bike, walk).

The following Program elements, which are related to the equity and climate considerations, were incorporated into all design options:

- Separated shared-use path for active transportation.
- Replacement of the North Portland Harbor bridge.

7.1.4 Hayden Island/Marine Drive Task Force

The purpose of the Hayden Island/Marine Drive task force was to have focused, detailed technical discussions on what transportation improvements the IBR Program could make to Hayden Island and Marine Drive and to understand local conditions, needs, and planned transportation improvements.

The Hayden Island/Marine Drive task force met 18 times between late spring 2021 and early winter 2022. There was an average of 50 participants per meeting, with staff from 10 local partner agencies and technical staff from the IBR Program. The task force discussions covered a wide variety of topics, including the interchange compatibility and function, integration of active transportation improvements, connections to the local street network, and reducing environmental impacts. These discussions assisted in the identification of site-specific needs and refining metrics for screening design options.

The IBR design team developed eight preliminary design concepts based on numerous design iterations and, in fall 2021, completed a tradeoffs matrix with the task force to identify design options to be advanced into screening.

The IBR team developed the pre-screening tradeoffs matrix with the goal of advancing one full interchange design option, one partial interchange design option, and one no-interchange design option at Hayden Island through screening. The purpose of the pre-screening was to find the best performing, lowest impact design option for each type of interchange to advance into the screening where it could be evaluated against the screening criteria.

The tradeoffs matrix listed features and challenges based on design work for task forces in summer/fall 2021. Features and challenges included the following:

- Footprint
- Safety
- Mobility
- Access and connectivity for auto, freight, transit, and active transportation
- Constructability
- Seismic resiliency
- Compatibility with other project components

Each of the four full interchange design options (including the 2013 Design) received a plus or minus for each feature/challenge relative to other full interchange design options (but not relative to partial and no-interchange design options). This was also completed for each of the three partial interchange design options, and for the single no-interchange option. Based on the features and challenges, the IBR team prepared a draft recommendation on whether to advance or not advance each design option into screening and provided explanatory documentation to support each recommendation.

The IBR team received feedback from the task force on the tradeoff matrix features/challenges, pluses/minuses, and recommendation/rationale.

7.1.5 Design Options Selected for Screening

Following agency and public input, the Hayden Island/Marine Drive task force identified five design options, in addition to the 2013 Design, to advance for screening:

- Design Option 1: Full Interchange
- Design Option 2: Partial Interchange 1
- Design Option 3: Partial Interchange 2
- Design Option 4: No Interchange
- Design Option 5: Partial Interchange 3

The 2013 Design (Design Option 0) was included in the screening and compared to the design options.

Each design option is described and illustrated below. All design options incorporate the following elements:

- Replacement of the North Portland Harbor bridge
- An arterial roadway connection between North Portland and Hayden Island
- An additional east-west local connection on Hayden Island
- Separated multi-use pathway for active transportation
- A high-capacity transit (HCT) station on Hayden Island
- A full interchange at I-5/Marine Drive.

High-level line drawings are provided below for the design options, which show roadway networks beyond the anticipated project limits; the extended network is provided for illustrative purposes. Section 7.1.6 details the results of the screening process, including why a design option was (or was not) advanced.

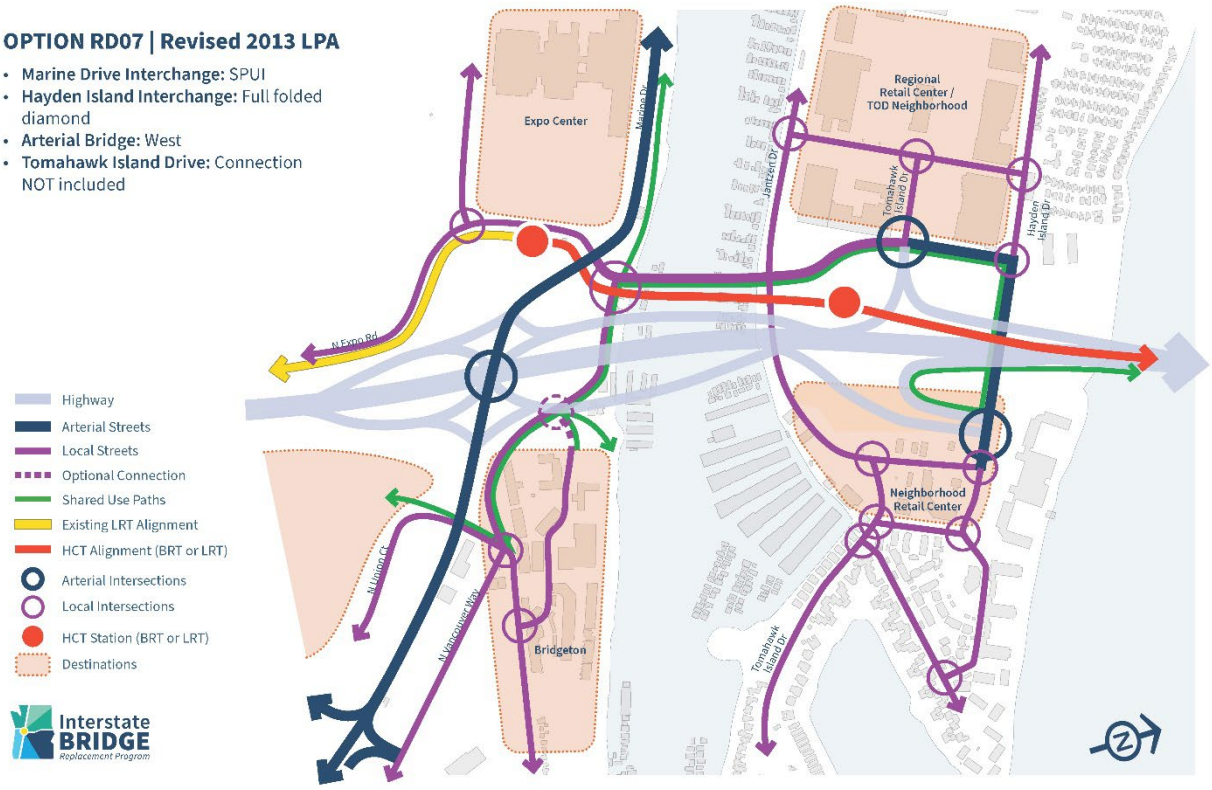
7.1.5.1 Hayden Island/Marine Drive Design Option 0: 2013 Design

The 2013 Design includes full interchanges on both Hayden Island and Marine Drive (Figure 3). The design includes local vehicular access between Marine Drive and Hayden Island on a local multimodal bridge.

The proposed configuration at Marine Drive was a single-point urban interchange (SPUI). With this configuration, the four ramps of the interchange would converge at a single signal-controlled intersection on Marine Drive over the I-5 mainline. Local traffic between Martin Luther King Jr. Boulevard/Marine Drive and Hayden Island would travel via a local multimodal bridge over North Portland Harbor, located to the west of I-5. A shared-use path west of I-5 would connect the river crossing bridge to the 40-Mile Loop Trail, with connections on Hayden Island. Improvements would include realignment of Expo Road.

The Hayden Island interchange would be reconfigured to improve safety for traffic merging on I-5 by providing sufficient ramp lengths parallel to I-5. Improvements would be included for Jantzen Drive and Hayden Island Drive; the roadways would be improved from a three-lane to a five-lane configuration to facilitate traffic using the interchange.

Figure 3. Hayden Island/Marine Drive Design Option 0: 2013 Design



7.1.5.2 Hayden Island/Marine Drive Design Option 1: Full Interchange

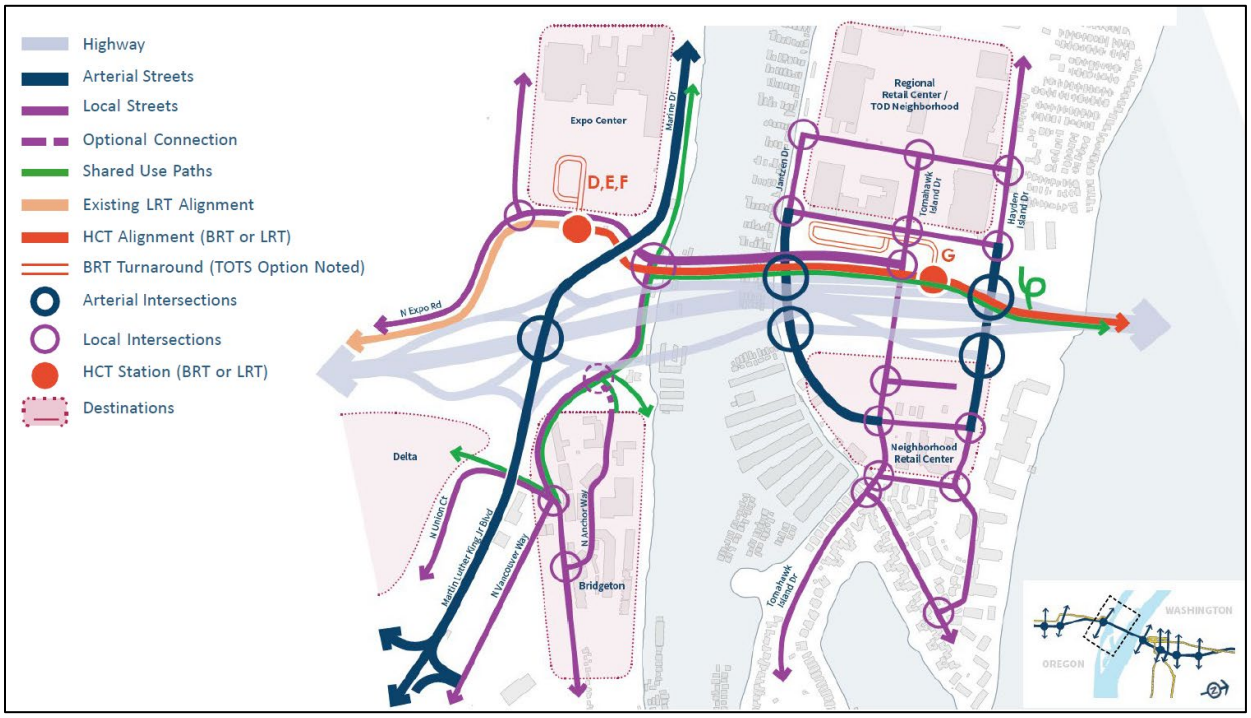
Like the 2013 LPA, Design Option 1 includes full interchanges on both Hayden Island and Marine Drive (Figure 4). This option would have a full, split tight diamond interchange at Hayden Island and a SPUI at Marine Drive. A shared-use path west of I-5 would connect the river crossing bridge to the 40-Mile Loop Trail, with connections on Hayden Island.

Local street connections on Hayden Island would be maintained under I-5 with some variations, including a third crossing under I-5 for Tomahawk Island Drive. An arterial bridge would connect Hayden Island to Expo Road (west of I-5) and Pier 99 Street. Roadway infrastructure would be farther west than in the 2013 LPA to accommodate the replacement of the North Portland Harbor bridge.

The following elements of Design Option 1 were studied in the CRC draft and/or final EIS.

- Full access SPUI at Marine Drive
- Full interchange on Hayden Island
- Tomahawk Island Drive extension under I-5
- Vancouver Way extension to Expo Road
- Arterial bridge to west of existing I-5 North Portland Harbor bridge
- New bike/pedestrian paths
- Martin Luther King Jr. (MLK) Boulevard gull wing interchange east of I-5

Figure 4. Hayden Island/Marine Drive Design Option 1: Full Interchange



7.1.5.3 Hayden Island/Marine Drive Design Option 2: Partial Interchange 1

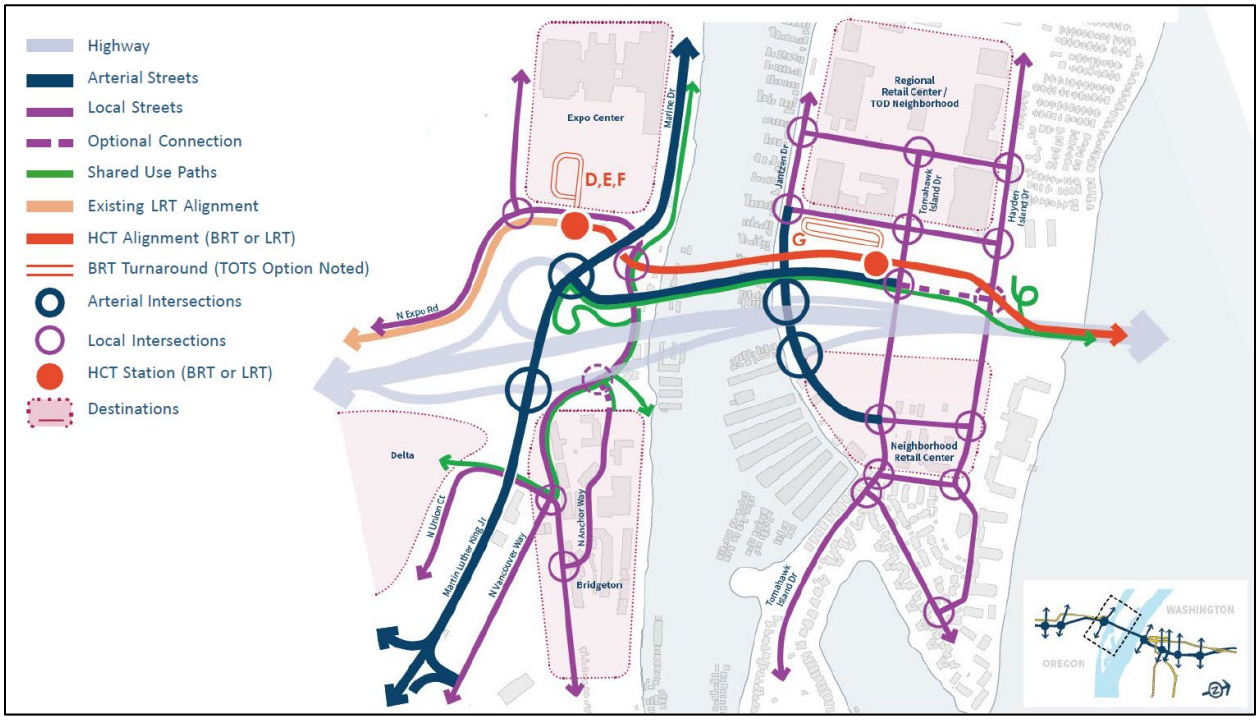
Design Option 2 would include a full access folded diamond interchange at Marine Drive and a half diamond interchange on Hayden Island (Figure 5). The partial interchange on Hayden Island would provide direct ramp connections between Jantzen Drive and I-5 north of Hayden Island. Hayden Island traffic traveling to/from the south would access I-5 by at the Marine Drive interchange through an arterial bridge that connects Tomahawk Island Drive and Marine Drive across the North Portland Harbor. A shared-use path west of I-5 would connect to the 40-Mile Loop Trail, with connections to other active transportation facilities on Hayden Island.

Local street connections on Hayden Island would be maintained under I-5 with some variations, including a third crossing under I-5 for Tomahawk Island Drive. Roadway infrastructure would be farther west than in the 2013 LPA to accommodate the replacement of the North Portland Harbor bridge.

The following elements of Design Option 2 were studied in the CRC draft and/or final EIS.

- Tomahawk Island Drive extension under I-5
- Vancouver Way extension to Expo Road
- Phased I-5 braided on- and off-ramps at Victory Boulevard
- New bike/pedestrian paths
- MLK Boulevard gull wing interchange east of I-5

Figure 5. Hayden Island/Marine Drive Design Option 2: Partial Interchange 1



7.1.5.4 Hayden Island/Marine Drive Design Option 3: Partial Interchange 2

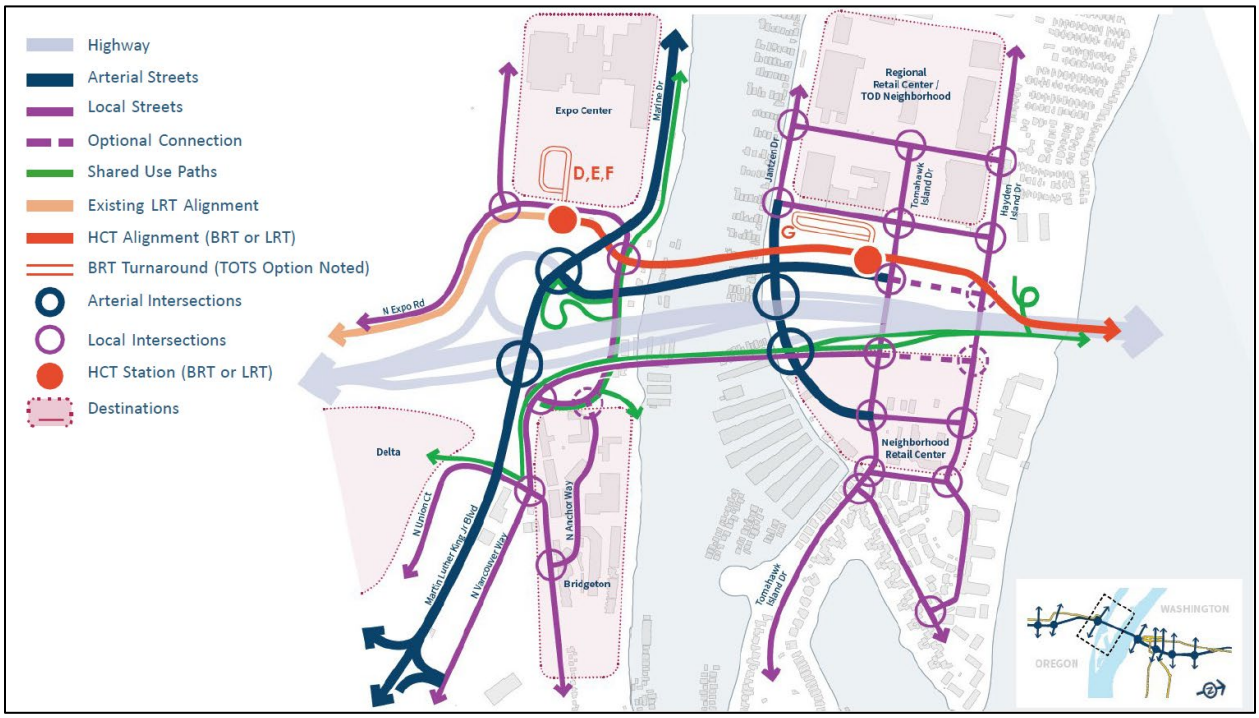
Design Option 3 would also have a full access folded diamond interchange at Marine Drive and a half diamond interchange on Hayden Island (Figure 6). Design Option 3 would have the same west arterial bridge configuration as Design Option 2 but would also add a local street bridge east of I-5. The local street bridge east of I-5 would provide a connection between Tomahawk Island Drive and Vancouver Way. A shared-use path would connect the river crossing bridge to the 40-Mile Loop Trail via the east arterial bridge, with connections on Hayden Island.

Local street connections on Hayden Island would be maintained under I-5 with some variations, including a third crossing under I-5 for Tomahawk Island Drive. Roadway infrastructure would extend farther west than in the 2013 LPA to accommodate the replacement of the North Portland Harbor bridge.

The following elements of Design Option 3 were studied in the CRC draft and/or final EIS.

- Tomahawk Island Drive extension under I-5
- Vancouver Way extension to Expo Road
- Phased I-5 braided on- and off-ramps at Victory Boulevard
- New bike/pedestrian paths
- MLK Boulevard gull wing interchange east of I-5

Figure 6. Hayden Island/Marine Drive Design Option 3: Partial Interchange 2



7.1.5.5 Hayden Island/Marine Drive Design Option 4: No Interchange

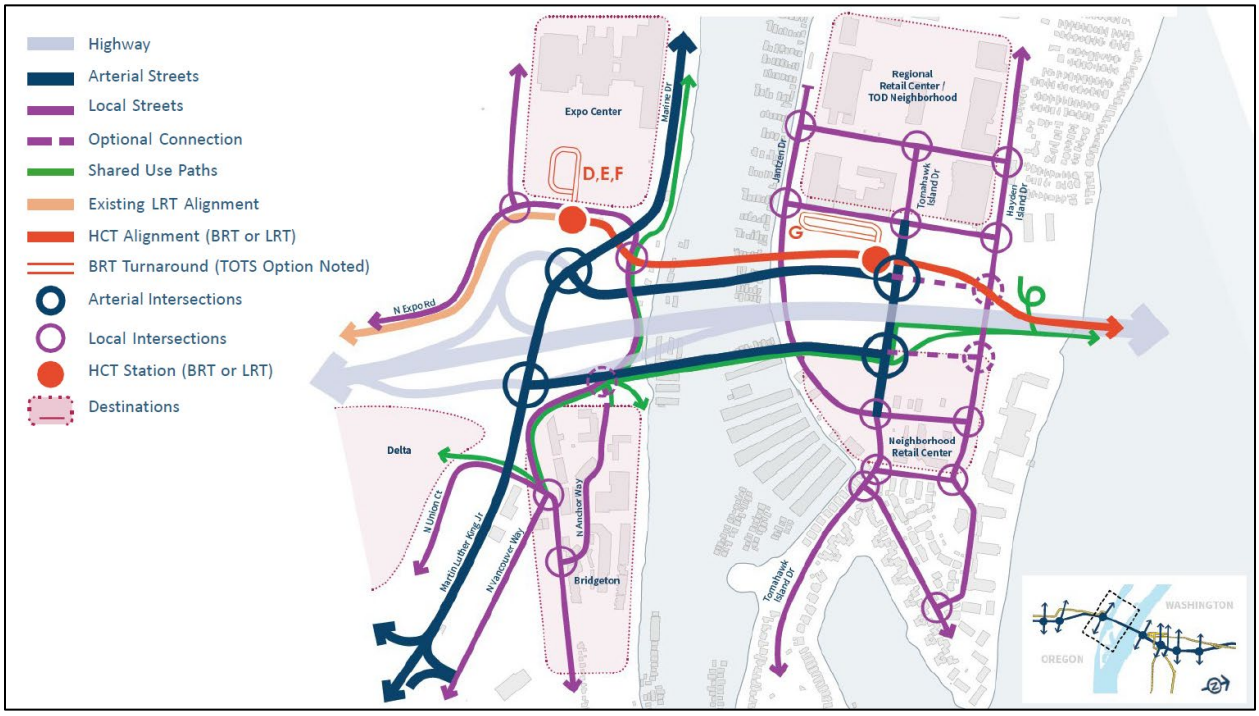
Under this design option, there would be no interchange on Hayden Island (Figure 7). Similar to Design Options 2 and 3, a full access folded diamond interchange would be located be at Marine Drive. All access to/from Hayden Island would be provided through the Marine Drive interchange with two arterial bridges that connect Tomahawk Island Drive to Marine Drive. A shared-use path would connect to the 40-Mile Loop Trail via the local street bridge, with connections on Hayden Island.

Local street connections on Hayden Island would be maintained under I-5 with some variations, including a third crossing under I-5 for Tomahawk Island Drive. Roadway infrastructure would extend farther west than in the 2013 LPA to accommodate the replacement of the North Portland Harbor bridge.

The following elements of Design Option 4 were studied in the CRC draft and/or final EIS.

- Tomahawk Island Drive extension under I-5
- Vancouver Way extension to Expo Road
- New bike/pedestrian paths
- MLK Boulevard gull wing interchange east of I-5

Figure 7. Hayden Island/Marine Drive Design Option 4: No Interchange



7.1.5.6 Hayden Island/Marine Drive Design Option 5: Partial Interchange 3

During the screening process, the Hayden Island/Marine Drive task force identified design and operational flaws in Design Options 2 and 3 that made them infeasible. In particular, routing all Hayden Island traffic to/from the south through the Marine Drive folded diamond interchange resulted in heavy traffic volumes on Marine Drive ramps that could not be accommodated in a safe manner. As a result, the task force developed a new partial interchange option (Design Option 5) that would address the issues identified in Design Options 2 and 3.

Similar to Design Options 2 and 3, the partial interchange configuration under Design Option 5 would provide I-5 ramps to/from the north to Hayden Island via Jantzen Drive (Figure 8). However, Design Option 5 would use a full access SPUI at Marine Drive, similar to Design Option 1, to resolve some of the challenges posed by the folded diamond interchange configuration.

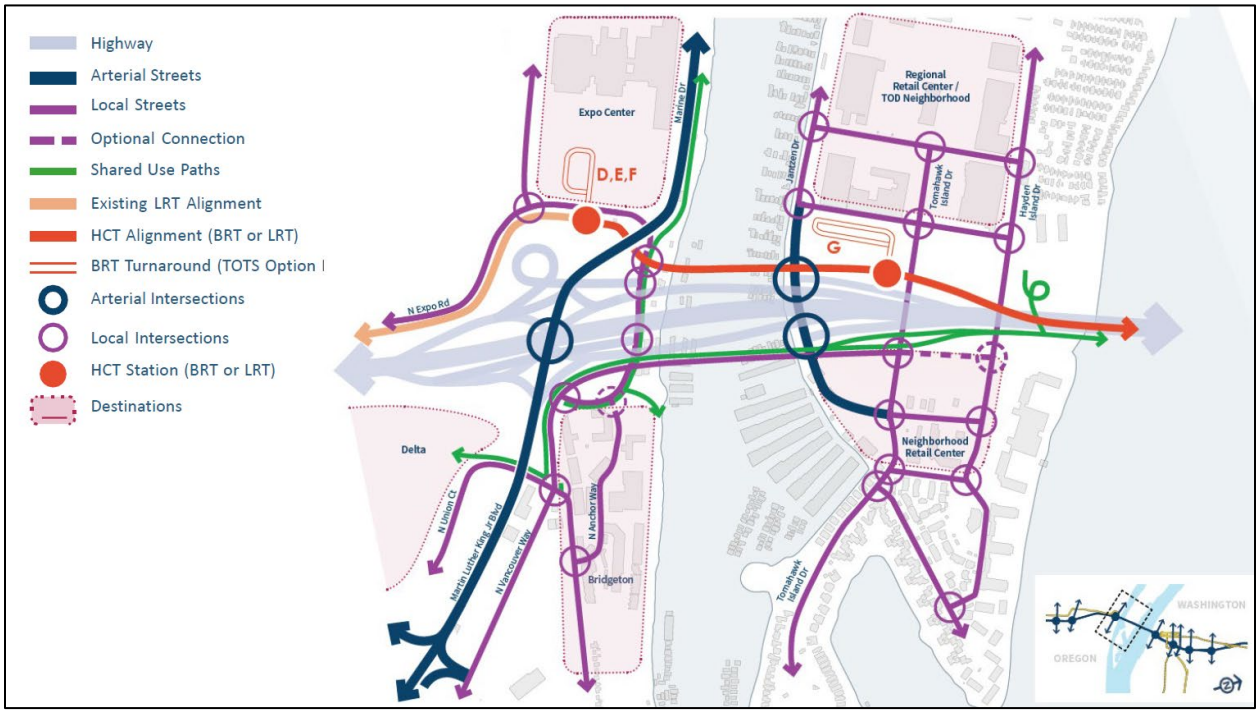
Hayden Island traffic to/from the south would use an arterial bridge east of I-5 between Tomahawk Island Drive and Vancouver Way to connect to two new I-5 ramps. The new I-5 ramps would cross under Marine Drive and connect to the arterial bridge through new interchange ramp terminals on Pier 99 Street. Similar to Design Option 3, a shared-use path would connect to the 40-Mile Loop Trail via the east arterial bridge, with connections to other active transportation facilities on Hayden Island.

Local street connections on Hayden Island would be maintained under I-5 with some variations, including a third crossing under I-5 for Tomahawk Island Drive. Roadway infrastructure would extend farther west than in the 2013 LPA to accommodate the replacement of the North Portland Harbor bridge.

The following elements of Design Option 5 were studied in the CRC draft or final EIS.

- Full access SPUI at Marine Drive
- Tomahawk Island Drive extension under I-5
- Vancouver Way extension to Expo Road
- Phased I-5 braided on- and off-ramps at Victory Boulevard
- New bike/pedestrian paths
- MLK Boulevard gull wing interchange east of I-5

Figure 8. Hayden Island/Marine Drive Design Option 5: Partial Interchange 3



7.1.6 Screening Results

The five design options described in Section 7.1.5, in addition to the 2013 Design, advanced from initial task force discussions to screening. During screening, the task force collected data for approximately 90 metrics and scored each design option against each other for a given metric. As described below, the task force recommended two design options for further consideration. The results are based on conceptual design and intended for a high-level screening effort; more precise estimates of impacts will be developed as the design is refined further and documented in the Draft SEIS.

Based on the screening results, the task force did **not recommend** advancing three design options, for the following reasons.

- Design Option 2 (Partial Interchange 1) and Design Option 3 (Partial Interchange 2) were dismissed due to the following key considerations and screening results:
  - High off-ramp volumes (1,600 to 2,000 vehicles per hour during the AM peak in 2045, 18 percent of which are trucks) would exceed the southbound I-5 loop ramp capacity.
  - The location of the loop ramp would not provide sufficient room for the distance required to navigate multiple lanes on a steep curve in a safe manner.
  - The steep grade from I-5 to Marine Drive is also not preferable for freight traffic.

  - The curve of the loop ramp, the steep grade, and limited sight distance for vehicles precluded the design from providing sufficient storage length for the high traffic volumes accessing the intersection on Marine Drive.
- Design Option 4 (No Interchange) was dismissed due to the following key considerations and results of the screening:
  - Based on preliminary traffic data, this design option was expected to have issues similar to Design Options 2 and 3; however, the magnitude of these traffic impacts would be greater because all Hayden Island traffic would have to use the Marine Drive Interchange. This would result in substantial traffic/freight impacts on Marine Drive and the ramp terminal intersections.
  - During peak times in the morning, the southbound off-ramp from I-5 to Marine Drive (which would also serve traffic destined for Hayden Island) would need to carry up to 2,500 vehicles per hour through a loop ramp. The geometric constraints of the loop ramp limit the amount of storage that can be provided at the intersection, resulting in queues at the off-ramp that would create unsafe conditions related to speed differences between the I-5 mainline and the off-ramp.
  - During peak times in the evening, the Marine Drive on-ramp to northbound I-5 (which would also serve traffic Hayden Island traffic accessing northbound I-5) would need to carry over 2,600 vehicles per hour through a ramp meter. This level of traffic could not be processed through the ramp meter and queues would back up from the meter, potentially constraining access to Hayden Island and impeding freight traffic on Marine Drive.
  - The only access from Hayden Island to northbound I-5 would require out of direction travel, south across the west arterial bridge, through the Marine Drive interchange, and then north across the west arterial bridge to the on-ramp to northbound I-5.

The 2013 LPA (Design Option 0) was included in the screening for comparison to Design Options 1 and 5, but it was not recommended to be advanced for inclusion in the Modified LPA. The 2013 LPA was not recommended for several reasons, including that it would retain the aging North Portland Harbor bridge, which does not meet the seismic resiliency desired across the Columbia River. Furthermore, it does not include a Tomahawk Island Drive or Vancouver Way extension and results in a larger footprint on Hayden Island.

Figure 10 shows the screening summaries side by side for each of the three design options. Table 3, Table 4, and Table 5 provide additional detail on the tradeoffs and benefits associated with Design Options 0, 1, and 5, respectively. The task force recommended Design Options 1 and 5 for Hayden Island/Marine Drive.

Figure 9. Hayden Island/Marine Drive – Relative Design Option Comparison

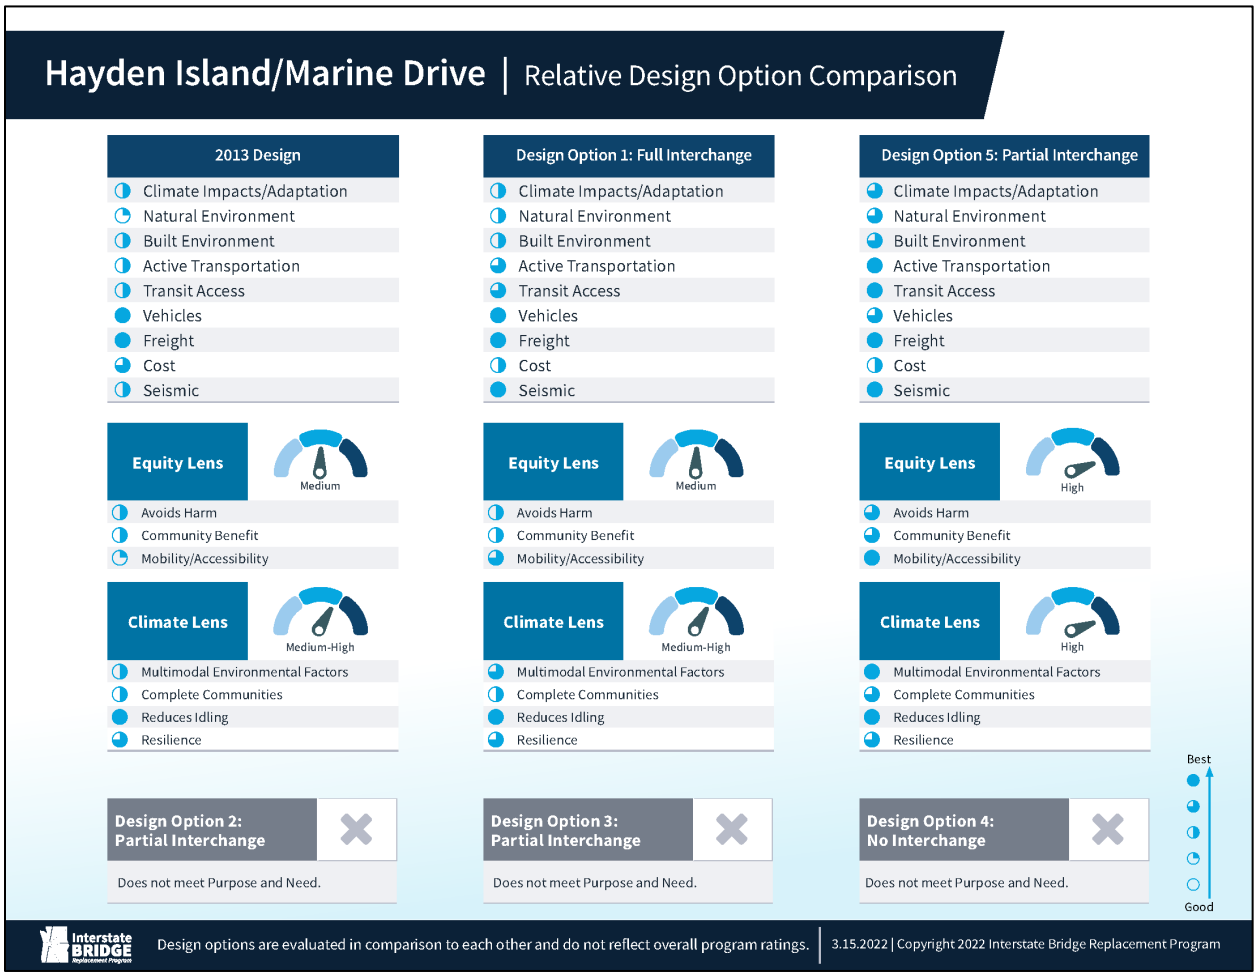


Table 3. Hayden Island/Marine Drive Design Option 0 – Screening Summary

Screening Category	Score	Design Option 0 Tradeoffs/Benefits
Climate Impacts/ Adaptation	◑	• Larger construction footprint (comparison is not based on expected user emissions) • Addresses future river elevation and integrates with new Levee Ready Columbia flood protection improvements (RES)
Natural Environment	◔	• Larger footprint over aquatic habitat • Larger footprint over terrestrial habitat
Built Environment	◑	• Most non-residential building impacts (AH) • More floating home displacements (AH) • Large scale and complexity of I-5 structures over Hayden Island challenge for local placemaking opportunities (AH, CB, CC) • Greater extent of local streets subject to Interchange Area Management Plan (IAMP) restrictions (CC) • Does not include Tomahawk Island Drive crossing (CC)
Active Transportation	◑	• Less direct north-south shared-use path (MA, ME) • Lower quality of active transportation experience on east-west streets (MA, ME) • Higher number of SUP road/transit crossings (MA)
Transit Access	◑	• Less east-west island connectivity because it does not include Tomahawk Island Drive (MA, ME) • Wider highway footprint (ME)
Vehicles	●	• Intersection traffic operations meet ODOT and City of Portland performance standards at Hayden Island and Marine Drive study area intersections (RID)
Freight	●	• Freight to/from Marine Drive area operates acceptably with minimal delay through the interchange (RID)
Cost	◕	• Lower construction cost • Higher estimated operations and maintenance cost
Seismic	◑	• Seismic retrofits North Portland Harbor bridge; does not replace

Equity Objectives
AH = Avoid further harm
CB = Community benefits
MA = Mobility and accessibility

Climate Objectives
CC = Supports complete communities
ME = Multimodal environmental
RES = Resilience
RID = Reduces idling

Design Options 1 and 5 performed best out of all design options. They have a similar freight/vehicle traffic performance on Marine Drive, including at ramp terminal intersections, and are both compatible with all transit investments currently under consideration.

To further differentiate between these two options, the task force compiled a list of tradeoffs and benefits between Design Options 1 and 5 (Table 6).

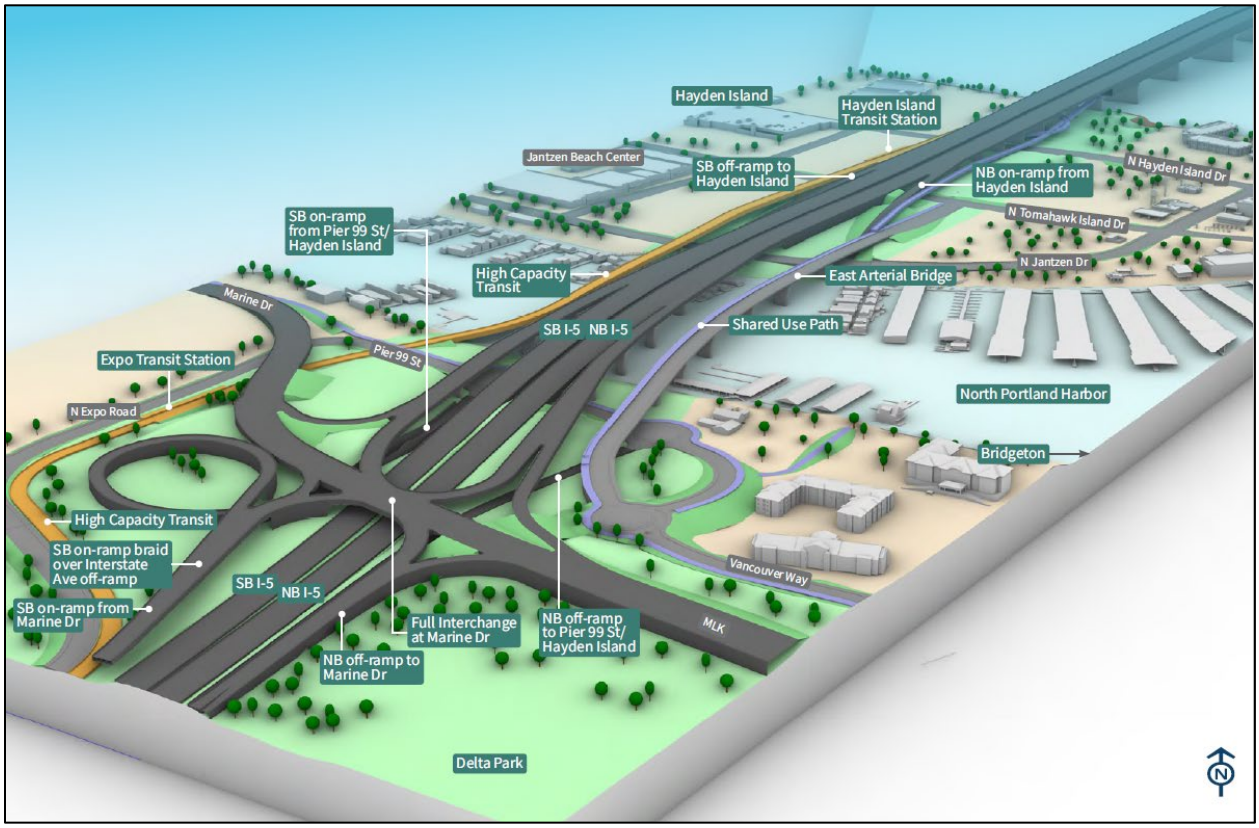
Table 6. Tradeoffs and Benefits Between Hayden Island/Marine Drive Design Options 1 and 5

Design Option 1: Full Interchange	Design Option 5: Partial Interchange
Larger footprint over North Portland Harbor	**Smaller** footprint over North Portland Harbor
More floating home impacts	**Fewer** floating home impacts
Larger scale/complexity of I-5 over Hayden Island provides **lower** quality experience for active transportation and transit access on east-west streets	**Smaller** scale/complexity of I-5 over Hayden Island provides **higher** quality experience for active transportation and transit access on east-west streets
Hayden Island vehicle/freight access to/from Portland **via Hayden Island Drive I-5 ramps**	Hayden Island vehicle/freight access to/from Portland **via local roads and I-5 ramps that cross under Marine Drive**
Hayden Island vehicle/freight access to/from Vancouver via Jantzen Drive I-5 ramps	Hayden Island vehicle/freight access to/from Vancouver via Jantzen Drive I-5 ramps
Scores **medium-high** from a **climate** perspective	Scores **high** from a **climate** perspective
Scores **medium** from an **equity** perspective	Scores **medium** from an **equity** perspective

Based on the findings in Table 6, the task force **recommended advancing** Design Option 5 (Partial Interchange) for further study and refinement (Figure 10). Because the design options were at a conceptual level of design detail during the screening process, the IBR Program will advance the design of Design Option 5 to explore opportunities to improve performance and reduce impacts. Specific areas for further study and design refinement include, but are not limited to:

- Optimize ramp terminal designs and associated access standards implications.
- Consider the integration of the levee and the interchange design, and how the levee would affect the operations of the Pier 99 Street ramp terminals.
- Consider including a southbound braided ramp between Marine Drive on-ramp and Interstate Blvd off-ramp, due to increased traffic volume and closely spaced ramps.
- Consider the lack of separation between local and interstate traffic on the proposed arterial bridge.
- Avoid wayfinding that is contrary to drive expectations (unconventional interchange splits and multiple turns).
- Evaluate additional traffic from Hayden Island on Expo Road (vehicle access, potential improvements, the lack of interstate connection between Hayden Island and Victory Boulevard).
- Consider potential impacts to the Vanport wetlands from the proposed loop ramp/braid at Marine Drive.
- Consider potential impacts to Delta Park from the proposed I-5 northbound off-ramp.

Figure 10. Hayden Island/Marine Drive Design Option 5: Partial Interchange 3 – Model Graphic



7.2 Main River Crossing

The river crossing area covers the main span of the Interstate Bridge over the Columbia River. This component extends from where the bridge begins on Hayden Island to where the bridge touches down in Vancouver. The Program was engaged in two separate but related discussions regarding the main crossing: the height and span of the crossing, which was a discussion with several agencies (see Section 7.2.2), and the general design of the crossing structure, which went through the design option screening process (see Section 7.2.3 through Section 7.2.7).

Supporting materials for the river crossing design options are provided in Attachment C, including the screening matrices and screening summaries.

7.2.1 Changes since 2013

The IBR Program identified the following changes in conditions since 2013 related to the main river crossing through advisory group input, community feedback, and input from agency partners serving on the River Crossing task force. These changes necessitated the development of design options for the river crossing.

- **Hayden Island/Marine Drive Design Options.** Design options for the river crossing are needed to accommodate the potential design changes identified for Hayden Island/Marine Drive (described in Section 7.1).
- **Bridge Permit.** The USCG bridge permit has expired, and the height and span of the replacement bridges need to be re-vetted with input from the USCG to ensure the replacement bridge design is viable and can obtain the required permits (see Section 7.2.2).
- **Vancouver Development**. Development has occurred in downtown Vancouver and the Vancouver waterfront. Design options are needed to minimize property impacts and improve access.
- **Multimodal Connections**. There have been changes in both existing and planned transit services and active transportation in Portland and Vancouver. Consideration is needed for how to best integrate the IBR Program with transit and active transportation systems.
- **Endangered Species Act.** New listed species and their critical habitat have been added to the threatened and endangered species list since 2013. This requires consideration of how to best avoid and minimize impacts to species and their habitat, including the timing of the in-water work and updating run timing for salmon species.

7.2.2 Height and Span Discussions

The IBR Program continues to coordinate discussions on the vertical height of the river crossing with the USCG in accordance with the Memorandum of Agreement (MOA) between the USCG and FHWA and the Memorandum of Understanding (MOU) between the USCG and FHWA, FTA and FRA. The IBR Program considered several options for the main river crossing, including tunnels, movable-span bridges, and fixed-span bridges. The Program dismissed tunnels for a number of design, structural, environmental, and cost reasons (see Attachment C-1 for details). As a result of the analysis, the IBR

Program recommended a mid-level fixed-span bridge with 116 feet of vertical clearance for the Modified LPA and completed a Navigation Impact Report based on this height.

The USCG issued a Preliminary Navigation Clearance Determination in June 2022 that set a requirement for a vertical clearance of 178 feet in order to provide for the reasonable needs of navigation. The IBR Program evaluated options to meet the horizontal and vertical clearance requirements established by the USCG consistent with the MOA and MOU. The IBR Program will continue to coordinate with the USCG during the NEPA process to develop design options that meet the USCG identified needs for reasonable navigation while still addressing the Purpose and Need.

7.2.3 Community Input

The community discussions and screening process focused on the general design of a mid-level fixed-span bridge. Community input came from a variety of events and sources. An online survey in the winter of 2021 was held to understand the community's values and priorities around various improvements, including the main river crossing. Most survey respondents (72 percent) identified improving travel times as a top priority.

Additional input on the main river crossing was collected from the Active Transportation Community Working Group (meetings held in September and November 2021), the Multimodal Commuter Community Working Group (meetings held in October and November 2021), and other outreach efforts detailed in the community engagement report (see Section 3.6). Feedback from the community on the main river crossing prioritized congestion relief and safety. Other priorities include improved accessibility, wayfinding, and protection from noise for active transportation users, plus improved connectivity between HCT and active transportation facilities.

7.2.4 Equity and Climate Considerations

See Section 6.1.2 for a discussion on how equity and climate were incorporated into the screening process. Equity considerations for the main river crossing screening were identified through coordination with the EAG, two equity-focused listening sessions (held in March 2021), and input from partner agencies on their equity programs and policies. To evaluate the IBR Program through an equity lens, the following considerations specific to the main river crossing structure were incorporated during development of the design options:

- Minimize impacts to property, including displacement of businesses and residences.
- Consider and minimize pedestrian and community exposure to noise and pollutants based on proximity of the shared-use path to vehicle lanes.

Climate considerations for the main river crossing screening were identified through input from the partner agencies during screening (See Section 6.1.2). To evaluate the IBR Program through a climate lens, the following considerations specific to the main river crossing structure were incorporated during development of the design options:

- Improve multimodal connectivity across the bridge and encourage a shift from vehicle trips to low or no emissions travel (e.g., transit, bike, walk, roll).
- Consider the bridge width and number of piers/foundations, which indicates the relative amount of construction material and embodied carbon.

The following project elements, which are related to the equity and climate considerations, were incorporated into all design options:

- Designed for dedicated HCT on the river crossing.
- Separated shared-use path for active transportation.

7.2.5 Task Force

The River Crossing task force met 11 times between summer 2021 and winter 2022. There was an average of 50 participants per meeting, with staff from nine partner agencies and technical staff from the IBR Program. The task force's discussions covered a wide variety of topics, including the bridge alignment and design, active transportation needs, integration with downtown Vancouver, urban design, and reduction of environmental impacts. These discussions assisted in the identification of site-specific needs and refining metrics for screening design options.

7.2.6 Mid-Level Fixed-Span Design Options Selected for Screening

The design options consider ways to move all modes across the river, as well as the configuration of these modes in relation to each other (e.g., the location of the shared-use path in relation to vehicle lanes and transit lines). The design options include variations designed for a two-bridge or one-bridge river crossing option, and they assume a mid-level fixed-span bridge that provides 116 feet of vertical clearance. Each of the design options has the same proposed horizontal navigation channel locations (shown in Figure 16) and 400-foot clearances (300-foot congressionally or USACE-authorized channel plus a 50-foot channel maintenance buffer on each side). A movable span could be accommodated on the bridge, depending upon further definition of the USCG bridge permit process.

Following agency and public input, the task force identified three design options to advance for screening, in addition to the 2013 Design:

- Design Option 1: Two Straight Bridges (Refined 2013 Design)
- Design Option 2: One Bridge (Double Stacked)
- Design Option 3: One Bridge (Hybrid Stacked)

The 2013 Design (Design Option 0) was included in the screening to provide a baseline for comparing the design options. Each design option is described and illustrated in the following sections.

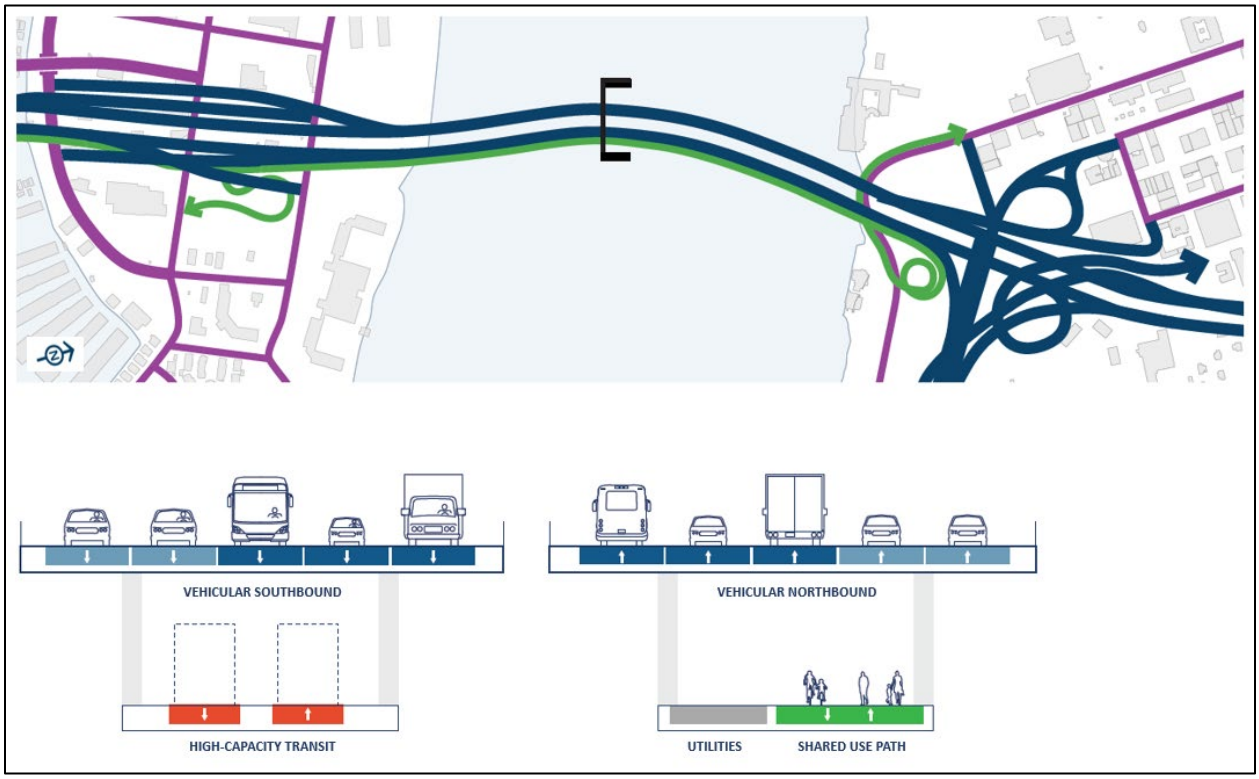
Section 7.2.7 details the results of the screening process, including why a design option was (or was not) advanced.

7.2.6.1 River Crossing Design Option 0: 2013 Design

The 2013 Design included construction of two new bridges across the main channel of the Columbia River (Figure 11). The parallel bridges that form the existing Interstate Bridge over the Columbia River would be replaced by two new parallel bridges. The eastern structure would accommodate northbound highway traffic on the upper bridge deck, with a bicycle and pedestrian path underneath; the western structure would carry southbound traffic on the upper bridge deck, with two-way transit below.

Figure 11. River Crossing Design Option 0: 2013 Design

Alignment (top) and cross section (bottom)



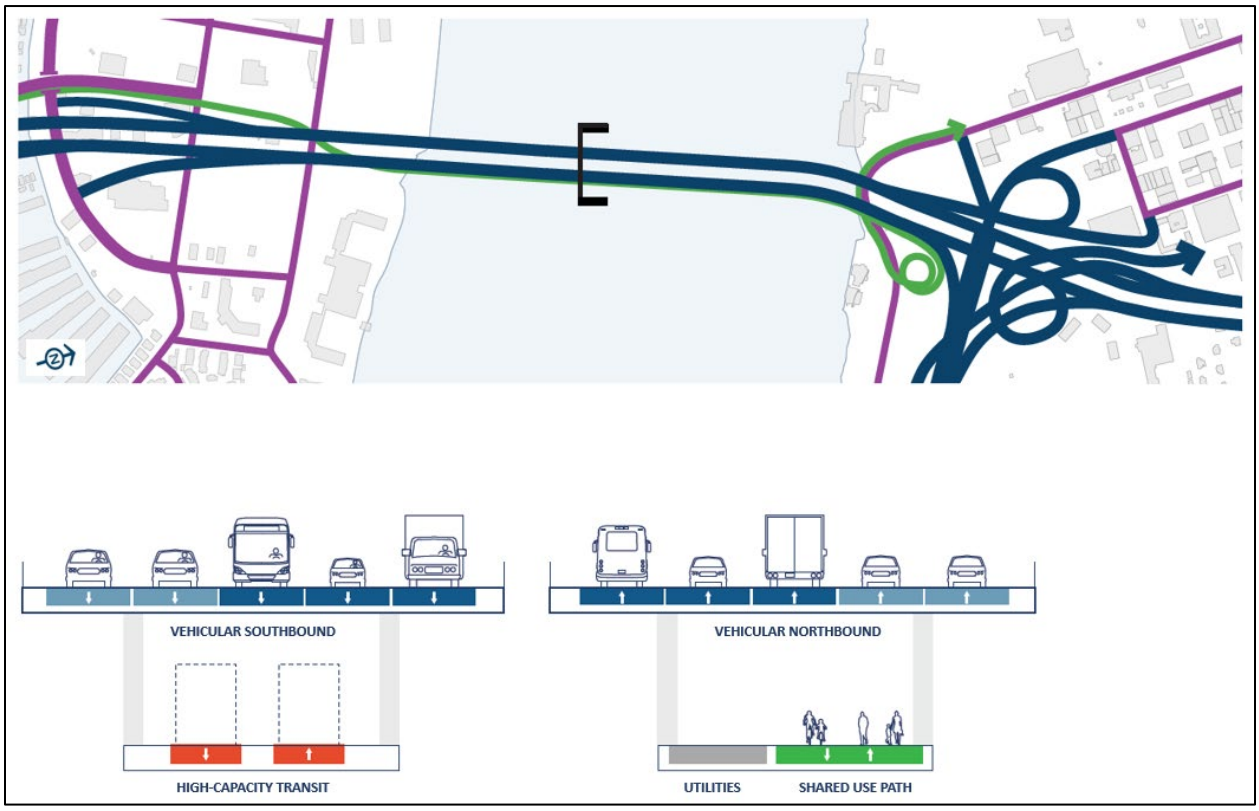
7.2.6.2 River Crossing Design Option 1: Two Straight Bridges

Design Option 1 was developed to address concerns over the complex bridge design (and associated costs) of the 2013 Design. Like the 2013 Design, this option would have two bridges; however, in this option the alignment for most of both bridges would be straight. This reduces the complexity of the bridge design and would be expected to reduce cost. This option would remove the curve as much as

possible while maintaining the two-bridge configuration with highway over the transit alignment and the shared-use path (Figure 12).

Figure 12. River Crossing Design Option 1: Two Straight Bridges

Alignment (top) and cross section (bottom)



7.2.6.3 River Crossing Design Option 2: One Bridge (Double Stacked)

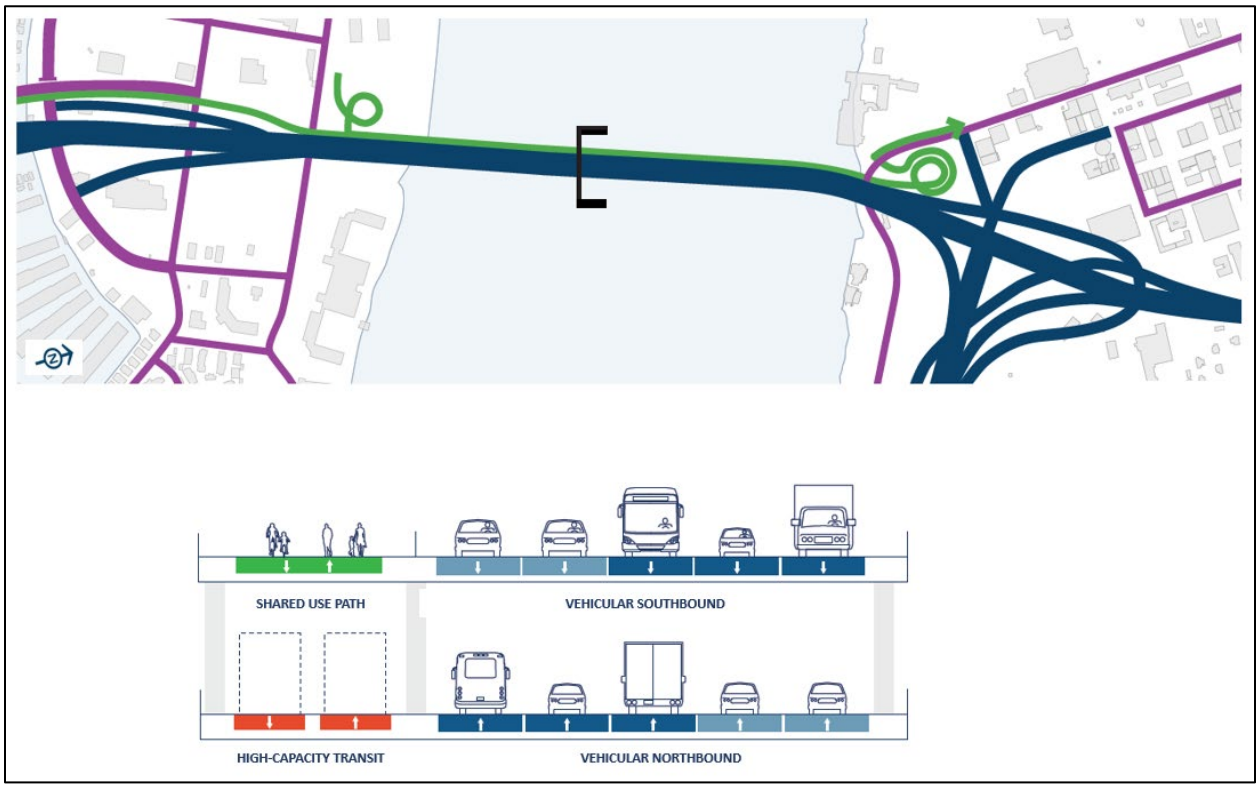
One-bridge options were developed to reduce the in-water footprint and associated construction timeline of the river crossing. One-bridge options would use a stacked highway alignment to consolidate all elements into one bridge, with southbound highway lanes on top of northbound highway lanes. North and south of the Columbia River, the southbound highway would remain higher for a longer distance than the two bridge options. This would be necessary to maintain vertical clearance over the northbound highway until it is no longer underneath the southbound highway. In comparison, both the southbound and the northbound highways in the two-bridge options can immediately start to descend north and south of the Columbia River.

In the Double Stacked Alignment Option, transit would be on the lower level just west of the northbound highway lanes, and the shared-use path would be on the upper level just west of the southbound highway lanes (Figure 13). This higher shared-use path would require longer ramps north and south of the Columbia River to connect to Hayden Island and downtown Vancouver.

The Double Stacked Alignment Option's bridge design would require a consistent highway width across most of the Columbia River, which changes the location of the southbound I-5 ramp connection from westbound SR 14. Whereas this ramp connects to southbound I-5 partially over the river in the two-bridge options, it would need to slide farther north in the Double Stacked Alignment Option. This would change this ramp's configuration from a loop west of I-5 to a hook-shaped ramp farther north and east of I-5. This would also prohibit the existing off-ramp connection from northbound I-5 to C Street, and the existing on-ramp connection from Washington Street to southbound I-5.

Figure 13. River Crossing Design Option 2: One Bridge (Double Stacked)

Alignment (top) and cross section (bottom)



7.2.6.4 River Crossing Design Option 3: One Bridge (Hybrid Stacked)

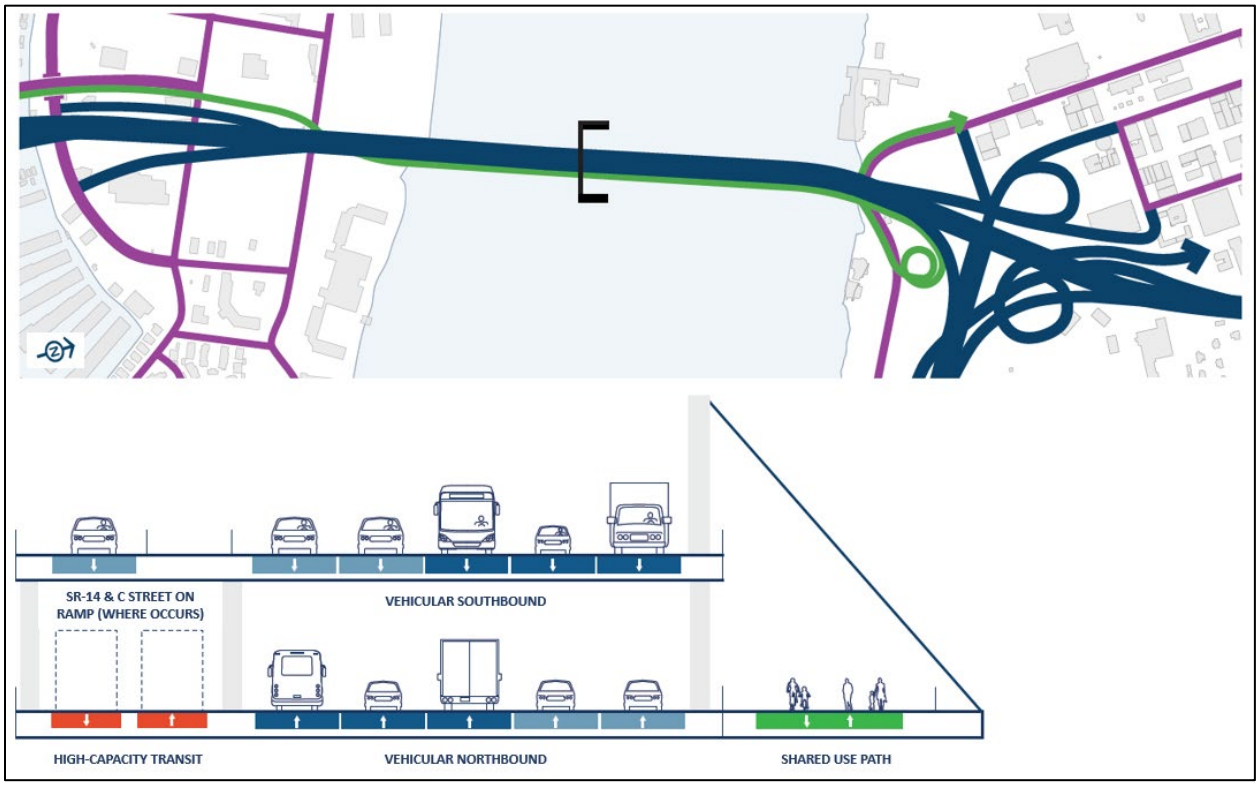
Like Design Option 2: One Bridge (Double Stacked), the Hybrid Stacked option would consist of a stacked highway alignment that would consolidate all elements into one bridge, with southbound highway lanes on top of northbound highway lanes (Figure 14). The shared-use path would be cantilevered from the lower level on the east side of the bridge. Transit would remain on the lower level of the west side of the bridge.

At the north end of the bridge, the area directly above transit on the upper level would be used to accommodate the ramp connection from westbound SR 14. This would allow the westbound SR 14

ramp to be a loop west of I-5, similar to the two-bridge options, which would also mean that the Hybrid Stacked option could include ramp connections to/from C Street. Because the one-bridge options need a consistent bridge width across the river, the area above the transit level would need to be included for the entire bridge, even though it is only needed for the SR 14 ramp connection on the north end of the bridge. No other use has been designated for this space for the rest of the bridge.

Figure 14. River Crossing Design Option 3: One Bridge (Hybrid Stacked)

Alignment (top) and cross section (bottom)



7.2.7 Screening Results

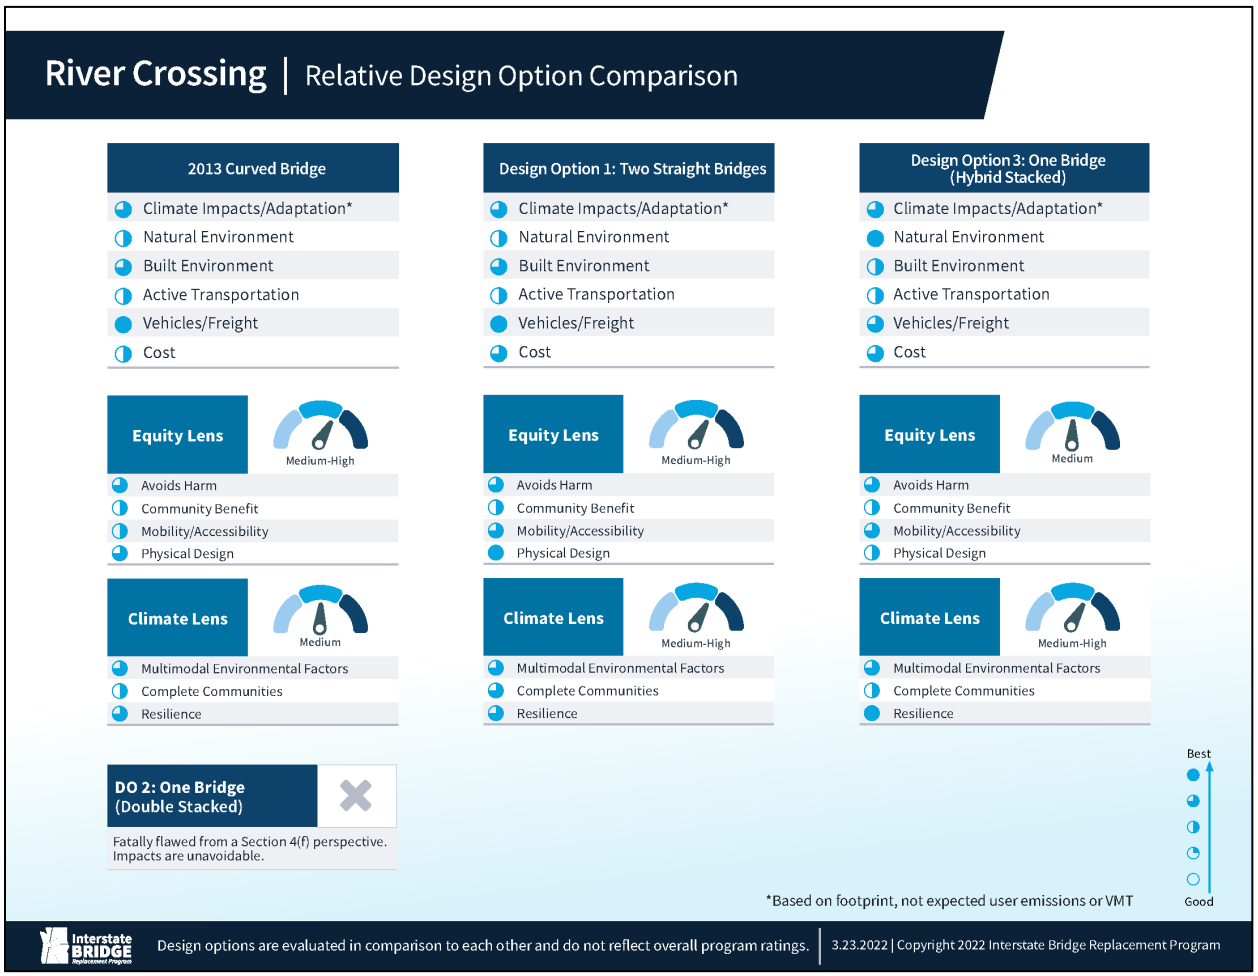
Three design options, described in Section 7.2.6, were advanced from initial task force discussions to screening. During screening, the task force collected data for approximately 90 metrics and scored each design option against each other for a given metric. As described below, the task force recommended two design options be advanced for further consideration and did not recommend the third design option.

During the screening process, the IBR team concluded that Design Option 2 would result in significant impacts to cultural and recreational resources. The bridge design would require the westbound SR 14 to southbound I-5 ramp to connect farther north on I-5, which would result in a hook-shaped ramp that would push the I-5 footprint farther east. This option would increase the amount of land

acquisition required from significant cultural and recreational resources, including Section 4(f) resources, and would likely result in additional adverse effects to cultural resources due to acquisitions. These anticipated impacts rendered Design Option 2 fatally flawed. In addition, the task force determined that there was insufficient space to maintain the existing ramp connections to and from C Street/Washington Street in downtown Vancouver. Based on the results of the screening, the task force decided **not to recommend** advancing Design Option 2.

The 2013 LPA (Design Option 0) was included in the screening for comparison to Design Options 1 and 3, but it was not recommended to be advanced for further consideration. Replacing the North Portland Harbor bridge (as proposed under the IBR Program) allows the I-5 alignment to shift to the west, which eliminates the need for a curved alignment (as proposed in the 2013 LPA). A straight alignment has several benefits, including potential cost savings and construction advantages. Figure 15 shows the screening summaries side by side for each of the three design options.

Figure 15. River Crossing – Relative Design Option Comparison



Each design option also has a more detailed summary that lists the tradeoffs and benefits behind each category to provide the rationale for each Harvey ball system score. Table 7, Table 8, and Table 9 show the screening summaries for Design Options 0, 1, and 3, respectively.

Table 7. River Crossing Design Option 0 Screening Summary

Screening Category	Score	Tradeoffs/Benefits
Climate Impacts/ Adaptation	◕	• Likely uses more construction materials (based on the footprint, not expected tailpipe emissions) • Improves transit and active transportation to draw mode shift (ME) • Design considers future climate disruption from flooding, extreme heat, storms and wind (RES) • Bridge elevation accounts for potential river elevation changes due to climate change (RES)
Natural Environment	◑	• More in-water piers and a larger footprint over aquatic habitat • Generates more in-water obstructions
Built Environment	◕	• Creates visually uncluttered structures on Hayden Island and scales them to surroundings (CB, PD) • Lowers Tomahawk Island Drive, if accommodated (MA) • Reduces shared-use path's exposure to traffic noise (MA) • Main Street extension provides new downtown connection to waterfront (CB, CC) • Zero displaced residences (AH) • More non-residential buildings impacts (AH) • Some cultural resources in footprint (AH) • Some high sensitivity noise receptors within 500 feet (AH)
Active Transportation	◑	• Creates a generously wide and accessible shared-use path (MA, ME) • Shelters shared-use path from elements (MA) • Lower deck shared-use path not visible to vehicular traffic, so does not benefit from "eyes on the path" (MA, ME) • Curved bridge makes for a longer crossing (MA, ME)
Vehicles/Freight	◑	• Maintains access to local streets and SR 14 • Compatible with Hayden Island full interchange design
Cost	◑	• Two bridges with complex bridge geometry results in high construction cost

Equity Objectives
AH = Avoid further harm
CB = Community benefits
MA = Mobility and accessibility
PD = Physical design

Climate Objectives
CC = Supports complete communities
ME = Multimodal environmental
RES = Resilience

Table 9. River Crossing Design Option 3 Screening Summary

Screening Category	Score	Tradeoffs/Benefits
Climate Impacts/ Adaptation	◕	• Uses marginally fewer construction materials (based on the footprint, not expected tailpipe emissions) • Improves transit and active transportation to draw mode shift (ME) • Design considers future climate disruption from flooding, extreme heat, storms and wind (RES) • Bridge elevation accounts for potential river elevation changes due to climate change (RES)
Natural Environment	●	• Fewest in-water piers and footprint over aquatic habitat • Creates fewer in-water obstructions
Built Environment	◑	• Provides open views from the shared-use path and for river users (CB, PD) • Results in complex bridge approaches on Hayden Island and in Vancouver (CB, PD) • Creates undesignated space on upper deck • Tomahawk Island Drive crosses straight across island (MA) • Increases shared-use path's exposure to traffic noise (MA) • Main Street extension provides new downtown connection to waterfront (CB, CC) • Zero displaced residences (AH) • Fewer non-residential building impacts (AH) • Some cultural resources in footprint (AH) • Some high sensitivity noise receptors within 500 feet (AH)
Active Transportation	◑	• Creates a generously wide and accessible shared-use path (MA, ME) • Allows some visibility between shared-use path and vehicular traffic on lower deck (MA, ME) • Exposes shared-use path to elements (MA) • Generates a higher proportion of space (openness above) (MA)
Vehicles/Freight	◕	• Maintains access to local streets and SR14 • Overhead structure complicates wayfinding • Compatible with Hayden Island full interchange design with design exceptions
Cost	◕	• Requires additional bridge width to accommodate shared-use path • Single straight bridge design results in straightforward manufacturing and construction

Equity Objectives
AH = Avoid further harm
CB = Community benefits
MA = Mobility and accessibility
PD = Physical design

Climate Objectives
CC = Supports complete communities
ME = Multimodal environmental
RES = Resilience

Scoring System
Good → Best
○ ◔ ◑ ◕ ●

Design Options 1 and 3 performed the best out of all the design options during the screening. They would each:

- Have a Main Street extension that provides a new downtown connection to the Vancouver waterfront.
- Allow Tomahawk Island Drive to cross straight across Hayden Island.
- Have fewer non-residential building impacts than the 2013 LPA.
- Maintain access to local streets and SR 14.
- Create a generously wide and accessible shared-use path.
- Improve transit and active transportation to draw mode shift.
- Consider future climate disruption from flooding, extreme heat, storms and wind.
- Their bridge elevations would account for potential river elevation changes due to climate change.
- Involve straightforward manufacturing and construction.

Design Options 1 and 3 are also compatible with a partial or full interchange on Hayden Island, making them compatible with the recommended design options for Hayden Island/Marine Drive (see Section 7.1.6).

To further differentiate between these two options, the task force compiled a list of tradeoffs and benefits between Design Options 1 and 3 (Table 10).

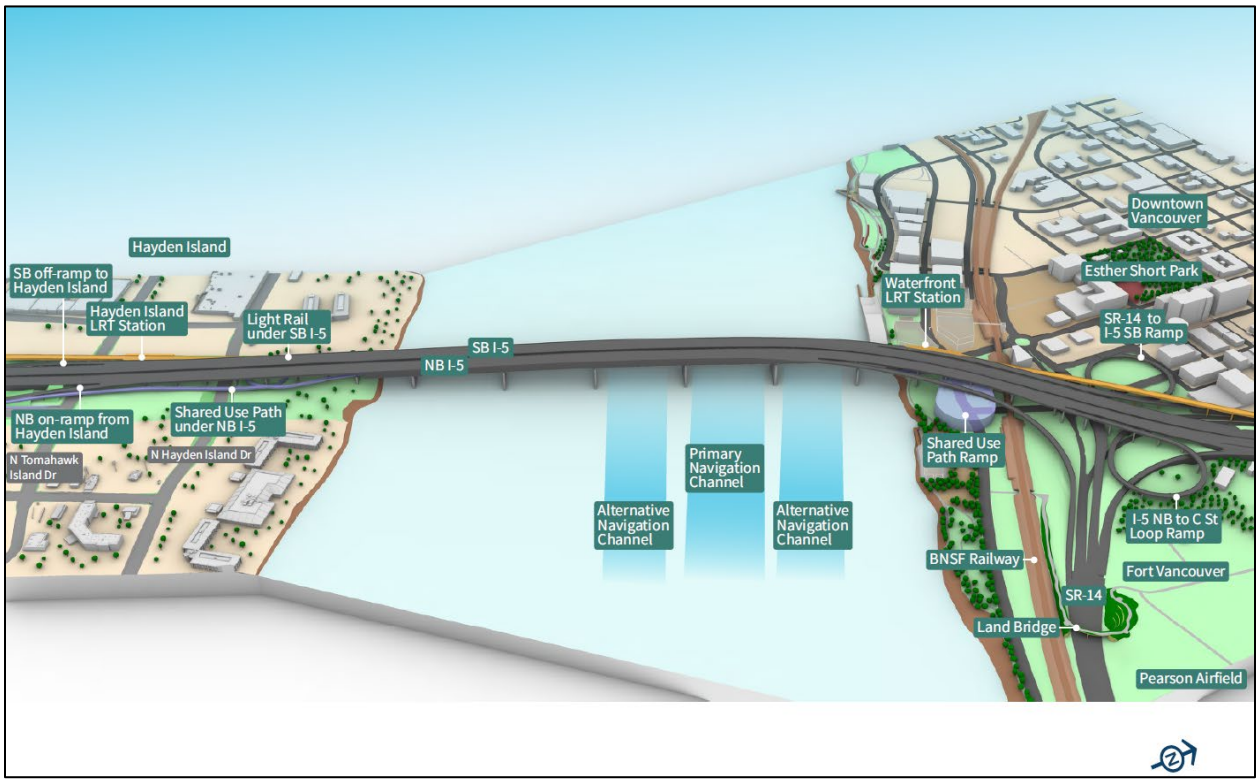
Table 10. Tradeoffs and Benefits Between River Crossing Design Options 1 and 3

Design Option 1: Two Straight Bridges	Design Option 3: One Bridge (Hybrid Stacked)
Reduces shared-use path users' exposure to noise/elements	**Increases** shared-use path users' exposure to noise/elements
Creates **visually uncluttered** structures on Hayden Island and scales them to surroundings	Results in **complex** bridge approaches on Hayden Island and in Vancouver
Easier to fund river crossing bridge because I-5 could be constructed and operational between Hayden Island and Evergreen Blvd.	**Harder** to fund river crossing bridge because I-5 must be constructed and operational between Marine Drive and Evergreen Blvd.
No undesignated space on upper deck	**Creates undesignated** space on upper deck
Fewer right-of-way acquisitions and impacts to Fort Vancouver	**More** right-of-way acquisitions and impacts to Fort Vancouver
Smaller footprint over land	**Larger** footprint over land

Design Option 1: Two Straight Bridges	Design Option 3: One Bridge (Hybrid Stacked)
Simpler wayfinding on northbound I-5	Overhead structure **complicates** wayfinding on northbound I-5 (requires approvals for signage smaller than standards)
Can maintain traffic on existing Interstate Bridge during construction	**Cannot maintain** traffic on existing Interstate Bridge during construction
Scores **medium-high** from an **equity** perspective	Scores **medium** from an **equity** perspective
Scores **medium-high** from a **climate** perspective	Scores **medium-high** from a **climate** perspective
Longer construction period	**Shorter** construction period
Emergency vehicles access shared-use path via **shared-use path ramps** on Hayden Island and downtown Vancouver	Emergency vehicles access shared-use path via **northbound I-5 or shared-use path ramps** on Hayden Island and downtown Vancouver
Likely uses **more** construction materials (based on the footprint, not expected tailpipe emissions)	Uses marginally **fewer** construction materials (based on the footprint, not expected tailpipe emissions)
More in-water piers/obstructions: • 12 in-water piers (each pair of piers measures ~200 feet combined in direction of river channel)	**Fewer** in-water piers/obstructions: • 6 in-water piers (each pier measures ~175 feet in direction of river channel)
Larger footprint over aquatic habitat (~12 acres)	**Smaller** footprint over aquatic habitat (~10 acres)
Lower deck shared-use path **not visible** to vehicular traffic, does not benefit from "eyes on the path" (a safety concern for active transportation users)	**Allows some visibility** between shared-use path and vehicular traffic on lower deck

Based on the benefits and tradeoffs, the task force **recommended advancing** Design Option 1 (Two Straight Bridges), which is illustrated on Figure 16.

Figure 16. River Crossing Design Option 1 (Two Straight Bridges) – Model Graphic



7.3 Transit – Mode, General Alignment, and Termini under Alignment

C-TRAN and TriMet both operate transit service in the Program area. A factor contributing to the overall transit component of the multimodal Program is the benefit gained by integrating established transit modes from both C-TRAN and TriMet. C-TRAN has designed their overall operations as a feeder-system to TriMet's expanded light rail service, which allows for the integration of a light rail terminus to provide effective reach into the transit services operated by C-TRAN.

Design options were developed and evaluated for thee transit components: mode, general alignment, and termini locations. Other components of the transit system will be studied further in the SEIS, including station locations, park-and-ride locations and sizes, operations and maintenance facilities, transit integration between TriMet and C-TRAN service and system improvements to transit speed and reliability. All design options (except bus on shoulder) included the assumption of dedicated right of way across the river for the transit investment to connect with TriMet's existing MAX Yellow Line.

Supporting materials for the transit design options are provided in Attachment D.

7.3.1 Changes since 2013

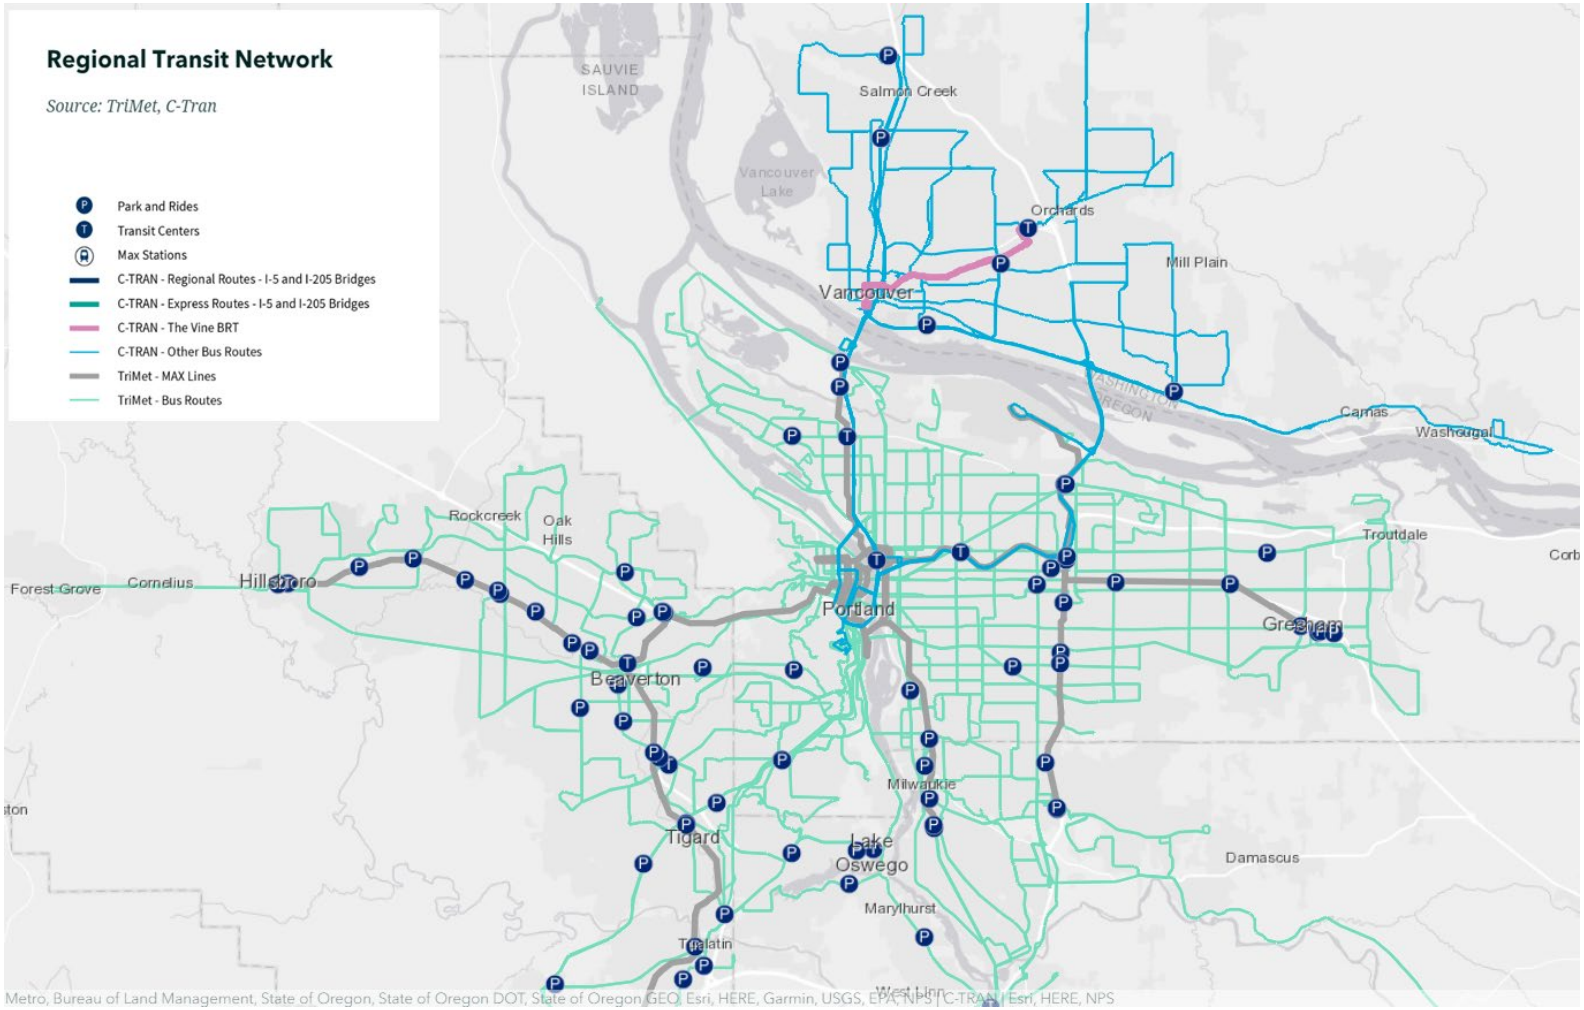
The IBR Program identified the following changes in conditions since 2013 related to transit through advisory group input, community feedback, and input from agency partners serving on TOTS. These changes led to the development of transit options that were analyzed.

- **Transit system.** In the years since the suspension of the CRC project, transit system enhancements have been advanced in both Oregon and Washington. Notably, C-TRAN has implemented BRT service, The Vine, in Clark County that provides service from downtown Vancouver east to the Vancouver Mall along Fourth Plain Boulevard. A second BRT line is currently under construction that will also serve downtown Vancouver and extend east along Mill Plain Boulevard, and a third BRT line extending north from downtown Vancouver along Highway 99 is in the planning stage. Figure 17 shows the regional transit network today.
- **Vancouver Development**. Development has occurred in downtown Vancouver and the Vancouver waterfront consistent with local development plans, including the Vancouver City Center Vision, Waterfront Master Plan, and Terminal 1 Concept Development Plan. Design modifications are necessary to minimize property impacts and improve access to the representative transit investment.

7.3.2 Community Input

Community feedback was collected in an online survey in the fall of 2021 to understand the community's values and priorities around transit improvements, and specific preferences and travel patterns of transit users. Survey participants prioritized improved travel time as the top priority for any new transit connection across the river. Reliability, safety, and ease of use were also noted as important considerations. Survey responses also indicated that most people would choose to access transit by car via park and ride, followed by walking, biking, or rolling directly to a station. When survey participants were asked what potential transit station locations they would use most often in the future, transit stations near the Vancouver waterfront, Clark College, Expo Center Transit Station, Hayden Island, and the Vancouver Library (C Street and E Evergreen Boulevard) were the five most noted locations, with the Vancouver waterfront ranked most often. Participants showed noted interest in the topic of transit by commenting in the open-ended comment section of the survey. Of the more than 1,700 open-ended comments received, almost half mentioned public transit, and 67 percent expressed support for expanded transit options across the bridge.

Figure 17. Regional Transit Network



Source: TriMet, C-TRAN

In addition to the survey, community input on transit was collected from a variety of events and sources. These include the Downtown Vancouver Community Working Group (meetings held in September and November 2021), the Multimodal Commuter Community Working Group (meetings held in October and November 2021), CAG meetings (transit-focused discussions were held in February, March and April of 2022), and other outreach efforts detailed in the community engagement report (see Section 3.6). Community feedback included:

- Desire for greater connectivity from Clark County into Portland and the regional transit system.
- Support for HCT options, with many preferring light rail or a combined light rail/BRT option.
- Strong support among residents in the entire region and solid majority support throughout Clark County for the concept of extending the MAX Yellow Line from Expo Station to Vancouver in a dedicated space across the new Columbia River bridges.
  - 79% of total community opinion survey respondents strongly or somewhat support light rail across the bridge, including 84% of Portland Metro area respondents and 61% of Clark County respondents.
- Reliability and travel time of mode expressed as the most important transit priorities.
- Equity priority communities expressed high interest in accessible and dependable transit options, including a desire for multiple transportation options that are efficient, reliable, and user-friendly and infrastructure that promotes HCT.
- Highest preferences for transit stations located at (or near) Expo Center, Hayden Island, Vancouver Waterfront, Vancouver Library (Evergreen) and Clark College.

Feedback from the CAG and EAG on the transit analysis included:

- Decisions should rely on data, especially potential rider demographics.
  - A 'one-seat ride' is desirable, and the fewer transfers riders need to make the better, especially considering impacts on people with disabilities.
  - The IBR Program's Equity Framework needs to be front and center in evaluating options.
  - Gentrification and displacement are major concerns.
  - There needs to be strong coordination between TriMet and C-TRAN to ensure the functionality of the overall transit system.
- Improving travel time and reducing congestion is a priority.
- Bicycle and active transportation improvements are important.
- Seismic resiliency (of the transit mode) is important.
- More options to cross the river are needed.
- Climate considerations are important.
- Reliability of mode is important.
- Crime statistics on different transit modes would be good to see.
- Bi-state cooperation should be considered when deciding on a mode.

- Protect and honor cultural history when looking at impacts and design.
- Including The Vine in all transit options is a good idea.
- BRT less is desirable, especially if ending at Delta Park.
- LRT is most dependable and has greater ridership capacity.
- LRT is an indicator of where transit-oriented development should be focused.
- From a freight perspective, the investment that leads to less traffic is best, which points to LRT.
- Predictive modeling for ridership is needed.
- Consensus for LRT is desirable.
- Having park and rides is important.
- For LRT, the terminus location is important.
- Equity perspective is needed – extend the terminus farther than Evergreen Boulevard.
- Appreciation for retaining the express bus service.

7.3.3 Equity and Climate Considerations

Section 6.2.2 provides background on how equity and climate were incorporated into the transit option screening process. Equity considerations for the transit screening were identified through coordination with the EAG (discussions on the transit options and screening were held in February and March 2022), two equity-focused listening sessions (held in March 2021), and input from partner agencies on their equity programs and policies. To evaluate the IBR Program through an equity lens, the following considerations were incorporated during development and screening of the design options:

- Minimizing gentrification and displacement.
- Prioritizing improved travel times and reduced congestion.
- Protecting and honoring cultural history when looking at impacts and design.

Climate considerations were identified through input from the CAG and partner agencies on their climate initiatives and policies (Section 6.2.2). To evaluate the IBR Program through a climate lens, the following considerations specific to transit were incorporated during development of the design options:

- Improving multimodal connectivity across the bridge and encouraging a shift from vehicle trips to low or no emissions travel (e.g., transit, bike, walk, roll).

7.3.4 Agency Input

Partner agency input on the transit design options and evaluation came from the TOTS group along with coordination and communication through the Travel Demand Modeling Working Group and other general coordination meetings with partner agency staff during the screening process. These groups are described in Section 3.1 and included participation by all Program partners.

7.3.5 Transit Options Evaluated

Table 11 lists the 13 representative transit investments considered to help evaluate the tradeoffs associated with choices around mode, alignment, and terminus. Attachment D includes results from the modeled representative transit investments.

Table 11. Representative Transit Investment Descriptions

Representative Transit Investment	General Description
A – No-Build	The No-Build scenario reflects planned systemwide increases in background transit service by both TriMet and C-TRAN as adopted by both Metro and the RTC in their Regional Transportation Plans but reflects no replacement of the current Interstate Bridge, no reconstructed interchanges, no tolls on the Interstate Bridge, and no extension of additional high-capacity transit service north from the existing MAX Yellow Line alignment into Vancouver.
B – 2045 CRC ROD	2013 CRC project LPA assuming fully dedicated LRT guideway extending from the MAX Expo Center Station to a terminus near McLoughlin/I-5 via the Vancouver central business district. Includes five new stations and three park and rides.
C – Bus on Shoulder	Express bus operating as bus on shoulder in Program area (both directions). Route 60 operating in auxiliary lanes between the Vancouver central business district and Hayden Island, Delta Park. No new stations or park and rides.
D – BRT Turtle Place to Expo	Dedicated BRT guideway between the MAX Expo Center Station and a terminus at Turtle Place in downtown Vancouver. Includes three initial stations: Expo Center, Hayden Island, and Turtle Place.
E – BRT I-5 to Kiggins Bowl	Fully dedicated BRT guideway between the MAX Expo Center Station and a terminus near McLoughlin Blvd./I-5. Dedicated guideway on Vancouver segment assumed to be adjacent to I-5, with a dedicated connection to Hayden Island and Expo Center Station similar to the 2013 LPA. Includes six initial stations: Kiggins Bowl, E 33rd, McLoughlin Blvd., Evergreen Blvd., Hayden Island, and Expo Center.
F – BRT in ROD Alignment	Fully dedicated BRT guideway between MAX Expo Center Station and a terminus near McLoughlin Blvd./I-5 to Expo Center station with alignment and station locations similar to 2013 ROD project. Includes six initial stations: I-5/McLoughlin, McLoughlin and Washington St. (southbound)/ 16th and Broadway (northbound), 12th and Washington (southbound)/13th and Broadway (northbound), Turtle Place, Hayden Island, and Expo Center.
G – Hybrid	Fully dedicated LRT guideway between MAX Expo Center Station and a new station at Hayden Island and fully dedicated BRT guideway between Hayden Island and Turtle Place. Includes two initial stations: Hayden Island and Expo Center.

Representative Transit Investment	General Description
H – LRT One Station in Vancouver	Fully dedicated LRT guideway between the MAX Expo Center Station and a terminus near Turtle Place in downtown Vancouver. Includes two initial stations: Hayden Island and Turtle Place.
I – LRT I-5 to McLoughlin	Fully dedicated LRT guideway between the MAX Expo Center Station and a terminus near McLoughlin Blvd./I-5. Dedicated guideway on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and Expo Center Station similar to 2013 LPA. Includes three initial stations: I-5/McLoughlin, Evergreen, and Hayden Island.
J – LRT I-5 to Kiggins Bowl	Fully dedicated LRT guideway from MAX Expo Center Station to a terminus near I-5/Kiggins Bowl. Dedicated guideway on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and Expo Center Station similar to 2013 LPA. Includes five initial stations: Kiggins Bowl, 33rd, I-5/McLoughlin, Evergreen, and Hayden Island.
K – LRT Delta Park to McLoughlin	Fully dedicated LRT Extension from Delta Park (joint Hayden Island / Expo Center station) to a terminus near McLoughlin / I-5 on an I-5 Adjacent Alignment (Center/West Side of I-5). This option was infeasible and removed from consideration early in the decision process.
L – LRT I-5 to McLoughlin with Columbia	Fully dedicated LRT guideway between MAX Expo Center Station to a terminus near McLoughlin Blvd./I-5. Dedicated guideway on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and Expo Center Station similar to 2013 LPA. Includes four initial stations: I-5/McLoughlin, Evergreen, Waterfront, and Hayden Island.
M – LRT I-5 to Evergreen with Columbia	Fully dedicated LRT guideway between MAX Expo Center Station to a terminus near I-5/Evergreen. Dedicated guideway on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and Expo Center Station similar to 2013 LPA. Includes three initial stations: Evergreen, Waterfront, and Hayden Island.

7.3.6 Evaluation Results

The IBR team found that all transit investments would substantially improve transit demand over the No-Build option. The modeling results indicated that there is strong demand for cross-river transit service, and therefore transit vehicle capacity is an important consideration for the Program for both the representative transit investment and other routes in the Program corridor. To accommodate the high level of transit demand, it is suggested that the Program include a combination of LRT and express bus across the Columbia River. Any option considered would include the intent to provide bus-on-shoulder capability through the Program area. The high transit demand and mode diversification needed to meet the level of transit demand would require efficient and comfortable

connections in the C-TRAN and TriMet systems. When comparing the same representative alignments, LRT options would have higher ridership, higher capital cost, and lower operating cost per rider than BRT options.

The analysis of model results showed that park-and-ride demand is robust in all of the representative transit investment scenarios, with park-and-ride lots that were at capacity for all locations added as part of the investment. This means representative transit investments that include more park-and-ride capacity will likely contribute more ridership to the HCT investment.

Because FTA Capital Investment Grant (CIG) funding is likely going to be important for the Program, the IBR team, in coordination with TriMet and C-TRAN, worked to develop a high-level assessment for screening. Using information available regarding cost (capital and operating) and ridership for the representative transit investments, the IBR team identified options that would rate medium or better for project justification criteria. The IBR Program along with its transit partners will continue to brief FTA and consider how any project change might impact CIG ratings.

To evaluate the transit investments through an equity lens, the IBR Program Equity Team applied a methodology to estimate access to jobs - and, by proxy, services - by transit for different demographics. The IBR Program worked with Metro to pull data from the regional travel demand model that showed how many jobs one could get to by transit assuming 30, 45, and 60 minute travel times using the Transportation Analysis Zones (TAZs). Transit travel times included all walk, wait (initial wait time as well as transfer wait time, if applicable) and in-vehicle time for travel between all TAZs. The IBR Program found that representative transit investments that include more stations would serve a higher number of residents, including BIPOC and low-income populations, within walking distance of transit stations. All transit investments would improve access to jobs for many residents, including BIPOC and low-income populations. LRT investments would improve access to jobs to a greater degree than BRT investments. Part of the reason for this is the travel time benefit LRT would experience as an extension that provides a one-seat ride as compared to BRT, which would include a transfer to the Yellow Line. All of the BRT investments included additional time for transferring between BRT and LRT at either Expo Center or Hayden Island, depending on the investment option being studied.

Moving forward, the Program will work with C-TRAN and TriMet on how to optimize transit service, considering decisions on mode, alignment and terminus that serves passengers to, from and through the Program area.

7.3.6.1 Mode

The Program considered three transit modes to meet transit demand: express bus operating in bus on shoulder, BRT, and LRT. As stated above, a transit investment that serves the identified markets and attempts to serve demand, would need to include a combination of modes. Bus-on-shoulder capability in the Program area was included in all representative transit investments and was removed from consideration as a standalone transit option.

Based on the analysis and coordination with partner agencies, the advantages and disadvantages listed in Table 12 were identified for BRT and LRT.

Table 12. Summary of Transit Mode Evaluation

Light Rail Transit (LRT)	Bus Rapid Transit (BRT)
• Higher vehicle capacity allows the Program to carry more people across the river. (MA, ME) • Compared to existing conditions and BRT, would improve access to jobs and services for many residents, including BIPOC and low-income populations. (MA, EO) • Allows for preservation of the current and future C-TRAN Vine and express bus system while providing convenient connections to new LRT stations. (MA, ME) • Offers a more competitive travel time compared with trips that require a transfer at the Expo Center. (MA, ME) • Extension of the MAX Yellow Line from the Expo Center into Vancouver best integrates existing transit investment in the region in a manner that maintains both C-TRAN's and TriMet's approaches to operations of their transit systems. • Based on initial estimates of how investments might perform if submitted to the FTA CIG Program, LRT is more competitive for FTA discretionary funding.	• Lower vehicle capacity than LRT and would require a transfer. • Less competitive travel time compared to LRT due to a required transfer at Expo Center. • Compared to existing conditions, would improve access to jobs for many residents including BIPOC and low-income populations. (MA, EO). • Allows for preservation of the current and future C-TRAN Vine and express bus system (ME). • Less competitive for FTA discretionary funding than LRT.

Equity Objectives
AH = Avoid further harm
EO = Economic Opportunity
MA = Mobility and accessibility

Climate Objectives
ME = Multimodal environmental

Based on the above findings, and when considering the specific needs of the HCT investment for the IBR Program, the Program **recommends LRT as the locally preferred mode**.

7.3.6.2 Alignment

As described in Section 7.3.5, twelve potential alignments were evaluated by the Program and partner agencies. These potential alignments fell into two categories: accessing Downtown Vancouver or aligning with the existing I-5 corridor. Detailed conceptual design work on the potential alignments (and their impacts) was brought to the advisory groups, community groups, and partner agencies.

When selecting an alignment, a key consideration for the Program is the need to integrate new transit investments while considering the existing and planned transit networks of TriMet and C-TRAN. Since the CRC project, C-TRAN has developed a BRT system, The Vine, with one BRT line in operation, one under construction, and one in planning. The Vine and C-TRAN express bus service provide frequent and reliable service within Clark County and to downtown Portland, respectively. Any transit investment should be made with a desire to complement The Vine system, including existing and planned service.

The City of Vancouver has worked with C-TRAN to design station environments for The Vine system on Broadway and Washington Streets in the Central Business District. With these investments in mind, it is desirable to coordinate design elements of the alignment to provide more efficient functionality within the larger transit network and respective operating environments. The downtown Vancouver alignment (which was part of the CRC LPA) would impact C-TRAN's BRT alignments in the downtown area. In addition to the existing and planned transit networks, there is existing development in the Program area that potential alignments could impact. In comparison to the I-5 alignment, the downtown Vancouver alignment would require additional property and streetscape impacts.

Based on conversations with the community and partners, **the Program and advisory committees recommended the I-5 general alignment** be advanced for further study (see the Recommended General Alignment in Figure 18).

7.3.6.3 Terminus

The Program evaluated terminus options for each alignment and mode (described above), including Hayden Island in Portland and Waterfront, Turtle Place, Evergreen/I-5, McLoughlin/I-5 and Kiggins Bowl in Vancouver.

The evaluation of Hayden Island as a terminus was a hybrid option that saw the extension of LRT north from Expo Center to Hayden Island and the extension of BRT from Turtle Place south to Hayden Island. It was an exploratory option that did not perform as well in the evaluation process from a ridership standpoint and ultimately was removed from consideration in combination with the decision on mode.

On the Vancouver side the five terminus options included two that would result in a single station just across the Columbia River (Waterfront and Turtle Place) and three that would extend farther north including one additional station (Evergreen/I-5), two additional stations (McLoughlin/I-5) or four additional stations (Kiggins Bowl). The single station terminus options were evaluated and did not perform as well as others that extended farther into Vancouver from a ridership standpoint regardless of which mode was considered. Alignments with stations north of Evergreen Boulevard offered more ridership, but with greater impacts to properties and increased costs.

Through analysis and conversations with partners, it was determined that an **Evergreen Boulevard terminus** would:[6]

- Have fewer potential property impacts compared to other locations. (AH)
- Have lower operating and capital costs compared to other locations.
- Avoid impacts to Clark Community College as a result of station, alignment and park and ride that were included as part of options that assumed McLoughlin/I-5 as a terminus.
- Avoid impacts to C-TRAN network and Vine service.
- Avoid impacts to the City of Vancouver's vision and downtown development.
- Provide increased transfer options to additional C-TRAN routes.
- Connect directly to downtown library, jobs, services and amenities. (CB)
- Support transit-oriented development opportunities at Library Square and on nearby City-owned parcels. (CB)
- Maximize transfer opportunities given planned direct connections to several local routes, as well as existing and planned BRT routes. (MA, ME)
- Provide convenient access to Evergreen Boulevard, which connects east over I-5 to the Historic Reserve, and west through downtown to Main Street and Esther Short Park via planned 9th Street pedestrian way. (CB)

Based on evaluation during screening along with feedback from partner agencies, the IBR Program and partner agencies **recommended advancing the terminus at Evergreen Boulevard** for further study and refinement.

Figure 19 shows the proposed alignment of the LRT with the planned transit system connections. Stations and park-and-ride locations will be refined moving into the SEIS.

[6] Equity Objectives: AH = Avoid further harm, CB = Community benefits, MA = Mobility and accessibility. Climate Objectives: ME = Multimodal environmental

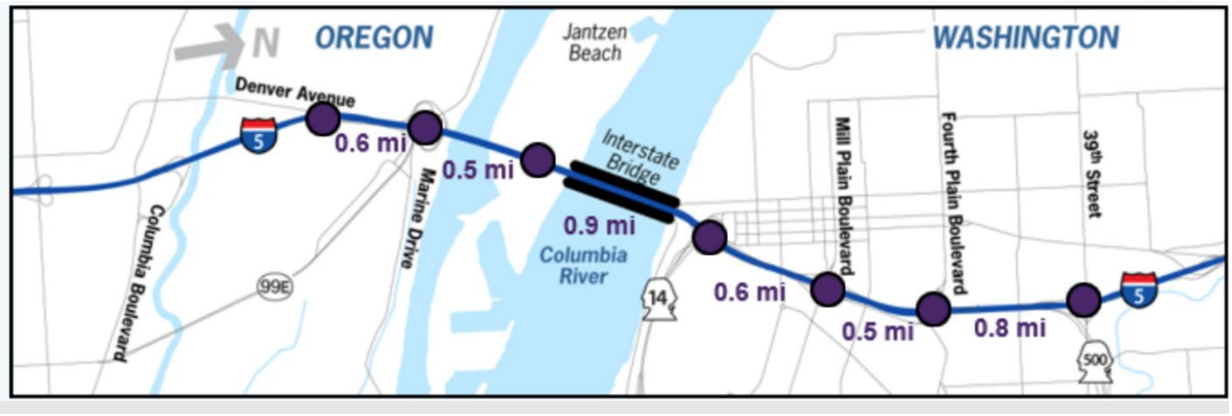
7.4 Auxiliary Lanes

Auxiliary lanes are ramp-to-ramp connections that allow vehicles to enter and exit the roadway outside of through-traffic lanes. While these ramp-to-ramp connections currently exist on I-5 in the Program area and various other locations in the Portland Metro region (e.g., Highway 217 off-ramp to the Lower Boones Ferry Road off-ramp near Tualatin, Oregon) they do not exist across the Interstate Bridge. Supporting materials for the auxiliary lanes design options are provided in Attachment E.

The use of auxiliary lanes improves traffic safety and reliability by providing sufficient merge, diverge, and weaving lengths for vehicles entering and exiting the freeway while allowing the through-traffic to maintain fuel-efficient driving speeds in the adjacent through lanes. Vehicles entering and exiting the highway have space to accelerate and decelerate without impeding traffic flow. A best practice is to space interchanges at least 1 mile apart in urban areas. As shown in Figure 20, all seven of the interchanges within the IBR Program area are spaced below minimum standards of 1 mile between interchanges.

Figure 20. Existing Interchange Spacing



Standard spacing – Desirable = 2 miles, Minimum = 1 mile

7.4.1 Changes since 2013

The IBR Program identified the following changes in conditions since 2013 related to auxiliary lanes through advisory group input, community feedback, and input from agency partners. These changes necessitated the development of design options for auxiliary lanes.

- **Traffic volumes**. Changes in traffic volumes and land use/development resulted in the need to update existing volumes to 2019 and future volumes to 2045 (the CRC project used 2030).

7.4.2 Community Input

Community input on auxiliary lanes came from the CAG and EAG (discussions on the auxiliary lanes design options and screening were held in April 2022) as well as public surveys. Feedback on the auxiliary lanes analysis included:

- Support for the addition of auxiliary lanes was consistently expressed
- Feedback received from advisory groups and surveys was mixed on the preference for the number of auxiliary lanes:
  - Prioritize the option that maximizes capacity and minimizes congestion
  - Both travel time and environmental impacts are important from an equity standpoint
  - Prioritize the option that is most environmentally friendly, including a reduction in greenhouse gas emissions
  - Combined with transit considerations, one auxiliary lane is appropriate
  - Two auxiliary lanes meet community values of congestion and safety issues
  - Clark County residents were more likely to select the two auxiliary lane option
  - Oregon residents were split between one and two auxiliary lane options

7.4.3 Equity and Climate Considerations

See Section 6.3.2 for a discussion on how equity and climate were incorporated into the screening process. Equity considerations for the auxiliary lanes analysis were identified through coordination with the EAG (discussions on the auxiliary lanes design options and screening were held in April 2022), two equity-focused listening sessions (held in March 2021), and input from partner agencies on their equity programs and policies. To evaluate the IBR Program through an equity lens, the following considerations were incorporated during development and screening of the design options:

- Understand the differences between one and two auxiliary lanes in terms of potential impacts, including to property, culture, and displacements.
- Both travel time and environmental impacts are important from an equity standpoint.
- Consider projected demographic changes (e.g., increasing number of seniors and people with disabilities means fewer and fewer people driving).

Climate considerations for the auxiliary lanes analysis were identified through input from the CAG and partner agencies on their climate initiatives and policies. To evaluate the IBR Program through a climate lens, the following consideration was incorporated during development of the design options:

- Consider how design options would support goals and policies to reduce greenhouse gas emissions.

7.4.4 Agency Input

Agency input on the auxuliary lane options and analysis came from coordination and communication through the Travel Demand Modeling Working Group and other general coordination meetings with partner agency staff during the screening process. These groups are described in Section 3.1 and included participation by all Program partners.

7.4.5 Design Options

Like the CRC project, the IBR Program would maintain the existing three through lanes in each direction across the bridge to match the context of the roadway on either side of the Program area, which also has three through lanes. The 2013 Design included two northbound and two southbound auxiliary lanes over the existing bridge, with one to two auxiliary lanes on I-5 extending throughout the corridor, depending on the location. The Program evaluated the addition of one or two auxiliary lanes in each direction across the bridge. Future analysis will occur around possible auxiliary lanes to the north and south of the bridge and will be documented in the SEIS. The IBR Program will ensure that information in the SEIS is consistent with and supports the Interchange Access Modification Request process, as it collaborates with and seeks approval from FHWA for the Program's proposed access revisions.

The IBR Program investigated ways to implement auxiliary lanes to accommodate the close interchange spacing, short merges, weaves and diverges, freight needs, and through-traffic vs. high on-ramp and off-ramp traffic volumes. These improvements would result in improved safety, a decrease in vehicle crashes, and more balanced travel lanes.

Auxiliary lane analysis was completed by modeling 2045 forecast traffic volumes for the following scenarios:

- No-Build in 2045.
- Three through lanes and one auxiliary lane in 2045.
- Three through lanes and two auxiliary lanes in 2045.

7.4.6 Evaluation Results

As described above, two design options were advanced for additional analysis and consideration by the partner agencies. A No-Build alternative was also included to serve as a baseline for the two design options. The results of the auxiliary lane evaluation are summarized in Table 13 and illustrated on Figure 21 through Figure 24.

Table 13. Summary of Auxiliary Lanes Evaluation Results

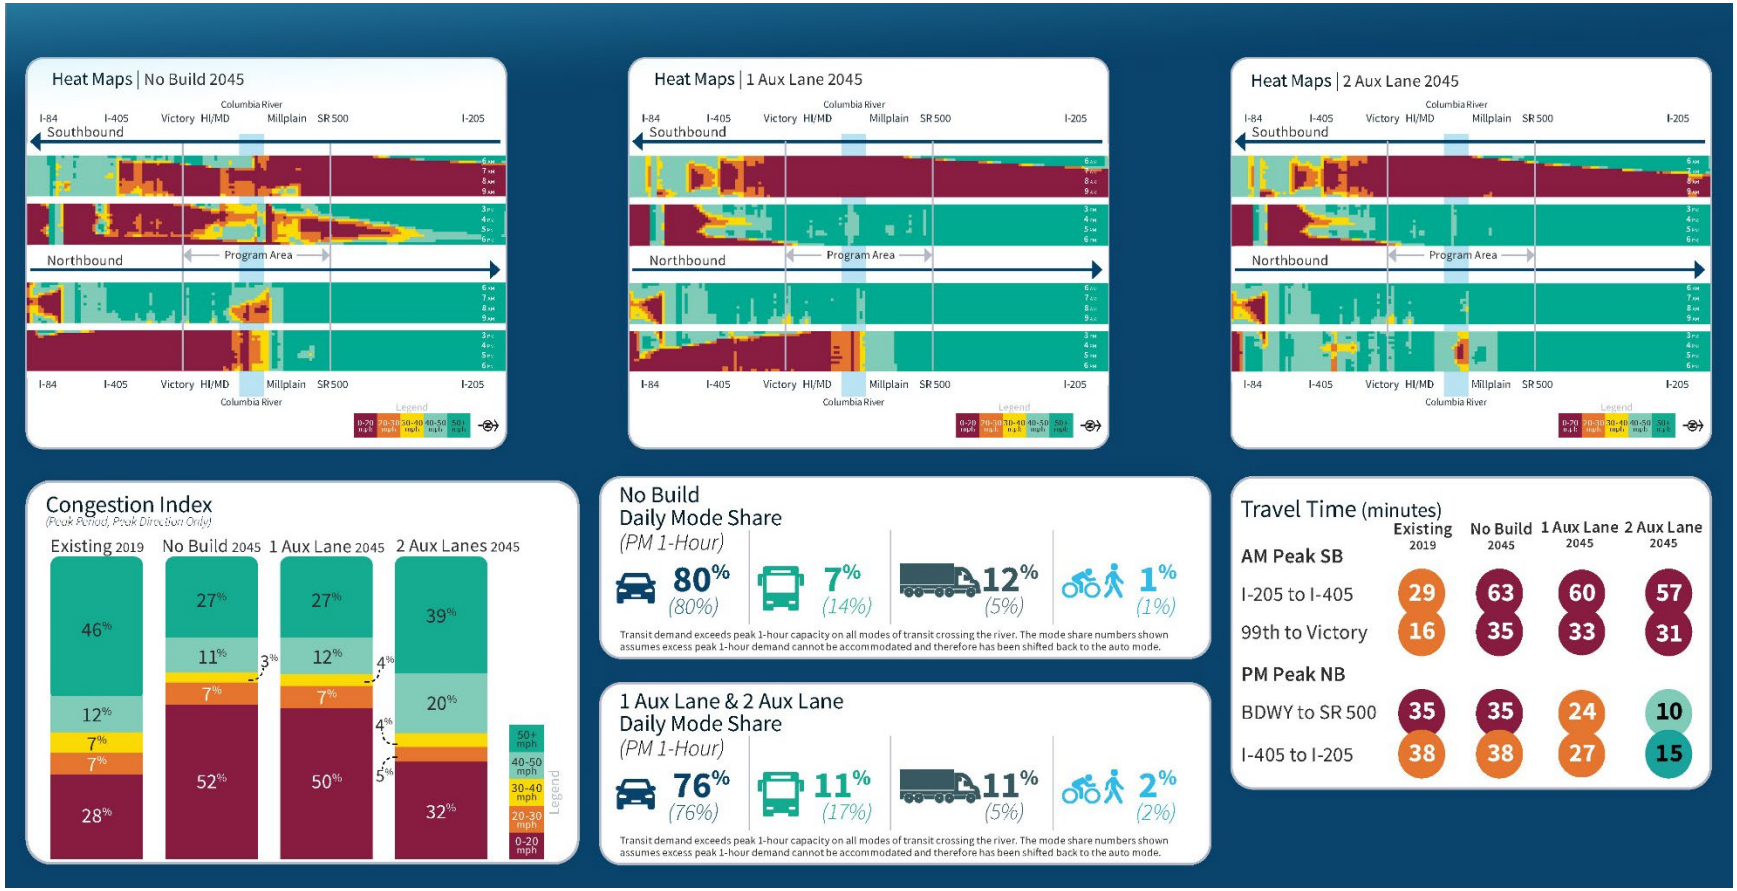
Benefits of one or two auxiliary lanes (compared to No-Build)	Supplemental benefits of one auxiliary lane	Supplemental benefits of two auxiliary lanes
• Mode choice benefits (HCT, bus on shoulder and active transportation) (MA, ME) • Mode shift: the daily transit share is expected to increase from 7% to 11% (ME) • Reduced overall congestion (MA, RID) • Off-peak benefits, including weekends • Less diversion to local streets (AH) • Faster congestion recovery from crashes and incidents (RID) • Fewer lane changes required (i.e., lane balance) • Safety improvements realized due to fewer sideswipe crashes and improved visibility • Lane widths to allow for current vehicle widths, turning, and comfort • Anticipated greenhouse gas reduction due to less congestion (RID)	• Travel time improvements compared to No-Build (MA, RID) – Southbound AM travel time would be reduced by 3 minutes (5 percent faster) between I-5/I-205 split and I-405 – Northbound PM travel time would be reduced by 11 minutes (30 percent faster) between Broadway Avenue and SR 500	• Travel time improvements compared to No-Build (MA, RID) – Southbound AM travel time would be reduced by 6 minutes (10 percent faster) between I-5/I-205 split and I-405 – Northbound PM travel time would be reduced by 25 minutes (70 percent faster) between Broadway Avenue and SR 500 • Reduced congestion compared to No-Build (RID) – Congestion would be reduced by 20 percent during the 8-hour AM/PM peak period

Equity Objectives
MA = Mobility and accessibility
PD = Physical design

Climate Objectives
ME = Multimodal environmental
RID = Reduces idling

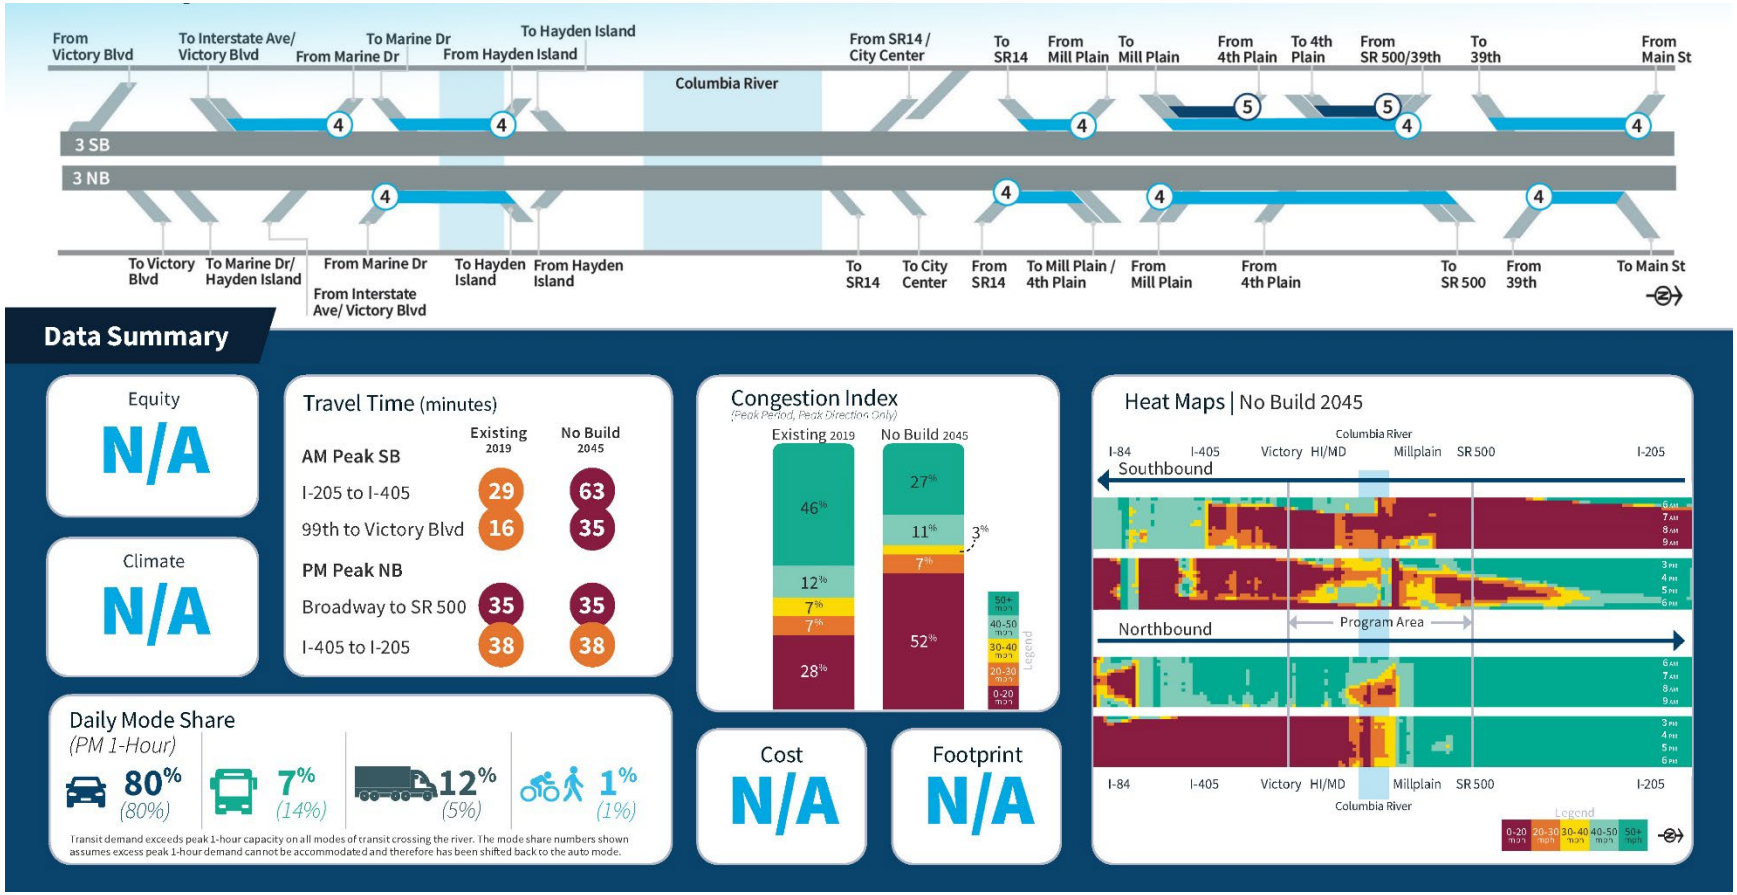
Based on initial results and feedback from the partner agencies, **one auxiliary lane northbound and one auxiliary lane southbound between Marine Drive and Mill Plain Boulevard was recommended** to be advanced in the Draft SEIS process. An addition of auxiliary lanes can help optimize the existing three through lanes and allow for more efficient movement through the corridor – improving safety, helping to relieve congestion with better traffic flow, and reducing emissions from vehicles idling in congestion. Studying one auxiliary lane in each direction during the environmental process recognizes the desire to balance all of the regional needs and priorities, including safe, efficient, and reliable travel, as well as equity and climate goals.

Figure 21. Auxiliary Lanes – Traffic Summary



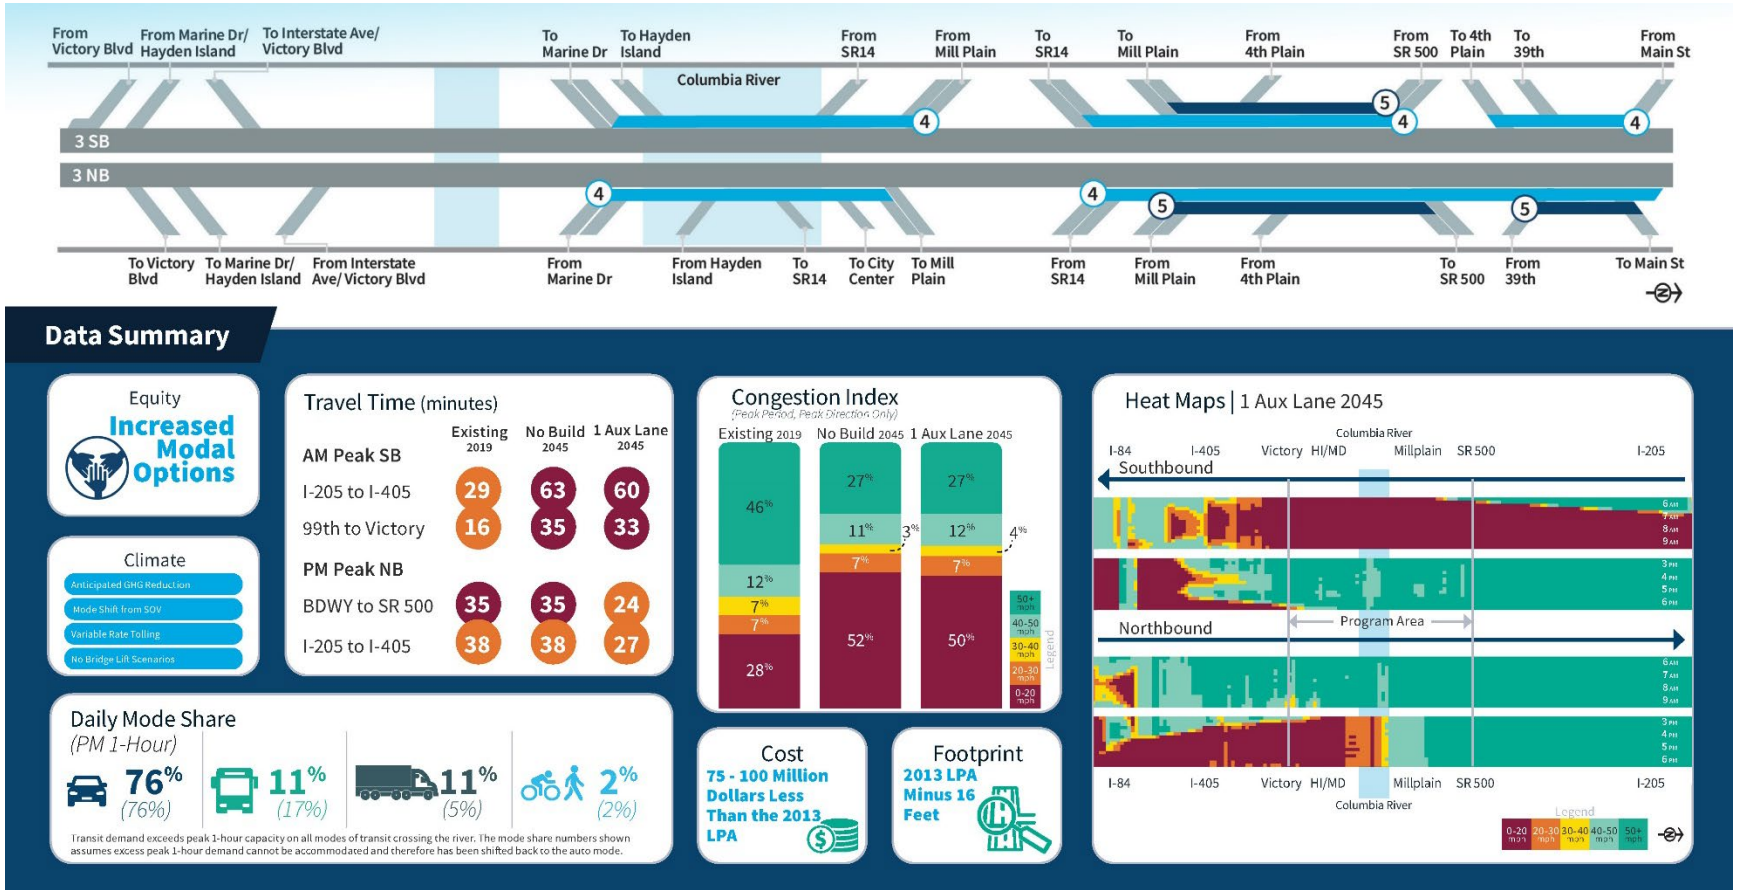
Note: Transit demand exceeds peak 1-hour capacity on all modes of transit crossing the river. The mode share numbers shown assume excess peak 1-hour demand cannot be accommodated and therefore has been shifted back to the auto mode.

Figure 22. Auxiliary Lanes – No-Build



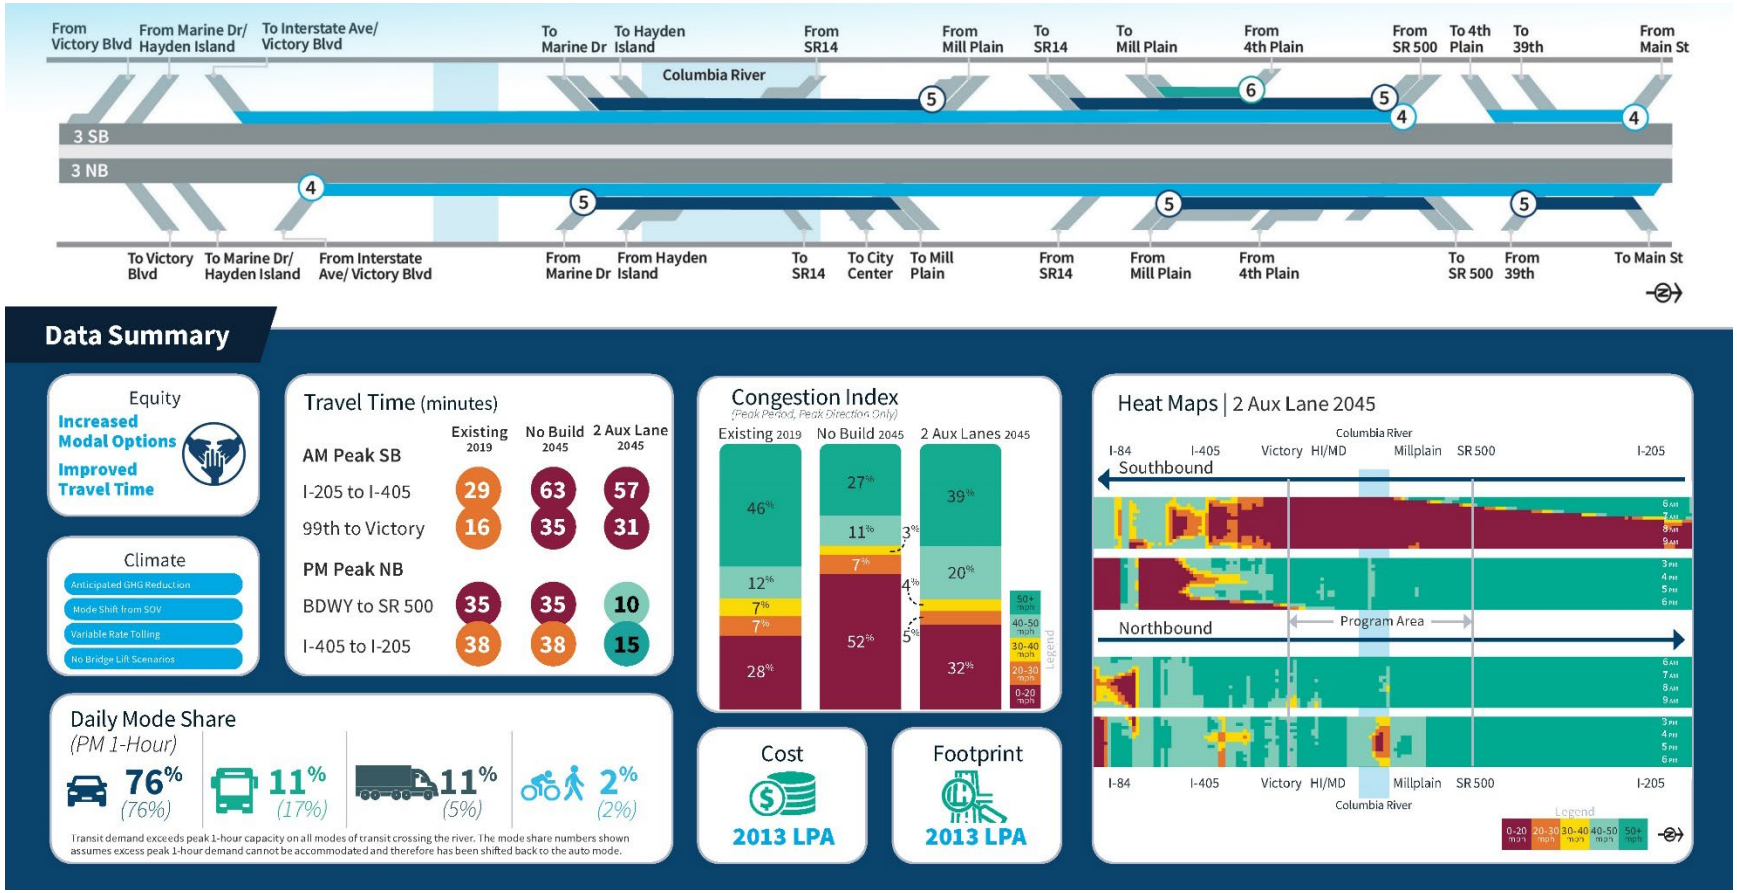
Note: Transit demand exceeds peak 1-hour capacity on all modes of transit crossing the river. The mode share numbers shown assume excess peak 1-hour demand cannot be accommodated and therefore has been shifted back to the auto mode. Travel time pairs coincide with express bus routing providing comparable locations for travel time analysis.

Figure 23. Auxiliary Lanes – One Auxiliary Lane



Note: Transit demand exceeds peak 1-hour capacity on all modes of transit crossing the river. The mode share numbers shown assume excess peak 1-hour demand cannot be accommodated and therefore has been shifted back to the auto mode. Travel time pairs coincide with express bus routing providing comparable locations for travel time analysis.

Figure 24. Auxiliary Lanes – Two Auxiliary Lanes



Note: Transit demand exceeds peak 1-hour capacity on all modes of transit crossing the river. The mode share numbers shown assume excess peak 1-hour demand cannot be accommodated and therefore has been shifted back to the auto mode. Travel time pairs coincide with express bus routing providing comparable locations for travel time analysis.

8. SUMMARY AND NEXT STEPS

This report summarizes how the IBR Program developed the preliminary preferred alternative, which will be advanced for study in an SEIS. The preliminary preferred alternative was developed through a year-long process that began with a multi-step, multi-agency alternatives screening process during the CRC project to arrive at a reasonable range of alternatives. These alternatives were evaluated in detail in the CRC project's EIS, with an LPA selected in the 2011 ROD and updated in two NEPA re-evaluations prepared in 2012-2013.

As detailed in this report, the IBR Program worked with agency partners to develop and screen a series of design options to update and modify the 2013 LPA, in order to better address physical and contextual changes since the CRC project.

Based on the results of the screening and evaluations detailed in this report, the IBR Program recommended the design options identified in Table 14 be advanced as part of the preliminary preferred alternative.

Table 14. Design Options Advanced for Study in the SEIS

Foundational Component	Design Option Advanced for Study in the SEIS
Interchanges for Hayden Island and Marine Drive	Construct a partial interchange at Hayden Island and a full interchange at Marine Drive, designed to minimize impacts while making improvement to freight and workforce traffic and active transportation on Hayden Island and Marine Drive.
Main river crossing	Construct two bridges from Hayden Island to Vancouver on a straight alignment. The eastern structure would accommodate northbound highway traffic on the upper bridge deck, with a bicycle and pedestrian path underneath; the western structure would carry southbound traffic on the upper bridge deck, with a two-way transit below.
Transit mode, general alignment and termini	Extend light rail from the Expo Center in Portland, Oregon north to a new station on Hayden Island, continuing across the Columbia River on the new bridges, following I-5 to multiple stations in the City of Vancouver, including a northern terminus at Evergreen Station in Vancouver, Washington.
Auxiliary lanes	Include one auxiliary lane northbound and one auxiliary lane southbound between Marine Drive and Mill Plain Boulevard to accommodate the safe movement of vehicles and freight.

These design options will be studied as part of the preliminary preferred alternative in the NEPA process for the IBR Program, along with the other components identified in Section 2.3.

As previously noted, the Modified LPA consists of recommendations for three key Program components (the interchanges on Hayden Island and Marine Drive; transit mode, general alignment and termini; and the number of auxiliary lanes). The guiding bodies of each of the eight Program partners, including the regional transit agencies, cities, MPOs and Ports, met between June 22 and July 14, 2022, to consider the Program's recommendation for the Modified LPA. These boards, councils, and commissions each voted in support of endorsing the Program's Modified LPA through their own agency's resolution. In addition to the Modified LPA resolutions, many partners included conditions reflecting their priorities and requests for additional work, considerations, and analysis. The Program acknowledges that additional work and/or analysis beyond what is reflected in the Modified LPA is necessary as the Program continues to develop a multimodal corridor solution. The Program will develop a workplan that identifies how each request made in the conditions might be addressed, including the timing most appropriate to the overall Program schedule.

Environmental analyses for the SEIS will be conducted to evaluate benefits and impacts to environmental and community resources (e.g., air quality, climate, land use, transportation) and to identify potential mitigation for adverse impacts. Additional opportunities will be provided to agencies, partners, advisory groups, and the public to provide input and feedback on the Modified LPA, preliminary preferred alternative, environmental analyses, and proposed mitigation. This will include a public comment period and a public hearing(s) held for the Draft SEIS, and other opportunities to be identified.

Attachment A. IBR Alignment with Partner Climate Goals and Policies

Interstate Bridge Replacement (IBR) Program Climate Goals – Alignment with Partner Climate Goals and Policies

Note for Reviewers: This document provides a summary of the partners' climate planning, policies and goals and shows where and how the IBR program climate framework and desired outcomes (as well as other program initiatives, efforts and goals – such as equity and public engagement) are aligned.

Aligned: IBR program goals are in alignment and in some cases directly contributes to achieving this partner goal. (Full circle)

Partial: IBR program goals may not directly relate but are not in conflict. (Half circle)

No: IBR program goals are not aligned with this partner goal. (Empty circle)

Not Applicable: Partner goal does not apply to IBR program; however, IBR program is not in conflict with this goal. (N/A)

To Be Decided (TBD): IBR program has not arrived at a decision, commitment, or goal for this topic yet.

Partner Agency – WSDOT	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
WSDOT Secretary's Executive Order 1113: GHG Reduction Goals	**GHG Reduction Target**. By 2030, reduce overall emissions of greenhouse gases in the state to fifty million metric tons, or 45% below 1990 levels;	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG. In areas where emissions cannot be reduced, IBR is considering offsets.	4
	GHG Reduction Target. By 2040, reduce overall emissions of greenhouse gases in the state to twenty-seven million metric tons, or seventy percent below 1990 levels;	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4
	GHG Reduction Target. By 2050, reduce overall emissions of greenhouse gases in the state to five million metric tons, or ninety-five percent below 1990 levels.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4
	Energy efficiency	**Yes – Aligned.** IBR climate goals include using a renewable power supply, high efficiency lighting, and an electric vehicle maintenance fleet, all of which contribute to the IBR's energy efficiency. *Reducing Climate Impacts – Maintenance and Operations*	4

Partner Agency – WSDOT	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Reducing pollution	**Yes – Aligned.** IBR climate goal to reduce GHG, which contributes to the reduction of pollution.	4
	Enhanced resilience	**Yes – Aligned.** IBR includes climate resiliency goals, such as designing for performance in a range of environmental conditions resulting from evolving climate, and considering climate impacts to future growth and population centers	4

Partner Agency – ODOT	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
ODOT Strategic Action Plan	Equity– Prioritize diversity, equity, and inclusion by identifying and addressing systemic barriers to ensure all Oregonians benefit from transportation services and investments.	**Yes – Aligned.** IBR prioritization of equity concerns will assist in advancing this goal	4
	Modern Transportation System – Build, maintain and operate a modern, multimodal transportation system to serve all Oregonians, address climate change, and help Oregon communities and economies thrive.	**Yes – Aligned.** IBR purpose directly corresponds to this goal. By shifting travel demands to lower GHG modes and improving transportation efficiency the replacement bridge will fit into this goal. *Reducing Climate Impacts – Transportation Options*	4
	Sufficient and Reliable Funding – Seek sufficient and reliable funding to support a modern transportation system and a fiscally sound ODOT.	**Yes – Aligned.** The IBR seeks sufficient and reliable funding.	4
ODOT Climate Action Plan (2021)	Reduce emissions from the transportation system.	**Yes – Aligned.** IBR aims to reduce vehicle-based GHG emissions. *Reducing Climate Impacts – Transportation Options* *Reducing Climate Impacts – Construction*	4
	Make the transportation system more resilient to extreme weather events.	**Yes – Aligned.** IBR directly addresses this, "Consider changes in environmental conditions resulting from changes in our climate" with goals to address increased weather extremes in the road surface, and expansion of the bridge. *Climate Resiliency- Environmental Changes*	4
Statewide Transportation Strategy (STS)	The Statewide Transportation Strategy: A 2050 Vision for Greenhouse Gas Reduction (STS) is Oregon's carbon reduction roadmap for transportation and includes strategies for substantially reducing GHG emissions from the transportation sector.	**Yes – Aligned**. IBR aims to lower emissions which will contribute to the goal of lowering overall state emissions. *Reducing Climate Impacts – Transportation Options* *Reducing Climate Impacts – Maintenance and Operations*	4
Governor's Executive Order 20-04: State GHG Reduction Goals	**GHG Reduction Target**. Per Executive Order 20-04, achieve State greenhouse gas emission reduction goals to at least 45 percent below 1990 emissions levels by 2035, and at least 80 percent below 1990 levels by 2050.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4

Partner Agency – ODOT	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
DLCD: Updated Transportation Planning Rules	Oregon Dept. of Land Conservation and Development (DLCD) is proposing updates to the statewide Transportation Planning Rules (TPR). Existing rules are not sufficient to meet the state's Metropolitan GHG Reduction Targets, so updated rules aim to reduce climate pollution. The amended rules would require local governments in metropolitan areas to: • Plan for greater development in transit corridors and downtowns, where services are located and less driving is necessary; • Prioritize system performance measures that achieve community livability goals; • Prioritize investments for reaching destinations without dependency on single occupancy vehicles, including in walking, bicycling, and transit; • Plan for and manage parking to meet demonstrated demand, and avoid over-building of parking in areas that need housing and other services; • Plan for needed infrastructure for electric vehicle charging; and • Regularly monitor and report progress.	**Yes – Aligned.** IBR aims to reduce vehicle-based GHG emissions by expanding transportation options for non-auto trips. This includes high capacity transit and safe, comfortable bike and pedestrian infrastructure. It also includes an equitable tolling program. Together the elements of the bridge program contribute to the region's livability and provide alternatives to driving.	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Climate Action Plan (2015)	**GHG Reduction Target**. Portland and Multnomah County have committed to reducing local carbon emissions by 80 percent below 1990 levels by 2050, with an interim goal of a 40 percent reduction by 2030.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4
	The City and County are committed to leveling this playing field. We're working to: • Increase access to transit, sidewalks, bike lanes and other transportation options. • Reduce exposure to pollution and excessive heat. • Improve access to parks and other natural resources. • Reduce burdens of housing and energy costs.	**Yes – Aligned.** IBR will increase access to transit and active transportation amenities. IBR is exploring ways to mitigate excessive heat through design and increasing tree cover. *Reducing Climate Impacts – Transportation Options* *Climate resiliency- Environmental Changes* **Not applicable.** IBR climate goals do not directly address air pollution, access to parks, housing and energy costs, but there is no conflict.	4
	By 2030 Reduce the total energy use of all buildings built before 2010 by 25 percent.	**Not applicable.** As a new structure, this goal does not directly apply to the replacement bridge. IBR is likely to include a renewable power supply and high efficiency lighting, allowing structures to fit within the energy efficiency parameters.	n/a
	By 2030 Achieve zero net carbon emissions in all new buildings and homes	**Yes – Partial.** Any buildings associated with IBR will comply with local standards. Primary elements do not include buildings or homes.	2
	By 2030 Supply 50 percent of all energy used in buildings from renewable resources, with 10 percent produced within Multnomah County from on-site renewable sources, such as solar.	**Yes – Aligned.** IBR aims to increase renewable power supply for energy needs. IBR will work with local utilities to access renewable energy sources. The team recognizes that the Clean Energy Transformation Act in WA will change the landscape for purchasing renewable energy; the law will require all electricity produced in the state to be GHG neutral by 2030 and GHG free by 2045. There may be opportunities for accessing renewable power within this timeframe. *Reducing Climate Impacts –Maintenance and Operations*	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Create vibrant neighborhoods where 80 percent of residents can easily walk or bicycle to meet all basic daily, non-work needs and have safe pedestrian or bicycle access to transit. Reduce daily per capita vehicle miles traveled (VMT) by 30 percent from 2008 levels.	**Yes – Aligned.** IBR includes reducing travel demand, shift travel demand to low GHG modes and improve transportation efficiency, which will contribute to this goal. *Reducing Climate Impacts –Travel Options*	4
	Improve the efficiency of freight movement within and through the Portland metropolitan area	**Yes – Aligned.** IBR will improve transportation efficiency, which will benefit all travelers, including freight. *Reducing Climate Impacts – Travel Options*	4
	Increase the fuel efficiency of passenger vehicles in use to 40 miles per gallon and manage the road system to minimize emissions.	**Yes – Partial.** IBR includes the use of electric vehicle maintenance fleet; Reducing Climate Impacts- Travel Options, improving transportation efficiency will also minimize emissions. *Reducing Climate Impacts – Maintenance and Operations*	2
	Reduce lifecycle carbon emissions of transportation fuels by 20 percent.	**Not applicable;** no conflict. While none of the IBR climate goals contribute or align directly, there is no conflict. IBR goals to lower emissions and reduce lifecycle emissions from materials and reduce transport distances support this goal.	n/a
	Reduce consumption-related emissions by encouraging sustainable consumption and supporting Portland businesses in minimizing the carbon intensity of their supply chains.	**Yes – Aligned.** IBR includes the use of local manufacturers, sourcing materials locally, and reducing transport which align well with this goal. *Reducing Climate Impacts -- Construction*	4
	Reduce food scraps sent to landfills by 90 percent.	**Not applicable.** As IBR has no effect on food, this goal doesn't have correlation to IBR climate goals; however there is no conflict.	n/a
	Recover 90 percent of all waste generated	**Yes – Aligned.** IBR has a zero-waste goal for demolition. *Reducing Climate Impacts - Construction*	4
	Reduce the consumption of carbon-intensive foods and support a community-based food system.	**Not applicable.** As IBR has no effect on food consumption this goal doesn't have correlation to IBR climate goals; no conflict.	n/a

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Sequester carbon through increased green infrastructure (trees, plants, soil) and natural areas. Reduce effective impervious areas by 600 acres. Expand the urban forest canopy to cover at least one-third of the city, with a minimum canopy cover of 25 percent of each residential neighborhood and 15 percent of the central city, commercial and industrial areas	**Yes – Partial.** IBR climate goal for GHG offsets will help to mitigate construction-related emissions that cannot be eliminated. Plans to create a robust landscape plan that relies on much higher than traditional tree and planting replacement rates in the public right of way could also bring Portland closer to the goal of expanding the urban forest canopy. *Reducing Climate Impacts- Offsets*	2
	Reduce risks and impacts from heat, drought, and wildfire by preparing for hotter, drier summers with increased incidence of extreme heat days.	**Yes – Aligned.** IBR climate goals for adaptive and resilient design are in alignment. *Climate resiliency- Environmental Changes*	4
	Reduce risks and impacts from flooding and landslides by preparing for warmer winters with the potential for more intense rain events.	**Yes – Aligned.** IBR climate goals for adaptive and resilient design are in alignment. *Climate Resiliency- Environmental Changes* *Reducing Climate Impacts – Construction*	4
	Build City and County staff and community capacity to prepare for and respond to the impacts of climate change.	**Yes – Aligned.** IBR construction and procurement will support DBE businesses in increasing capacity for climate-responsive practices. *Reducing Climate Impacts – Construction* *Climate Resiliency –Development and Behavioral Changes*	4
	Build City and County staff and community capacity to ensure effective implementation and equitable outcomes of climate action efforts.	**Yes – Aligned.** IBR engagement and equity efforts are focused on equitable process and equitable outcomes, in support of this goal. *Climate Resiliency –Development and Behavioral Changes*	4
Climate Emergency Declaration (2020)	**GHG Reduction Target**. Be it further resolved, that the City of Portland adopts a new target of achieving **at least a 50% reduction in carbon emissions below 1990 levels by 2030** and net-zero carbon emissions before 2050. These targets will be carried forward into future Climate Action Plan updates and work plans	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	GHG Reduction Target. To inform future Climate Action Plan updates and workplans, the City of Portland will analyze decarbonization pathways to **achieve carbon neutrality by 2050** with clear interim goals, including a commitment to monitoring any remaining emission sources and implementing policies or mechanisms to reduce those emissions, including but not limited to the role of urban sequestration and negative carbon technologies.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4
Transportation System Plan: Policies (2020)	**Transportation Policy:** Mode share goals and vehicle miles travelled (VMT) reduction: Increase the share of trips made using active and low-carbon transportation modes. Reduce VMT to achieve targets set in the most current Climate Action Plan and Transportation System Plan, and meet or exceed Metro's mode share and VMT targets.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Transportation Policy: Transportation strategy for people movement: Implement a prioritization of modes for people movement by making transportation system decisions according to the following ordered list: • Walking • Bicycling • Transit • Fleets of electric, fully automated, multiple passenger vehicles • Other shared vehicles • Low or no occupancy vehicles, fossil-fueled non-transit vehicles When implementing this prioritization, ensure that: • The needs and safety of each group of users are considered, and changes do not make existing conditions worse for the most vulnerable users higher on the ordered list. • All users' needs are balanced with the intent of optimizing the right-of-way for multiple modes on the same street. • When necessary to ensure safety, accommodate some users on parallel streets as part of a multi-street corridor. • Land use and system plans, network functionality for all modes, other street functions, and complete street policies, are maintained. • Policy-based rationale is provided if modes lower in the ordered list are prioritized.	**Yes – Partial**. IBR serves primarily to improve mobility and access for I-5, part of the interstate highway system, so the modal prioritization is not aligned. Even so, IBR will improve and expand safe, direct travel options for people walking, biking/rolling and taking transit within the project area.	2
	Transportation Policy – GHG Reduction Target: By 2035, reduce Portland's transportation-related carbon emissions to 50% below 1990 levels, at approximately 934,000 metric tons.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Pricing Options for Equitable Movement (2021)	**We are in a climate crisis.** The transportation sector contributes more than 40% of greenhouse gas emissions in the Portland region. Reducing transportation emissions will take a three-pronged approach: 1. Reducing driving by making other options safer and more attractive. 2. Shifting the trips that remain on the road to zero-emission vehicles (including cars, buses and freight). 3. Planning and building connected, inclusive, and complete neighborhoods to reduce the need for long trips.	**Yes – Partial**. IBR is centering climate and equity outcomes that influence all stages of decision making. - Expanding transportation options is one of the most significant means that the IBR program has to reduce driving trips. - IBR supports the transition to zero-emission vehicles. The IBR climate program will explore ways to electrify the fleet used for construction and ongoing operations and maintenance. - IBR is contributing to building connected and complete communities in the project area.	2
	The City should utilize the Equitable Mobility Framework to guide pricing policy deliberations and commit to evaluating equitable mobility impacts of the existing system and any future proposed transportation policy. This includes impacts to moving people and goods, safety, climate and health, and the economy.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. IBR is committed to evaluating equitable tolling structures.	tbd
	The City must engage community stakeholders, especially those representing BIPOC communities, Portlanders living on low incomes, people with disabilities, multi-lingual and displaced communities in the next stage of pricing policy development, as well as ongoing evaluation.	**Yes – Aligned**. IBR will continue to uphold its commitment to meaningfully engage the public and priority equity communities in decision making. Equity and equitable access to travel is a shared priority, and IBR is committed to evaluating equitable tolling structures.	4
	The City must advance complementary strategies alongside pricing to improve equitable mobility outcomes. Pricing is just one policy tool and not a stand-alone solution. Additional transportation demand management programs; multimodal infrastructure, operations and service investments; land use policies; affordable housing; and more must also be prioritized to create a more equitable and sustainable mobility system.	**Yes – Aligned**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. Equity and equitable access to travel is a shared priority, and IBR is committed to evaluating equitable tolling structures.	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Prioritize the goal of reducing traffic demand and using the existing transportation system as efficiently as possible to move people and goods in a more climate-friendly and equitable way. While pricing generates revenue and the reinvestment of revenue is a critical way to make pricing strategies equitable, revenue generation should never be the top priority.	**Yes – Aligned**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand.	4
	Recognize that a pricing policy is only effective if it reduces traffic demand and/or raises enough revenue to fund effective demand management or multimodal improvements. • Setting rates or surcharges too low to affect demand or fund improvements is inequitable. • Programs should be designed to be data driven and regularly reviewed for impact. Rates and surcharges should be set to meet policy goals.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand.	tbd
	Provide exemptions for households living on low incomes. • The City should develop one set of income-based policy standards that can be applied to current and future pricing programs to limit administrative costs and complexity. • Until a universal basic income can be guaranteed, exempting households living on low- incomes should be the highest priority to avoid exacerbating current inequities. • When exemptions are not possible, cash rebates or payments to households living on low incomes is preferred as it allows individuals to make the best transportation decisions for their personal situation. • More evaluation and community engagement are needed to determine what specific design would be most equitable and would minimize overall burdens, while still achieving demand management outcomes. • Pricing programs should build off existing means-testing systems wherever possible to not add additional program access burdens.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. IBR will continue to uphold its commitment to meaningfully engage priority equity communities in decision making. Equity and equitable access to travel is a shared priority, and IBR is committed to evaluating equitable tolling structures.	tbd

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Center climate and equity outcomes (e.g., reducing greenhouse gas emissions, reducing transportation cost burdens, expanding job access, etc.) throughout pricing program design. • This includes evaluating how different variable-rate designs, where prices change based on factors like income, time of day, congestion levels, occupancy, geography, and fuel efficiency may further advance climate and equity goals, with a bias toward equitable outcomes. • Evaluation should not unnecessarily delay implementation but should be thorough and focused on understanding impacts to BIPOC community members, Portlanders with low incomes, and people with disabilities. The City should also commit to ongoing evaluation of equity implications of policies once implemented. • To move with the urgency required by the climate crisis, pricing policies that focus on managing demand for people with the most options should be prioritized. As stated above, exemptions for drivers with low incomes are critical	**Yes – Aligned**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. IBR centers climate and equity outcomes. Equity and equitable access to travel is a shared priority, and IBR is committed to evaluating equitable tolling structures.	4

Partner Agency – City of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Reinvest revenue generated from pricing in strategies that further expand equitable mobility. • Pricing revenue should be reinvested to support frequent, competitive and high-quality multimodal access to areas where pricing is implemented and to mitigate potential negative impacts of traffic diversion. • High-priority complementary investment areas include transit service, operations and infrastructure; biking and walking infrastructure; affordable housing near transportation options; and multimodal discounts and financial incentives, including driving options for those without access who need it. Additional investment areas include electrification infrastructure and rebates as well as maintaining the existing infrastructure necessary for multimodal mobility. • Community stakeholders should always be involved in revenue allocation decisions.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. IBR is committed to evaluating equitable tolling structures. Use of the revenues has not yet been examined.	tbd
	Reduce unequal burdens of technology and enforcement. • Technology and payment systems must be designed to reduce barriers for individuals with limited access to bank accounts (e.g., by allowing use of prepaid debit cards). • Technology and payment systems should include strong privacy protections. • The location of pricing infrastructure should be considered so it doesn't overtly impact BIPOC or communities living on low incomes. • Automated enforcement mechanisms should be used to reduce the potential for enforcement bias. • Tickets and fines for non-compliance should be means-based (i.e., structured by income level) to mitigate disproportionate impacts.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. IBR centers climate and equity outcomes. Equity and equitable access to travel is a shared priority, and IBR is committed to evaluating equitable tolling structures. Technology and enforcement mechanisms have not yet been examined.	tbd

Partner Agency – Metro	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Metro Climate Smart Strategy (2014)	Implement adopted local and regional land use plans	**Yes – Aligned.** IBR does not have land use authority. However, the program will be designed to align with current land use plans and solutions will be forward compatible with denser, transit-oriented communities. Additionally, IBR climate goals support finding design solutions that foster complete and walkable communities.	4
	Make transit convenient, frequent, accessible, and affordable	**Yes – Aligned.** IBR includes goals to shift travel demand to low GHG modes, which includes high-capacity transit, which will contribute to Metro's goal. *Reducing Climate Impacts –Transportation Options*	4
	Make biking and walking safe and convenient	**Yes – Aligned.** IBR includes goals to increase and improve accessibility for people who walk, bike, and roll. The IBR solution will include major improvements to bicycle and pedestrian options. *Reducing Climate Impacts –Transportation Options*	4
	Make streets and highways safe, reliable, and connected	**Yes – Aligned.** IBR goals clearly align with this goal. The IBR solution will improve transportation efficiency, which aims to reduce congestion, design for traffic smoothing, and target moderate speeds. In addition to reducing emissions, it will also improve road safety. *Reducing Climate Impacts –Transportation Options*	4
	Use technology to actively manage the transportation system	**Yes – Aligned.** IBR includes goals to improve transportation efficiency which includes the use of Transportation Management systems and ITS. *Reducing Climate Impacts –Transportation Options*	4
	Provide information and incentives to expand the use of travel options	**Yes – Aligned.** IBR climate goals include transportation demand management strategies and increasing range of transportation options. *Reducing Climate Impacts –Transportation Options*	4
	Make efficient use of vehicle parking and land dedicated to parking	**Yes – Aligned.** If Park and Rides are included, this goal will be applied.	4
	Support transition to cleaner, low carbon fuels and more fuel-efficient vehicles	**Yes – Aligned.** IBR climate goals include an electric vehicle maintenance fleet for ongoing facility maintenance and operations. *Reducing Climate Impacts – Maintenance and Operations*	4
	Secure adequate funding for transportation investments	**Yes – Aligned.** IBR is a transportation investment in itself.	4

Partner Agency – Metro	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Regional Transportation Plan (2018)	**GHG Reduction Target.** Reduce transportation-related greenhouse gas emissions to at least 20% below 2005 emissions levels by 2035 and 35% below 2005 levels by 2050 for the Portland metropolitan area *(Table 2.5: GHG emissions reduction targets)*	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4
	Climate Leadership Policy 1: Implement adopted local and regional land use plans.	**Yes – Aligned.** IBR recognizes the importance of local and regional land use planning, and its influence on travel patterns and climate outcomes.	4
	Climate Leadership Policy 2: Make transit convenient, frequent, accessible, and affordable.	**Yes – Aligned.** Existing transit options are limited. IBR will provide high-capacity transit that improves transit service frequency and reliability.	4
	Climate Leadership Policy 3: Make biking and walking safe and convenient.	**Yes – Aligned.** Existing active transportation facilities are inadequate; IBR will improve the active transportation network and make it easier for people to walk, roll and bike.	4
	Climate Leadership Policy 4: Make streets and highways safe, reliable, and connected.	**Yes – Aligned.** IBR will improve safety, connectivity and reliability for I-5 and connecting streets. The program will address seismic vulnerability, safety concerns with the existing roadway design, congestion and travel time reliability, limited public transit, impaired freight movement, and inadequate active transportation facilities.	4
	Climate Leadership Policy 5: Use technology to actively manage the transportation system and ensure that new and emerging technology affecting the region's transportation system supports shared trips and other Climate Smart Strategy policies and strategies.	**Yes – Aligned.** IBR will incorporate intelligent transportation systems (ITS) and demand management tools to actively manage the roadway network.	4
	Climate Leadership Policy 6: Provide information and incentives to expand the use of travel options.	**TBD.** IBR has not yet made decisions regarding information and incentives, but expanding transportation options is a key component of the IBR climate framework, and there is no conflict.	tbd

Partner Agency – Metro	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Climate Leadership Policy 7: Make efficient use of vehicle parking spaces through parking management and reducing the amount of land dedicated to parking.	**TBD.** IBR does not yet have goals specific to parking management, but there is no conflict.	tbd
	Climate Leadership Policy 8: Support Oregon's transition to cleaner fuels and more fuel-efficient vehicles in recognition of the external impacts of carbon and other vehicle emissions.	**Yes – Aligned.** IBR supports the transition to zero-emission vehicles. The IBR climate program will explore ways to electrify the fleet used for construction and ongoing operations and maintenance.	4
	Climate Leadership Policy 9: Secure adequate funding for transportation investments that support the RTP climate leadership goal and objectives.	**Yes – Aligned.** IBR is a transportation investment in itself.	4
RTP Appendix J: Climate Smart Strategy Implementation and Monitoring (2018)	The full list of RTP Climate Smart Strategy **performance monitoring targets** are shown on page 15 of the document.	**TBD.** IBR is working with partners to establish GHG reduction targets. IBR has not set climate performance targets for operations after construction. The design option screening process incorporates many climate metrics to inform design selection.	tbd
Regional Congestion Pricing Study (2021)	*Best Practices for Implementing Congestion Pricing Programs in an Equitable Manner.* Pricing program design impact on equity outcomes: A more equitable pricing and investment strategy would include the following components: **Variable pricing; Targeted exemption; focus on transit; focus on vulnerable communities.** A less equitable pricing and investment strategy would include: 24-hr flat rate pricing; no supportive investments in transit; no focus on vulnerable communities Congestion pricing programs and projects can improve equity outcomes by (**1)** Reducing harm and increasing benefits if agencies are willing to **focus engagement on historically impacted residents and other stakeholders traditionally at a disadvantage** and ensure they have a role in decision making at every step in the process.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. IBR will continue to uphold its commitment to meaningfully engage priority equity communities in decision making. Equity and equitable access to transportation is a shared priority, and IBR is committed to evaluating equitable tolling structures.	tbd

Partner Agency – Metro	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Congestion pricing programs and projects can improve equity outcomes by (**2) Committing to targeted investments** of net toll revenues for locally supported improvements such as improved transit infrastructure and services and traffic safety improvements.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. Transit investment will be key to the overall program. IBR is currently considering a range of high-capacity transit options, all of which would greatly improve transit frequency and reliability compared to today.	tbd
	Congestion pricing programs and projects can improve equity outcomes by (**3) Exploring who pays and to what degree**, and considering a suite of affordability programs such as rebates or exemptions for low-income drivers, a "transportation wallet", or other investments that address affordability.	**TBD**. IBR has not established details of a pricing program yet, but variable pricing will be a key component to manage demand. Equity and equitable access to transportation is a shared priority, and IBR is committed to evaluating equitable tolling structures.	tbd

Partner Agency – TriMet	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Climate Action Plan	**GHG Reduction Target.** Reduce operational emissions to reach net zero by 2050. Benchmarks: In 2022, reduce operational emissions 60% below baseline In 2030, reduce operational emissions 70% below baseline In 2040, reduce operational emissions 90% below baseline In 2050, reduce operational emissions to net zero TriMet will be separately evaluating how growing transit mode share and growing ridership can help reduce regional emissions.	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4
TriMet Sustainability	Convert MAX to 100% wind power in 2020	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict. Similarly, IBR will be considering integration of renewable power generation.	n/a
	Stop diesel bus purchases after 2025	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict.	n/a
	Convert buses to renewable diesel beginning in April 2020	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict.	n/a
	Convert non-bus fleet to electric & non-bus heavy-duty vehicles to renewable diesel by 2030	**Yes – Partial.** IBR climate goals include goals to use low emissions vehicles. Construction goal aims to use low emissions construction equipment and vehicles, and Maintenance and Operations goal aims to have an electric fleet of vehicles for maintenance. These goals support this by setting an example of other agencies using low impact vehicles. *Reducing Climate Impacts – Construction* *Reducing Climate Impacts - Operations and Maintenance*	2
	Support Youth Pass Program	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict.	n/a
	Conduct a carbon baseline analysis and develop a net zero carbon strategy	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict.	n/a

Partner Agency – TriMet	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Develop a carbon lens	**Yes - Aligned.** IBR climate framework aims to put climate at the center of the design process, similar to a "carbon lens."	4
	Support regional air quality testing	**Not applicable.** IBR climate goals are not in conflict.	n/a

Partner Agency: Port of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Climate Change Strategy	Our goal by 2020 is to lower all our carbon emissions by 15 percent below 1990 levels.	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict.	n/a
	Reduce diesel particulate matter by 75% from Port-controlled operations from 2000 baseline levels by 2020.	**Not applicable**; no conflict. Does not apply to IBR climate goals but has no conflict.	n/a
Environmental Objectives and Targets (year)	[Need document details]		
Environmental Objectives and Targets (2016-2017)	**Minimize impacts to air quality:** The Air Quality Program facilitates implementation of the Port's Air Quality Policy, which has a primary goal of promoting clean air for all who live in airsheds affected by Port activities. To do this, the Port utilizes emissions inventories and aspect/impact analyses of its planned and actual activities that have, or can have, a significant impact on the airshed. Recognizing that not all emission sources are under the Port's direct control, the Port seeks opportunities to improve air quality by facilitating and encouraging partnerships, education, and outreach to assist customers, tenants, and other stakeholders in reducing marine and aviation-related emissions. The Port supports efforts of the International Maritime Organization and International Civil Aviation Organization to set global standards to reduce emissions from marine vessels and aircraft	**Yes – Aligned.** IBR climate goals aim to lower emissions which will contribute to the goal of lowering overall state emissions and improving air quality. *Reducing Climate Impacts – Transportation Options* *Reducing Climate Impacts – Construction*	4
	Reduce energy consumption and carbon emissions: The Port developed the Energy and Carbon Management Master Plan to reduce energy consumption and carbon emissions. The plan aligns closely with the Air Quality program and presents a six-	**Yes – Aligned.** IBR climate goals aim to lower emissions which will contribute to the goal of lowering overall state emissions. *Reducing Climate Impacts – Transportation Options* *Reducing Climate Impacts – Construction*	4

Partner Agency: Port of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	point strategy for reaching the Port's GHG reduction goal. The master plan sets the foundation for establishing targets and a portfolio of projects identified and scheduled for implementation.		
	Minimize impacts and seek opportunities to enhance natural resources: The Natural Resources Program seeks to ensure the development and maintenance of a consistent, ecosystem-based framework for all decisions involving natural resources at the Port. The Port takes a proactive approach to managing natural resources and is responsible for the long-term management of its mitigation commitments. Engaging with the community to identify opportunities has been an important aspect in target selection to support regional conservation goals and initiatives.	**Yes – Aligned.** IBR climate goals aim to create a robust landscape plan that relies on much higher than traditional tree and planting replacement rates in the public right of way. This renews natural resources and supports conservation goals. IBR additionally will take a proactive approach to natural resources protection and avoiding impacts where possible. *Reducing Climate Impacts – Offsets*	4
	Minimize impacts to water resources: The Port of Portland's Stormwater Management Program is designed to prevent, reduce, and eliminate the discharge of polluted stormwater to the Columbia Slough and Willamette and Columbia rivers. In addition, the Port continues to set targets in support of the Water Conservation Strategy developed in 2014 that defines strategies to eliminate waste, improve efficiency and use alternative water sources across the Port. It strives to further integrate water conservation into the Port's daily operations, business planning, maintenance, and capital projects.	**Yes – Aligned.** IBR design will include elements that managing stormwater due to increased storm intensities, this will have an overall impact in reducing water pollution. Additionally, the program will be designing additional stormwater treatment beyond what is provided by current facilities. *Climate Resiliency- Environmental Changes*	4
	Reduce waste generation and hazardous materials use: Five Years to Zero Waste is the Port of Portland's ambitious plan developed in 2014 to create a guidance framework for the actions necessary to reach "Zero-Waste" status, which the EPA defines as landfill waste diversion of 90% or greater. This plan	**Yes – Aligned.** IBR climate goals include zero waste goals for demolition, helping to directly support this goal. *Reducing Climate Impacts – Construction*	4

Partner Agency: Port of Portland	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	has been developed through an ongoing partnership with Portland State University's Community Environmental Services, as part of the Port's commitment to innovative, industry-leading waste minimization efforts within the broader framework of the Port's EMS. This plan sets out a framework to achieve Zero Waste status by implementing broad strategies in key areas, with specific actions, priorities, and targets. The Port has made great strides toward Zero Waste at Port-owned properties.		

Partner Agency – City of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Climate Action Plan: Goals and Policies (2022)	[Plan forthcoming August 2022]		
City Council Statement on GHG Reduction	**GHG Reduction Target.** The City of Vancouver is advancing its positive direction to achieve the leading-edge climate action goals it endorsed in 2021. On Monday, June 6, following in-depth analysis and discussion, Vancouver City Council unanimously approved an amended version of the City's Climate Priority Resolution that calls for adopting some of the most ambitious goals in the nation, including: • An 80% reduction in municipal operations Greenhouse Gas (GHG) emissions by 2025 • An 80% reduction in GHG emissions by the Vancouver community by 2030 • Carbon neutrality by both municipal operations and the Vancouver community by 2040	**Yes – Aligned.** IBR is working with partners to establish GHG reduction targets. IBR has a goal to contribute to reducing GHG emissions. The goals associated with transportation options aim to shift travel demand to low GHG modes, constructions goals center around reducing construction-based emissions, goals for maintenance and operations are all aiming to reduce GHG, and in areas where emissions cannot be reduced goals are included to offset the emissions.	4

Partner Agency – City of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Sustainability Plan	Greenhouse gas emissions meet existing and emerging state and federal requirements.	**Yes – Aligned.** IBR desired outcomes include reducing GHG emissions and will met all state and federal requirements.	4
	Environmental health is protected or improved by minimizing and where possible, eliminating: 1. The use of hazardous or toxic materials by residents, businesses, and City operations. 2. The levels of pollutants entering the air, soil, and water. 3. The risks that environmental problems pose to human and ecological health.	**Yes – Aligned.** IBR has set goals for low emissions construction methods, equipment, and vehicles which align with the goals of reducing hazardous or toxic materials. IBR Climate Resiliency goals consider the impacts that climate change can have on the bridge and the communities around the bridge. These goals are aligned with reducing the risks that environmental problem s pose to human and ecological health. *Reducing Climate Impacts – Construction* *Climate Resiliency – Development and Behavior Change*	4
	No one geographic or socioeconomic group in the City is being unfairly or disproportionately impacted by environmental pollution	**Yes – Aligned.** IBR environmental justice and equity commitments to avoid disproportionate harms are aligned with this goal.	4
	Consumption of fresh, locally produced, organic produce and foods increases to promote public health and to minimize resource consumption and negative environmental impacts.	**Not applicable**; no conflict.	n/a
	City and community consumption - specifically consumption on non-local, nonrenewable, non-recyclable and non-recycled materials, water, energy, and fuels - decrease. City takes a leadership role in encouraging sustainable or green procurement and considers ways to become a zero-waste city over the long term.	**Yes – Aligned.** IBR sets the goal to use local manufacturers and source materials locally, this directly aligns and supports this goal. *Reducing Climate Impacts – Construction*	4

Partner Agency – City of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	The use of local, non-polluting, renewable, and recycled resources is encouraged	**Yes – Aligned.** IBR sets the goal to use local manufacturers and source materials locally, this directly aligns and supports this goal. Additionally, IBR climate goals include lifecycle analysis for environmental impacts of materials, which will help to support this goal by ensuring that materials used are sustainable. *Reducing Climate Impacts – Construction* *Reducing Climate Impacts – Maintenance and Operations*	4
	A multi-modal transportation system exists that minimizes and, where possible, eliminates pollution and motor vehicle congestion while ensuring safe mobility and access for all without compromising our ability to protect public health and safety.	**Yes – Aligned.** IBR will contribute to this goal. Reducing travel demand, shifting travel demand to low GHG modes, and improving transportation efficiency will all contribute to the outcomes desired in this goal. *Reducing Climate Impacts – Transportation Options*	4
	Auto dependency is reduced and affordable alternative, sustainable modes of travel are increased.	**Yes – Aligned.** IBR will contribute to this goal. IBR aims to minimize auto travel demand and shift travel demand to low GHG modes such as walking, biking, or transit. *Reducing Climate Impacts – Transportation Options*	4
	Vancouver has a diverse, vibrant, stable, local economy that supports the basic needs of all segments of the community.	**Yes – Aligned.** IBR supports this goal by setting a goal to use local manufacturers. *Reducing Climate Impacts – Construction*	4
	Businesses, organizations, and non-profits within the city work with the City of Vancouver to increase efficient use of resources through sustainable business practices.	**Yes – Aligned.** IBR supports this goal by setting a goal to use local manufacturers and provide support for small firms and DBE firms to increase capacity for sustainable practices. *Reducing Climate Impacts – Construction*	4
	Sustainable or “green” businesses are encouraged to locate in the City of Vancouver.	**Yes – Aligned.** IBR plans to utilize local and sustainable manufactures and will act as a reliable transportation option for local businesses but should otherwise have no negative impact on this goal.	4

Partner Agency – City of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	A sufficient open-space system is developed and maintained so that it is diverse in uses and opportunities and includes natural functions/wildlife habitat, as well as passive and active recreation with equitable distribution of parks, trees, pathways throughout the City.	**Yes – Aligned.** IBR includes a goal to create a robust landscape plan that relies on much higher than traditional tree and planting replacement rates in the public right of way. Assisting this goal in that it will increase greenspace and tree cover in the area that mitigation is done. *Reducing Climate Impacts – Offsets*	4
	Land use and transportation planning and policies create compact, mixed-use projects, forming urban villages designed to maximize affordable housing and encourage walking, bicycling and the use of existing or future public transit options.	**Yes – Aligned.** IBR includes the goal to minimize travel demand and increase the walkability of the area, and shift travel demand to low GHG modes such as biking, or transit. These goals will support Vancouver's goals by expanding walkability and bikeability within the program area of impact and beyond. *Reducing Climate Impacts – Transportation Options*	4
	Residents recognize that we all share the local ecosystem with other living things that warrant respect and responsible stewardship. Vancouver uses land efficiently in order to minimize the need to expand the urban footprint to accommodate growth.	**Yes – Partial.** IBR does not have land use authority; however, the program will prioritize transportation solutions that are compatible with more compact, walkable and transit-oriented communities. *Reducing Climate Impacts – Transportation Options* *Reducing Climate Impacts – Offsets*	2
	All development meets the 2030 Challenge in urban growth areas. Clark County and cities have an integrated approach to achieving sustainability.	**Yes – Partial.** IBR is considering options for sustainability certification from third parties such as Greenroads, Envision (ISI), and Living Building Challenge (Living Future). These are similar to the 2030 Challenge, but specifically for infrastructure projects.	2
	A mix of affordable, livable, and green housing types is achieved and maintained throughout the City of Vancouver for people of all socio-economic/cultural/household groups, including seniors, singles and the disabled.	**Not applicable**; no conflict. The IBR goals will have no negative impacts on the housing types in the City of Vancouver.	n/a

Partner Agency – City of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	LEED-certified or equivalent commercial new buildings are encouraged and promoted.	**Yes – Aligned.** While IBR is not focused on building construction it does have goals that include using low emissions methods, materials, equipment, and vehicles during construction. IBR is looking at infrastructure sustainability rating systems that match or exceed LEED standards	4
	All residents of Vancouver are able to meet their basic needs and are empowered to enhance their quality of life.	**Yes – Partial.** IBR climate goals will have no negative impact on this goal. However, having a new sustainable bridge may facilitate this goal. IBR prioritization of equity concerns will assist in advancing this goal.	2
	Community members have access to housing, health and social services, education, economic opportunity, and cultural and recreational resources.	**Yes – Aligned.** IBR will increase transportation options and broaden access for people walking, rolling, and taking transit. The bridge provides a necessary avenue for access to the listed resources.	4
	There is respect and appreciation of the value added to the community by differences among its members in race, religion, gender, age, economic status, sexual orientation, disabilities, immigration status and other special needs.	**Yes – Aligned.** The IBR equity program will assist in advancing this goal.	4
	Community members of all ages participate actively and effectively in civic affairs and community improvement efforts.	**Yes – Aligned.** IBR equity and engagement programs are in alignment and will assist in advancing this goal.	4
	An actively engaged community helps the City of Vancouver to carry out and improve Vancouver's Sustainability Plan	**Yes – Partial.** IBR climate goals will have no negative impact on this goal. IBR prioritization of equity concerns, process equity, and inclusive engagement will assist in advancing this goal.	2
	Community members of all ages and cultures understand the basic principles of sustainability and use them to guide their decisions and actions, personally and collectively.	**Yes – Partial.** IBR supports community education in sustainability and will have no negative impact on this goal.	2

Partner Agency – C-TRAN	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
C-TRAN	C-TRAN services contribute positively to the region's sustainability, livability, and economic vitality by helping manage traffic congestion, reduce dependence on foreign oil, lower carbon emissions, contain transportation costs for employers and employees, enable denser land use and development of urban areas, and provide essential transport to persons with no other means of travel.	**Yes – Aligned.** IBR climate goals aim to shift travel demand to low GHG modes this includes increasing access and connection for high-capacity transit, supporting this goal. *Reducing Climate Impacts – Transportation Options*	4

Partner Agency – Port of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
Port of Vancouver Climate Action Plan	Apply sustainability standards to new construction projects	**Yes – Aligned.** IBR is evaluating adherence to several sustainability rating systems for substantial project elements.	4
	Develop sustainable construction standards such as low-carbon concrete and asphalt, low-emission construction vehicles, construction waste reduction, and materials reuse	**Yes – Aligned.** IBR climate goals include sustainable materials selection. *Reducing Climate Impacts – Construction*	4
	Continue lighting retrofits	**Not applicable**; no conflict. Does not apply to IBR but has no conflict. Similarly, IBR will be designing for energy efficient lighting.	n/a
	Install occupancy sensors, building controls, programmable thermostats and smart meters	**Not applicable**; no conflict. IBR assets will be designed including sensors for smart operations	n/a
	Replace aging HVAC units with energy efficient technology	**Not applicable**; no conflict. IBR assets will be designed including energy efficient technology	n/a
	Explore renewable energy opportunities including onsite solar power generation, small-scale wind generation, geothermal energy, and replacement of natural gas	**Not applicable**; no conflict. IBR assets will be designed to optimize access to renewable energy sources.	n/a
	Electrify or hybridize diesel and gasoline powered vehicles and equipment	**Yes – Aligned.** Reducing emissions associated with maintenance and operations includes a goal to utilize an electric vehicle maintenance fleet, the use of an electric vehicle maintenance fleet by a public agency often increases the support/accessibility for other agencies to switch as well.	4
	Install EV charging infrastructure	**Yes – Aligned.** IBR is looking at integrating charging needs into the transportation system.	4
	Replace use of diesel with low carbon fuels such as renewable diesel	**Yes – Aligned.** Reducing emissions associated with maintenance and operations includes a goal to utilize a renewable power supply and to use electric vehicles for the maintenance fleet, this goal aligns with that.	4

Partner Agency – Port of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Work with C-Tran to provide transit service to the Port and provide transit subsidies to employees	**Not applicable**; no conflict.	n/a
	Install bicycle infrastructure such as secure parking and showers to promote bicycle commuting	**Yes – Aligned.** IBR includes goals to reduce vehicle-based emissions and shifting to transit and active transportation, including bicycles. If routes that commuters use are accessible to bicycles, it will support this goal.	4
	Support effective carpool options	**Yes – Aligned.** IBR includes goals to reduce vehicle-based emissions and shifting to transit and active transportation, including a carpool/HOV lane.	4
	Promote telecommuting through enhanced virtual work infrastructure and policies	**Not applicable**; no conflict.	n/a
	Offset emissions from business travel	**Not applicable**; no conflict.	n/a
	Promote use of low-carbon ground transport options for business travel	**Yes – Aligned.** IBR will include high-capacity transit that can serve business travelers across the region. *Reducing Climate Impacts – Transportation Options*	4
	Provide recycling services and infrastructure	**Not applicable**; no conflict.	n/a
	Develop a waste reduction plan	**Yes – Aligned.** The IBR has zero waste goals for demolition, these goals don't support each other, but show an alignment in the area.	4
	Promote the use of green infrastructure to manage stormwater	**Yes – Aligned.** IBR design will incorporate sustainable stormwater management strategies.	4
	Explore water system efficiencies	**Yes – Aligned.** IBR design will incorporate sustainable design practices, such as water efficiency.	4
	Develop sustainability standards for new construction projects on port property	**Not applicable**; no conflict.	n/a

Partner Agency – Port of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Develop sustainable construction standards such as low-carbon concrete and asphalt, low-emission construction vehicles, construction waste reduction, and materials reuse for projects occurring on port property	**Yes – Aligned**. IBR aims to reduce construction-related emissions and support	4
	Explore carbon reduction during collaborations on agreements with tenants/customers	**Not applicable**; no conflict.	n/a
	Pursue partnerships, incentives, and grant opportunities to support tenant/customer energy efficiency, equipment electrification and other carbon reduction initiatives	**Yes – Partial.** IBR climate goals aim for similar expansion of energy efficient systems.	2
	Emphasize and increase marketing efforts to pursue innovative business opportunities and renewable, clean energy projects	**Not applicable**; no conflict.	n/a
	Promote lighting retrofits by tenants	**Not applicable**; no conflict.	n/a
	Promote installation of occupancy sensors, building controls, programmable thermostats and smart meters by tenants	**Not applicable**; no conflict.	n/a
	Promote replacement of aging HVAC units with energy efficient technology in tenant facilities	**Not applicable**; no conflict.	n/a
	Support onsite renewable energy generation by tenants	**Not applicable**; no conflict.	n/a
	Encourage tenants to replace natural gas use with low carbon/renewable alternatives	**Not applicable**; no conflict.	n/a
	Promote the electrification and hybridization of diesel and gasoline powered vehicles and equipment	**Yes – Aligned.** Reducing emissions associated with maintenance and operations includes a goal to utilize an electric vehicle maintenance fleet, the use of an electric vehicle maintenance fleet by a public agency often increases the support/accessibility for other agencies to switch as well.	4
	Install common use EV charging infrastructure	**Yes – Aligned.** IBR is looking at integrating charging facilities into the design.	4

Partner Agency – Port of Vancouver	Partner Agency – Specific Goal	Alignment with IBR Program Goals	Match
	Promote the replacement of diesel with low carbon fuels such as biodiesel, renewable diesel, and hydrogen	**Yes – Aligned.** Reducing emissions associated with maintenance and operations includes a goal to utilize an electric vehicle maintenance fleet, the use of an electric vehicle maintenance fleet by a public agency often increases the support/accessibility for other agencies to switch as well.	4
	Evaluate the use of fuel cells for heat and power, mobile equipment, and locomotives	**Not applicable**; no conflict.	n/a
	Promote the use of clean trucks and low carbon drayage vehicles	**Yes – Aligned.** Reducing emissions associated with maintenance and operations includes a goal to utilize an electric vehicle maintenance fleet, the use of an electric vehicle maintenance fleet by a public agency often increases the support/accessibility for other agencies to switch as well.	4
	Evaluate the use of shore power options for vessels visiting the Port	**Not applicable**; no conflict.	n/a
	Facilitate the development of a terminal equipment inventory to help target new investments and grant opportunities	**Not applicable**; no conflict.	n/a
	Encourage visits by cleaner or more fuel-efficient vessels	**Not applicable**; no conflict.	n/a
	Explore partnerships to promote shipping via the river system for eastbound cargo	**Not applicable**; no conflict.	n/a
	Promote idle reduction by rail vehicles/equipment (including locomotives)	**Not applicable**; no conflict.	n/a
	Evaluate the development of infrastructure to support electric locomotives for on-port switching operation	**Not applicable**; no conflict.	n/a

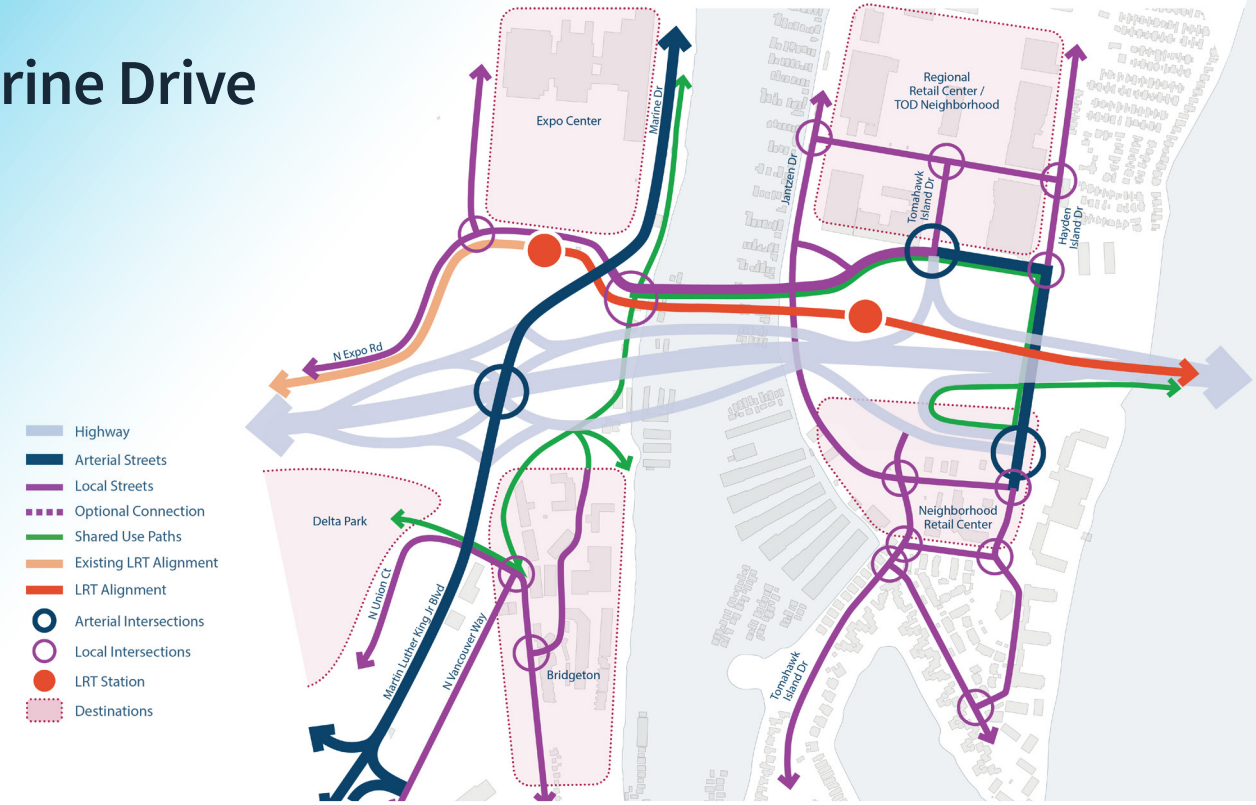
Hayden Island/Marine Drive

2013 Design

☑ Meets Purpose and Need



Screening Summary

2013 Design		
Climate Impacts/Adaptation	◑	- Larger construction footprint (comparison is not based on expected user emissions) - Addresses future river elevation and integrates with new Levee Ready Columbia flood protection improvements **(RE)**
Natural Environment	◔	- Larger footprint over aquatic habitat - Larger footprint over terrestrial habitat
Built Environment	◑	- Most non-residential building impacts **(AH)** - More floating home displacements **(AH)** - Large scale and complexity of I-5 structures over Hayden Island challenge for local placemaking opportunities **(AH, CB, CC)** - Does not includes Tomahawk Island Drive crossing **(CC)**
Active Transportation	◑	- Less direct north-south shared use path **(MA, ME)** - Lower quality of active transportation experience on east-west streets **(MA, ME)** - Higher number of shared use path road/transit crossings **(MA)**
Transit Access	◑	- Less east-west island connectivity because it does not include Tomahawk Island Drive **(MA, ME)** - Wider highway footprint **(ME)**
Vehicles	●	- Intersection traffic operations meet ODOT and City of Portland performance standards at Hayden Island and Marine Drive study area intersections **(RI)**
Freight	●	- Freight to/from Marine Drive area operates acceptably with minimal delay through the interchange **(RI)**
Cost	◕	- Lower construction cost - Higher estimated O&M cost
Seismic	◑	- Seismic retrofits North Portland Harbor Bridge; does not replace

Hayden Island/Marine Drive

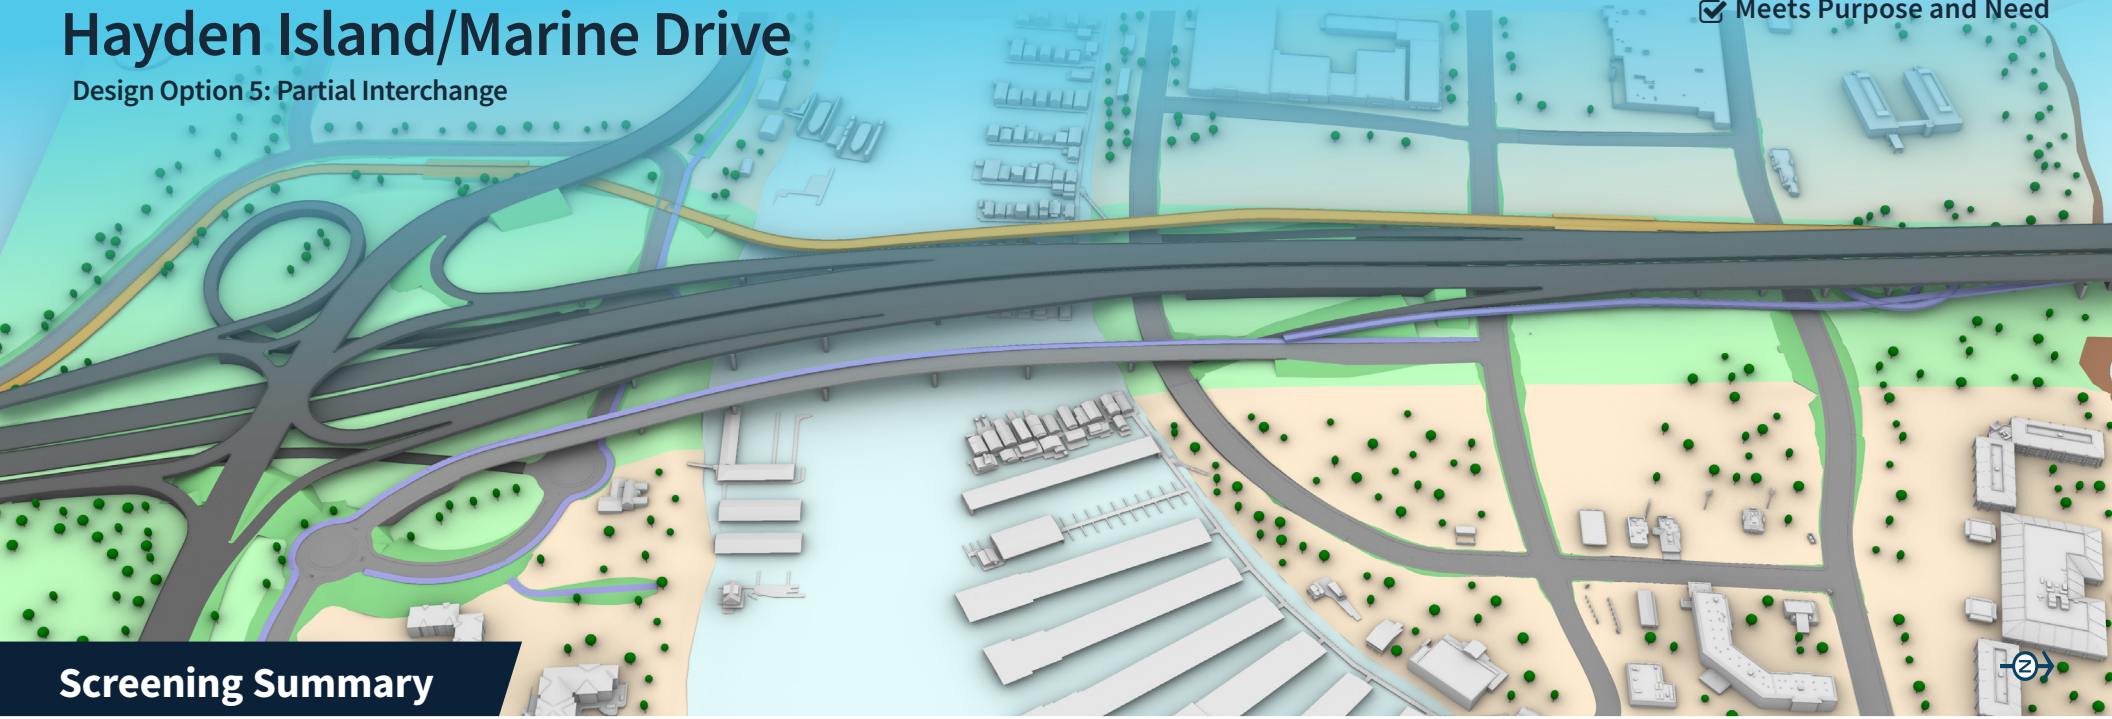
Design Option 5: Partial Interchange

☑ Meets Purpose and Need



Screening Summary

Design Option 5: Partial Interchange		
Climate Impacts/Adaptation	◕	- Smaller construction footprint (comparison is not based on expected user emissions) - Addresses future river elevation and integrates with new Levee Ready Columbia flood protection improvements **(RE)**
Natural Environment	◕	- Smaller footprint over aquatic habitat - Smaller footprint over terrestrial habitat - Levee closure structure part of freeway interchange ramps
Built Environment	◕	- Fewer non-residential building impacts **(AH)** - Least floating home displacements **(AH)** - Smaller scale and complexity of I-5 structures over Hayden Island is less challenging for local placemaking opportunities **(AH, CB, CC)** - Includes Tomahawk Island Drive crossing **(CC)**
Active Transportation	●	- Most direct north-south shared use path **(MA, ME)** - Higher quality of active transportation experience on east-west streets **(MA, ME)** - Lower number of shared use path road/transit crossings **(MA)**
Transit Access	●	- Inclusion of Tomahawk Island Drive improves east-west island connectivity **(MA, ME)** - Narrower highway footprint **(ME)**
Vehicles	◕	- Intersection traffic operations meet ODOT and City of Portland performance standards at Hayden Island and Marine Drive study area intersections **(RI)** - Longer routing and more challenging wayfinding for Hayden Island traffic to/from Portland via I-5 and/or Interstate Ave
Freight	●	- Freight to/from Marine Drive area operates acceptably with minimal delay through the interchange **(RI)**
Cost	◑	- Higher construction cost
Seismic	●	- Replaces North Portland Harbor Bridge

Interstate BRIDGE Replacement Program		Marine Drive/Hayden Island Interchanges		●/● = least impact, high scoring ◑/◑ = few impacts, middle scoring ○/○ = more/most impact, low scoring	Green Harvey balls are subsets of blue Harvey balls, where applicable.	Note: All data are approximate. More detailed impacts will be determined during the NEPA analysis. Some numbers have been rounded.
Metric	**Desired Outcomes Supported**	**Equity Objectives Supported**	**Climate Objectives Supported**	**2013 Design (RD00)**	**Design Option 1: Full Interchange (RD03)**	**Design Option 5: Partial Interchange 3 (RD20)**	**Qualitative Description**
Climate							
Climate impacts of construction (footprint)	CL.1, CL.2		CONST	116.7 acres ○	117.1 acres ○	109.7 acres ◑	Design option footprint is used as surrogate for construction impacts. Larger footprints are assumed to have greater construction impacts and associated emissions.
Future climate disruption/events are integrated into design performance standards	CL.3		RES	Yes ●	Yes ●	Yes ●	All options address river elevation interests. No option is unique in preparedness for temperature extremes. Future design refinements of selected option will allow for evaluation of materials and other adaptation interests.
Support long-term climate change adaptation where feasible (e.g., increased flooding, etc.)	CL.3, CL.4		RES	● Flooding: Yes, will integrate with new Levee Ready Columbia flood protection improvements ● Heat retention potential: most significant due to footprint size (116.7 acres) ◑	● Flooding: Yes, will integrate with new Levee Ready Columbia flood protection improvements ● Heat retention potential: most significant due to footprint size (117.1 acres) ◑	● Flooding: Yes, will integrate with new Levee Ready Columbia flood protection improvements ● Heat retention potential: moderate to high due to footprint size (109.7 acres) ◑	All options address river elevation interests. No option is unique in preparedness for temperature extremes. Future design refinements of selected option will allow for evaluation of materials and other adaptation interests. NOTE - construction footprint area values may suggest greater heat effect for larger footprints.

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Environment and Community Health							
Built Environment							
Aesthetics				◑	○	●	
User experience surrounding the structure (design option).	EQ.3	AH, CB	ACT, CC	◑ Large scale of structure Very cluttered and wide bridgehead at north of Hayden Island *does not support local plan for positive park environment below structure Cleanest (uncluttered) bridge alignment over North Portland Harbor Potentially unprogrammed spaces between and under I-5 infrastructure	○ Large scale of structure Cluttered and wide bridgehead at north of Hayden Island *does not support local plan for positive park environment below structure Many crossing structures at different heights create visual clutter over North Portland Harbor Potentially unprogrammed spaces between and under I-5 infrastructure	● Scale of structure is smaller Clean and narrow bridgehead at north of Hayden island *supports local plan for positive park environment below structure Clean (uncluttered) bridge alignment over North Portland Harbor Less potentially unprogrammed spaces between and under I-5 infrastructure	
User experience on the structure (design option).	EQ.3	AH, CB	ACT, CC	Constantly changing relationship between SUP and vehicle lanes, challenge for SUP clarity and comfort ○	Constantly changing relationship between SUP and vehicle lanes, challenge for SUP clarity and comfort ○	SUP on edge of local road bridge (good opportunity for low speed placemaking and good views) ●	
Air Quality				●	●	●	
Traffic volumes by mode and intersection delay and level of service	CL.1, CL.4, EQ.2		RID	●	●	●	This is the same data as was summarized in rows 98.
Proximity of design option's pedestrian/bicycle infrastructure to vehicle lanes (potential emissions for "next to" or "below" vehicles)	EQ.1, EQ.2, EQ.6	AH, MA		◑	◑	◑	The distance between high-volume roadway or rail corridors and pedestrian infrastructure has an inverse relationship for air quality outcomes, with the influence extending about 500-600' downwind from travel corridors. This metric is not a differentiator between design options on Hayden Island or Marine Drive
Community resources. Number of known community or cultural resources within the design option footprint and in equity priority areas or identified through community engagement (*Hayden Island Community Church*)	EQ.6	AH		0 ●	0 ●	0 ●	Hayden Island Community Church was identified by CAG leads. HI members of the CAG were also asked, but have not identified additional sites.

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Cultural/historic resources. Number of known or potentially eligible historic and cultural resources within the design option footprint				Known eligible: 2 Known not eligible: 1 Unknown eligibility: 18 ◑	Known eligible: 2 Known not eligible: 0 Unknown eligibility: 19 ◑	Known eligible: 2 Known not eligible: 0 Unknown eligibility: 19 ◑	Buildings constructed in 1982 or older will be assessed for eligibility in NRHP. No known archeological sites near the design option footprints.
Hazardous Materials. Potential Priority Hazardous Material Sites within the footprint				12 ◑	19 ◑	17 ◑	
Land Use				○	◑	●	
Placemaking opportunities supported by project based on what is appropriate for the location compatible with adopted land use plans and initiatives			CC	Least opportunities, less connected urban fabric due to widest footprint of freeway and ramps ○	Fewer opportunities, less connected urban fabric due to wider footprint of freeway and ramps ◑	Greater opportunities, more connected and contiguous urban fabric due to narrower footprint of freeway and ramps ●	Wider infrastructure footprint creates a wider break between urban fabric on east and west side of the infrastructure. Placemaking opportunities benefit from greater continuity in the urban fabric and smaller breaks. This metric is based on "Size of Footprint" metric below.
Planned station location(s) supportive of land uses in comprehensive plans			CC	Less supportive. Station is shown close to Jantzen Dr which differs from Hayden Island Plan ◑	More supportive. Station can be located near Tomahawk Island Drive, better serving both north, east, south, and west sides of the island ●	More supportive. Station can be located near Tomahawk Island Drive, better serving both north, east, south, and west sides of the island ●	
Design option supportive of local street network and land use/City development vision on Hayden Island			CC	Not supportive. Tomahawk Island Drive connection not included ○	Somewhat supportive. Tomahawk Island Drive included, supports Hayden Island Plan street grid. Provides local bridge connectivity. ◑	Somewhat supportive. Tomahawk Island Drive included, supports Hayden Island Plan street grid, finer street grid better bike & pedestrian connectivity and transit supportive land uses. Provides local bridge connectivity. ◑	
Existing direct highway access maintained to/from Hayden Island				●	●	◑	
Size of footprint of design option on land over Hayden Island				97.6 acres ◑	98.1 acres ◑	89.4 acres ●	

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Neighborhoods and populations				○	○	◑	
Approximate number of non-residential buildings impacted by footprint	EQ.6	AH		Commercial: 20 Industrial: 4 Recreation: 0 Utilities: 4 TOTAL: 28 ○	Commercial: 14 Industrial: 4 Recreation: 0 Utilities: 4 TOTAL: 22 ◑	Commercial: 15 Industrial: 4 Recreation: 0 Utilities: 4 TOTAL: 23 ◑	Updated building impacts for all options based on refined building data (added missing buildings).
Approximate number of displaced floating homes	EQ.6			21-25 ◑	27-37 ○	18-22 ●	
Number of east-west local streets on Hayden Island	EQ.1, EQ.2	MA	ACT, CC	1 with highway ramp connections 1 with local street grid only ◑	2 with highway ramp connections 1 with local street connection ○	1 with highway ramp connections 1 with arterial connection 1 with local street grid only ◑	
Kenton-Hayden Island-Bridgeton neighborhoods connected to one another by local multimodal streets (Local east-west street adjacent to Marine Drive under I-5) .	EQ.1, EQ.2	MA	ACT, CC	Kenton uses west arterial bridge with option to use I-5. Bridgeton uses west arterial bridge via Marine Drive and Force Avenue to access HI. # local routes 2 Avg local route distance: 2.1 miles ○	Kenton and Bridgeton neighborhoods can use west arterial to access Hayden Island. Kenton has option to use I-5. # local routes 2 Avg local route distance: 1.3 miles ◑	Kenton to HI would use Expo Rd to Vancouver Way extension to east arterial bridge; Bridgeton to HI would use east arterial bridge. # local routes 2 Avg local route distance: 1.3 miles ◑	
Arterial bridges provide non-freeway connections between Hayden Island and North Portland communities (show differences in access for Bridgeton, Kenton, etc.)	EQ.1, EQ.2	MA	ACT, CC	◑ 1 local street bridge Hayden Island to Bridgeton: 5 intersections (via Expo Road to Force Ave to MD/MLK) Hayden Island to Kenton (Victory Blvd): 1 intersection (via Expo Road)	◑ 1 local street bridge Hayden Island to Bridgeton: 2 intersections (via local bridge) Hayden Island to Kenton (Victory Blvd): 2 intersections (via Expo Road)	◑ 1 arterial bridge Hayden Island to Bridgeton: 1 intersection (via local bridge) Hayden Island to Kenton (Victory Blvd): 4 intersections (via Expo Road)	

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Noise				●	◑	◑	
Number of high sensitivity and residential receptors within 500 feet of highway in design option		AH		Category 1: 0 Category 2: 42 (all floating homes) ◑	Category 1: 0 Category 2: 52 (all floating homes) ○	Category 1: 0 Category 2: 53 (all floating homes) ○	FTA Category 1, High Sensitivity: Buildings or parks where quiet is an essential element of their purpose. FTA Category 2, Residential: Buildings where people normally sleep (e.g., residences, hospitals, and hotels)
Proximity of highway in design option to manufactured home community (eastern edge) on Hayden Island	EQ.2, EQ.6	AH		620 feet ●	690 feet ●	690 feet ●	(Noise/vibration for manufactured homes was a community concern for the 2013 LPA.)
Noise generation potential due to design parameters (grades, intersections, # of ramps, etc.)				4 ramps on HI ◑	4 ramps on HI ◑	2 ramps on HI ◑	
Parks, Recreation, and Open Space (PROS). Area of acquired or converted existing or planned PROS (by effect and by type of resource)				0 existing 0 planned ●	0 existing 0 planned ●	0 existing 0 planned ●	Hayden Island Plan (2009): The planned park would be located under the new bridge; therefore the options do not require acquisition/conversion. See Section 4(f) metric for additional details.
Parks, Recreation, and Open Space (PROS). Area of acquired or converted PROS in equity priority areas or identified through community engagement (by effect and by type of resource)		CB	RES	N/A	N/A	N/A	There are no equity priority areas within the design options' footprints
Section 4(f). Use of non-historic Section 4(f) resources (net benefit, temporary occupancy, *de minimis* , use or constructive use)				●	●	●	Anticipated impacts were developed with input from discussions with the Section 4(f) technical lead. Any impacted trails would be rerouted/reconstructed. HI park is planned to be under the bridge.
Section 4(f). Use of non-historic Section 4(f) resources (net benefit, temporary occupancy, *de minimis* , use or constructive use) in equity priority areas or identified through community engagement		AH		N/A	N/A	N/A	There are no equity priority areas within the design options footprints

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Natural Environment							
Water quality and hydrology. Area of new impervious surface within FEMA-mapped floodplains (proxy for volume of fill)	CL.3, CL.4		RES	2.1 acres ◑	1.6 acres ●	1.4 acres ●	
Water quality and hydrology. Levee impacts (i.e., difference in how levee system functions)	CL.3, CL.4		RES	The MDw-5S on-ramp is placing fill over the top of the Denver Ave Hook levee. This should not impact levee operations as we are not cutting into or reducing the top of levee elevation. ◑	The MDw-5S on-ramp will be filling over the top of the Denver Ave Hook levee. This should not impact levee operations as we are not cutting into or reducing the top of levee elevation. I-5 is being re-aligned slightly to the west in the MD interchange area which will require the reconstruction of both NB and SB lanes and will have some potential impacts to the Denver Ave levee during construction. ◑	The 5S loop on-ramp and the MDw-5S on-ramp are placing fill over the top of the Denver Ave Hook levee. The new alignments are being placed on fill so impacts to the levee is minimal, but the roadway is now part of the levee which is not preferred by the USACE. I-5 is being re-aligned slightly to the west in the MD interchange area which will require the reconstruction of both NB and SB lanes and will have some potential impacts to the Denver Ave levee during construction. Levee closure structure could interact with southbound on-ramp. ○	
Wildlife and habitat. Total acreage of habitat areas (upland and riparian) crossed by design option	CL.4		RES	5.6 acres ◑	4.8 acres ◑	3.7 acres ●	
Wildlife and habitat. Total acreage of potential shaded aquatic habitat (proxy for in-water work, shading, and construction duration)	CL.4		RES	12.4 acres ○	12.5 acres ○	10.8 acres ◑

				Vancouver to 40-mile loop: no clear SUP route across Hayden Island ○	Vancouver to 40-mile loop: clear SUP route across Hayden Island ●	Vancouver to 40-mile loop: clear SUP route across Hayden Island ●	
				Vancouver to Hayden Island: indirect route if going north from Hayden Island; unclear access to SUP bridge from west of I-5 ○	Vancouver to Hayden Island: direct route if going north from Hayden Island; clear access to SUP bridge from island ●	Vancouver to Hayden Island: direct route if going north from Hayden Island; clear access to SUP bridge from island ●	
				Hayden Island to 40-mile loop: direct route across west arterial bridge from intersection with 40-mile loop ●	Hayden Island to 40-mile loop: direct route adjacent to transit bridge from intersection with 40-mile loop ●	Hayden Island to 40-mile loop: route across east arterial bridge crosses over the 40-mile loop trail; however direct route to Delta Park ●	
Proportion of space below I-5	5.1, 5.3, CL.1		ACT	○	◑	●	
				Hayden Island Drive: moderate length with high and wide proportions of route below I-5; views toward water ◑	Hayden Island Drive: moderate length with high and wide proportions of route below I-5; views toward water ◑	Hayden Island Drive: short length with high and wide proportions of route below; views toward water ●	
				N/A - No Tomahawk Island Drive	Tomahawk Island Drive: some visual structural depth out of proportion to space below I-5; long length with low and narrow route below I-5 ◑	Tomahawk Island Drive: proportional visual depth to clearance below I-5; short length, with low and wide route below I-5 ●	
				Jantzen Drive: visual depth is out of proportion with space below I-5; long length with low and narrow proportions of route below I-5 ○	Jantzen Drive: some visual depth out of proportion with space below I-5; long length with low and narrow proportions of route below I-5 ◑	Jantzen Drive: proportional visual depth to clearance below I-5; moderate length (with gaps) with low and wide (open towards water) proportions below I-5 ●	
				N/A	Vancouver Way Extension: visual depth is out of proportion with space below I-5; long length with low and narrow (views to water blocked by levee) proportions below I-5 ○	Vancouver Way Extension: proportional visual depth to clearance below I-5; shorter length with low and narrow (views to water blocked by levee) proportions below I-5 ○	
Direct route on SUP between Delta Park and Hayden Island (Tomahawk Island Drive)	5.4, CL.1		ACT	4,630 feet ◑	4,700 feet ◑	4,080 feet ●	<4,000 ft ; 4,000ft - 5,000 ft, > 5,000 ft
Direct route on SUP from Delta Park to Columbia Way (Portland-Vancouver)	5.4, CL.1		ACT	11,750 feet ○	8,970 feet ●	8,490 feet ●	<9,000 ft; 9,000 ft - 11,000 ft; > 11,000 ft
Marine Drive Interchange Ped/Bike Signal Progression				SPUI: 2-3 crossing stages	SPUI: 2-3 crossing stages	SPUI: 2-3 crossing stages	Assumes ped actuated signals at RT lane crossings. SPUI = single point urban interchange.
Number of Marine Drive conflict points			ACT	SPUI: 8 ◑	SPUI: 8 ◑	SPUI: 8 ◑	Absolute number of pedestrian street crossings required to cross I-5 on Marine Dr

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Number of Pedestrian crossings of Hayden Island ramp terminals		MA	ACT	Folded diamond: 3 crossings	Tight diamond: 4 crossings	Half diamond: 2 crossings	Absolute number of pedestrian street crossings
Provides new or improved local street access points and east-west connections for active transportation	5.2, 5.4, CL.1	MA	ACT, CC				
Number of SUP conflict locations (crossings)	5.3, CL.1	MA	ACT				
Number of local anchors connected by SUP	5.1, 5.4, CL.1		ACT	3	3	3	Anchors: W Hayden Island, E Hayden Island, Expo Center/Kenton, Delta Park/Bridgeton
Number of SUP conflict points (crossings) near transit stations	5.2, 5.3, CL.1	MA	ACT				
Transit Access							
Transit user experience, personal security, and ease of access to station (bike/ped/vehicle)	3.1, CL.1	MA	CC, TRA				
LRT HCT options				Does not provide east island access via Tomahawk Is. Dr.	Less connected urban fabric due to wider footprint of freeway and ramps. Tomahawk Is. Dr. provides east island access.	More connected urban fabric due to narrower footprint of freeway and ramps. Tomahawk Is. Dr. provides east island access.	LRT station would likely be elevated
BRT HCT options				N/A	Less connected, more fragmented urban fabric due to wider footprint of freeway and ramps	Connected and contiguous urban fabric due to narrower footprint of freeway and ramps	BRT station would likely be elevated
LRT/BRT HCT option				N/A	Transfer required	Transfer required	LRT station and BRT station would likely be elevated
Bus-on-shoulder Option with local service to Hayden Island				N/A	Not HCT	Not HCT	
Transit station environment (high adjacency to local streets and low adjacency to freeway & ramps)			TRA	Less adjacency to local streets, more adjacent to freeway & ramps	High adjacency to local streets, less adjacent to freeway & ramps	High adjacency to local streets, less adjacent to freeway & ramps	Stations that are adjacent to local streets link riders to the ped/bike network and increase "eyes on the station".
Hayden Island transit station vertical assumption				Elevated	Elevated	Elevated	Considerations: HCT travel time, steep grades (~5-7%), track geometry, at-grade crossing of Tomahawk Island Dr, climate resiliency (existing ground is only 3-5 feet above 100 yr flood elevation), station access, "eyes on station," cost
North-south flexibility of Hayden Island transit station location			TRA	Close to Jantzen Drive	Between Tomahawk Island Drive and Hayden Island Drive	Between Jantzen Drive and Hayden Island Drive	Flexibility assumes elevated station

Metric	Desired Outcomes Supported	Equity Objectives Supported	Climate Objectives Supported	2013 Design (RD00)	Design Option 1: Full Interchange (RD03)	Design Option 5: Partial Interchange 3 (RD20)	Qualitative Description
Freight/Vehicles							
Compatible with applicable design standards for all vehicle modes (i.e., anticipate design exceptions for ODOT, WSDOT, COV, or AASHTO)	4.1, 4.2, 4.3			Yes ●	Yes ●	Yes ●	
Ability of design to accommodate peak traffic demand				Yes ●	Yes ●	Yes ●	
Wayfinding and routing on local streets				●	●	Longer routing and more challenging wayfinding for Hayden Island traffic to I-5 Soutbound and Victory Blvd/Denver Ave/Interstate Ave ○	
Total entering volume at Marine Drive/I-5 intersections (vph) AM/PM peak hour	1.3, 4.4, CL.1		ACT, CC, RID	SPUI 4,360/4,000	SPUI 4,360/4,000	SPUI 4,360/4,000	
Intersection Level of Service, Delay, and ICU at Marine Drive and Hayden Island Ramp Intersections	1.3, 4.4, CL.1		ACT, CC, RID	●	●	●	see supplemental figure
Delay Differential	1.4 , CL.1		RID	●	●	●	
Delay Differential (AM peak hour) on routes originating from I-5 southbound Route 1: I-5 SB to Hayden Island Drive/Parker Route 2: I-5 SB to Tomahawk/Parker Route 3: I-5 SB to Marine Drive/Force Ave Route 4: I-5 SB to Marine Drive/6th Ave to Route 5: I-5 SB to Jubitz (via Vancouver Way)				Route 1: 19 seconds Route 2: 28 seconds Route 3: 23 seconds Route 4: 48 seconds Route 5: 48 seconds ●	Route 1: 38 seconds Route 2: 23 seconds Route 3: 24 seconds Route 4: 46 seconds Route 5: 46 seconds ●	Route 1: 41 seconds Route 2: 26 seconds Route 3: 22 seconds Route 4: 47 seconds Route 5: 47 seconds ●	Delay (in seconds) differential for 5 routes (noted in column A) through interchange intersections - lower delay is better. (travel time is the same through intersections outside of the study area)
Delay Differential (PM peak hour) on routes originating from I-5 southbound Route 1: I-5 SB to Hayden Island Drive/Parker Route 2: I-5 SB to Tomahawk/Parker Route 3: I-5 SB to Marine Drive/Force Ave Route 4: I-5 SB to Marine Drive/6th Ave to Route 5: I-5 SB to Jubitz (via Vancouver Way)				Route 1: 19 seconds Route 2: 30 seconds Route 3: 3 seconds Route 4: 54 seconds Route 5: 54 seconds ●	Route 1: 38 seconds Route 2: 23 seconds Route 3: 3 seconds Route 4: 49 seconds Route 5: 49 seconds ●	Route 1: 40 seconds Route 2: 25 seconds Route 3: 4 seconds Route 4: 54 seconds Route 5: 54 seconds ●	Delay (in seconds) differential for 5 routes (noted in column A) through interchange intersections - lower delay is better. Fully compatible with side-by-side highway bridge configuration (two bridge)				Yes	Yes	Yes	
	Teal highlighting is used to identify which design option has the highest score for a given metric						
	Grey highlighting it used when a metric is not a differentiator of design options						

Equity Objectives for Screening Criteria	Climate Objectives for Screening Criteria
AH = Avoid further harm: Avoid rather than simply mitigate disproportionate impacts on equity priority groups. CB = Community benefits: Find opportunities for and implement local community improvements in addition to required mitigations EO = Economic opportunity: Ensure that economic opportunities generated by the program benefit minority and women owned firms, BIPOC workers, workers with disabilities, and young people. MA = Mobility and accessibility: Improve mobility, accessibility, and connectivity, especially for lower income travelers, people with disabilities, and communities who experience transportation barriers.	ACT = Supports mode shift to low or no emission travel (i.e., active transportation: walking, rolling, biking) CC = Supports complete communities CONST = compatible with low carbon construction ITS = Supports intelligent transportation systems O&M = Supports low emission operations and maintenance RES = Improves resilience to uncertain climatic conditions RID = Reduces idling of vehicles (freight, single-occupancy vehicles, transit) TRA = Supports mode shift to transit (i.e. improves access, travel time, reliability, etc.)

1. INTRODUCTION

The Interstate Bridge Replacement (IBR) program is a continuation of the Interstate 5 (I-5) Columbia River Crossing (CRC) Project and will replace the aging I-5 bridges across the Columbia River with a modern, seismically resilient, multimodal structure. The Federal Highway Administration (FHWA) and Federal Transit Administration (FTA) are the lead federal agencies responsible for ensuring that the program complies with the National Environmental Policy Act (NEPA) and associated regulations and policies.[1]

The IBR program must define the type of river crossing that will replace the existing bridges over the Columbia River. In June 2022, the U.S. Coast Guard (USCG) responded to the IBR's program's Navigation Impact Report (NIR) and issued a Preliminary Navigation Clearance Determination for the IBR program that prescribed a vertical and horizontal navigation clearance for the river crossing that would have a high likelihood of obtaining a favorable permit decision. The USCG also requires that the horizontal navigation clearance meet the U.S. Army Corps of Engineers (USACE) requirement, which is currently set to equal to or greater than 400 feet. The IBR program continues to coordinate with the USACE regarding their requirement for a 400 feet horizontal clearance and proposed shift in the primary navigation channel toward the center of the Columbia River. The IBR program anticipates a final decision from the USACE in 2023. Based on technical evaluations, agency coordination, public outreach, and discussions with partner agencies, the IBR program recommends a fixed-span bridge with a vertical clearance of 116 feet.

This report provides context for the replacement crossing, identifies the various river crossing options, including their advantages and disadvantages, and provides the IBR program's reasoning for the recommended bridge configuration and height.

[1] In addition to FHWA and FTA, there are six joint lead agencies: Oregon Department of Transportation, Washington State Department of Transportation, Oregon Metro (Metro), and Southwest Washington Regional Transportation Council, Tri County Metropolitan Transportation District (TriMet), and Clark County Public Transportation Benefit Area (C-TRAN).

2. PURPOSE AND NEED

A "Purpose and Need" statement is a foundational document under NEPA that identifies and defines the transportation problem(s) that a project must address. The adopted statement for the IBR program is paramount to considering various river crossing options because the selected option must address the identified transportation problems.

As part of the NEPA process, the IBR program worked with regional and local partner agencies and the public to confirm the program's Purpose and Need statement. Through work completed in 2021, the IBR program determined that the needs identified in the CRC Project's Purpose and Need statement are still pertinent. Thus, the Purpose and Need statement for the IBR program, provided below, remains the same as in the 2011 Record of Decision (ROD) for the CRC Project. The Purpose and Need statement was developed by the lead agencies, project sponsors, and the CRC Task Force.[2]

Note: The text of the Purpose and Need statement has not been edited or updated, with the exception of references to the program name. More recent data and supplemental information are provided in sidebars.

2.1 Project Purpose

The purpose of the proposed action is to improve I-5 corridor mobility by addressing present and future travel demand and mobility needs in the IBR program area. The program area extends from approximately Columbia Boulevard in the south to State Route (SR) 500 in the north. Relative to the No-Build Alternative, the proposed action is intended to achieve the following objectives: a) improve travel safety and traffic operations on the I-5 bridges and associated interchanges; b) improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the program area; c) improve highway freight mobility and address interstate travel and commerce needs in the program area; and d) improve the I-5 river crossing's structural integrity (seismic stability).

[2] The CRC Task Force was a 39-member group formed in 2005 comprising leaders representing a broad cross section of Washington and Oregon communities. Public agencies, businesses, civic organizations, neighborhoods, and freight, commuter, and environmental groups were represented on the task force. The group met 23 times over the course of the project development phase to advise the CRC Project team and provide guidance and recommendations at key decision points. The task force concluded its work in summer 2008 after making its recommendation on the locally preferred alternative.

2.2 Project Need

The specific needs to be addressed by the proposed action are:

- **Growing travel demand and congestion**: Existing travel demand exceeds capacity of the I-5 bridges and associated interchanges. This corridor experiences heavy congestion and delays lasting 4 to 6 hours daily during the morning and afternoon peak travel periods and when traffic accidents, vehicle breakdowns, or bridge lifts occur. Due to excess travel demand and congestion in the I-5 bridge corridor, many motorists take the longer, alternative Interstate 205 (I-205) route across the river. Spillover traffic from I-5 onto parallel arterials such as Martin Luther King Jr. Boulevard and Interstate Avenue increases local congestion. In 2005, the two crossings carried 280,000 vehicle trips across the Columbia River daily. Daily traffic demand over the I-5 crossing is projected to increase by more than 35% during the next 20 years, with stop-and-go conditions increasing to approximately 15 hours daily if no improvements are made.
- **Impaired freight movement**: I-5 is part of the National Truck Network and the most important freight highway on the West Coast, linking international, national, and regional markets in Canada, Mexico, and the Pacific Rim with destinations throughout the western United States. In the center of the program area, I-5 intersects with the Columbia River's deep-water shipping and barging, as well as two river-level transcontinental rail lines. The I-5 crossing provides direct and important highway connections to the Port of Vancouver and Port of Portland facilities located on the Columbia River, as well as the majority of the area's freight consolidation facilities and distribution terminals. Freight volumes moved by truck to and from the area are projected to more than double over the next 25 years. Vehicle-hours of delay on truck routes in the Portland-Vancouver area are projected to increase by more than 90% over the next 20 years. Growing demand and congestion will result in increased delay, costs and uncertainty for all businesses that rely on this corridor for freight movement.

The duration of **congestion** on the I-5 bridges roughly doubled over the past 14 years. In 2019 there were almost 12 hours of congestion per day.

Travel demand in 2019 exceeded capacity during peak periods on the Interstate Bridge on weekdays and weekends. The total number of vehicles using the bridge was 143,400 (average weekday daily traffic).

Over 14,000 **freight trips** crossed the Interstate Bridge daily in 2019, accounting for just under 10% of daily traffic across the bridge. Freight volumes moved by truck, to and from the area, are expected to increase by 50% to 75% over the next 25 years.

Bus travel times in 2019 were four times longer during the morning peak period compared to off-peak periods.

- **Limited public transportation operation, connectivity, and reliability**: Due to limited public transportation options, a number of transportation markets are not well served. The key transit markets include trips between the Portland Central City and the city of Vancouver and Clark County; trips between north/northeast Portland and the city of Vancouver and Clark County; and trips connecting the city of Vancouver and Clark County with the regional transit system in Oregon. Current congestion in the corridor adversely impacts public transportation service reliability and travel speed. Southbound bus travel times across the bridge are currently up to three times longer during parts of the a.m. peak compared to off peak. Travel times for public transit using general purpose lanes on I-5 in the program area are expected to increase substantially by 2030.
- **Safety and vulnerability to incidents**: The I-5 river crossing and its approach sections experience crash rates more than twice the statewide averages for comparable facilities. Incident evaluations generally attribute these crashes to traffic congestion and weaving movements associated with closely spaced interchanges and short merge distances. Without breakdown lanes or shoulders, even minor traffic accidents or stalls cause severe delay or more serious accidents.
- **Substandard bicycle and pedestrian facilities**: The bike/pedestrian facilities on the I-5 bridges are about 3.5 to 4 feet wide, narrower than the 10-foot standard, and are located extremely close to traffic lanes, thus impacting safety for pedestrians and bicyclists. Direct pedestrian and bicycle connectivity are poor in the program area.
- **Seismic vulnerability**: The existing I-5 bridges are in a seismically active zone. They do not meet current seismic standards and are vulnerable to failure in an earthquake.

The program area experiences **crash rates** nearly three times higher than statewide averages for comparable facilities. There were seven fatal crashes in the program area between 2015 and 2019. Crashes in the IBR Program area could increase by over almost 30% by 2045 if no improvements are made.

The existing **shared use paths** are narrower than current standards and are not compliant with the Americans with Disabilities Act. The paths are in close proximity to traffic lanes, which for bicyclists and pedestrians increases the exposure to vehicular traffic, noise, and emissions.

Seismic issues include that the structures lack the ductility of similar modern bridges and that both bridge spans are supported by hundreds of timber piles that sit within loose sand that will liquefy during a strong earthquake. The combined effect—settlement and lateral movement—would prove devastating to the bridge spans, likely triggering their collapse even if the bridge managed to somehow survive the shaking.

3. CRC PROJECT ALTERNATIVES ANALYSIS, SCREENING, AND SELECTED ALTERNATIVE

For the CRC Project, an alternatives development, screening, evaluation, and refinement process was conducted under NEPA, which led to the selection of a reasonable range of alternatives that were studied in the CRC Draft Environmental Impact Statement (EIS). A wide range of transportation alternatives and improvements were considered during screening and subsequent evaluation, including bored tunnels as well as supplemental and replacement bridges of different heights and types, such as movable-span bridges and fixed-span bridges.

Two rounds of evaluation and screening (known as Step A and Step B) were conducted for the CRC Project to narrow these components. In April 2006, the Step A screening evaluated 37 transit and crossing components. Step A focused on whether a component could meet the Purpose and Need statement; any components that failed to meet the Purpose and Need were dismissed from further study. The screening eliminated 22 river crossing types and transit modes, including a replacement bored tunnel and high-level bridges (such as cable stay or suspension bridges) that would encroach on protected airspace for Pearson Airfield and not improve safety or decrease vulnerability to incidents compared to a mid-level bridge.

During the Step B screening in June 2006, the remaining 15 crossing and transit components were scored on the adopted project values,[3] which were developed and formalized by the CRC Task Force. The intent of the Step B screening was to evaluate the remaining components against a more detailed set of criteria, so that only the most promising and potentially effective components would be advanced into alternatives packaging and modeling. All of the components that entered the Step B round were advanced for further evaluation.

While all components passed Step B, additional analysis was being completed at the same time to further screen several components. Further evaluations and additional information revealed substantial issues with several river crossing components, including low-level bridges and a supplemental bored tunnel, and these were dismissed from further study. At the June 14, 2006, CRC Task Force committee meeting, members passed two motions without opposition to eliminate further consideration of all supplemental and replacement movable-span and tunnel alternatives. Representatives of partner agencies, including City of Portland, City of Vancouver, Oregon Metro (Metro), Southwest Washington Regional Transportation Council, Tri-County Metropolitan Transportation District of Oregon (TriMet), Clark County Public Transportation Benefit Area Authority (C-TRAN), Port of Vancouver, and Port of Portland, were in attendance.

[3] The adopted project values were community livability and human resources; mobility, reliability, accessibility, congestion reduction, and efficiency; safety; regional economy, freight mobility; stewardship of natural resources; and distribution of benefits and impacts.

As summarized above and detailed in the CRC Final EIS, a thorough and detailed alternatives analysis was conducted for the CRC Project that considered numerous types of river crossings. The outcome of this process identified the reasonable range of alternatives that were evaluated in the Draft EIS, which consisted of four build alternatives (two supplemental crossings and two replacement crossings) and one no-build alternative.

The approved Selected Alternative for the CRC Project was described in the 2011 ROD and included a replacement fixed-span bridge with 95 feet of vertical clearance over the primary navigation channel. Following the issuance of the ROD, the project entered the final design and permitting phase. In response to the concerns raised by the USCG, impacts on the ability of the USACE dredge Yaquina to transit the bridge, and concerns raised by other river users over the bridge height in the ROD, the project team evaluated options for a mid-level bridge with greater vertical clearance for navigation. Based on the analysis in the CRC NIR, the project team decided to refine the bridge design and increase the vertical clearance to 116 feet. In 2012, the CRC Project team conducted a NEPA reevaluation to determine whether refining the bridge's proposed vertical clearance to 116 feet and the new information on river users and vessels would result in any new significant adverse environmental impacts that were not evaluated in the previous NEPA process. The reevaluation concluded that there were no new significant impacts under NEPA for the 116-foot bridge. A permit application and supporting materials were provided to the USCG and a permit was issued for a bridge with this vertical clearance in 2013; however, that permit was contingent on securing other required permits and authorizations as well as implementing mitigation to affected marine users. The mitigation effort was halted when the CRC project was suspended, therefore making the permit issued by the USCG inexecutable.

A bridge height of 116 feet was selected based on the vessel analysis contained within the 2012 NIR and because that height balances the needs of navigation and surface transportation while minimizing additional landside and environmental impacts. A bridge height of 116 feet would allow the project to avoid or minimize impacts to nearly all river users and vessels and to mitigate the remaining impacts.

As detailed in Section 2 and Section 3, the Purpose and Need statement and the proposed main river crossing component of the program have not changed since 2013. The proposed replacement of the existing two lift span bridges with two fixed-span bridges that provide a vertical navigational clearance of 116 feet over the primary navigation channel is the result of several decades of work, which included a thorough review of various river crossing options to select a crossing that best meets the needs of all users while addressing the Purpose and Need statement. The IBR program conducted a NEPA reevaluation in 2021 that evaluated physical and contextual changes in the program area since 2013. Based on the reevaluation, FHWA and FTA determined that a supplemental EIS is required to update and supplement the design, evaluation of impacts and benefits, and mitigation commitments that led to the CRC ROD in 2011 and subsequent updates in 2012–2013.

4. SITE CONDITIONS

This section describes the site conditions at the river crossing location, including navigation considerations, existing conditions in the built and natural environment, and anticipated future conditions.

4.1 Navigation Considerations

The Columbia River, including both the main channel and the North Portland Harbor,[4] is considered a navigable waterbody. Vertical constraints on vessels are determined largely by vessel height, bridge height, and river water levels. As part of requirements for the Rivers and Harbors Act Section 9 Bridge Permit, the IBR program completed a NIR that included a survey of vessels that typically pass through the location of the bridges, including their vertical clearance needs. The following sections summarize existing navigation conditions on the Columbia River, anticipated future navigational needs, and the potential impacts to vessels from different vertical clearances at the Interstate Bridge.

4.1.1 Existing Navigation Conditions

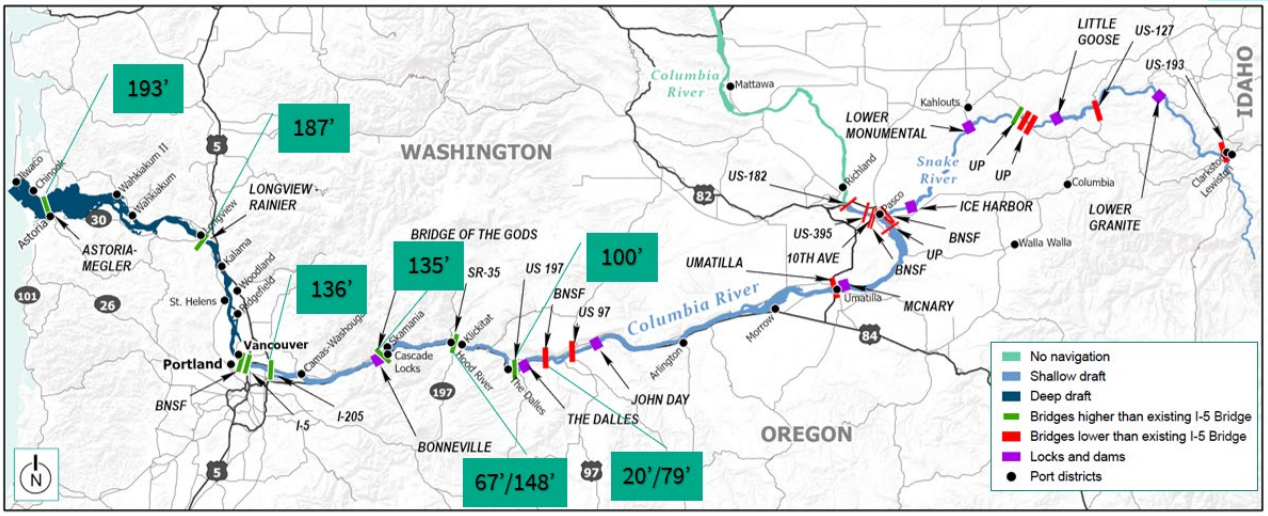
Through the Portland-Vancouver metropolitan area, the Columbia River is crossed by bridges at four locations: the I-5 crossing, known as the Interstate Bridge; the I-205 crossing, known as the Glenn L. Jackson Memorial Bridge; the BNSF Railway (BNSF) Vancouver railroad bridge; and the North Portland Harbor bridge. Figure 1 identifies the existing bridges over the Columbia River and their vertical clearances. The I-205 bridge is the closest crossing upriver (east) of the existing bridges and any vessels traveling upriver are restricted by that bridge's vertical clearance of 136 feet. An analysis of river users showed that most cargo comes from or is dropped at locations upriver of the I-5 bridges. There are numerous bridges between Vancouver and the cargo origins/destinations that have much lower vertical clearances, and the vessels are designed to accommodate those lower clearances.

Existing land uses are described in Appendix A of the NIR (Attachment A to this report). There are four existing water-dependent industrial sites within the jurisdiction of the City of Vancouver: CBC, Vigor, Marine Park marina, and the Western Forest Products property. It is likely that these areas will continue in industrial use. Only the uses at the CBC are currently height constrained, as detailed in the NIR. In addition, there are two marinas (McCuddy's Steamboat Landing Marina and Tidewater Cover Marina) and several private docks associated with private residences.

On the south side of the river, between the I-5 bridges and the I-205 bridge, there are many recreational marinas that are used by both powerboats and sailboats. See Attachment A for additional information on existing land uses and navigation needs.

[4] The North Portland Harbor is a side channel of the Columbia River that separates Hayden Island and the Oregon shore. This waterway is also known as the Oregon Slough.

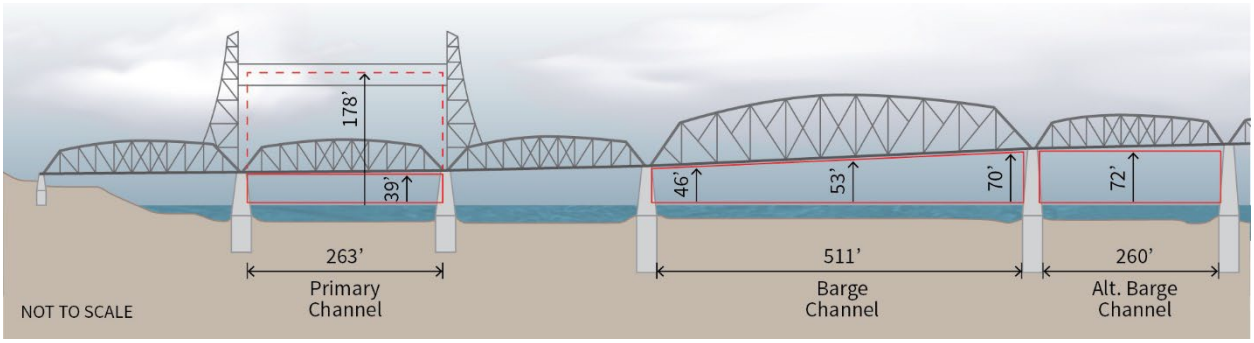
Figure 1. Existing Bridges Over the Columbia River



Under the I-5 bridges, vessels[5] pass through one of three channels: the primary channel, the barge channel, or the alternate barge channel. Figure 2 shows the vertical clearances provided by the existing I-5 bridges at both the lift span and fixed spans that align with the federal navigation channels. As shown, the primary channel lies under the existing lift spans and has a horizontal clearance of 263 feet and a vertical clearance of 39 feet in the closed position and 178 feet in the fully raised position. The highest clearance of the barge and alternate barge channels provides a vertical clearance of 72 feet.

[5] Vessels currently using the river in the vicinity of the IBR program area include tugs and barges, recreational sailboats and powerboats, marine contractor barges with construction cranes and materials, cruise and passenger boats, dredges, government vessels, vessels transporting shipments of marine industrial businesses and fabricators, and others.

Figure 2. Vertical Clearances Provided by the Existing I-5 Bridges



*Vertical clearance shown relative to 0 feet Columbia River Datum

Note: This figure is looking east (upriver), with the City of Vancouver to the left and the City of Portland to the right.

Most vessels do not require an opening of the lift span because they are low enough to transit the bridge using the vertical clearance provided by one of the three channels. Between 2012 and 2020, the lift span was used for vessels an average of 157 times per year (i.e., excluding lifts for maintenance and training). The existing I-5 bridges are opened for approximately 5% to 7% of river traffic. Figure 3 shows the number of bridge lifts per vessel type. Tugs and barges are responsible for the largest share of bridge openings (58%), followed by sailboats (33%).

Figure 3. Annual Bridge Openings: 2012–2020

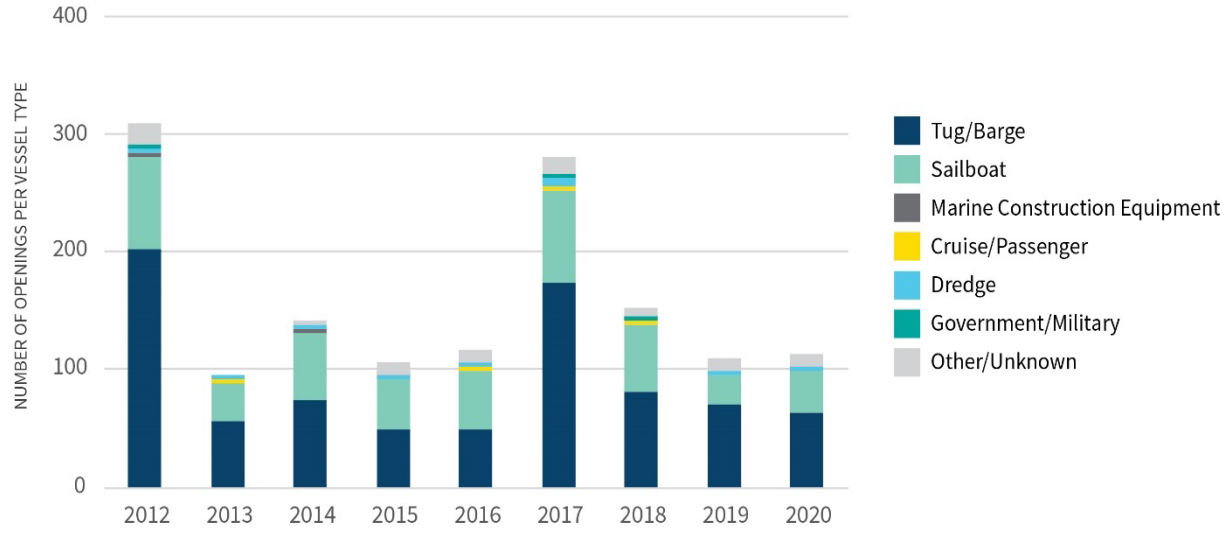


Table 1 lists the number of estimated openings per year and the number of vessels that would require an opening and could be restricted from passing at specific times when the bridge is restricted from

opening per federal regulations. This does not include separate openings that may be needed for maintenance and training. The Code of Federal Regulations (CFR) stipulates that the current bridge shall not be opened for vessels Monday through Friday from 6:30 a.m. to 9 a.m. or from 2:30 p.m. to 6 p.m. (CFR Title 33 Chapter I Subchapter J, Part 117 § 117.869), corresponding to peak commute times. A replacement bridge with an opening would likely include similar restrictions and, depending on the vertical clearance provided in the closed position, may seek to further restrict openings to the period of lowest vehicular traffic (i.e., midnight to 4 a.m.).

Table 1. Number of Bridge Lifts per Year by Vertical Clearance

Bridge Height[a] (closed or highest fixed span)	Estimated Openings/Year	Number of Vessels/Users Requesting a Bridge Opening
116 feet[b]	85[c]	9[d]
95 feet	154[e]	53[e]
72 feet	157[f]	270[g]

a. Bridge heights as measured from 0 feet Columbia River Datum. For purposes of calculating potential bridge openings, water is assumed to be 16 feet Columbia River Datum.

b. During the CRC Project, agreements were negotiated with the four impacted users that were unable to modify operations (such as accepting an air gap of less than 10 feet) in order to transit a bridge height of 116 feet. Three upstream fabricators entered into agreements with the CRC Project. The anticipated agreements would have resulted in payments to the companies that would be used by the companies at their business discretion and control. Payments were never made as the project was stopped. The remaining vessel owner decided to terminate negotiations that involved a payment to compensate the owner for vessel modifications and an agreement was never finalized.

c. Based on vessels identified in the 2021 Navigation Impact Report and reported frequency of transit provided by user.

d. Represents worst case scenario. Five of the nine vessels would not require an opening based on mitigation such as accepting a lesser air gap, thereby also reducing the estimating openings per year.

e. Based on the CRC Navigation Impact Report and updated with 2012 to 2020 lift data and updated user information from the 2021 Navigation Impact Report.

f. Based on the average number of lifts for vessels for the existing bridge from 2012 to 2020, as 72 feet is the height of the highest fixed span on the existing bridge. This likely overestimates the number of openings by a small number because some openings are not due to height constraints. Additional lift data analysis is underway to narrow the potential overestimates regarding the number of openings.

g. Represents the number of distinct vessels noted in bridge logs from 2012 to 2020. Not every vessel requires a lift every year, and some vessels occur only once in the data.

Table 2 identifies the various categories of vessels and notes whether they would or would not be affected by a span with vertical clearances of 100 feet, 116 feet, and 125 feet. The majority of vessels and river traffic would not be impacted by any of the fixed-span bridges shown. However, a bridge height of 100 feet would result in certain key vessels not being able to transit the bridge, such as the dredge Yaquina, that are critical for river operations as well as certain marine construction equipment and the tallest sailboats that are locally based. Certain marine contractors and industrial fabricators would be impacted at any of the heights shown.

Table 2. Bridge Height Impacts Comparison, 2012–2020

Vessel Type	Air Draft (typical)	100 feet	116 feet	125 feet	Vessel Frequency	Annual Lift Frequency
Tugs and Tows	<60 feet	Not impacted	Not impacted	Not impacted	High	64.2
Sailboats	<90 feet[a]	Impacted	Not impacted	Not impacted	High	18.8
Marine Contractor Equipment	40 to 90 feet[b]	*Sometimes impacted*	*Sometimes impacted*	*Sometimes impacted*	Unknown	Unknown
Cruise Ships	48 to 63 feet	Not impacted	Not impacted	Not impacted	High	0.1
Tall Ships	90 feet[c]	*Sometimes impacted*	Not impacted	Not impacted	Very Low	0.4
USCG Juniper Class Buoy Tenders	83 feet	Impacted	Not impacted	Not impacted	Not impacted	0.2
USACE Dredge Yaquina	92 feet	Impacted	Not impacted	Not impacted	Not impacted	2.4
U.S. Navy Vessels	43 to 59 feet	Not impacted	Not impacted	Not impacted	Not impacted	0
Fabricators/ Industrial Freight	Up to 178 feet	Impacted	Impacted	Impacted	Very Low	Unknown[d]

a. One sailboat with a reported vessel height of 120 feet was responsible for two bridge lifts during the 8-year period. This vessel is no longer based in the area.

b. Two contractors reported vessel heights of 120 feet or greater.

c. Step down mast to 65 feet.

d. Only Thompson Metal Fab Inc. reported trip details. Lift data from the Oregon Department of Transportation does not have detail to determine other trips. From 2012 to 2020, Thompson Metal reported 14 trips. Of these, 12 would be able to transit a bridge height of 100 feet, one trip would have not been able to transit a bridge height of 125 feet or less and one trip would not have been able to transit a bridge height of 100 feet or less.

4.1.2 Future Navigation Needs

The lifespan of the proposed replacement bridge, future industrial development upstream of the I-5 bridges, and future vessel sizes were considerations taken into account when identifying future navigation needs on this section of the Columbia River. The replacement river crossing will likely be designed for a service life of 100 years or more, and the NIR considered potential impacts from prospective upstream commercial development that could result in different navigation on the

waterway. The analysis concluded that both political and geographic constraints were the primary factors affecting commercial/industrial development along the upstream waterway.

Land use restrictions imposed by the Columbia River Gorge National Scenic Area, topography, transportation access parallel to shorelines (SR 14, Interstate 84, and BNSF and Union Pacific Railroad), and existing open spaces limited the areas for future water-dependent land uses. All of the industrial uses between the BNSF bridge and BNSF Celilo Falls rail bridge are in urban areas and primarily within established industrial parks (e.g., Columbia Business Center, Port of Cascade Locks Industrial Park). According to the Future Use Analysis conducted for the NIR, there are no planned developments within the subject area[6] that would be served by marine transport that could be limited by a proposed replacement bridge with a vertical navigation clearance of 116 feet.

Efforts are underway in upriver counties to reuse vacant or underutilized industrial waterfront parcels in forest products manufacturing (which is not height constrained) or in non-water-dependent uses, including commercial business parks, mixed-use residential/commercial developments, and tourist centers.

There has been an overall trend in the shipping industry to larger vessel sizes.[7] This is particularly evident for container ships and other ocean-going vessels to take advantage of efficiencies and the increased ability of major navigation routes such as the Panama Canal.[8] Some vessels of this type operate in the Lower Columbia River, but there are no suitable origins or destinations located upstream of the I-5 bridges. The majority of the vessel traffic on the Columbia River are tugs and barges. These are limited by the size of the Columbia River lock system and other upstream vertical and horizontal constraints and have not seen a change in sizes or dimensions during the same period as ocean-going vessels. Because there are no destinations for ocean-going vessels upstream of the I-5 bridges, this increase in vessel size is not expected to impact future navigation needs.

Vessels engaged in national defense activities or emergency response are also not expected to change. Current activity would not be limited by a proposed replacement bridge with a vertical navigation clearance of 116 feet. Larger vessels operated by the Military Sealift Command, such as the USNS Mercy hospital ship, infrequently visit the Lower Columbia River primarily for maintenance activities at the Vigor Swan Island facility or at other berths in the Columbia River. No needs to travel past the I-5 bridges have been identified in comments from agencies on the replacement bridge.

[6] The subject area for the Future Use Analysis was defined as extending from the I-5 bridges to the BNSF Railway rail bridge at Celilo Falls and landward from the river approximately 0.5 miles.

4.2 Existing Conditions

4.2.1 Airspace

There are two airports in proximity to the program area: Portland International Airport (PDX) in Portland, Oregon, and Pearson Field in Vancouver, Washington. PDX is located approximately 3 miles southeast on the Oregon side of the Columbia River and is the major regional airport. Pearson is located directly east of the existing I-5 bridges and is an active airfield managed by the City of Vancouver, serving general aviation users.

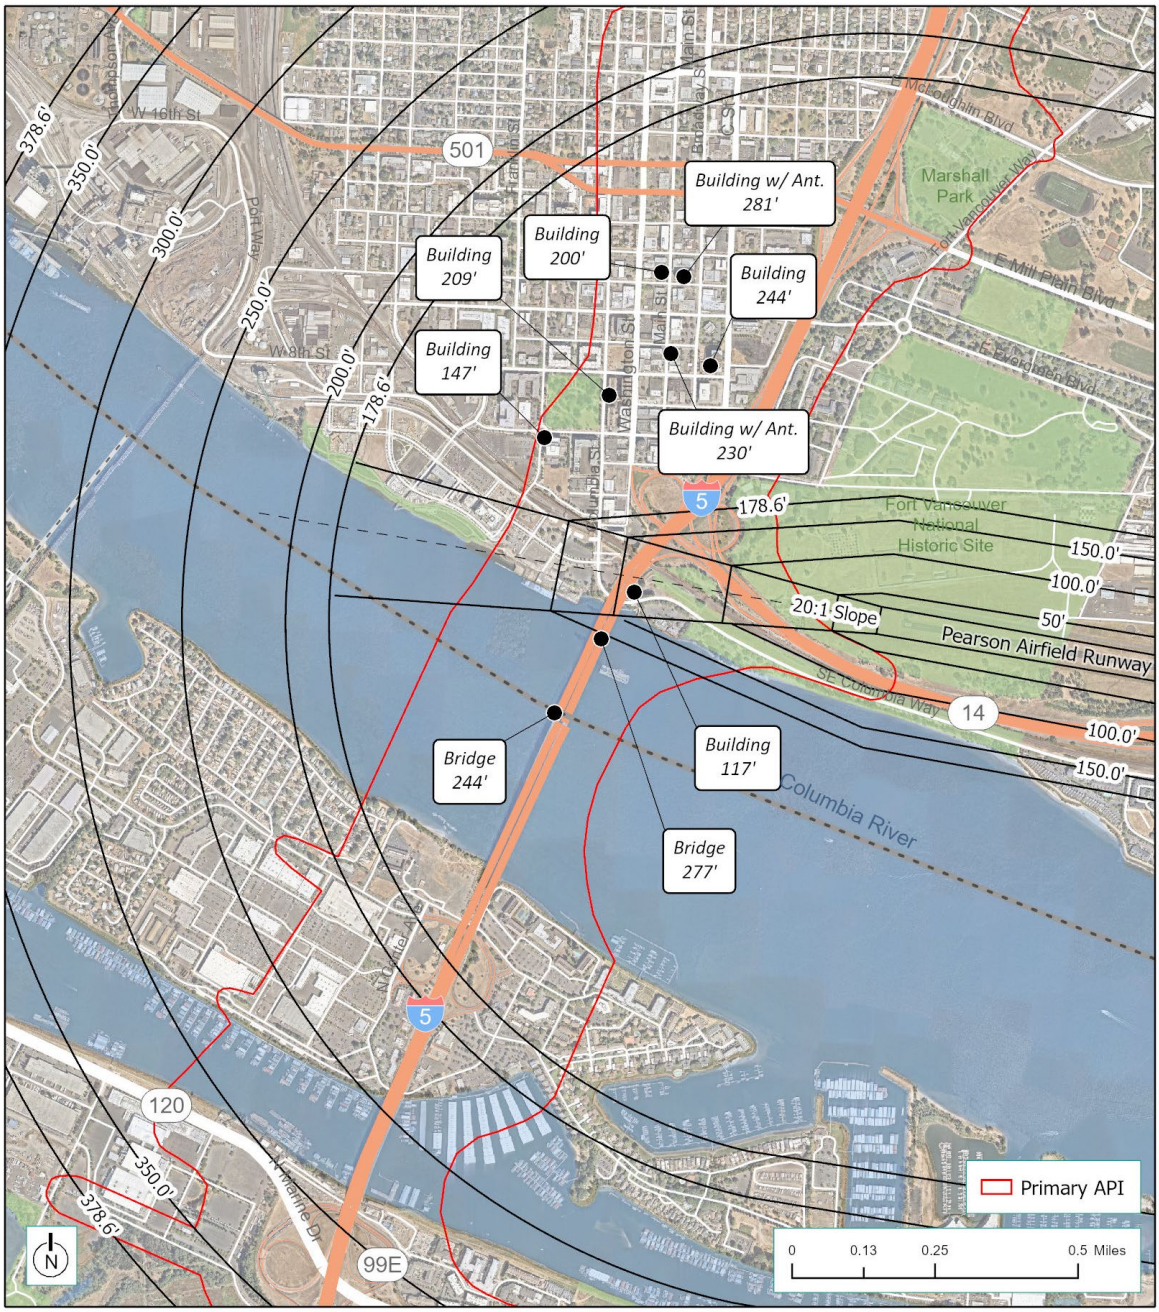
The departure and approach zones of both Pearson and PDX extend above the existing bridges and would therefore extend over the area of potential impact of a replacement river crossing. The previous analysis conducted for the CRC Project identified different types of airspace impacts that could occur with the CRC Project. The CRC analysis indicated that none the alternatives under consideration in the Draft EIS would have long-term effects on aviation activities at PDX, but they did have the potential to affect the aviation activities at Pearson. These included departure impacts associated with the proposed SR 14 interchange ramps and lighting and the proposed I-5 sign structures.

Any proposed changes to the Pearson Field Part 77 Airspace[9] will require review and approval by the Federal Aviation Administration (FAA). The IBR program would be required to submit a Form 7460 to the FAA for the program's design (by the designer) and one for construction (by the contractor). Each form would delineate any penetrations of the Part 77 Surface that would occur (permanent works relative to design and temporary works pertaining to construction). The FAA will use that information to determine if the proposed facility poses a hazard to air navigation or causes inefficient use of airspace.

Figure 4 shows the existing Part 77 airspace penetration for Pearson Field. As shown, the towers of the existing I-5 bridges currently penetrate this airspace as well as that of several buildings in downtown Vancouver. Pearson has special departure and take-off procedures that help the aircrafts avoid obstacles; aircrafts typically avoid flying directly over the existing bridges.

[9] FAA Title 14 CFR Part 77, Objects Affecting Navigable Airspace.

Figure 4. Existing Pearson Field Part 77 Airspace Penetration



If the FAA's review results in a hazard or inefficient use of airspace determination, the bridge or the means and methods of construction may have to be adjusted. Alternatively, it may be possible to restrict construction and/or airfield operations to accommodate any temporary intrusions. Permanent intrusions could require permanent airfield operational adjustments and the bridge owner would likely have to assume liability for any mishaps associated with the penetration(s). In the event

the bridge is determined to be a hazard and/or results in efficient use of airspace, the Authority Having Jurisdiction would have the option to take legal action to force a revision to or terminate the development.

4.2.2 Cultural Resources, Section 106, and Section 4(f)

There are numerous cultural and recreational resources in and near the IBR program area, including resources protected by Section 106 of the National Historic Preservation Act and/or Section 4(f) of the U.S. Transportation Act. Section 106 resources are properties that are listed or eligible for listing in the National Register of Historic Places, defined in the Section 106 regulations as "historic properties." Section 4(f) resources are publicly owned parks and recreation areas, waterfowl and wildlife refuges, and historic sites considered to have national, state, or local significance. A historic property is identified during the Section 106 evaluation and carried through to the Section 4(f) evaluation.

The historic built environment within the program area includes approximately 250 above-ground resources. These resources include residential, commercial, maritime, aviation, transportation, military, and other structures.

There is also a rich history of intertribal presence within the program area since time immemorial. As a result, the program area includes numerous high-significance resources. For the CRC Project, it was determined that all alternatives would be likely to impact these resources. Similarly, because potential impacts would be challenging to minimize or avoid under any alternative, it is anticipated that the IBR program would result in adverse effects on some archaeological resources as well.

There are approximately 200 Section 4(f) resources within the program area, including eligible historic resources, cultural resources, and public parks and recreation areas. As a result, Section 4(f) use and *de minimis* impact determinations are expected throughout the program area. Fort Vancouver, which is a National Historic Site managed by the National Park Service includes a plethora of sensitive resources (above and below ground) located throughout the property. These resources are protected under various regulations, including Section 106 and Section 4(f). Because of its proximity to the program area, adverse indirect and visual impacts to Fort Vancouver are possible. Figure 5 identifies the Section 4(f) parks and recreation resources near the program area, including National Historic Sites that are open to the public.

Figure 5. Section 4(f) Recreation Resources

4.2.3 Tribal Considerations

Native Americans have occupied this area since time immemorial. Pre-contact peoples established a strong relationship with the natural environment in addition to an expansive trade hub with other communities, fostering a cultural stronghold in the region across millennia. In the early 19th century, the Hudson's Bay Company established their regional headquarters at Fort Vancouver, building upon and integrating with the existing indigenous trading empire to establish a commercial epicenter and one of the largest settlements in the American West and connecting a wide range of diverse cultures with the resources in the region.

The IBR program recognizes and respects this expansive natural and cultural history, consulting with 11 Tribes and various natural resource organizations to ensure the program considers resources appropriately. Government-to-government consultation with 10 federally recognized Tribes is conducted regularly in addition to formal consultation under Section 106 of the National Historic Preservation Act.

Tribal considerations include culturally sensitive sites, impacts to aquatic species (including salmonid species and lamprey), aquatic and upland habitat, and water quality. Culturally sensitive sites include cultural resource locations on land and in the water, associated with the expansive cultural history of the area. Potential impacts on aquatic species and habitat and water quality include effects on fisheries upriver, downriver, and within the program area; treaty fishing sites above Bonneville; and culturally important species such as salmon, steelhead, lamprey, and eulachon. Potential sources of impacts include construction (e.g., pile driving and in-water work), direct habitat impacts, and stormwater runoff.

4.2.4 Habitat

The program area contains several different habitat types, including the Columbia River as well as North Portland Harbor and the Columbia Slough.[10] The Columbia River and North Portland Harbor provide habitat for a variety of native fish species (including Endangered Species Act [ESA]-listed species), such as several salmon and trout species, Pacific eulachon, and Pacific lamprey. Marine mammals are also present in the program area. The Columbia Slough is located in North Portland and provides habitat for many of the fish and wildlife species that use the Columbia River. The Columbia Slough provides some of the only remaining off-channel and refugia habitat[11] in the lower Willamette River area.

Terrestrial habitat within the program area includes fragmented forested riparian and wetland habitat, which supports species that are tolerant of human disturbance. The most highly functioning

[10] The Columbia Slough is a waterway just south of the program area.
[11] A location that supports an isolated and/or relict population of a once more widespread species. Relict populations are species that were more diverse and/or widespread in the past.

terrestrial habitats are those that still have connectivity to other areas with intact habitat. Figure 6 shows potential habitat areas in Vancouver, and Figure 7 shows potential habitat areas in Portland.

Key concerns for habitat related to the river crossing options include in-water work disturbing fish habitat and migration patterns, benthic habitat disturbance, and shading. Benthic habitats refer to the lowest ecological zone of a water body, including the sediment and substrate, and are generally areas of high biological activity, providing processes such as primary production, consumption, nutrient cycling and decomposition.[12] Benthic habitats provide a source of primary productivity for native fish, including several populations of ESA-listed salmon and steelhead, Pacific eulachon, white sturgeon, Pacific lamprey, and river lamprey.[13]

The river crossing options would have different impacts on habitats due to differences in the size of in-water structures (e.g., piers), length of time needed for in-water work, and construction methods (e.g., drilled shafts and pile driving for bridges or cut/cover and dredging for tunnels).

The program's effects on the different habitat types during construction would range from temporary to permanent impacts. Avoidance and minimization measures and best management practices would be implemented during construction to reduce habitat impacts. Impacts that are unavoidable would be mitigated through agency compensatory mitigation requirements, such as mitigation for waters of the U.S. Additional conservation efforts would be implemented for any impacts to habitats that are not currently covered under existing regulations, such as species of importance to Tribes.

[12] Benthic habitats within the Columbia River have been substantially altered from their historic condition by a variety of factors, including dredging activities; however, they continue to provide substantial habitat function to the aquatic species that rely on them.

[13] Shallow water benthic habitats in particular are important for out-migrating juvenile salmonids. Benthic habitats may provide substrate conditions that are suitable for adherence and incubation of Pacific eulachon eggs. Larval Pacific and river lamprey ammocetes burrow into benthic substrates and filter feed on algae, diatoms, and detritus for multiple years before metamorphizing into juveniles and out-migrating.

Figure 6. Potential Habitat in Vancouver, Washington

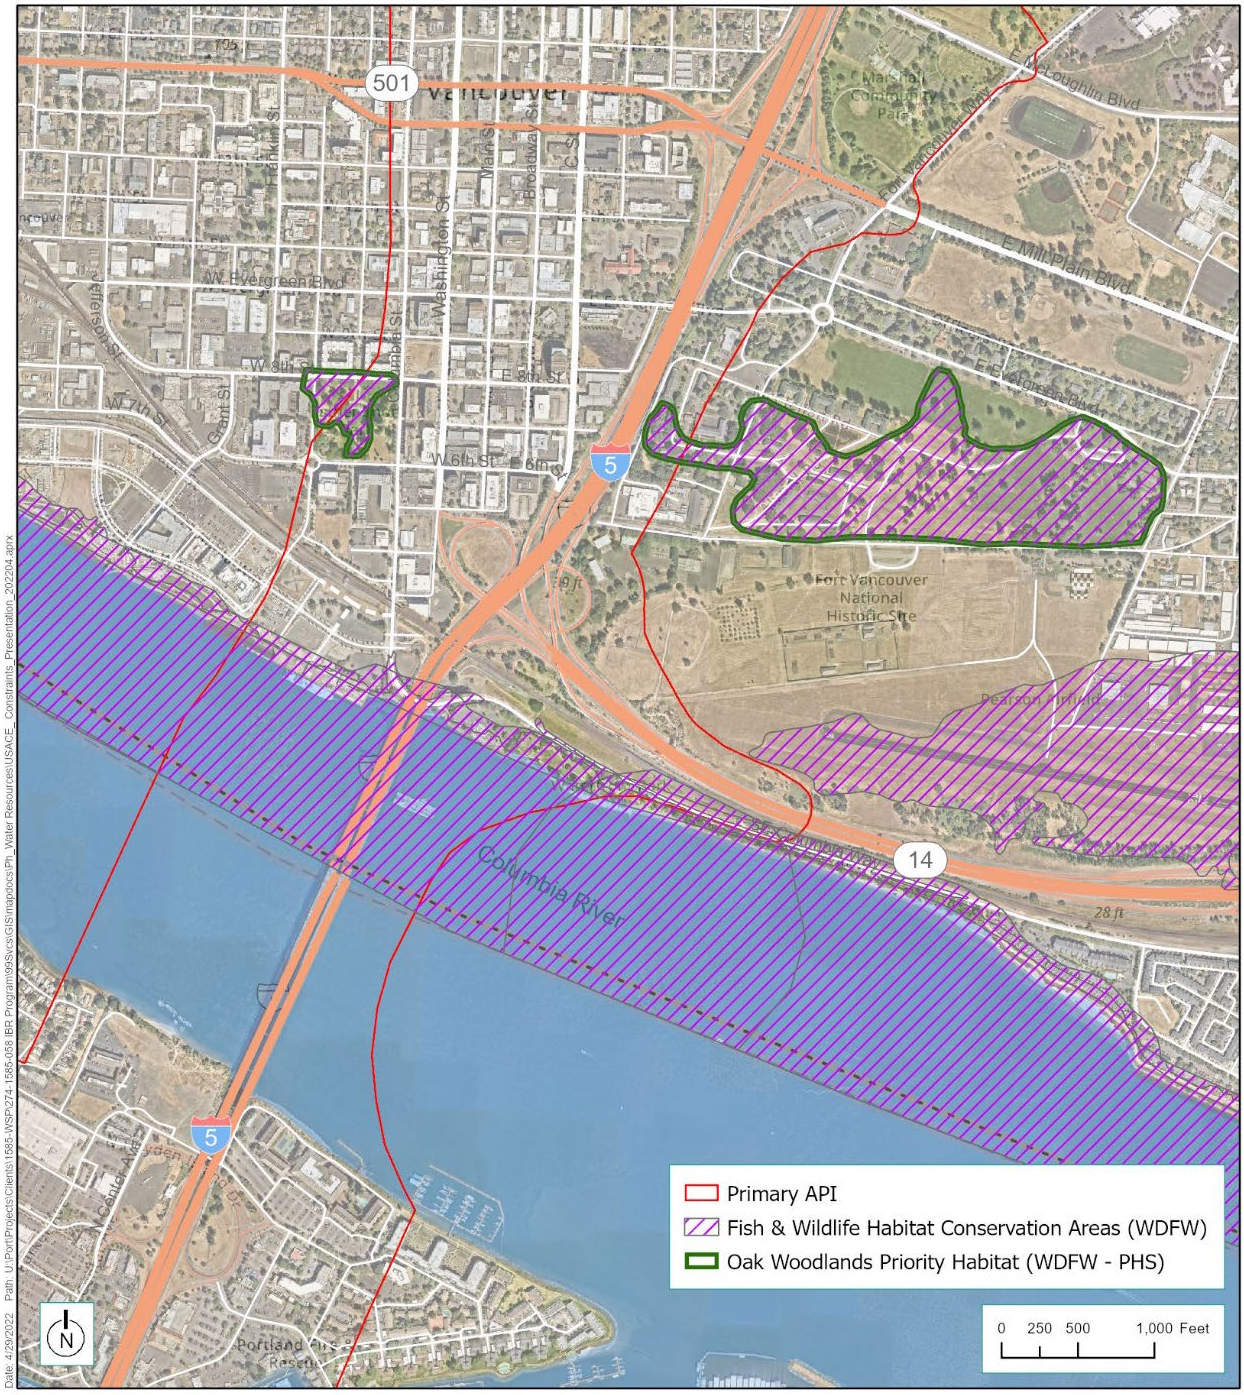


Figure 7. Potential Habitat in Portland, Oregon

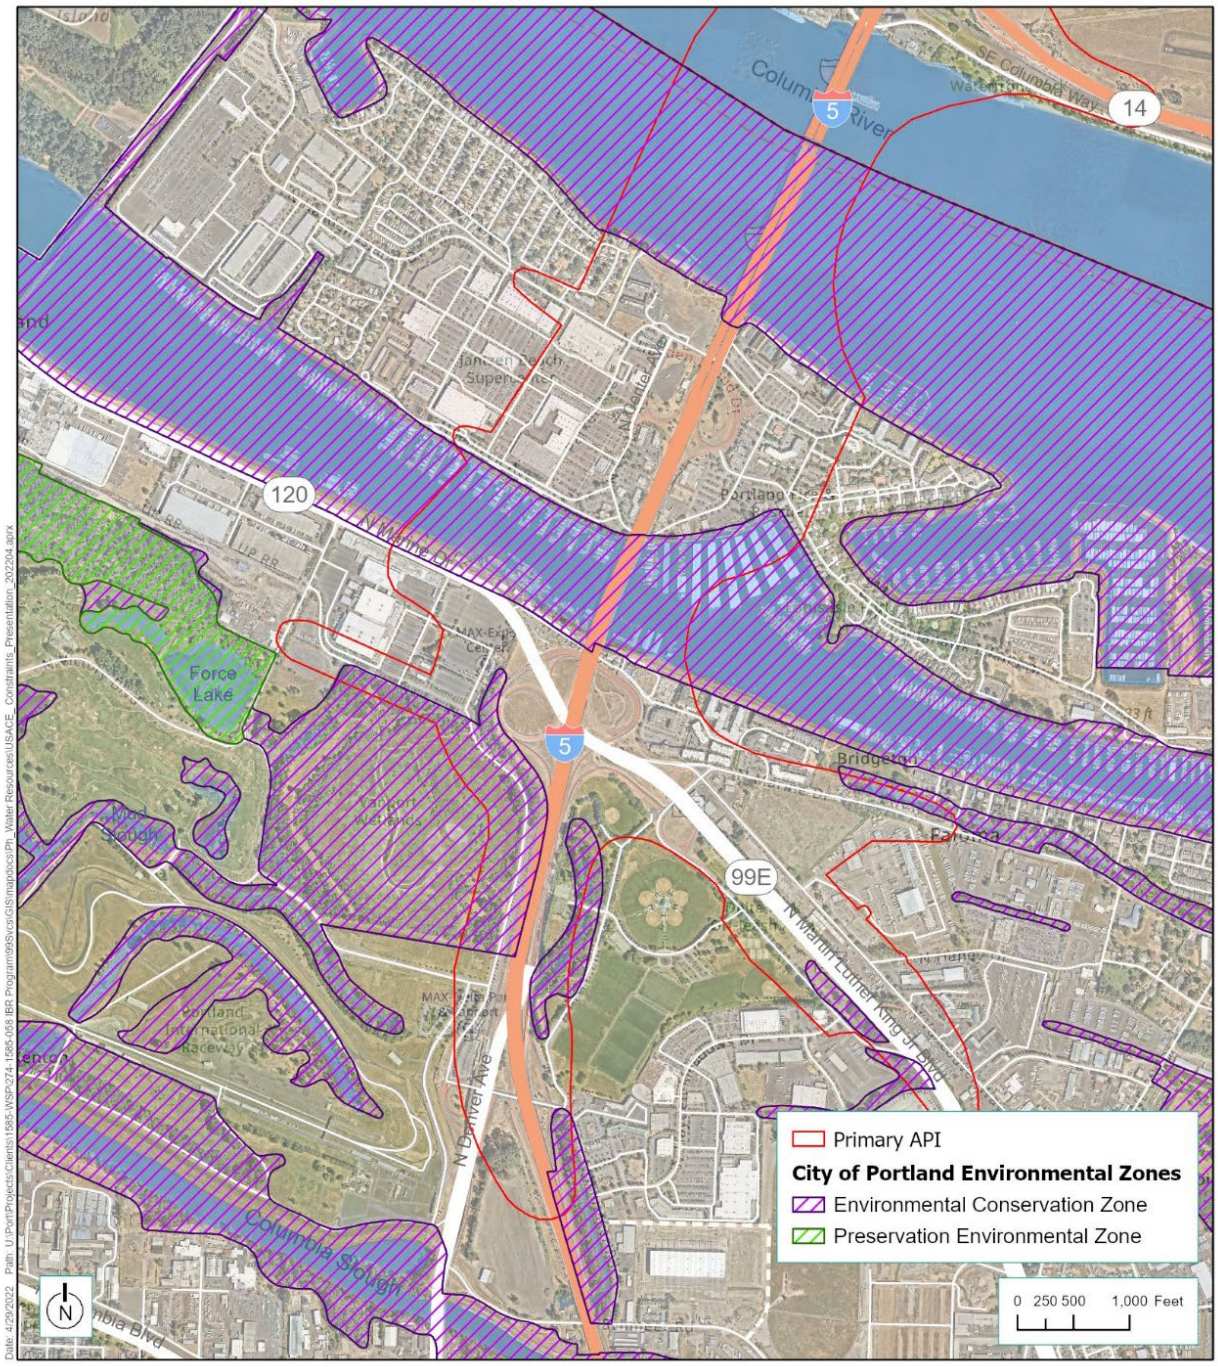


4.2.5 Highway and Local Road Connections

Traffic data from 2019 shows that the various highway and local road connections experience different levels of daily vehicle volumes. Table 3 and Table 4 show the northbound and southbound daily vehicle volumes at the SR 14, Downtown Vancouver (Washington Street and C Street), and Hayden Island on and off ramps. The largest volumes are at the on ramp and off ramp to SR 14. The various river crossing options, which are described in Section 5, have different effects on how vehicles access these ramps and local streets.

Table 3. 2019 Daily Vehicle Volumes at Highway and Local Road Connections on I-5 Southbound

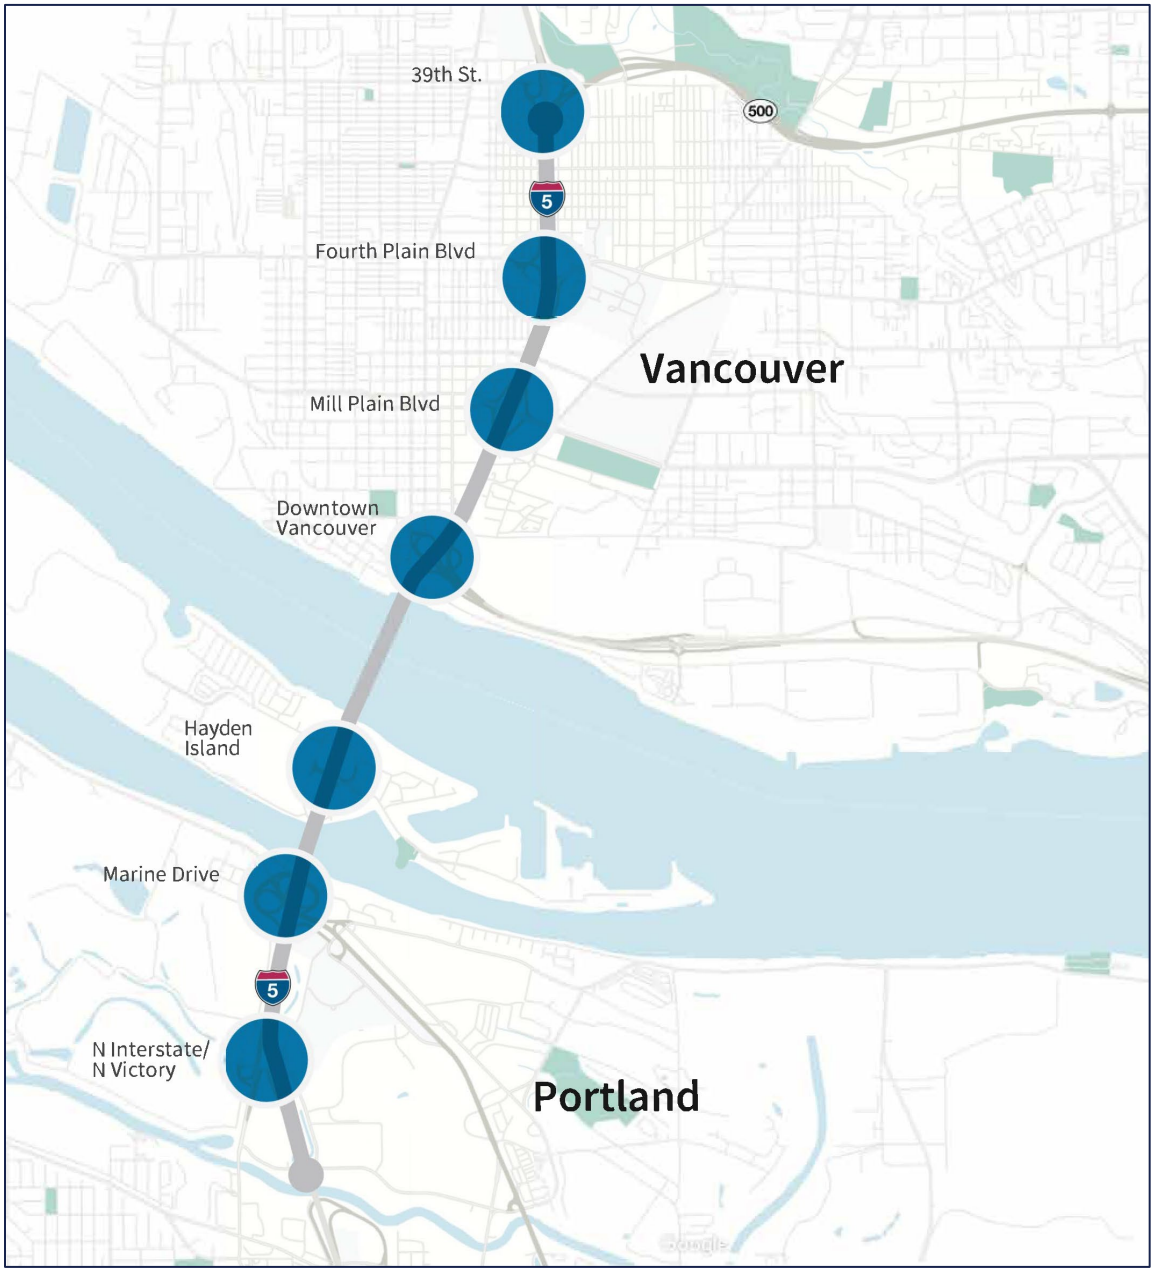
I-5 Southbound	2019 Daily Vehicle Volume
Off Ramp to SR 14 Eastbound	14,545
On Ramp from Washington Street (Downtown Vancouver)	3,680
On Ramp from SR 14 Westbound	11,220
Off Ramp to Hayden Island	8,730
On Ramp from Hayden Island	10,040

Table 4. 2019 Daily Vehicle Volumes at Highway and Local Road Connections on I-5 Northbound

I-5 Northbound	2019 Daily Vehicle Volume
On Ramp from SR 14 Westbound	16,505
Off Ramp to C Street (Downtown Vancouver)	3,110
Off Ramp to SR 14 Eastbound	13,110
On Ramp from Hayden Island	7,990
Off Ramp to Hayden Island	10,040

Figure 8 identifies the seven existing interchanges on I-5 within the program area. Depending on the type of river crossing selected, some of these interchanges may be eliminated if an option cannot connect to the existing routes in these locations. Eliminated interchanges would, in turn, affect the daily vehicle volumes experienced at other interchanges.

Figure 8. Interchanges in the Program Area



4.3 Future Considerations

Future considerations that may affect the river crossing include sea-level rise and the planned transportation networks in Portland and Vancouver, including active transportation, high-capacity transit, and highway design. The future transportation improvements described below include improvements proposed by the IBR program and local/regional partners.

4.3.1 Sea-level Rise

The IBR program is considering the potential effects of sea-level rise on the program, including how future conditions such as river levels and extreme weather events might impact the river crossing. Information on anticipated future conditions from the Climate Change Impacts Group[14] and the U.S. Geological Survey[15] was reviewed. Because of the distance from the ocean and the height above sea level, the anticipated effects of sea-level rise are reduced at the program site. A 0.5-foot increase in Columbia River levels is expected at Vancouver, based on a 3.3-foot (1-meter) sea-level rise.

Because the best available science provides no quantitative predictions of how daily or monthly average flows could change, it is difficult to translate the general climate change predictions into precise conclusions regarding future vessel clearances. However, a 0.5-foot increase would not be expected to change any vessel impacts due to the use of the ordinary high-water mark (OHWM) for determining available vertical clearance. Water levels are below the OHWM over 98% of the time and the river already has daily fluctuations greater than the predicted 0.5 foot increase due to tidal influence; therefore, the effect of sea level rise on water levels near the bridge area would be negligible.

In addition to river level changes caused by global sea-level rise, two planning efforts are underway and would have the potential to influence water levels at the I-5 bridges: the modernization of the international Columbia River Treaty between the U.S. and Canada and the proposed removal of the four lower Snake River dams. The IBR program is aware of these ongoing plans and all river crossing options will be designed in consideration of potential impacts in the program vicinity.

For these reasons, sea-level rise can be planned for/accommodated under any of the river crossing options (but may require specific design details).

A collaboration of Washington Sea Grant, University of Washington Climate Impacts Group, University of Oregon, University of Washington, and U.S. Geological Survey. Prepared for the Washington Coastal Resilience Project. Updated July 2019.
[15] Assessment of Columbia and Willamette River Flood Stage on the Columbia Corridor Levee System at Portland, Oregon, in a Future Climate. Scientific Investigations Report 2018–5161.

4.3.2 Active Transportation

Active transportation refers to human-powered modes of transportation, such as walking, biking, or rolling (e.g., using a wheelchair or scooter). Feedback from the community reinforced that improved connectivity between high-capacity transit and active transportation facilities is an important priority of the program. As part of the IBR program, there would be active transportation improvements, including a separated shared use path (SUP) on the river crossing. The SUP would have transit connections and connections to existing/planned trails and destinations, such as the Renaissance Trail, Columbia Way, and Hayden Island. Additionally, the highway design proposed by the IBR program will have a grade less than or equal to 5%, meeting Americans with Disabilities Act standards for the SUP.

4.3.3 High-capacity Transit

C-TRAN and TriMet both operate transit service in the program area. There is a benefit gained by integrating the established transit modes from both C-TRAN and TriMet with the transit component of the IBR program. C-TRAN designed their overall operations as a feeder-system to TriMet's expanded light rail service, which allows for the integration of a light rail terminus to provide effective reach into the transit services operated by C-TRAN.

The IBR program, with the support of local partners, is proposing a light rail transit extension of the TriMet's Yellow line from the Expo Center across the Columbia River and into Vancouver, terminating at Evergreen Boulevard, which best integrates existing transit investments in the region. To merge the two metro area transit systems together, the Evergreen bus terminus offers the best opportunity for faster, safer, and more reliable service while minimizing disruptions to downtown Vancouver.

4.3.4 Highway Design

The IBR program includes highway improvements on I-5 between SR 500 and Victory Boulevard, including modifications to seven interchanges. The general configuration of five interchanges would not change, but two interchanges would be modified: a full interchange would be located on Marine Drive and a partial interchange would be on Hayden Island. The IBR program is proposing a partial interchange on Hayden Island and a full interchange on Marine Drive and adding one auxiliary lane northbound and one auxiliary lane southbound between Marine Drive in Portland and Mill Plain Boulevard in Vancouver.

The IBR program also proposed adding one auxiliary lane northbound and one auxiliary lane southbound between Marine Drive in Portland and Mill Plain Boulevard in Vancouver, including on the replacement river crossing.

5. RIVER CROSSING OPTIONS

There are several types of river crossings that could be used to cross the Columbia River, either going under the river (tunnels) or over the river (bridges). These options provide different horizontal and vertical clearances for maritime navigation. Each option has both advantages and disadvantages in terms of meeting the Purpose and Need statement (Section 2), potential impacts to site conditions (Section 4), and other considerations, such as constructability and cost. The following sections provide an overview of each crossing option and identify the advantages, disadvantages, and other considerations that must be taken into account when identifying the preferred river crossing option for the IBR program.

The concepts assessed in this report are preliminary. They are not under design and remain at the planning conceptual level. They will not be advanced to the design stage until or unless deemed appropriate and necessary by program leadership in coordination with agency partners.

5.1 Tunnels

The IBR program investigated two types of tunnels that could potentially be used as a crossing for the Columbia River: a bored tunnel and an immersed tube tunnel (ITT). As described below, these tunnels differ in construction methods, possible alignments, general design, and some impacts (e.g., they have different upland connections) but are similar in other impacts (e.g., they both provide unlimited vertical clearance and eliminate over-water shading, etc.).

5.1.1 Bored Tunnel

A bored tunnel is constructed using a tunnel boring machine (TBM), which digs a bore (or tube) under the ground surface. For the IBR program's anticipated traffic and transit needs, a bored tunnel option would likely include four discrete bores, including two adjacent bores for vehicles (each up to 60 feet in diameter and spaced 60 feet apart) and two adjacent bores for transit (each 21 feet in diameter and spaced 20 feet apart); however, consideration would be given to a single, large-diameter transit bore during design development. Given this preliminary side-by-side layout, a bored tunnel option under the Columbia River would result in a footprint approximately 260 feet wide.

Figure 9 shows a cross section of the SR 99 tunnel in Seattle, which consists of a single 56-foot bored tunnel with two lanes of traffic each way. A similar cross-section would initially be considered for the large-diameter vehicular bores for the IBR program.

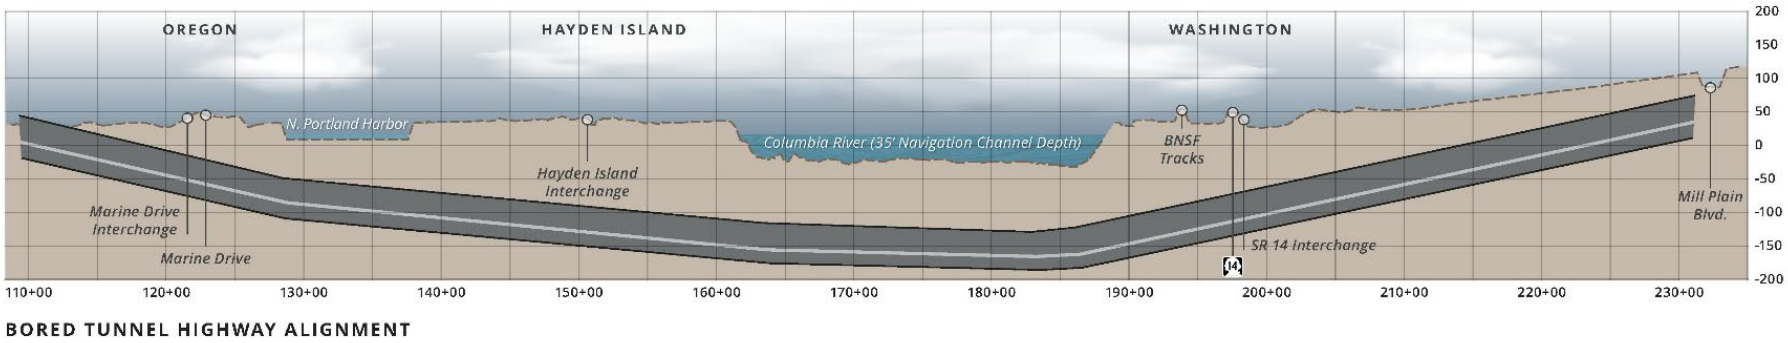
Figure 9. Bored Tunnel Example – SR 99 Tunnel in Seattle

A profile concept for the larger, vehicular tunnel bores is provided in Figure 10. As shown, the bored tunnels would daylight south of Victory Boulevard and north of Mill Plain Boulevard, eliminating the existing interchanges (and their local connections) at Victory Boulevard, Marine Drive, Hayden Island, SR 14, and Mill Plain Boulevard. The top of the bores would initially be set at approximately 60 feet below river bottom, extending to approximately 175 feet below river bottom (at the lowest point of the tunnels). The steepest road grade in each tunnel would be between 4% and 4.5%. Transit stations between the tunnel portals would need to be located at significant depth below street level; however, it should be noted that a twin bore solution for the transit tunnel would allow for shallower tunnel and station depths than a four-bore tunnel, and refinement of layout of the respective bores would occur during design development. Additionally, design development for the bored tunnel would entail assessing ground improvements below the river to shallow up the profile of the respective bores, thereby reducing length and cost. This approach would require environmental clearances and would be evaluated on the basis of its benefits and/or impacts to the project cost and schedule.

In addition to the IBR program's evaluation, it should also be noted that bored tunnel options, including replacement and supplemental tunnels, were evaluated as part of the alternatives screening process during the CRC Project's alternatives analysis (described in Section 3). A replacement tunnel would be the only structure for the crossing as the I-5 bridges would be demolished. A supplemental tunnel would accommodate approximately half of the vehicular traffic on I-5, and the existing bridges would be retrofitted to handle the remainder.

In recent discussions with partner agencies, the IBR program revisited prior evaluations, reconfirmed the findings of the CRC screening process, and concluded that a bored tunnel would still not meet the Purpose and Need. Specifically, a replacement bored tunnel would fail to fulfill four needs because the tunnel would surface south and north of much of the program area, thereby not serving most of the access needs for this section of I-5, including the needs of active transportation, transit, private vehicles, and freight. In addition, a bored tunnel option presents significant, though not insurmountable, construction challenges and impacts, such as potential impacts to Fort Vancouver and temporary loss of local connections.

Figure 10. Bored Tunnel – Potential Highway Alignment Under the Columbia River



5.1.2 Immersed Tube Tunnel

An ITT consists of a series of prefabricated tunnel segments that are constructed on land and then sunk into a dredged trench (approximately 360 to 540 feet wide and 2,600 feet [0.5 miles] long) under the river bottom. In-water excavation would require approximately 4 million cubic yards of material. Total excavation for the tunnel facility would be approximately 8 to 9 million cubic yards of material. Tunnel segments would then be connected under water, and the tunnel would be dewatered. Recognizing that the previous planning effort assumed a bored tunnel, the IBR program assembled a group of professionals with international experience in tunnel design and construction to provide a comprehensive conceptual review of the suitability of an ITT.

The Tunnel Concept Assessment (Attachment B) details the technical considerations of designing, constructing, and operating an ITT, including the dredging process and soil removal. The ITT concept developed by the IBR program for the Concept Assessment would accommodate all three transportation modes: roadway, high-capacity transit, and an SUP for active transportation (Figure11). The tunnel section would consist of six adjacent cells, separated by concrete walls, located within a rectangular tube approximately 180 to 184 feet wide. One cell would accommodate four lanes of traffic for northbound I-5 and another cell would accommodate four lanes of traffic for southbound I-5. Two cells, one for each direction, would accommodate northbound and southbound high-capacity transit. One cell would accommodate the SUP. One cell would accommodate the operations and maintenance/egress route. It is assumed that all of these modes would be housed within a single immersed tube cross-section.

Figure 11. ITT – Conceptual Cross-Section Below the Columbia River

AT = Active Transportation

A profile of a potential ITT replacement crossing is provided in Figure 12. The land side approaches of the ITT would transition from an immersed tube to a cut and cover tunnel, and then to an open-air

section as the tunnel returns to grade. Temporary easements would be required for construction, while permanent right-of-way would be the same (or similar) to what is currently needed for I-5.

As shown, an ITT would likely daylight on the southern end of Hayden Island in Portland and near Evergreen Boulevard in Vancouver. This would eliminate connections to I-5 at SR 14 and Hayden Island. An ITT would require in-water work and trenching in the Columbia River. Transit stations between the two tunnel portals would be located approximately 50 to 100 feet below street level.

The top of the ITT would be approximately 10 feet below the river bottom, extending to approximately 70 feet below the river bottom (at the lowest point of tunnel). Like a bored tunnel, the steepest roadway grades would be between 4% and 4.5%.

The Tunnel Concept Assessment concluded that an ITT is technically feasible; however, there are numerous challenges, as identified in Table 5. These challenges include significant out-of-direction travel for drivers, freight, transit users, bicyclists and pedestrians; the inability to tie into existing connections, such as SR 14, Vancouver City Center, and Hayden Island; safety concerns for bicyclists and pedestrians; and significant archaeological, cultural, and environmental impacts. In-water work and trenching in the Columbia River would require substantial mitigation for impacts to habitat and species, including benthic habitat, salmonid species, and lamprey. Additionally, cost estimates for the ITT would be substantially higher than cost estimates for a replacement bridge and approaches (a comparison of tunnel options to bridge options is provided in Section 5.4). Notably, the cost estimate does not include other highway, interchange, and high-capacity transit improvements that would be necessary.

PROFILE: DOWNSTREAM ALIGNMENT

5.1.3 Tunnel Crossing Evaluation and Considerations

Table 5 lists key details for the tunnel options that should be considered when selecting a river crossing for the IBR program. While there are some key differences in the impacts and considerations between a bored tunnel and an ITT, the tunnel options have many similarities (as identified by merged cells in the table below).

Table 5. Evaluation and Considerations for Tunnel Options

Topic	Bored Tunnel	ITT
Active Transportation/ SUP	• **Safety concerns** due to enclosed SUP for over 1 mile (e.g., no "eyes on the path," emergency egress, fire and life safety) • **Missed** direct connectivity from the SUP on the river crossing to local trails on both sides of the river (e.g., Renaissance Trail, Marine Drive Trail) • Opportunities to **improve connectivity** between existing trails on the Washington shore and potential for more park space along the river due to removal of existing I-5 connections	
Aviation	• **No penetration** into Pearson airspace	
Columbia River Navigation	• **Unlimited** horizontal and vertical navigation clearances • **Compatible** with to existing navigation channels • **Eliminates navigation hazards** at the bridge location (e.g., bridge piers, bridge deck) in/over the river	

Topic	Bored Tunnel	ITT
Construction Considerations	• Requires **significant, challenging** launching pits for the TBM(s) • Requires a **record or near-record diameter** TBM for vehicular tunnel bores	• Requires **unconventional and complex** below-grade construction to accommodate interchange connections consisting of cut and cover tunnels with large temporary excavations. This would make **construction impractical** • Construction would require **negotiation and approval of a permit from BNSF** to construct over/under/through their right-of-way (ROW); it is unlikely that BNSF would accept interruptions of their operations, and therefore construction would likely require the program construct a temporary alternative route; **there is no readily available route**
Cost Considerations	• Due to the significant disadvantages of a bored tunnel (e.g., would eliminate five interchanges), a conceptual cost estimate was not developed. However, it is certain that a bored tunnel would be **more expensive than an ITT** (due to such factors as increased construction method costs, significantly increased tunnel length, and increased construction risk mitigation)	• A conceptual construction cost estimate[a] of $**2.5 billion** for an ITT (from grade to grade) was developed based on previously completed projects and the collective expertise of the team

Topic	Bored Tunnel	ITT
Environmental Considerations	• **Eliminates over-water shading** impacts to fish and marine habitat. While a bored tunnel would go under the river, thus reducing/avoiding impacts to the river, **an ITT would require dredging the river bottom** – see below for impacts specific to an ITT • **Potential to reuse riverfront properties**/land above the tunnel; construction noise, vibration, and congestion impacts to businesses, impacts to neighborhoods and parks/recreation due to tunnel portals and local connections; utilities would require substantial relocations • **Impacts on local communities and neighborhoods** from construction of the cut and cover sections, tunnel portals, and local connections, including displacement of businesses and residences and neighborhood isolation • **Removes the bridge from the viewshed**, which benefits historic properties, parks and trails, and other resources	
	• Construction could **avoid impacts** to aquatic plants, fish, and other marine animals/plants by boring below the river bottom	• **In-water trenching and dredging** would disturb the river bottom across the entire width of the Columbia River, including the riverbanks (in-water excavation would require approximately 4 million cubic yards of material) • Dredged material would need to be placed in an in-water or upland site and **may require special handling** if contaminated materials are found; disturbance of the river bottom and nearshore habitat would require mitigation • **In-water construction** would impact aquatic plants, fish and other amphibians, marine mammals, and birds (including ESA-listed species) • Concerns with **cultural resources** along the shoreline and underwater; could impact

Topic	Bored Tunnel	ITT
		Fort Vancouver and Old Apple Tree Park; size and volume of excavation and vibration could **disturb or permanently impact resources** • **Disturbance and suspension of potentially contaminated materials in the river**; large excavation of contaminated soil on land may exceed capacity of existing disposal locations • Excavation of soil would be under constant threat by sand perpetually swept downstream by the Columbia River. **Supplemental dredging would be required** to clean out and reestablish the excavation geometry and possibly enlargement of the excavation.
Geotechnical Considerations	• **Control of ground loss** during tunneling, particularly under the river • **Groundwater control and water tightness** in temporary excavations (e.g., launch pits) and permanent underground structures (e.g., stations) • **Balancing incorporation of ground improvements** for ground strengthening and liquefaction mitigation with tunnel profile depth to mitigate against tunnel buoyancy	• **Ground improvement would likely be required** to improve the soils of the river bottom above, below, and around the ITT, which contributes **to high construction schedule and cost risks**
High-Capacity Transit	• An underground station could result in **high costs and construction risks** due to ground conditions near the river	

Topic	Bored Tunnel	ITT
Highway Traffic	• Due to missed connections (loss of **five** interchanges), large volumes of traffic would be **rerouted through local streets** to access I-5	• Due to missed connections (loss of **two** interchanges), large volumes of traffic would be **rerouted through local streets** to access I-5
Highway/Local Connections	• **Eliminates five**[b] I-5 interchanges, resulting in a loss of access to local streets and requiring modifications to the adjoining corridors	• **Eliminates two**[c] I-5 interchanges, resulting in a loss of access to local streets and require modifications to the adjoining corridors
Operational Considerations	• Requires a **full-time staffed operations center** for monitoring the mechanical, electrical, and traffic control systems and security • Requires **additional and different systems requirements** (fixed firefighting systems; mechanical ventilation systems [jet fans]; standpipe system; tunnel thermal protection systems; drainage systems; traffic monitoring systems; security systems)	
Safety	• Requires **extensive fire and life safety systems** • Requires **additional and different safety requirements**[16] (fixed firefighting systems; mechanical ventilation systems [jet fans]; standpipe system; tunnel thermal protection systems; drainage systems; traffic monitoring systems; security systems) • Fire prevention and ventilation **difficult** at abrupt changes in geometry • Hazardous materials are **not typically permitted in tunnels** (would require approval at the state level) • **Safety concerns due to enclosed tunnel** with two points of access (e.g., potential delays in emergency response, road blockage due to a collision)	
Structural Considerations	• Requires **more rigorous design efforts** and specialty contractors	

[16] Note: These requirements are also listed under "Operational Considerations." The listed requirements also pertain to safety considerations.

Topic	Bored Tunnel	ITT

[a] The conceptual construction costs do not include an allowance for soft costs such as design, construction management, contingency, or life-cycle considerations. These costs are for a facility that would accommodate I-5, high-capacity transit, and the SUP. This estimate does not include other highway, interchange, or high-capacity transit improvements that would be necessary. See Attachment B.

[b] Victory Boulevard, Marine Drive, Hayden Island, SR 14, and Mill Plain Boulevard

[c] Hayden Island and SR 14

5.2 Movable-Span Options

This assessment assumes that the upstream and downstream spans between Piers 5 and 6 (which flank the proposed primary navigation channel) would be movable. All other spans of the river crossing would be fixed. The movable spans would accommodate vehicular traffic, light rail transit, and a SUP. Refer to Attachment C for a comprehensive assessment of the movable-span options.

The three types of movable spans considered are described as follows:

1. A **vertical lift span** is similar to the type of movable span that exists on the crossing today, in which the span would rise vertically while remaining parallel with the deck.
2. A double-leaf **bascule span** would open in the middle, with each leaf rotating from a normal horizontal position to a nearly vertical position; to reach this position, each leaf would pivot around a horizontal axis on trunnion shafts attached to each side of the span.
3. A **swing span** is similar to the downstream BNSF bridge; in this design, the span opens by pivoting on a central pier and then rotating in a horizontal plane around a center support (vertical axis). For the IBR program, two swing spans would be required in order to provide the necessary horizontal clearance.

5.2.1 Vertical Lift Span

Vertical lift span bridges have been constructed with navigation channel (horizontal) clearances in the range of up to 500 feet and vertical clearance of approximately 200 feet. This type of span would provide a predetermined vertical clearance for river navigation, which, in this case, has been prescribed by the USCG to meet or exceed that of the current lift span (178 feet).

The cross-section of a vertical lift span would be consistent with that proposed for the fixed-span bridge with two[17] double-deck side-by-side bridges. The upstream bridge would have northbound I-5 lanes on the upper deck and a SUP on the lower deck, and the downstream bridge would have southbound I-5 lanes on the upper deck and two-way light rail transit on the lower deck.

The lift spans would be located between Piers 5 and 6 to provide up to 178 feet of vertical clearance over the proposed primary channel. Vertical lift spans are required to be on a straight section of bridge that has a level (or nearly level) deck.

Figure 13 shows an example of a single double-deck vertical lift bridge in Houghton, Michigan. The IBR program would require two side-by-side double-deck vertical lift bridges to accommodate multimodal traffic.

[17] The combination of the length, width, and depth of the lift spans required for the IBR program would result in one of the biggest, if not the biggest, lift span in the world. A single, wider lift span was not considered as it would significantly exceed the widest movable bridge span in the world.

Figure 13. Double-deck Vertical Lift Bridge Example – Portage Lake Bridge, Houghton, MI

5.2.2 Bascule Span

The practical limit for a double-leaf bascule span is approximately 350 feet long. If the IBR program were to use this type, the bascule spans would hinge from Piers 5 and 6 to provide unlimited vertical clearance over the proposed primary channel. Bascule spans are required to be on a straight section of bridge that has a level (or nearly level) deck.

A double-leaf bascule arrangement would be needed to accommodate the required width of the navigation channel. This option could be accommodated by a two-bridge double-deck arrangement[18] similar to the fixed-span bridge options. Figure 14 shows an example of a double-deck double-leaf bascule bridge in Chicago, Illinois.

[18] Due to the machinery required to operate movable spans of this size, the bascule span option could also comprise three single-deck bridges by adding a third bridge, such that the upstream bridge would accommodate northbound I-5, the adjacent downstream bridge would accommodate southbound I-5, and a third bridge would be adjacent to the southbound I-5 bridge and accommodate light rail transit and the SUP.

Figure 14. Double-deck Double-leaf Bascule Bridge Example – Wells Street Bridge, Chicago, IL

5.2.3 Swing Span

The swing span option would require one double-deck swing span on Pier 5 and one on Pier 6. The spans would be approximately 150 feet wide to accommodate the width of both directions of I-5 on the upper deck and light rail transit and the SUP on the lower deck. The swing spans would pivot on Piers 5 and 6 to provide unlimited vertical clearance for river navigation on the primary navigation channel. The span would need to be approximately 550 feet long to provide the 400-foot-wide horizontal river navigation channel.

The cross-section of a swing span would be similar to that proposed for the fixed-span bridge, except there would be one bridge instead of two. Northbound and southbound I-5 would be on the upper deck, and a SUP and two-way light rail transit would be on the lower deck.

Figure 15 shows an example of a single-deck double-swing bridge in York County, Virginia. For this assessment, the swing span would be double-deck.

Figure 15. Single-deck Double-swing Bridge Example – Coleman Bridge, York County, VA

5.2.4 Movable-Span Evaluation and Considerations

Table 6 identifies key details for each of the movable-span options. As shown, all options have advantages and disadvantages that should be taken into consideration when selecting a river crossing replacement.

Table 6. Evaluation and Considerations for Movable-Span Options

Topic	Vertical Lift Span	Bascule Span	Swing Span
Active Transportation/ SUP	• **Delay to SUP** users during a bridge opening; no suitable detour route is available • Lower bridge elevation would be a **benefit for path users** (reduced grades would increase ease of access and operability of the SUP)		
Aviation	• Lift span towers would **permanently** penetrate Pearson airspace	• Leaves would **temporarily** penetrate Pearson airspace when open	• **No penetration** into to Pearson airspace

Topic	Vertical Lift Span	Bascule Span	Swing Span
Columbia River Navigation	• Provides **178 feet or unlimited vertical clearance** for navigation • **Openings required** to accommodate tall vessels/cargo • **Lower vertical clearance** (in the closed position) than that provided by a fixed-span bridge (see Section 5.3) • Requires 400 feet of horizontal clearance per the USACE • Movable-span operations, and thus river navigation operations, would likely need to be **restricted to nighttime openings** to minimize impacts to vehicle traffic and transit operations • Primary navigation channel would be **moved south**		
Construction Considerations	• **Extended construction schedule** (approximately 1 to 2 years) due to in-water work, equipment, and specialized workforce required		
	--	• **Additional schedule extension** with third bridge configuration	--
Cost Considerations	• Construction cost of two 450-foot lift spans: $500 million • Total bridge cost (Pier 1-8): **$930 million**	• Three bridge option: Construction cost of three 400-foot single-level bascule spans: $600 million Total bridge cost: **$1.03 billion** • Two bridge option: Construction cost of two 400-foot double-deck bascule spans: $550 million. Total bridge cost (Pier 1-8): **$980 million**	• Construction cost of two 550-foot swing spans: $800 million. • Total bridge cost (Pier 1-8): **$1.23 billion**

Topic	Vertical Lift Span	Bascule Span	Swing Span
Environmental Considerations	• **Increased air quality pollutant and greenhouse gas emissions** due to vehicular idling during a bridge opening • **Increased in-water work** due to size of foundations would increase impacts to biological resources, hazardous materials, and historic structures and archaeological resources • **Challenging stormwater containment** due to the bridge joints that allow the movable span to function		
	• **Permanent visual impacts** due to lift towers	• **Additional displacement of benthic habitat** with third bridge configuration • **Additional over-water shading** with third bridge configuration • **Visual impact** during bridge opening	• **Increased land use and development impacts** due to downstream location of bridge (required for construction)
Geotechnical Considerations	• **Requires more substantial river piers and pier foundations** to support the span as compared to a fixed-span (movable parts are more sensitive to foundation settlement) to ensure smooth operation over its lifetime.		
High-Capacity Transit	• **Reduced train speed** over bridge • **Interruptions to operations** during a bridge opening throughout 18-mile service network unless openings are restricted to nighttime only. Nighttime openings could also impact the start of service. • **Extensive maintenance** to keep communications, power and track operable • Opportunity to decrease the profile elevation and grade could **improve connections** to the Vancouver Waterfront station for transit vehicles and transit patrons		

Topic	Vertical Lift Span	Bascule Span	Swing Span
Highway Traffic	• The cycle time for a bridge opening would be 20 to 30 minutes. • Daytime bridge lifts **could impact traffic volumes** for up to an hour or more; nighttime bridge lifts would not impact traffic volumes for multiple hours a day • To reduce congestion and improve mobility, movable-span operations would likely **need to be restricted to specific days and/or times**		
	--	• **Fastest cycle time** to open and close the bridge resulting in less congestion	--
Highway/Local Connections	• **Maintains** local highway and street connections • **Retains** existing interchange locations • Reduced grades would **increase the ease of ramp connections**, primarily on the Hayden Island end of the bridge		
Operational Considerations	• More likely to result in **misalignment or damage** from a seismic event • **Requires a bridge operator** on site • Requires **additional maintenance** associated with mechanical and electrical systems		
Safety	• Crash rate is expected to be **3 to 4 times higher** during a bridge lift than during normal operating conditions		

Topic	Vertical Lift Span	Bascule Span	Swing Span
Structural Considerations	• Requires more **rigorous design efforts** and **specialty contractors**		
	• Towers up to **60 feet taller** than vertical clearance required • Counterweights in the towers would require **additional seismic design considerations** to mitigate earthquake impacts	• Would be **one of the largest** double-leaf bascule spans in the world • Potential for **operational problems** due to span imbalance, keeping counterweight pit dry, and center locks issues • Must resist seismic and wind loading **to a greater extent** than other movable bridge types	• Would be **one of the largest** movable spans of its type in the world • Low profile and **does not require expensive counterweights.** • **Less massive piers** than a bascule or vertical lift bridge • **More machinery** than a bascule or vertical lift bridge: an end-centering device and end-lifting devices

5.3 Fixed-Span Bridges

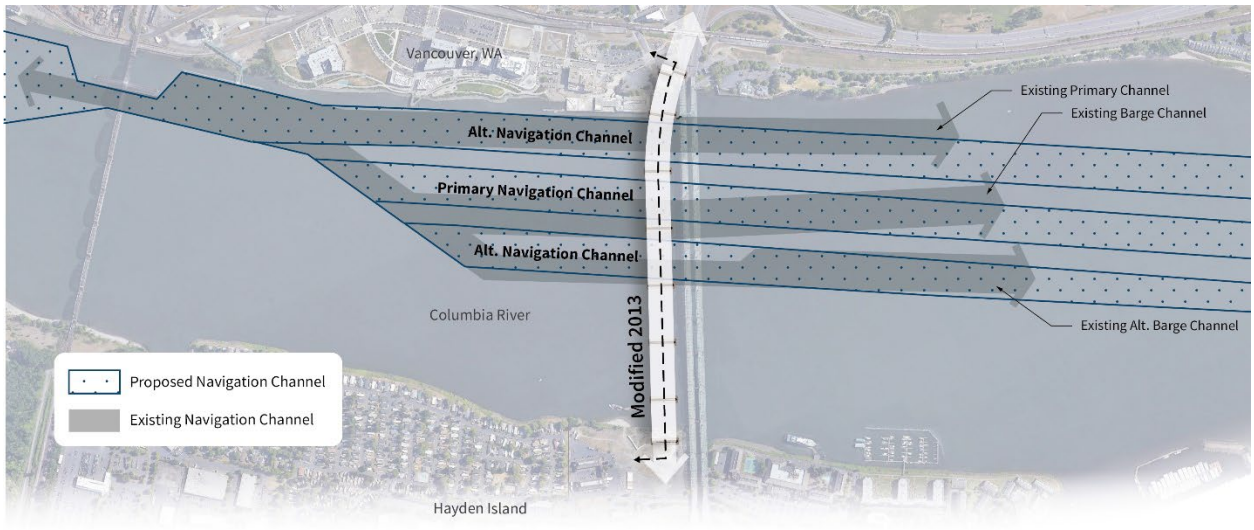
A fixed-span bridge is a bridge with no moving parts (as opposed to a bridge with a movable span). A local example of a high-level fixed-span bridge is the Astoria-Megler Bridge, which provides nearly 205 feet of vertical clearance for navigation (Figure 16). An example of a mid-level fixed-span bridge is the Vicksburg Bridge between Louisiana and Mississippi, which provides 116 feet of vertical clearance (Figure 17).

Figure 16. High-level Fixed Bridge Example – Astoria-Megler Bridge, Astoria, OR, and Point Ellice, WA

Figure 17. Mid-level Fixed Bridge Example – Vicksburg Bridge, Delta, LA, and Vicksburg, MS

Figure 18 shows a conceptual bridge plan (aerial view) of a fixed-span replacement bridge over the Columbia River, which could apply to a high-level fixed-span bridge (178 feet of vertical clearance) or a mid-level fixed bridge (116 feet of vertical clearance). As shown, a fixed-span bridge would require changes to the existing federal navigation channels in order to align the channels with the bridge piers and to align the primary channel with highest point of the bridge profile.

Figure 18. Conceptual Bridge Plan: Fixed-span Bridge



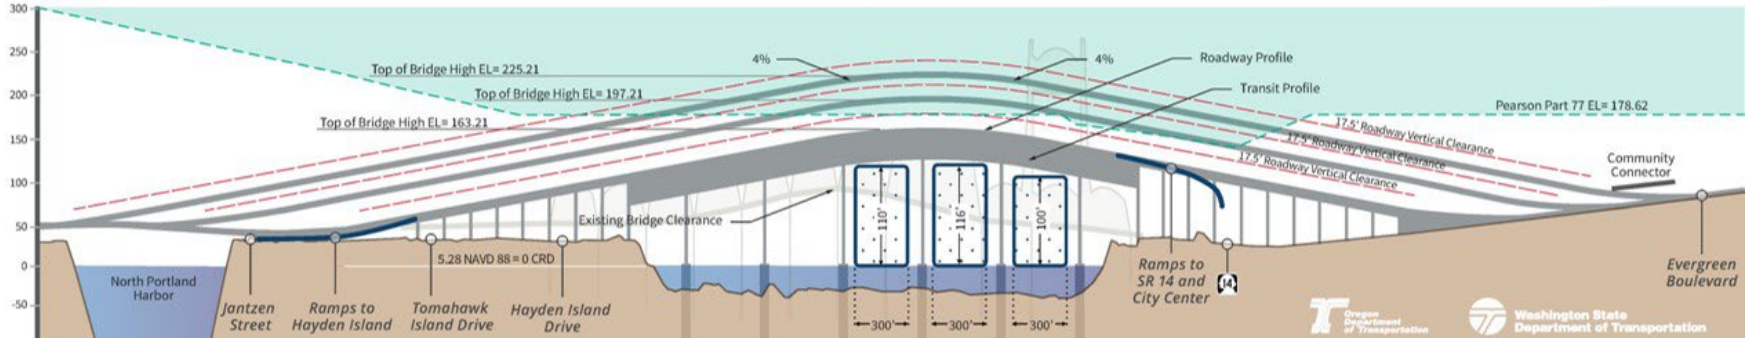
An evaluation of a high-level and mid-level fixed-span bridges is provided below, along with a summary of the advantages and disadvantages of these river crossing options.

5.3.1 High-Level Fixed Span

A high-level fixed-span bridge would provide up to 178 feet of vertical clearance over the Columbia River, which is the current vertical clearance under the existing lift spans (when open). This height would require long transitions from the peak elevation down to match the existing grades of I-5. Due to grade limitations of highways, light rail, and SUPs, the 4% grade is the maximum profile recommended, but with the higher clearance, the length of grade is longer to match to existing I-5 grades north and south of the river crossing. The higher profile would make connections to SR 14 and Hayden Island extremely challenging and unrealistic to accomplish.

Figure 19 illustrates the anticipated bridge profile (side view, looking west) for a high-level fixed-span bridge. The figure shows two navigational clearances, 178 feet and 150 feet, and a comparison to the 116-foot mid-level clearance. As shown, interchanges at SR 14 and Hayden Island would be removed, transit stations on Hayden Island and Vancouver waterfront would be extremely high, path users would climb to higher elevations, path connections to Hayden Island and the Vancouver Waterfront would be more challenging, and the bridge would encroach in the FAA Pearson Field restricted airspace (area highlighted in green in the figure).

Figure 19. Bridge Profile: High-level Fixed-span Bridge



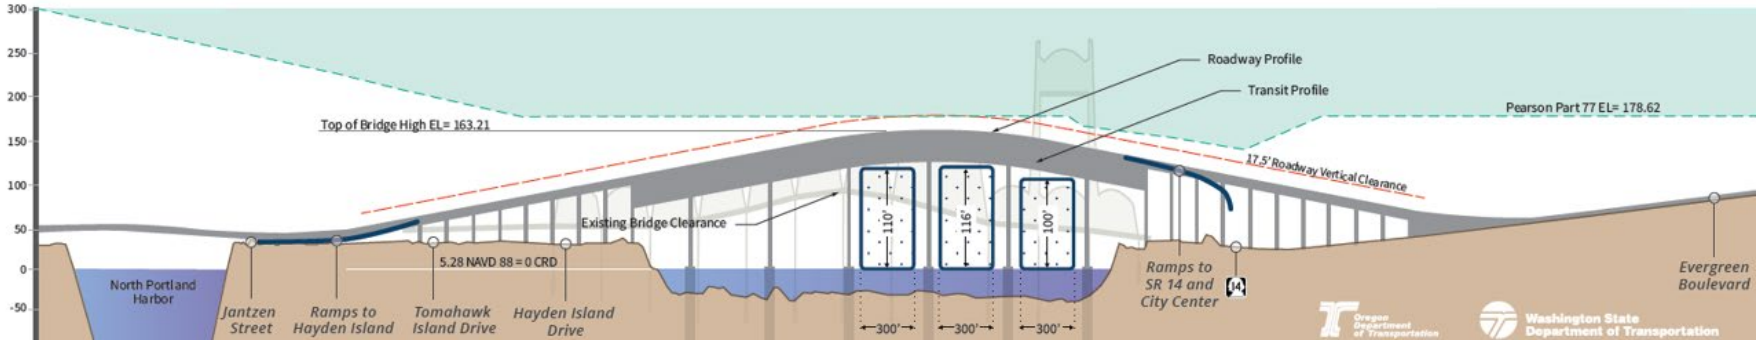
5.3.2 Mid-Level Fixed-span

A mid-level fixed-span bridge would provide 116 feet of vertical clearance over the Columbia River.[19] A mid-level fixed-span bridge would connect to the existing I-5 grades on Hayden Island and south of Evergreen Boulevard in Vancouver with a recommended maximum grade of 4%.

Figure 20 illustrates the anticipated bridge profile (side view, looking north) for a mid-level fixed span. As shown, this option would touch down on Hayden Island in Portland and south of Evergreen Boulevard in Vancouver. The bridge height would fall below the Part 77 FAA Pearson Field airspace (i.e., it would not penetrate the airspace). The bridge would provide 116 feet of vertical clearance in the primary channel and 100 to 110 feet in the barge and alternative barge navigation channels.

[19] As noted in Section 3, the vertical clearance over the primary channel was raised to 116 feet as part of a NEPA reevaluation. The USCG issued a Section 9 bridge permit for this clearance in 2013; however, that permit was contingent on securing other required permits and authorizations as well as implementing mitigation to affected marine users.

Figure 20. Bridge Profile: Mid-level Fixed-span Bridge



5.3.1 Fixed-Span Bridge Evaluation and Considerations

Table 7 identifies key details for both a high-level and mid-level fixed-span bridge. As shown, both options have advantages and disadvantages that should be taken into consideration when selecting a river crossing replacement.

Table 7. Evaluation and Considerations for Fixed-span Bridge Options

Topic	High-level Fixed	Mid-level Fixed
Active Transportation/ SUP	• Connections to Hayden Island and Vancouver waterfront **would be challenging** due to height above ground	• Connections to existing grade at Hayden Island and Vancouver waterfront **can be achieved** with ramps
Aviation	• **Permanent protrusion** into Part 77 FAA Pearson airspace	• **Likely penetration** into Part 77 FAA Pearson airspace (lights and signs only – the bridge would not protrude)
Columbia River Navigation	• Primary navigation channel would be **moved south** to the bridge profile high point	
	• Would accommodate a vertical clearance **up to 178 feet** for river navigation	• Would accommodate a vertical clearance **up to 116 feet** for river navigation • Would **reduce** navigation clearances as they exist today • **Mitigation** proposed for 4 vessels/users (reported approximately 70 trips/year)[a]
Construction Considerations	• **Conventional** construction methods and risks	

Topic	High-level Fixed	Mid-level Fixed
Cost Considerations	• The work completed for CRC, and supported by the IBR program, suggested **higher costs** for a higher fixed-span bridge. This is in part due to the changes that would occur at each land side connection, accounting for differences in interchanges, transit stations, and active transportation connections	• Construction cost of two 450-foot fixed spans: $70 million • Total bridge cost (Pier 1-8): **$500 million**
Environmental Considerations	• **Smaller aquatic footprint** compared to tunnels and movable-span bridges; **less in-water work/structures** than tunnel options, and **smaller pier foundations** compared to movable-span bridges	
	• Sustained 4% grade would result in **increased greenhouse gas emissions** • Sustained 4% grade would create **noise** impacts due to the use of Jake brakes for freight vehicles on the descent • **New visual impacts** to/from Fort Vancouver and to/from Hayden Island	• Shorter sustained 4% grade would result in **less greenhouse gas emissions** than high-level fixed • Shorter sustained 4% grade would result in less **noise** impacts than high-level fixed • Would have **less viewshed** impacts than a high-level bridge
Geotechnical Considerations	• **Smaller** piers and foundations than a movable span	• **Smaller** piers and foundations than movable span or a high-level fixed
High-Capacity Transit	• **Avoids impacts** to transit operations related to a movable span	
	• Station locations (Hayden Island, downtown Vancouver) would be **very elevated**, which would make **fire and life safety more challenging**	• Station location on Hayden Island would be a **typical** elevated station, one level up • Station in downtown Vancouver would be elevated **but more reasonably able to accommodate fire and life safety**

Topic	High-level Fixed	Mid-level Fixed
Highway Traffic	• **Avoids** traffic safety impacts related to a movable span	
	• Sustained 4% grade would **slow down freight** • Due to missed connections at **two interchanges**, large volumes of traffic would be **rerouted through local streets** to access I-5	• Shorter sustained 4% grade would have a **lesser impacts on freight speed**
Highway/Local Connections	• **Missed** local connections (would touch down at Marine Drive and at Mill Plain) • Would **eliminate two** I-5 interchanges (Hayden Island, SR 14/Downtown Vancouver)	• **Maintains** local highway and street connections • **Retains** existing interchange locations
Operational Considerations	• **Does not require** on-site or specialized operation staff	
Safety	• **Avoids traffic safety impacts** related to a movable span	
Structural Considerations	• No significant differentiators identified	

a. During the CRC Project, agreements were negotiated with the four impacted users that were unable to modify operations (such as accepting an air gap of less than 10 feet) in order to transit a bridge height of 116 feet. Three upstream fabricators entered into agreements with the CRC Project. The anticipated agreements would have resulted in payments to the companies that would be used by the companies at their business discretion and control. Payments were never made because the project was stopped. The remaining vessel owner decided to terminate negotiations that involved a payment to compensate the owner for vessel modifications, and an agreement was never finalized.

5.4 Comparison of River Crossing Options

Table 8 provides a detailed side-by-side comparison of each of the river crossing options in terms of effects on active transportation, aviation, Columbia River navigation, construction considerations, cost considerations, environmental considerations, geotechnical considerations, high-capacity transit, highway traffic, highway and local connections, operational considerations, safety, and structural considerations. The table is color coded and provides a symbol to indicate if a consideration is an advantage (green, with a "+" symbol), disadvantage (red, with a "-" symbol), or neutral (yellow, with a "•" symbol).

More detailed analyses of the tunnel options and the movable-span options can be found in Attachments B and C, respectively.

Table 8. River Crossing Option Comparison

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
Active Transportation/SUP	– **Safety concerns** due to enclosed SUP for over 1 mile (e.g., no "eyes on the path, emergency egress, fire and life safety) – **Missed direct connectivity** from the SUP on the river crossing to local trails on both sides of the river (e.g., Renaissance Trail, Marine Drive Trail) + Opportunities to **improve connectivity** between existing trails on the Washington shore and potential for more park space along the river due to removal of existing I-5 connections		– **Delay to SUP users** during a bridge opening; **no suitable detour route** is available + Lower bridge elevation would be a **benefit for path users** (reduced grades would **increase ease of access and operability** of the SUP)			– Active transportation connections to Hayden Island and Vancouver waterfront **would be challenging** due to height above ground	+ Connections to existing grade at Hayden Island and Vancouver waterfront **can be achieved with ramps**
Aviation	+ **No penetration** in Pearson airspace		– Lift span towers would **permanently penetrate** Pearson airspace	• Leaves would **temporarily penetrate** Pearson airspace when open	+ **No penetration** in Pearson airspace	– **Permanent penetration** into Pearson airspace	• **Likely penetration** of lights and signs into Pearson airspace
Columbia River Navigation	+ **Unlimited** horizontal and vertical navigation clearances + **Compatible** with existing navigation channels + **Eliminates navigation hazards** (e.g., bridge piers, bridge deck) in/over the river		+ Provides **178 feet or unlimited vertical clearance** for navigation – **Openings required** to accommodate tall vessels/cargo – **Lower vertical clearance** (in the closed position) than that provided by the fixed-span bridge – Movable-span operations and thus river navigation operations would likely need to be **restricted to nighttime openings** to minimize impacts to vehicle traffic and transit operations • Primary navigation channel would be **moved south** • Requires **400 feet** of horizontal clearance per the USACE			+ **No change in vertical clearance** • Primary navigation channel would be **moved south** to the bridge profile high point	• Would accommodate a vertical clearance **up to 116 feet** for navigation • Would **reduce** navigation clearances as they exist today • Primary navigation channel would be **moved south** to the bridge profile high point – **Mitigation** for 4 vessels/users is proposed (reported approximately 70 trips/year)[a]

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
Construction Considerations	– Requires **significant, challenging** launching pits for the TBM(s) – Requires a **record or near-record** diameter TBM for vehicular tunnel bores	– Requires **unconventional and complex** below-grade construction to accommodate interchange connections consisting of cut and cover tunnels with large temporary excavations. This would make **construction impractical** – Construction would require **negotiation and approval of a permit from BNSF** to construct over/under/through their ROW; it is unlikely that BNSF would accept interruptions of their operations, and therefore construction would likely require the program construct a temporary alternative route; **there is no readily available route**	• **Extended construction schedule** (approximately 1 to 2 years) due to in-water work, equipment, and specialized workforce required			+ **Conventional** construction methods and risks	
			--	• Additional **schedule extension** with third bridge configuration	--		

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
Cost Considerations	– Due to the significant disadvantages of a bored tunnel (e.g., would eliminate five interchanges), a conceptual cost estimate was not developed. However, it is certain that a bored tunnel would be **more expensive than an ITT** (due to such factors as increased construction method costs, significantly increased tunnel length, and increased construction risk mitigation)	– Total tunnel cost (from grade to grade): **$2.5 billion**	– Construction cost of two 450-foot lift spans: $500 million – Total bridge cost (Pier 1-8): **$930 million**	Three bridge option: – Construction cost of three 400-foot single-level bascule spans: $600 million – Total bridge cost (Pier 1-8): **$1.03 billion** Two bridge option: – Construction cost of two 400-foot double-deck bascule spans: $550 million – Total bridge cost: **$980 million**	– Construction cost of two 550-foot swing spans: $800 million – Total bridge cost (Pier 1-8): **$1.23 billion**	• The work completed for CRC and supported by the IBR program suggested **higher costs** for a higher fixed-span bridge. This is, in part, due to the changes that would occur at each land side connection, accounting for differences in interchanges, transit stations, and active transportation connections.	+ Construction cost of two 450-foot fixed spans: $70 million + Total bridge cost: **$500 million**
Environmental Considerations	+ **Eliminates over-water shading** impacts to fish and marine habitat. While a bored tunnel would go under the river, thus reducing/avoiding impacts to the river, an ITT would require dredging the river bottom – **see below for impacts specific to an ITT** + **Potential to reuse riverfront properties**/land above the tunnel + **Removes the bridge from the viewshed**, which benefits historic properties, parks and trails, and other resources – Construction **noise, vibration, and congestion** impacts to businesses – **Impacts to neighborhoods and parks/recreation** due to tunnel portals and local connections – Utilities would require **substantial relocations** – **Impacts on local communities and neighborhoods** from construction of the cut and cover sections, tunnel portals and local connections, including displacement of businesses and residences and neighborhood isolation		– **Increased air quality pollutant and greenhouse gas emissions** due to vehicular idling during a bridge opening – **Increased in-water work** due to size of foundations would increase impacts to biological resources, hazardous materials, and historic structures and archaeological resources – **Challenging stormwater containment** due to the bridge joints that allow the movable span to function			+ **Smaller aquatic footprint** compared to tunnels and movable-span bridges + **Less in-water work/structures** than tunnel options + **Smaller pier foundations** compared to movable-span bridges	

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
	+ Construction could **avoid impacts to aquatic** plants, fish, and other marine animals/plants by boring below the river bottom	– **In-water trenching and dredging would disturb the river bottom** across the entire width of the Columbia River, including the riverbanks (in-water excavation would require approximately 4 million cubic yards of material) – Disturbance of the river bottom and nearshore habitat **would require mitigation** – Dredged material would need to be placed in an in-water or upland site and **may require special handling** if contaminated materials are found – **In-water construction** would impact aquatic plants, fish, amphibians, marine mammals, and birds (including ESA-listed species) – **Concerns for cultural resources** along the shoreline and underwater; could impact Fort Vancouver and Old Apple Tree Park; size and volume of excavation and vibration could disturb or permanently impact resources – Disturbance and suspension of **potentially contaminated materials in the river**; large excavation of	– **Permanent visual impacts** due to lift towers	– **Additional displacement of benthic habitat** with third bridge configuration; additional over-water shading with third bridge configuration – **Visual impact** during bridge opening	– **Increased land use and development impacts** due to downstream location of bridge (due to construction considerations)	– Sustained 4% grade would result in **increased greenhouse gas emissions** – Sustained 4% grade would create **noise impacts** due to the use of Jake brakes for freight vehicles on the descent – **New visual impacts** to/from Fort Vancouver and to/from Hayden Island	+ Shorter sustained 4% grade would result **in less greenhouse gas emissions** than high-level fixed + Shorter sustained 4% grade would result in **less noise** impacts than high-level fixed. + Would have **less viewshed impacts** than a high-level bridge

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
		– contaminated soil on land may exceed capacity of existing disposal locations – Excavation of soil will be under constant threat by sand perpetually swept downstream by the Columbia River. **Supplemental dredging would be required** to clean out and re-establish the excavation geometry and possibly enlargement of the excavation.					
Geotechnical Considerations	– **Control of ground loss** during tunneling, particularly under the river – **Groundwater control and water tightness** in temporary excavations (e.g., launch pits) and permanent underground structures (e.g., stations) – **Balancing incorporation of ground improvements** for ground strengthening and liquefaction mitigation with tunnel profile depth to mitigate against tunnel buoyancy	– **Ground improvement would likely be required** to improve the soils of the river bottom above, below and around the ITT, which contributes to **high construction schedule and cost risks**	• **Requires more substantial river piers and pier foundations** to support the span as compared to a fixed span (movable parts are more sensitive to foundation settlement) to ensure smooth operation over its lifetime			+ **Smaller** piers and foundations than a movable span	+ **Smaller** piers and foundations than movable span or a high-level fixed
High-Capacity Transit			– **Reduced** train speed over bridge			+ **Avoids impacts** to transit operations related to a movable span	

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
	– An underground station could result in **high costs and construction risks** due to ground conditions near the river		– **Interruptions to operations** during a bridge opening throughout 18-mile service network, unless openings are restricted to nighttime only – **Extensive maintenance** to keep communications, power and track operable + Opportunity to decrease the profile elevation and grade could **improve connections** to the Vancouver Waterfront station for transit vehicles and transit patrons			– Station locations (Hayden Island, downtown Vancouver) would be **very elevated**, which would make **fire and life safety more challenging**	• Station location on Hayden Island would be a **typical** elevated station, one level up • Station in downtown Vancouver would be elevated **but more reasonably able to accommodate fire and life safety**
Highway Traffic	– Due to missed connections (**loss of five interchanges**), large volumes of traffic would be **rerouted through local streets** to access I-5	– Due to missed connections (**loss of two interchanges**), large volumes of traffic would be **rerouted through local streets** to access I-5	– The cycle time for a bridge opening would be **20 to 30 minutes** – Daytime bridge lifts **could impact traffic volumes** for an hour or more; nighttime bridge lifts would not impact traffic volumes for multiple hours a day – To reduce congestion and improve mobility, movable-span operations would **likely need to be restricted** to specific days and/or times + Reduced length of grade of the lower profile **would benefit freight and other vehicles** that might be affected by the lower speeds caused by steeper grades			+ **Avoids traffic safety impacts** related to a movable span	
			--	+ **Fastest cycle time** to open and close the bridge resulting in less congestion	--	– Sustained 4% grade would **slow down freight** – Due to missed connections at **two interchanges**, large volumes of traffic would be **rerouted through local streets** to access I-5	+ Shorter sustained 4% grade would have a **lesser impact on freight speed**
Highway/Local Connections	– **Eliminates five I-5 interchanges**. This would result in a loss of access to local streets and require modification to the SR 14 corridor	– **Eliminates two I-5 interchanges.** This would result in a loss of access to local streets and require modification to the SR 14 corridor	+ **Maintains** local highway and street connections + Reduced grades would **increase the ease of ramp connections**, primarily on the Hayden Island end of the bridge – **Retains** existing interchange locations			– **Missed** local connections (would touch down at Marine Drive and at Mill Plain) – Would **eliminate two I-5 interchanges** (Hayden Island, SR 14/Downton Vancouver)	+ **Maintains** local highway and street connections – **Retains** existing interchange locations

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
Operational Considerations	– Requires a **full-time staffed operations center** for monitoring the mechanical, electrical, traffic control systems, and security – Requires **additional and different systems requirements** (fixed firefighting systems; mechanical ventilation systems [jet fans]; standpipe system; tunnel thermal protection systems; drainage systems; traffic monitoring systems; security systems)		– More likely to result in **misalignment or damage** from a seismic event – **Requires a bridge operator** on site – Requires **additional maintenance** associated with mechanical and electrical systems			+ **Does not require** on-site or specialized operation staff	
Safety	– Requires **extensive fire and life safety systems** would be required – Requires **additional and different** safety requirements (fixed firefighting systems; mechanical ventilation systems [jet fans]; standpipe system; tunnel thermal protection systems; drainage systems; traffic monitoring systems; security systems) – Fire prevention and ventilation **difficult at abrupt changes** in geometry – **Hazardous materials are not typically permitted** in tunnels (would require approval at the state level) – Safety concerns due to **enclosed tunnel with two points of access** (e.g., potential delays in emergency response, road blockage due to a collision)		– Crash rate is expected to be **3 to 4 times higher during a bridge lift** than during normal operating conditions			+ **Avoids traffic safety impacts** related to a movable span	
Structural Considerations	– Requires **more rigorous design efforts** and specialty contractors		– Requires **more rigorous design efforts** and specialty contractors – Towers up to **60 feet taller** than vertical clearance required – Counterweights in the towers would **require additional seismic design** considerations to mitigate earthquake impacts	– Would be **one of the largest** double-leaf bascule spans in the world – Potential for **operational problems** due to span imbalance, keeping counterweight pit dry, and center locks issues – Must **resist seismic and wind loading** to a greater extent than	– Would be **one of the largest** movable spans of its type in the world – **More machinery** than a bascule or vertical lift bridge: an end-centering device and end-lifting devices • Low profile and **does not require**	+ **Traditional** major complex bridge design delivery	

	Bored Tunnel	Immersed Tube Tunnel	Lift Span	Bascule Span	Swing Span	High-level Fixed	Mid-level Fixed
				other movable-span options	expensive counterweights • **Less massive piers** than a bascule or vertical lift bridge		

[a] During the CRC Project, agreements were negotiated with the four impacted users that were unable to modify operations (such as accepting an air gap of less than 10 feet) in order to transit a bridge height of 116 feet. Three upstream fabricators entered into agreements with the program. The anticipated agreements would have resulted in payments to the companies that would be used by the companies at their business direction and control. Payments were never made because the project was stopped. The remaining vessel owner made a decision to terminate negotiations that involved a payment to compensate the owner for vessel modifications, and an agreement was never finalized.

6. CONCLUSION

As part of the NEPA process, the IBR program will identify the type of river crossing that will be advanced for further study in the Supplemental Draft EIS. This report provides a summary of the different river crossing options that could be used to replace the I-5 bridges over the Columbia River.

Table 9 identifies how the river crossing options would (or would not) meet the six needs identified in the Purpose and Need statement.

Table 9. River Crossing Options and Purpose and Need

F = Fail; P = Pass

Purpose and Need	Tunnel (Bored and ITT)	Movable (Bascule, Swing, and Lift)	Fixed (High-level, Mid-level)
Growing travel demand and congestion	**F:** Missed connections would cause diversion onto local streets	**P:** Improved over existing conditions, although delays associated with openings	**F (High-level):** Missed connections would cause diversion onto local streets **P (Mid-level):** improved over existing conditions
Impaired freight movement	**F:** Missed connections at Hayden Island and SR 14/downtown. Vancouver would have negative impacts on freight movement	**P:** Lower grade would be more conducive to freight movement; Freight moving at night would be subject to delays	**F (High-level):** Missed connections at Hayden Island and SR 14/downtown Vancouver would have negative impacts on freight movement **P (Mid-level):** Would improve freight movement
Limited public transportation operation, connectivity, and reliability	**F:** Would not improve service due to missed connections	**P:** Feasible, although complicated due to disruptions and operations and maintenance	**F (High-level):** Cannot accommodate preferred grade **P (Mid-level):** Can accommodate preferred grade

Purpose and Need	Tunnel (Bored and ITT)	Movable (Bascule, Swing, and Lift)	Fixed (High-level, Mid-level)
Safety and vulnerability to incidents	**P:** May reduce potential for collisions compared to existing conditions	**P:** Similar potential for collisions compared to existing conditions	**P:** Would reduce potential for collisions compared to existing conditions
Substandard bicycle and pedestrian facilities	**F:** Problematic due to enclosed route for over 1 mile (safety, missed connections)	**P:** Lower grade would be better than fixed-span bridge, although there would be delays during openings	**F (High-level):** Cannot accommodate preferred grade **P (Mid-level):** Can accommodate preferred grade
Seismic vulnerability	**P:** Can be constructed to current seismic standards	**P:** Can be constructed to current seismic standards (although more likely to suffer misalignment or damage in a seismic event)	**P:** Can be constructed to current seismic standards

As shown in the table, the tunnel options and high-level fixed-span bridge fail to meet the Purpose and Need. The movable-span options could be designed and operated (i.e., bridge openings restricted to a limited nighttime window) to meet the Purpose and Need.

The replacement fixed-span bridge option with 116 feet of vertical clearance is the result of extensive technical and environmental work, as well as many years of public and agency coordination. In 2011, the CRC Project's Selected Alternative, which consisted of a replacement fixed-span bridge with 95 feet of vertical clearance, was adopted in the ROD. In 2011/2012, the CRC Project raised the vertical clearance to 116 feet in response to feedback from the USCG and river users. A 2012 NEPA re-evaluation on the height increase concluded there were no new significant impacts, and in 2013 the USCG issued a bridge permit for 116 feet (contingent on receipt of the USACE Section 408 authorization and agreements with affected river users). As noted previously, the IBR program's update to the NIR in 2021 concluded that there have been no significant changes related to river users since the CRC Project.

Based on technical evaluations, agency coordination, public outreach, and discussions with partner agencies, all of which are reflected in this report and its attachments, the IBR program recommends a fixed-span bridge with a vertical clearance of 116 feet as the Modified LPA and will continue to study movable-span options. The rationale and analysis summarized in this report demonstrates that the identified option provides the best replacement river crossing for the community and region. A fixed

bridge with 116 feet of vertical clearance is a solution that balances the needs of all users and modes of transportation, including freight and personal vehicles, transit, active transportation, aviation, and river users. This river crossing option has the best ability to meet the Purpose and Need statement, meet the community's values and priorities,[20] minimize environmental impacts, contributes to achievement of climate and equity goals and other program desired outcomes, and will use conventional design and construction methods, contributing to a lower cost.

[20] Community values and priorities for the IBR program were developed and adopted by the Community Advisory Committee and are available at: https://www.interstatebridge.org/media/t0kh3ey4/revised-community-values-priorities-5-20-21_remediated-1.pdf

EXECUTIVE SUMMARY

The Interstate Bridge Replacement (IBR) program, previously referred to as the Columbia River Crossing (CRC) Project, is a bridge, public transit, highway, and active transportation improvement project that would improve safety and mobility in the Interstate 5 (I-5) corridor between Portland, Oregon, and Vancouver, Washington. The IBR program includes replacement of the existing I-5 crossings of the Columbia River and Oregon Slough.

Construction of the proposed I-5 bridges will require bridge permits issued pursuant to Section 9 of the Rivers and Harbors Act of 1899 by the U.S. Coast Guard (USCG). One requirement of the process is the completion of a Navigation Impact Report (NIR) to assess impacts on navigation from the proposed bridges. The CRC Project developed an NIR in 2012 in support of a bridge permit that was issued by the USCG, but the permit subsequently expired. The IBR program utilized the navigation information developed for the CRC Project and updated and validated the information to reflect changed conditions since development of the CRC NIR and to reflect the USCG bridge permitting guidance adopted since 2012.

To determine updated navigation information, known river users, including commercial, recreational, passenger cruise, and federal users, as well as marine contractors and fabricators, were contacted to confirm the accuracy of existing information and determine whether any changes had occurred to their vessels or operations. To capture information about users that may not have been included in prior studies, additional outreach was conducted directly with marinas, through maritime and general publications, through an online survey, and through presentations to maritime groups. In addition, I-5 bridge lift data and other river use information were updated to reflect the time between the prior CRC NIR and the present. Land use data were also collected to identify land use changes or activities that could affect future navigation. Additional water level data were evaluated to update river levels and potential impacts on vertical navigation clearance.

Required openings of the I-5 bridge declined from an average of 289 per year from 1997 to 2011 to 157 per year from 2012 to 2020. From 2012 to 2020, 58% of the bridge openings were for tugs, 17% for sailboats, and the remainder for other vessel types. These openings represent 5% to 7% of the river traffic based on openings of the BNSF railroad bridge just downstream of the I-5 bridges and use of the locks at the Bonneville dam. Some vessel traffic has changed due to new vessels being added by existing users such as Tidewater Barge Lines, changed practices such as the Navy no longer using escort vessels for reactor shipments to Hanford, and vessels no longer in service in the area, such as the *Hawaiian Chieftain*. No deep-draft vessel use was documented as passing upriver of the I-5 bridge. There have been limited new marine development activities upriver of the I-5 bridge, and a number of facilities have ceased operations.

An impact analysis was conducted using the navigation information collected and comparing the information against the proposed bridge heights. Bridge heights of 116 feet and 121 feet (as measured above 0 Columbia River Datum [CRD]) were considered. These heights represent the Locally Preferred Alternative from the CRC that balances the needs of navigation with other constraints, including aviation, environmental impacts, and surface transportation needs and an allowance of an additional 5

feet that could potentially be provided by refined bridge designs but may reduce the horizontal clearance between bridge piers. The ordinary high water mark of 16 feet above 0 CRD was used to represent water levels and is a level that has only been exceeded 1.2% of the time from 1972 to 2020. An air gap of 10 feet was also used and represents an additional distance above the air draft of the vessel (highest point of the vessel above the water) to provide a safety margin.

The analysis found that construction of a 116-foot bridge would result in impacts to eight vessels/users. Further analysis showed that reducing the air gap to 5 feet and modifying specific vessel operations would reduce the impacts to four vessels/users. Increasing the bridge height to 121 feet would result in the same reduction in impacts. Table ES-1 summarizes the impacted vessels.

Table ES-1 Impacted Vessels/Users

Vessel	Owner	Vessel Type	Air Draft (feet)	Trip Frequency
TBD (fabricator's tallest future shipment)	Greenberry Industrial	Barge with fabricated materials	136	Any time of the year
TBD (fabricator's tallest future shipment)	Vigor	Barge with fabricated materials	130	Any time of the year
TBD (fabricator's tallest reported shipment)	Thompson Metal Fab	Barge with fabricated materials	165	Any time of the year
DB Taylor	JT Marine	Marine contractor vessel	131	Up to 10 trips per month at all times of the year

The IBR program has committed to mitigation for these impacted users. Specific mitigation agreements would be determined prior to application for a bridge permit and undertaking construction.

Navigation under the I-5 bridge across the Oregon Slough is limited to small recreational vessels and limited commercial vessels that can navigate under the existing fixed bridge height of 35 feet. The IBR program has committed to meeting or exceeding the vertical and horizontal clearance provided by the

existing bridge for new and replacement bridges on the Oregon Slough. No impacts to navigation or mitigation have been identified for Oregon Slough users.

1. PART 1: INTRODUCTION AND BACKGROUND

1.1 Summary

As one of the largest rivers in North America, the Columbia River is among the defining geographic features of the Pacific Northwest. It serves as an important transportation corridor, and its resources have provided the economic and cultural foundations of Native American and western settlements.

Through the Portland-Vancouver metropolitan area, the Columbia River is crossed by bridges at four locations: the Interstate 5 (I-5) crossing, known as the Interstate Bridge; the Interstate 205 (I-205) crossing, known as the Glenn L. Jackson Memorial Bridge; the BNSF Vancouver railroad bridge; and the I-5 Oregon Slough (also known as the North Portland Harbor) Bridge. Like the river, the I-5 corridor is a major regional and national resource. It is the principal north-south corridor for the movement of goods and services on the West Coast of the U.S. from Canada to Mexico. Within the metropolitan area, it provides access to major economic centers such as the Ports of Portland and Vancouver and commercial and business districts throughout the region.

The Interstate Bridge Replacement (IBR) program, previously referred to as the Columbia River Crossing (CRC) Project, is a bridge, public transit, highway, and active transportation improvement project that would improve safety and mobility in the I-5 corridor between Portland, Oregon, and Vancouver, Washington. The IBR program area begins at State Route (SR) 500 in Vancouver and extends to Columbia Boulevard in Portland and includes the existing I-5 crossing of the Columbia River. Replacing the aging bridges across the Columbia River with modern, seismically resilient, multimodal structures that provide improved mobility for people, goods and services is a high priority for Oregon and Washington.

Construction of the proposed I-5 bridge will require bridge permits issued pursuant to Section 9 of the Rivers and Harbors Act of 1899 by the U.S. Coast Guard (USCG). The USCG permits the location and plans of bridges in the interest of public navigation. A bridge permit is the written approval of the location and plans of a bridge constructed across a navigable waterway of the U.S. The Columbia River, including both the main channel and the Oregon Slough, is considered a navigable waterbody.

A primary requirement of the Section 9 permit is the completion of a Navigation Impact Report (NIR) to assess the impacts on navigation from the proposed bridge. NIRs provide the most accurate picture of current and prospective navigation on a waterway. The NIR is submitted to the USCG and used as part of the USCG's evaluation and issuance of a preliminary navigational clearance determination. The application for bridge permits will be completed after the National Environmental Policy Act (NEPA) process has been finalized and when construction funding has been secured or is more certain. Separate bridge permits will be necessary for the main span I-5 bridges and the separate bridge(s) over the Oregon Slough. This NIR report was prepared consistent with Appendix A of the USCG Bridge Permit Application Guide (BPAG) (USCG 2016). This report is an update to the 2012 CRC NIR (ODOT and WSDOT 2012) to reflect changed conditions since development of the original NIR and to reflect the

USCG guidance adopted since the CRC Project was stopped. Part 1 of this report provides background information and project details. Part 2 addresses the requirements of Appendix A to the BPAG.

1.2 Prior Efforts

An Environmental Impact Statement (EIS) was prepared for the CRC Project, with a Final EIS (FEIS) published in September 2011 and a Record of Decision (ROD) in December 2011. Following the ROD, the CRC NIR was completed in 2012 in support of the Section 9 bridge permit application. The CRC NIR contains the results of a comprehensive analysis of the navigation needs of the Columbia River at the project site, as well as conclusions regarding the impacts to navigation of the then-proposed replacement of the existing I-5 bridge over the Columbia River. The data collected regarding navigation needs of the Columbia River at that time represent a significant resource that will be used as a data source for completing the Section 9 bridge permit for the IBR program. These data are assumed to be accurate but will require validation for any changes that may have occurred regarding the navigation needs described in the CRC NIR.

The CRC FEIS and NIR evaluated navigation impacts, costs, and environmental and landside impacts of mid-level bridges ranging from 95 to 125 feet above 0 feet (Columbia River Datum [CRD].) All bridge heights and vertical clearances noted in this report are based on a water level of 0 feet CRD unless specified otherwise. Bridge heights greater than 125 feet had been dismissed during the alternatives screening process for the CRC Project because they would encroach on protected airspace for Pearson Field airport and provided only a minimal reduction in navigation impacts while increasing costs and resulting in other landside impacts. Low-level bridges were similarly dismissed because they would have required a movable span that would disrupt traffic, cause more accidents, impact navigation, and be more expensive to construct, maintain and operate. The CRC Project proposed to construct a bridge with a vertical clearance of 116 feet because that design balanced the needs of navigation, airfield operations, and surface transportation, while minimizing additional landslide and environmental impacts, as discussed in the 2012 CRC Bridge Height NEPA Re-Evaluation (CRC 2012).

A Section 9 permit from the USCG was granted in September 2013 for the construction of the replacement bridges as proposed by the CRC Project. That permit expired when the CRC Project was stopped and construction had not commenced within three years, and a new Section 9 permit(s) will be required for the IBR program.

1.3 Proposed Project

The Interstate Bridge Replacement Program (IBR) program is a multimodal transportation project to improve Interstate 5 (I-5) corridor mobility by addressing present and future travel demand and mobility needs in the program area. The IBR program will implement new river crossings over the Columbia River and the Oregon Slough, with associated improvements to I- 5. This report provides detailed consideration of a fixed-span bridge over the Columbia River with a vertical clearance of 116 feet to 121 feet above 0 feet Columbia River Datum (CRD). For the Oregon Slough crossing(s) the replacement or supplemental bridges will meet or exceed the vertical and horizontal clearances provide by the existing I-5 bridge.

The existing I-5 bridges over the Columbia River have a maximum vertical clearance of 178 feet provide by the lift span with varying fixed clearances at the barge channel and alternate barge channel. The existing I-5 bridge over the Oregon Slough provides for a vertical clearance of 35 feet. The vertical clearance design evaluated in this report was considered during the NEPA process for the CRC Project. The analysis in this report provides updated vessel and river use data and user impact analysis. A detailed description of the IBR program and the bridge design used for conducting the impact analysis is contained in Section 1.5.

1.4 Purpose of this Report

This report is provided to meet the requirements for a Navigation Impact Report (NIR) as defined in the USCG Bridge Permit Application Guide (BPAG) Appendix A (USCG 2016). The purpose of the NIR is to accurately determine the current and prospective navigation on the waterway and to analyze the navigational impacts of bridge design alternatives. This report describes the physical features of the Columbia/Snake River system, the current and prospective navigation needs, the proposed replacement bridges, potential navigation impacts to navigation as result of the proposed replacement bridges, and potential mitigation strategies to address identified impacts to navigation. The report follows the order of information consistent with BPAG Appendix A beginning at Part 2. This introductory section provides background information regarding the IBR program.

Information and findings in this report will be used by the USCG to issue a preliminary navigation clearance determination and help inform the program's application for a bridge permit from the USCG. The preliminary navigation clearance determination is the USCG's evaluation of whether the proposed bridge clearances meet the reasonable needs of navigation and are a reasonable alternative to be analyzed in the environmental documentation. As outlined in the BPAG and in the 2014 Memorandum of Understanding between the USCG, Federal Highway Administration (FHWA), Federal Transit Administration (FTA), and Federal Railroad Administration, this preliminary determination is normally completed prior to or concurrent with the NEPA scoping process (USCG 2014). Since a ROD was already issued for the CRC Project the process will vary from that described in the BPAG. The IBR program is undertaking a NEPA re-evaluation and expects to complete a Supplemental Environmental Impact Statement (EIS) to reflect changes to the program and existing conditions. Issuance of the preliminary navigation clearance determination is expected to occur prior the Supplemental EIS so that its findings can be used in the NEPA process.

1.5 Project Description

The IBR program will implement replacement river crossings over the Columbia River with associated improvements to I- 5. This report provides details regarding replacing the current bridges over the main Columbia River channel with fixed-span bridges with a vertical clearance of 116 to 121 feet. The I-5 Oregon Slough bridge will also be replaced and will provide horizontal and vertical clearance that meets or exceeds what is currently provided at the existing bridge. Other project elements could include:

1. Improvements to the existing I-5 mainline and interchanges within Washington and Oregon.

2. A variety of active transportation improvements throughout the project corridor, including a multiuse path connecting to the existing system. The path would allow users to travel from north Portland, to and across Hayden Island and over the Columbia River, into downtown Vancouver.
3. Provisions for high-capacity transit.
4. Transportation demand and system management measures to be implemented with the program, including the use of tolls, subject to the authority of the Washington and Oregon transportation commissions.

While the IBR program will utilize past work to inform the current effort, the details of a bridge replacement solution have not been finalized. Given the variety of changes that have occurred since the CRC Project, design refinements will need to be considered by the IBR program including to the bridges. Upcoming efforts to identify a multimodal solution that meets community needs and priorities include working with local agencies and the community to look at such design options as high-capacity transit options, interchange improvements, urban design, interchanges, travel lanes, bridge height and type, and multiuse path facilities and connections. The bridge design for the main channel that is used in evaluating impacts to navigation is the design of the bridge permitted by the USCG in 2014 and is reflected in the details below. The actual design of the program that will be permitted may be different than that described herein, but vertical and horizontal clearances are expected to be maintained.

1.5.1 Columbia River Bridges

The parallel bridges that form the existing I-5 crossing over the Columbia River will be replaced by two new parallel bridges with an upper and lower deck. The eastern structure will accommodate northbound highway traffic on the bridge deck, with a bicycle and pedestrian path on the lower deck; the western structure will carry southbound traffic on the bridge deck, with transit provisions on the lower deck. Whereas the existing bridges have only three lanes each, with virtually no shoulders, each of the new bridges was designed to be wide enough to accommodate three through lanes and up two add/drop lanes. Lanes and shoulders will be built to full Washington State Department of Transportation (WSDOT) and Oregon Department of Transportation (ODOT) design standards. The existing bridges will be completely removed following construction of the replacement bridges.

1.5.1.1 Location

The replacement bridges will be located just downstream of the existing bridge to accommodate maintenance of traffic during construction.

1.5.1.2 Vertical and Horizontal Clearance

The replacement bridges, as selected in the ROD and the 2014 NEPA Re-evaluation, will have a maximum vertical clearance of 116 feet for the primary channel and 113 feet and 99 feet respectively for the alternate barge channel and barge channel spans each over a 300-foot-wide navigation clearance. To provide 300 feet of navigation clearance between bridge piers would require bridge spans greater than 400 feet. The design includes spans of 465 feet. The IBR program is evaluating

design options that may allow for additional vertical clearance without additional encroachment on the protected airspace for Pearson Airfield. To reflect this potential, an alternative is included that increases the vertical clearance by 5 feet.

A history of the different bridge heights considered, and the reasoning behind the bridge height of 116 feet is detailed later in this report.

1.5.1.3 Pier Locations

The existing bridges over the Columbia River have nine in-water pier sets. Each of the new bridges will be built on six pairs of in-water piers plus two pairs of piers on land. Each of these pier sets will be supported by a foundation of approximately sixteen 10-foot-diameter drilled shafts. Each group of shafts will be tied together with a concrete cap measuring approximately 75 by 75 feet at the water line. Columns or pier walls will rise from the shaft caps and connect to the superstructure of the bridges.

1.5.1.4 Oregon Slough Bridge(s)

The existing bridge over the Oregon Slough will be replaced. In 2012, the CRC Project did not propose replacing the existing structure and proposed adding one or more bridges for transit and other roadways. The IBR program has determined that the existing structure will need to be replaced for seismic safety. The design of the replacement bridge including the need for supplemental bridges has not been developed, but the IBR program has committed to providing vertical and horizontal clearances that will be the same or greater than the existing clearances of the Oregon Slough bridge. This would result in a minimum vertical clearance of 35 feet and a minimum horizonal clearance of 215 feet. The location of the Oregon Slough crossing has not been determined. It is likely that new or replacement bridges will need to be located at least partly outside the current bridge footprint to accommodate maintenance of traffic during construction as well as transit and active transportation connections.

1.5.1.5 Columbia River Bridge Heights Considered during CRC Project NEPA Process

Elements of the CRC Project have been proposed and studied since the early 1990s. In 2002, the I-5 Transportation and Trade Partnership produced an evaluation of multiple highway, transit, and river crossing improvements in this corridor and other parts of I-5 (Portland-Vancouver 2002). This process gathered public and stakeholder input on issues and potential solutions for transportation problems in the I-5 corridor, and the partnership recommended that the region move forward with several specific projects, including the CRC Project in 2012, and now the IBR program.

After FTA and FHWA issued a Notice of Intent to prepare an EIS in September 2005, the CRC Project team began working closely with the public, stakeholders, and local jurisdictions to develop the CRC Project's purpose and need. Following the adoption of the purpose and need, the project team developed an evaluation framework that is based on the purpose and need and set forth the criteria by which project components would be evaluated and screened for further consideration. The project team began soliciting ideas and identifying possible transportation components (for example, various

transit technologies and river crossing types and locations), and over 70 such components were identified. With public and agency input, the project team performed two rounds of evaluation and screening, as well as conducted additional evaluation and research, to narrow these options and assemble these components into 12 alternative packages. The project team then analyzed how well each alternative would address the criteria from the evaluation framework. In January 2007, the project team launched an intensive public involvement effort to present the results of this evaluation and invite comments on which alternatives should move forward into the DEIS.

During the CRC Project's early NEPA analysis and community outreach, a variety of bridge types and heights were considered. Bridge heights were evaluated in relation to impacts on river users; traffic safety; airspace; transit; downtown Vancouver, Washington; Hayden Island, Oregon; and the overall project footprint. Local communities and the two states recognized the need to balance these sometimes competing interests as potential solutions were evaluated. The bi-state CRC Task Force considered the need for the following:

1. Improved navigational safety and access.
2. Observing Federal Aviation Administration requirements that obstructions should be avoided for the safe operation of aircraft.
3. Replacement of substandard features and improved sightlines for safety on I-5.
4. Improved interstate traffic and freight mobility.
5. Grades that would accommodate transit.
6. Bridge landings that are compatible with local land use and community plans.
7. Improved bicycle and pedestrian access.
8. Safer connections to the adjacent state highway system.

In 2006, a long list of project components—including multiple transit modes, various bridge heights, various highway configurations, and other options—were evaluated to determine which should advance into further alternatives analysis. For the purposes of the analyses at that time, three representative bridge heights were evaluated for the main span: low with a movable span (around 65 feet), mid (95 to 110 feet), and high (around 130 feet). Based on study results and input, the bi-state task force recommended the following:

1. Removing the low level, movable span bridge components from consideration due to negative impacts to highway mobility, highway safety, freight movement, maintenance costs, and the lack of a significant difference in community impacts when compared to a higher mid-level fixed-span bridge.
2. Removing four high-level bridge components (greater than 130 feet) because of safety concerns with Pearson Field and 2004 findings that all known commercial and recreational vessels could be accommodated at 125 feet.
3. Advancing the mid-range height component based on the 2004 boat survey findings that a fixed span of 80 feet would accommodate all but six known vessels.

Also in 2006, the USCG accepted "cooperating agency" status and provided critical guidance to the project, including offering a public hearing for review and comment of a mid-level replacement bridge. At the September 2006 USCG public hearing, 17 people testified; one construction barge owner requested a bridge with a "high" level of navigation clearance, and one fabricator requested 100 feet.

During this same period, the Federal Aviation Administration reported it had "no objections" to the mid-level bridge height provided for the agency's consideration.

The bi-state task force moved the mid-level bridge component forward within different multimodal alternatives for technical analysis in the DEIS. About 1,600 public and agency comments were received on the DEIS in 2008. Of the comments stating a preference on the bridge element, the majority favored a replacement (mid-level bridge) as compared to no action or a supplemental bridge. Of the 1,024 comments expressing an opinion on the replacement bridge, 66% were favorable and 34% were unfavorable. Only 346 comments expressed an opinion on the supplemental bridge, with 48% favorable and 52% unfavorable.

Based on the technical analysis in the DEIS and public and agency comments, the bi-state task force and six boards and councils of each local sponsor agency unanimously recommended a replacement bridge at mid-range height with an extension of light rail to Clark College in Vancouver for the Locally Preferred Alternative (LPA). The development and refinement of the LPA was informed by public input—over 29,000 public contacts at more than 1,000 public events.

In early 2011, the Oregon and Washington governors initiated a three-month bridge type review process and ultimately identified a composite deck truss design for the replacement river crossing structures. More than 250 people and organizations provided comment. Of those, 12 commented on vertical navigational clearance or highway grade. Only one (a private citizen) said the mid-level height would potentially impede river navigation. The other 11 suggested that a higher bridge could impact aviation and bicycle and pedestrian mobility. The USCG did not submit comments at that time.

During 2011, approximately three years after the DEIS was issued, the USCG forwarded an amended height request from an existing river user, and a new river user was also identified with concerns about the bridge height. In September 2011, the FEIS was published. During this time, the USCG expressed written concern regarding the proposed 95-foot bridge height based on comments received from river users and notified the project team that 125 feet clearance would be given serious consideration during their review.

Following the issuance of the ROD the project entered the final design and permitting phase. In response to the concerns raised by the USCG, impacts to the ability of the USACE dredge *Yaquina* to transit the bridge and concerns raised by other river users over the bridge height in the ROD, the project evaluated options for a mid-level bridge with greater vertical clearance for navigation. Based on the analysis in the CRC NIR and this additional evaluation the project decided to refine the bridge design and increase the vertical clearance to 116 feet.

In 2012 the CRC Project team conducted a NEPA re-evaluation to determine whether refining the bridge's proposed vertical clearance to 116 feet and the new information on river users and vessels would result in any new significant adverse environmental impacts that were not evaluated in the

previous NEPA process. The re-evaluation concluded that there were no new significant impacts under NEPA for the 116-foot bridge (CRC 2012). A permit application and supporting materials were provided to the USCG and a permit was issued for a bridge with this vertical clearance in 2013.

A bridge height of 116 feet was selected based on the vessel analysis contained within the 2012 NIR and because that height balances the needs of navigation and surface transportation, while minimizing additional landside and environmental impacts. A bridge height of 116 feet would allow the project to avoid or minimize impacts to nearly all river users and vessels, and to mitigate the remaining impacts. A mid-level bridge higher than 116 feet would provide only minimal reductions in navigation impacts, but would add construction costs and increase environmental and landside impacts as follows:

1. 120- or 125-foot bridge would have the same impact on the tallest known vessels/users as the 116-foot bridge. Without mitigation, these vessels could not pass at any time of year. The mitigation for these vessels/users would be the same with each of these vertical clearances.
2. A 120-foot or 125-foot bridge would have higher landside and environmental impacts than a 116-foot bridge (as discussed in the 2012 NIR) and higher construction costs.

A bridge lower than 116 feet would have lower construction costs, but would have greater impacts on navigation:

1. A bridge with 115 feet or less of vertical clearance would not meet the vertical clearance requested by the USACE for their dredge vessel Yaquina.
2. A bridge with 110 feet of vertical clearance would reduce the construction cost, but would potentially impact up to seven additional vessels.
3. A bridge with 105 feet of vertical clearance would reduce the construction cost, but would potentially impact up to 14 additional vessels.

Design issues and impacts associated with increased bridge heights are summarized generally below:

4. Maximum mainline grades: The maximum grade of the mainline traffic lanes on the north and south ends of the bridges. Typically, the higher the bridge, the steeper the mainline grade required. As the grade increases traffic performance and traffic safety may decrease because it is more difficult for vehicles to accelerate and maintain speeds as they climb steeper grades.
5. Changes in entrance ramp grades: Higher bridges will result in longer or steeper on-ramps, which will require additional traffic analyses and potentially design changes to ensure safe merging and weaving operations, especially for heavy trucks.
6. Transit grade and stations: On the Washington side, increased bridge heights will result in changes in the grade of dedicated transit elements. This could affect transit performance and could create changes in station locations and affect the planned downtown Vancouver street network.
7. Protected airspace: Take-offs and landings from the Pearson Field are directed to use Federal Aviation Administration-designated air space (known as the Part 77 Imaginary Surface). With increasing bridge heights (greater than 95 feet of vertical clearance), there are two primary locations where intrusions into the protected airspace are of concern. One location is on the main span of the bridge over the Columbia River, and the other is at the SR 14/I-5 interchange

(the loop ramp in the northeast quadrant of the interchange). Typical illumination on the interstate is in the range of 50 feet above the road surface. With bridge heights of 105 to 110 feet and above, luminaires on the bridge would penetrate the Part 77 surface. Luminaires and sign gantries on the highest ramps within the SR 14 interchange would start to penetrate the Part 77 surface when the bridge exceeds about 115 feet.

8. Foundation sizes: The size of the bridge piers and foundations. This is of concern not only because of increasing costs, but also because of the potential for impacts to the river beyond those previously identified and addressed.
9. Southbound I-5 access from Vancouver: Under some of the bridge heights considered, the planned southbound on-ramp to I-5 from 6th Street may no longer be feasible because of the change to on-ramp alignment. This would be a direct result of the lengthened structures on the bridge touch down points in Vancouver.

The effects of bridge heights from 95 feet to 125 feet in increments of 5 feet on each of these elements was detailed in Section 7.3.2 of the 2012 NIR. Additional analysis was also provided in Section 7.3.2 for bridge heights providing up to 178 feet of vertical clearance and for a bridges incorporating a movable span.

1.6 IBR Program Purpose and Need

The purpose and need statements below are based on the 2012 FEIS and ROD, which was developed by the lead agencies, project sponsors, and CRC Task Force. The IBR program is using the ROD as the basis of the program and will not change the purpose and need.

1.6.1 Project Purpose

The purpose of the proposed action is to improve I-5 corridor mobility by addressing present and future travel demand and mobility needs in the IBR program area. The program area extends from approximately Columbia Boulevard in the south to SR 500 in the north. Relative to the No-Build Alternative, the proposed action is intended to achieve the following objectives: a) improve travel safety and traffic operations on the I-5 bridges and associated interchanges; b) improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the program area; c) improve highway freight mobility and address interstate travel and commerce needs in the program area; and d) improve the I-5 river crossing's structural integrity (seismic stability).

1.6.2 Project Need

The specific needs to be addressed by the proposed action are:

1. **Growing travel demand and congestion**: Existing travel demand exceeds capacity of the I-5 bridges and associated interchanges. This corridor experiences heavy congestion and delays lasting 4 to 6 hours daily during the morning and afternoon peak travel periods and when traffic accidents, vehicle breakdowns, or bridge lifts occur. Due to excess travel demand and congestion in the I-5 bridge corridor, many motorists take

the longer, alternative I-205 route across the river. Spillover traffic from I-5 onto parallel arterials such as Martin Luther King Jr. Boulevard and Interstate Avenue increases local congestion. In 2005, the two crossings carried 280,000 vehicle trips across the Columbia River daily. Daily traffic demand over the I-5 crossing is projected to increase by more than 35% during the next 20 years, with stop-and-go conditions increasing to approximately 15 hours daily if no improvements are made.

2. **Impaired freight movement**: I-5 is part of the National Truck Network, and the most important freight highway on the West Coast, linking international, national, and regional markets in Canada, Mexico, and the Pacific Rim with destinations throughout the western U.S. In the center of the program area, I-5 intersects with the Columbia River's deepwater shipping and barging, as well as two river-level transcontinental rail lines. The I-5 crossing provides direct and important highway connections to the Port of Vancouver and Port of Portland facilities located on the Columbia River, as well as the majority of the area's freight consolidation facilities and distribution terminals. Freight volumes moved by truck to and from the area are projected to more than double over the next 25 years. Vehicle-hours of delay on truck routes in the Portland-Vancouver area are projected to increase by more than 90% over the next 20 years. Growing demand and congestion will result in increased delay, costs and uncertainty for all businesses that rely on this corridor for freight movement.
3. **Limited public transportation operation, connectivity, and reliability**: Due to limited public transportation options, a number of transportation markets are not well served. The key transit markets include trips between the Portland Central City and the city of Vancouver and Clark County; trips between north/northeast Portland and the city of Vancouver and Clark County; and trips connecting the city of Vancouver and Clark County with the regional transit system in Oregon. Current congestion in the corridor adversely impacts public transportation service reliability and travel speed. Southbound bus travel times across the bridge are currently up to three times longer during parts of the a.m. peak compared to off-peak. Travel times for public transit using general purpose lanes on I-5 in the program area are expected to increase substantially by 2030.
4. **Safety and vulnerability to incidents**: The I-5 river crossing and its approach sections experience crash rates more than twice the statewide averages for comparable facilities. Incident evaluations generally attribute these crashes to traffic congestion and weaving movements associated with closely spaced interchanges and short merge distances. Without breakdown lanes or shoulders, even minor traffic accidents or stalls cause severe delay or more serious accidents.
5. **Substandard bicycle and pedestrian facilities**: The bike/pedestrian facilities on the I-5 bridges are about 3.5 to 4 feet wide, narrower than the 10-foot standard, and are located extremely close to traffic lanes, thus impacting safety for pedestrians and bicyclists. Direct pedestrian and bicycle connectivity are poor in the program area.
6. **Seismic vulnerability**: The existing I-5 bridges are in a seismically active zone. They do not meet current seismic standards and are vulnerable to failure in an earthquake.

2. PART 2: NAVIGATION IMPACTS

2.1 Means of Data Collection

This section describes the methods used to obtain navigation data.

2.1.1 Methodology

To obtain information on the current and potential future navigation needs and characteristics of the vessels that transit the bridge location, the program team conducted the following activities.

1. Identified known river users. The CRC River User Data Report (CRC report) was the primary source for known river users, including commercial, recreational, passenger cruise, and federal users, as well as marine contractors and fabricators. Additional and updated information was obtained from the Hood River-White Salmon Bridge Replacement Project NIR (completed in September 2019). Contact information for known river users was also updated and/or verified through internet research and consultation with industry groups and organizations. Known recreational users were identified through contact with area marinas and other recreational vessel service providers within an approximately 3-mile radius of the project location.
2. Prepared and distributed (via email as the preferred method) a letter and river user data sheet to identified known river users to request vessel navigation and dimensional characteristics.
3. Prepared an online survey to collect river user data from the general public (unknown users) and distributed via public notices (described below) and through the IBR program website.
4. Collected USACE data on lock usage at Bonneville and BNSF data on bridge openings on the Columbia River and Oregon Slough.
5. Collected bridge lift data from ODOT to determine if vessels required a lift that were not otherwise captured in the outreach to known river users. For the users that were not included within the known users data and did not provide information through the river user survey, attempts were made to locate the vessels through internet research and/or contact the owners through email and/or telephone.
6. Held discussions with specific users such as fabricators and shipyards to discuss unique user needs.
7. Prepared a public notice for distribution and publication in the USCG Local Notice to Mariners, in local newspapers and specialty publications as identified in Appendix C, and on the program website and social media accounts.
8. Conducted presentations about the program to the Pacific Northwest Waterways Association, the Lower Columbia River Harbor Safety Committee and indicated the need to obtain river user data. The program team encouraged attendees to complete the river user data survey and/or update or verify the information on the known river user data sheets.
9. Sent an email notice and request for information for distribution by the Pacific Northwest Waterways Association to its members.

10. Reviewed land use and zoning along the waterway and public port authority plans to identify future business/industrial property plans that could influence the types and characteristics of vessels that would require transit under the proposed bridge.
11. Followed up with specific river users via telephone or email after they had received the river user data sheet to answer any questions and facilitate a timely response.

2.1.1.1 River User Data

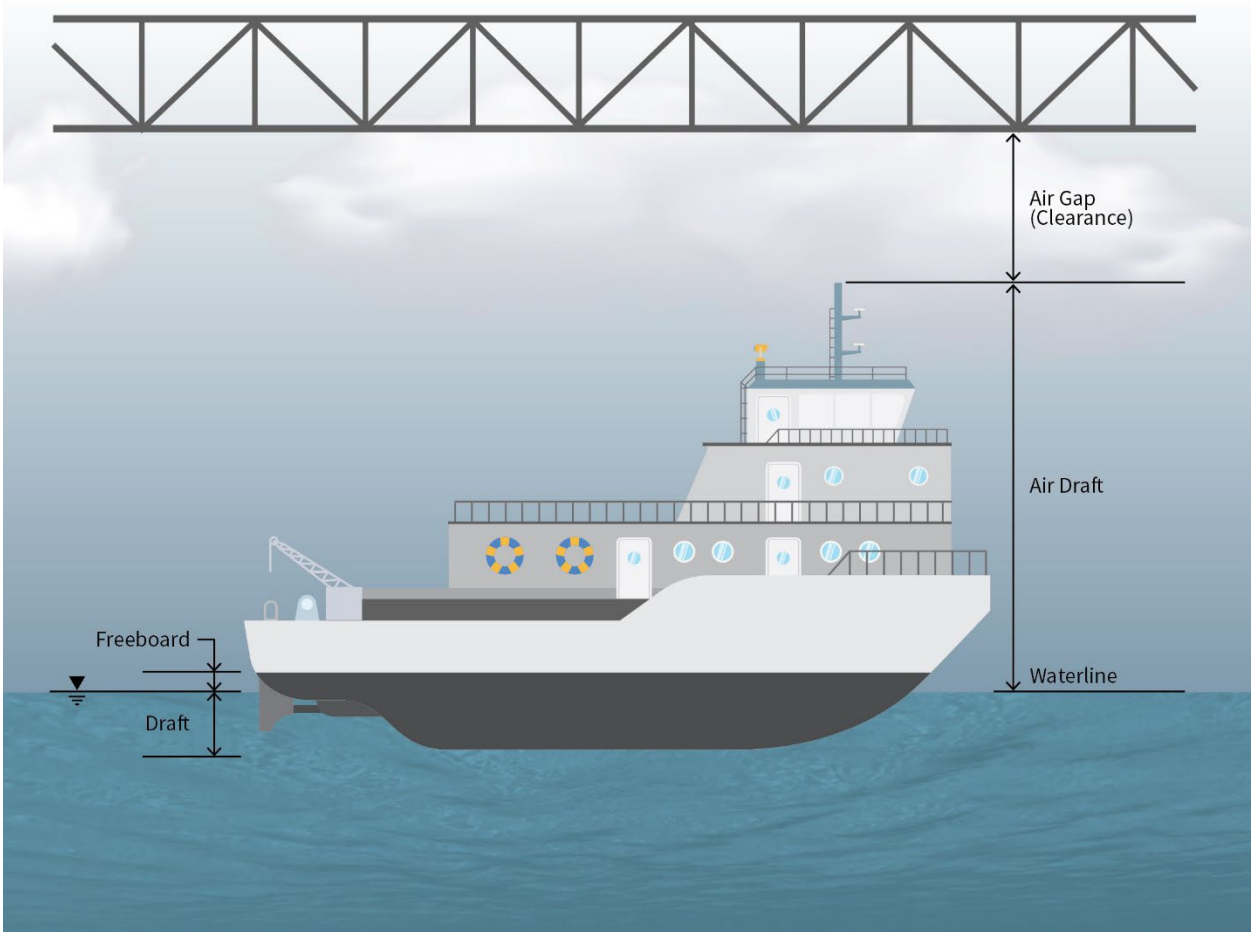
The following information was collected through the river user outreach efforts. A copy of all correspondence and a full reporting of the outreach efforts is included in Appendix B and C. Known Columbia River users who transit under the existing bridges were contacted and surveyed regarding the navigation and dimensional features of their vessels and equipment. Known river users were identified consistent with the methodology identified above. Vessel data sheets were provided, requesting the following information:

1. Company and/or owner of the vessel and contact information.
2. Vessel name.
3. Vessel type.
4. Specialized vessel (e.g. limited maneuverability due to design or mode of operation).
5. Vessel category.
6. USCG document number.
7. Primary mooring location.
8. Type and quantity of cargo, if applicable.
9. Length (overall) in feet.
10. Beam (width) in feet.
11. Draft (depth of hull below waterline, unladen) in feet.
12. Air draft (height of the highest fixed point above the waterline, unladen) in feet.
13. Air gap for vessel (desired clearance from the highest fixed point on the vessel to lowest part of the bridge) in feet.
14. Safety margin (horizontal clearance required by vessel to navigate through the bridge) in feet.
15. Transit speed under Interstate Bridge and load configuration.
16. Time of year of passage.
17. Tug assistance requirement.
18. Frequency of passage under Interstate Bridge main channel (typical per month).
19. Frequency of passage under the Oregon Slough (North Portland Harbor) bridge (typical per month).

Information on recreational vessels was obtained through the online survey, marina contacts, and individual contact with vessel owners if needed. All the information gathered during the user survey was self-reported. However, some information was verified by field surveys for the CRC Project. Figure

2.1-1 is a diagram of vertical reference descriptions listed on the river user data sheet using a tug as the example vessel.

Figure 2.1-1. Vertical Reference Diagram



The bridge vertical clearance is the distance from the water surface to the lowest member of the bridge structure. The air gap is the additional height above the highest point on a vessel necessary to allow for a safety factor when transiting under a bridge due to wave- and wind-induced movements in the vertical plane. This is especially applicable for sailboats and other low weight vessels since they have greater responses to wave conditions. Vessel responses are unique for a given ship's geometry and weight distribution and vary with the ship's forward speed, the channel bathymetry, and environmental conditions such as wind and wave direction, height, and length. The amount of air gap is also influenced by visibility. For a project with a long design life, the long-term impacts caused by changing river runoff characteristics, sea level rise, and land subsidence are potential considerations as well. Air gap is in general provided by the vessel operator but may be adjusted if a request air gap seems unreasonable.

Since the river level fluctuates, a river level that is exceeded only 1.2% or less of the time during the life of a project is a conservative design criterion for determining the near maximum surface for a heavily used channel. At the I-5 bridges, this design river level is 16 feet CRD and is used to determine whether a vessel is height restricted.

Users Contacted

Known river users were identified from the CRC report and the Hood River-White Salmon Bridge Replacement NIR. Users were contacted by email and telephone. Users were divided into the following categories: commercial tugs, tows, and barges; marine contractors; federal/emergency/maintenance; passenger cruise; and recreation.

Commercial, Marine Contractor, Passenger Cruise, and Federal Users

Forty commercial, marine contractor, fabricator, shipyard owner, federal, and passenger cruise users were contacted. Approximately half have responded confirming the vessel data obtained from prior reports and/or providing updated vessel information. Table 2.1-1 lists the commercial, marine contractor, passenger cruise, and federal river users contacted, the vessel category, and indicates if a response was received. Many responders in these categories operate multiple vessels.

Table 2.1-1. Commercial, Marine Contractor, Passenger Cruise, and Federal River Users Contacted

Company Name	Category	Response
Advanced American Construction	Marine Contractor	No
American Cruise Lines	Passenger Cruise	Yes
American Queen Steamboat Company	Passenger Cruise	No
American Waterways, Inc.	Passenger Cruise	Yes
Bergerson Construction	Marine Contractor	No
Bernert Barge Lines	Commercial Tugs/Tows/Barges	Yes
Brusco Tug and Barge	Commercial Tugs/Tows/Barges	No
Cadman	Industrial	Yes
Cal Portland	Marine Contractor	No
Centerline Logistics (previously Olympic Tug & Barge)	Commercial Tugs/Tows/Barges	No
Diversified Marine	Marine Contractor	Yes
The Dutra Group	Marine Contractor	No
Foss	Commercial Tugs/Tows/Barges	No
General Construction (Kiewit)	Marine Contractor	Yes
Greenberry Industrial LLC	Fabricator	Yes
Grays Harbor Historical Seaport	Passenger Cruise	No
Hickey Marine	Marine Contractor	No
JE McAmis	Marine Contractor	No

Table 2.1-1. Commercial, Marine Contractor, Passenger Cruise, and Federal River Users Contacted

Company Name	Category	Response
JT Marine	Marine Contractor	Yes
Knife River	Marine Contractor	No
Legendary Yachts	Shipyard	Yes
Lindblad/National Geographic Expeditions	Passenger Cruise	Yes
Manson Construction	Marine Contractor	No
Mark Marine Service	Marine Contractor	No
NorthBank Civil and Marine	Marine Contractor	Yes
Puget Sound Naval Shipyard	Federal	Yes
Ross Island	Marine Contractor	Yes
SDS Tug & Barge	Commercial Tugs/Tows/Barges	No
Schnitzer Steel Industries	Fabricator	Yes
Schooner Creek Boat Works	Shipyard	Yes
Shaver	Commercial Tugs/Tows/Barges	Yes
Thompson Metal Fab	Fabricator	Yes
Tidewater	Commercial Tugs/Tows/Barges	Yes
Tongue Point Job Corps (Maritime Training Program)	Federal	No
UnCruise	Passenger Cruise	No
USACE	Federal	Yes
USCG, Marine Safety Unit (Portland)	Federal	Yes
Vigor Works, LLC	Fabricator	Yes

Recreational Users

Recreational users were not generally contacted individually, and information was obtained from recreational marinas in the project vicinity, as well as through responses to the online river user survey. Marinas contacted are listed below. Of the marinas contacted, only Hood River and St. Helens provided a response. Both marinas indicated they do not have boats that exceed 80 feet in height. The marinas that did not respond may have distributed the online survey link to their tenants, as several respondents to the online survey indicated a mooring location at one of the marinas listed below.

Marinas Contacted

1. Astoria Yacht Club
2. Big Eddy Marina
3. Camas-Washougal Marina
4. Columbia River Yacht Club

5. Dolphin Yacht Club
6. Grand Banks Yacht Club
7. Hayden Bay Marina
8. Hayden Island Yacht Club
9. Hood River Marina
10. Jantzen Bay Marina
11. Longview Yacht Club
12. McCuddy's Marina
13. Multnomah Channel Yacht Club
14. Nots Boating Club
15. Portland Yacht Club
16. Riverside Yacht Club
17. Rose City Yacht Club
18. Sauvie Island Yacht Club
19. St. Helens Marina
20. The Dalles Marina
21. Tomahawk Bay Marina
22. Tomahawk Bay Yacht Club
23. Tyee Yacht Club

Online Survey

As of the date of this report, the online survey has received 39 responses. Five surveys were received for commercial vessels, three for cruise vessels (one large passenger cruise vessel and two smaller vessels that self-reported as cruise vessels), seven for recreational motor vessels, 23 for sailboats, and one for a kayak.

2.1.1.2 Bridge Opening Data

The primary channel under the existing Interstate Bridge provides a vertical clearance of 39 feet when the lift span is in the lowered position. Navigation lights below the structure reduce the clearance to 38 feet in the lowered position. The barge channel and alternate barge channel provide for vertical clearance of 58 feet and 72 feet, respectively. Vessels that require a clearance greater than this or that cannot safely negotiate the alternate channels require that the lift span be raised.

Vessels that require the lift span to be raised indicate that the particular vessel could be impacted by the replacement bridge height. However, as noted above, the lift spans are also raised because of

maneuverability limitations, and thus not all vessels that require a lift span are constrained by the height of the existing fixed spans, and this must be considered in reviewing bridge opening trends. To identify vessels that have historically and currently required bridge lift span openings, the program team reviewed bridge lift data provided by ODOT. The bridge tenders operating the lift spans of the existing bridges record details of each lift in a logbook. Information recorded in the log includes the date and time of the opening, the name of the vessel or vessels transiting, the type of vessel, the lift elevation, the current water level, and weather conditions, among other data. The 2012 CRC NIR reported lift data from January 1, 1987, to December 17, 2011, and this was supplemented with data from 2012 to 2020.

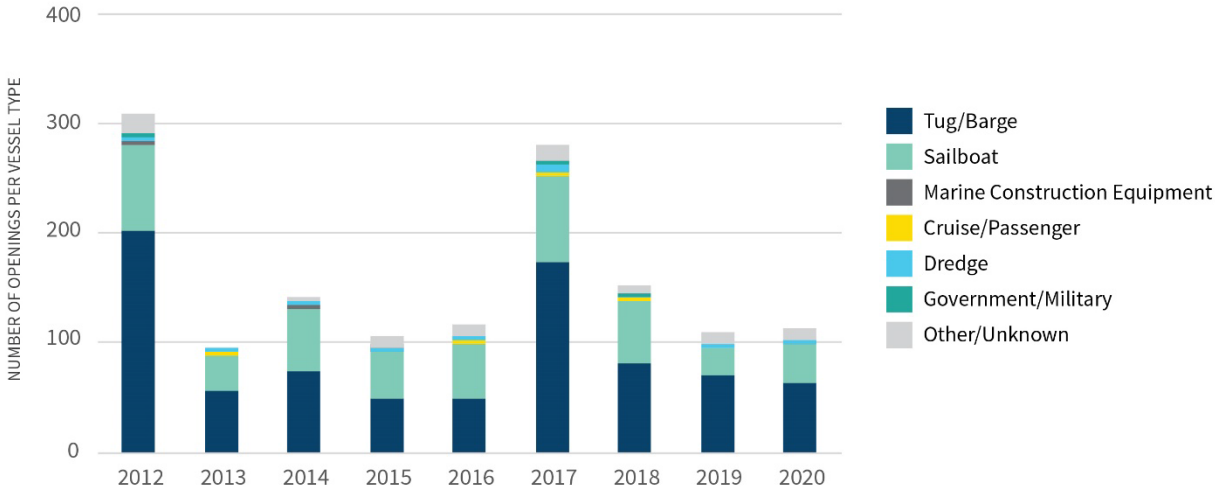
The program team reviewed the logs and categorized bridge openings by type of vessel:

- Tugs and barges (including tugs proceeding with no barge or with barges in tow).
- Sailboats.
- Construction equipment (defined as power barges, crane barges, derricks, etc.).
- Cruise and passenger boats (vessels providing passenger service between downriver and upriver locations).
- Dredges (including the USACE dredge Yaquina and other privately owned dredges).
- Government or military vessels (U.S. Navy, USCG, and the Astoria Job Corps, etc.).
- Other/Unknown (vessels that had no name or designation).

Many vessels that transit under the existing bridges do not require an opening of the lift span. These vessels are either are low enough to pass through the lift span in the lowered position or use one of the two alternate channels to the south of the lift span.

Bridge opening trends from 2012 to 2020 are presented in Figure 2.1-2. The number of bridge opening events (excluding openings for bridge maintenance, in which no vessel transited) ranged from a low of 92 events (2013) to a high of 309 events (2012), with an average of 157 events per year. This compares with a low of 70 events (2004) and a high of 863 events (1997), with an average of 289 events per year from 1997 through 2011. A spreadsheet of all bridge openings from 1997 to 2020 is included in Appendix E.

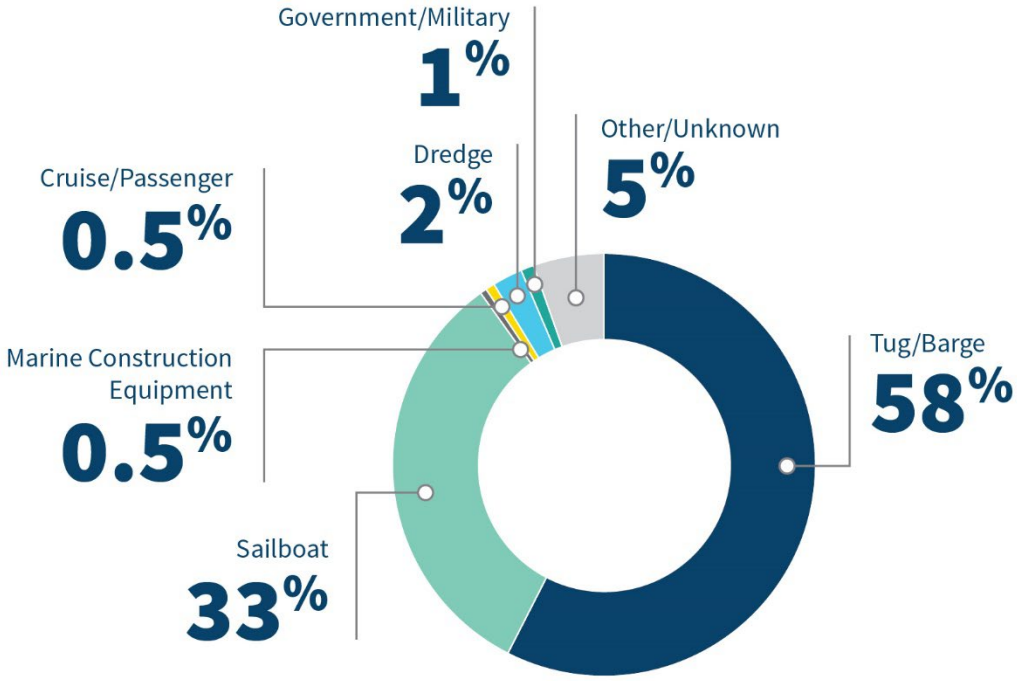
Figure 2.1-2. Bridge Opening by Vessel Type by Year: 2012 to 2020



Source: I-5 Bridge Tender Logs as categorized by the project team.

Figure 2.2-3 summarizes the share of bridge opening events by type of vessel over a nine-year period (2012 to 2020). Tugs and barges accounted for over half (58%) of all openings, followed by sailboats at 33% and vessels where a type could not be determined at 5%. Each of the remaining vessel types accounted for between 1 and 2%. Comparing this with the data from 1987 and 2011 shows little change in openings except for the reduction in lifts involving construction equipment. From 1987 to 2011, tugs and barges accounted for over half of all openings, followed by sailboats at 22% and construction equipment at 17%, with each of the remaining vessel types accounting for 1% to 4%.

Figure 2.1-3. Bridge Openings by Vessel Type 2012 to 2020



Source: I-5 Bridge Tender Logs as categorized by the project team.

2.1.1.3 Bridge Openings as a Share of Total Navigation Activity

There are no sources of information that directly compare the number of bridge opening events with all river activity because the only recorded transits of the bridge are those that require a bridge opening. However, data are available that characterize the annual vessel activity for commercial tugs and barges and recreational boats, as discussed below.

The number of commercial lockages at the Bonneville dam provides a useful estimate of the total transits (or events) that occur at the existing bridges, because nearly all of the traffic passing through the Bonneville lock was linked to terminals located downriver of the bridges. BNSF bridge opening data also provide information on vessel transits that may also occur at the existing I-5 bridge as most commercial vessels and sailboats require an opening of the BNSF bridge.

Bonneville lock data from the years 2000 through 2011, as reported in the CRC NIR, show an average of 2,596 commercial lockages at the dam, where the share of this traffic that required an opening at the bridges represented an average of 3.6% of estimated total trips. From 2012 through 2020, 22,584 passages were recorded, showing an average of 2,258 per year (USACE 2021d). Where the share of this traffic that required an opening at the bridges represented an average of 7% of estimated total trips.

The number of openings of the BNSF bridge can provide information on total commercial vessel traffic and most sailboats, as they require an opening to navigate the bridge, and there are limited origins/destinations between the BNSF bridge and the existing I-5 bridge, and most vessels would have to pass both bridges. The BNSF rail bridge (BNSF Columbia Draw 9.6) saw a total of 19,636 openings between the years 2015 and 2020, where the share of this traffic that required an opening at the bridges represented an average of 4% of estimated total trips.

2.2 Present Governing Structures

Existing bridges and other structures spanning the river, such as electric transmission lines, can restrict vessel use based on their existing horizonal and vertical clearances. This section describes the governing structures affecting navigation at the project location and defines the limits of navigation that could be impacted by the proposed replacement bridges.

2.2.1 Columbia River

Table 2.2-1 contains details of the existing structures crossing the Columbia River between the mouth of the Columbia River and the BNSF railroad bridge at Celilo. The existing Interstate Bridge is a governing structure as all bridges downstream currently provide greater vertical clearance. The BNSF bridge at Celilo is located at RM 201.2, which is approximately 10 miles upriver from The Dalles lock and dam (RM 191.5). The lift span provides a maximum vertical clearance of 79 feet above the normal pool elevation behind The Dalles dam when open, making it a controlling factor for vertical clearance. This means that the height constraint imposed by a vertical clearance of 116 to 121 feet potentially affects river traffic vertical clearance for approximately 95 miles, or 20% of the river system. Vessels originating upstream of this location or downstream and traveling to an upstream destination upriver of the BNSF rail bridge at Celilo, are limited to a vertical clearance of 79 feet included an air gap in order to transit through the bridge. Upstream of the BNSF rail bridge at Celilo, there are other bridges with navigation clearances lower or similar. These include the Interstate 82 Bridge (71 feet), and Union Pacific Railroad Bridge upriver of McNary Dam (72 feet). A complete list of bridges and other crossings are shown in Appendix D.

Table 2.2-1. Existing Columbia Navigation Clearances

Bridge	River Mile	Horizontal Clearance (feet)	Vertical Clearance (feet)	Vertical Clearance with Span Open (feet)
Astoria-Megler Bridge	13.5	1,070	193	NA
Power Cable	40.0	NA	230	NA
Power Cable	62.4	NA	216	NA
Lewis & Clark Bridge	66.0	1,120	187	NA
Power Cable	104.2	NA	220	NA
BNSF Rail Bridge	105.6	200	39	Unlimited
Existing Interstate Bridge	106.5	263	39	178
Glenn L. Jackson Memorial Bridge (I-205)	112.7	469	136	NA
Power Cable (directly west of Bonneville Lock and Dam)	145.1	NA	210	NA
Bonneville Lock and Dam (navigation lock)	145.3	86	Unknown	Unlimited
Power Cable	146.6	NA	190	NA
Bridge of the Gods	148.3	655	135	NA
Hood River-White Salmon Bridge	169.8	246	67	148
Power Cable	171.1	NA	155	NA
Power Cable	173.8	NA	159	NA
Power Cable	186.2	NA	155	NA

Table 2.2-1. Existing Columbia Navigation Clearances

Bridge	River Mile	Horizontal Clearance (feet)	Vertical Clearance (feet)	Vertical Clearance with Span Open (feet)
The Dalles Bridge (navigation lock approach)	191.6	250	100	NA
The Dalles Bridge (main span)	191.6	551	81	NA
The Dalles Lock & Dam	191.8	86	NA	100
Power Cable	191.9	NA	125	NA
Power Cable	201	NA	123	NA
BNSF Celilo Bridge	201.2	300	20	79

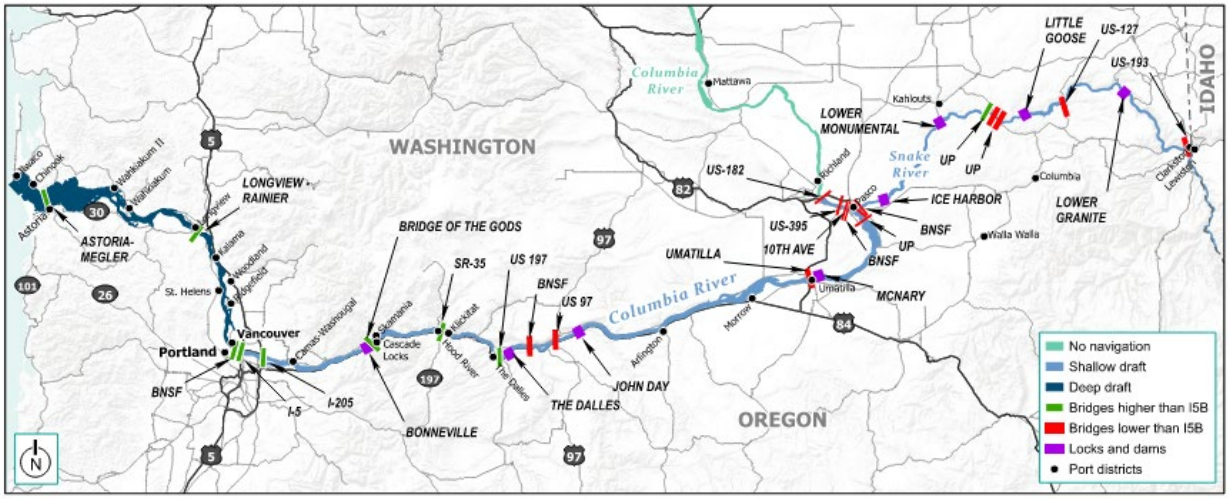
Key:
NA = not applicable
I-205 = Interstate 205

The Bonneville Lock and Dam at the navigation lock approach (RM 145.3) is currently the most restrictive horizontal clearance at 86 feet. This is not representative of the horizonal clearance at bridges as vessels approach and depart the locks at low speeds but does represent the limiting factor for vessels navigating above the Bonneville dam. The most restrictive horizonal clearance of 200 feet is provided by the BNSF railroad bridge, located approximately 1 mile downstream of the existing I-5 bridges in Vancouver.

Plans are currently underway for a fixed height bridge to replace the existing SR 35 bridge located in Hood River (RM 106.5) identified in Table 2.2-1. The existing SR 35 bridge includes a lift span with a vertical clearance of 67 feet in the closed position and 148 feet in the open position above the normal pool elevation behind the Bonneville dam. The analysis for replacement bridges assessed impacts to users based on two proposed navigation envelopes—80 feet of vertical clearance across a 450-foot horizontal clearance and 90 feet of vertical clearance across a 250-foot horizontal clearance at the center span of the bridge (WSP 2019). A preliminary navigation clearance determination was issued by the USCG for the replacement bridge. This NIR does not consider the replacement bridge but were this bridge to be completed it would change the governing structures and reduce the area with the potential to be impacted by height restrictions from the IBR program.

Figure 2.2-1 shows the location of the governing structures on the Columbia-Snake River System. Appendix D includes details on the navigation clearances for all bridges, cables, and locks across the Columbia River (from the mouth to Richland, Washington), and across the Snake River (from the mouth to Lewiston, Idaho).

Figure 2.2-1. Columbia-Snake River System Map



2.2.2 Oregon Slough

Table 2.2-2 contains details of the existing structures on the Oregon Slough.

Table 2.2-2. Existing Structures on the Oregon Slough

Bridge	River Mile[1]	Horizontal Clearance (feet)	Vertical Clearance (feet)	Vertical Clearance with Span Open (feet)
Power Cables	104.2	NA	160	NA
BNSF Railroad	105.6	200	39	Unlimited
I-5	106.5	215	35	NA
Power Cable	106.7	NA	54	NA

Note:
[1] River mile reference is to the Columbia River since Oregon Slough is not numbered separately

Key:
I-5 = Interstate 5
NA = not applicable

Because the existing I-5 bridge across the Oregon Slough has vertical clearance of 35 feet, it represents the most restrictive vertical clearance on the waterway. The most restrictive horizontal clearance is the BNSF Railroad bridge.

2.3 Waterway Characteristics

The following section identifies the navigational characteristics of these two navigable waters in the immediate program area.

2.3.1 Introduction

The Columbia River headwaters are located in in British Columbia, Canada, through which it flows for approximately 425 miles before entering the continental U.S. in northeast Washington. From the border in flows generally south to its confluence with the Snake River where it turns west and forms the boundary between Washington and Oregon for the remainder of its course to the Pacific Ocean. The river is an important natural resource and also serves a vital role for power generation, irrigation, navigation, and recreational purposes. The river is navigable for deep-draft vessels from its mouth to Portland, Oregon, and Vancouver, Washington, and for shallow-draft vessels to Lewiston, Idaho via the Snake River.

The Columbia River's deep-draft navigation system provides for a 43-foot-deep by 600-foot-wide channel from inside the Columbia River Bar upriver to ports on both the Washington and Oregon sides of the river at approximately river mile (RM) 106. The upriver end of this section of the channel, known as the Columbia and Lower Willamette, is just downriver from the existing I-5 bridges.

From just downstream of the I-5 bridges to the head of navigation in Lewiston, Idaho, the Columbia River is maintained as a shallow-draft system predominantly supporting tug and tow vessel traffic. The shallow-draft system has a controlling depth of approximately 15 feet. Just east of The Dalles is a BNSF railroad bridge at Celilo Falls with a vertical clearance of 79 feet, which is notably less than the bridge heights under consideration for the IBR program.

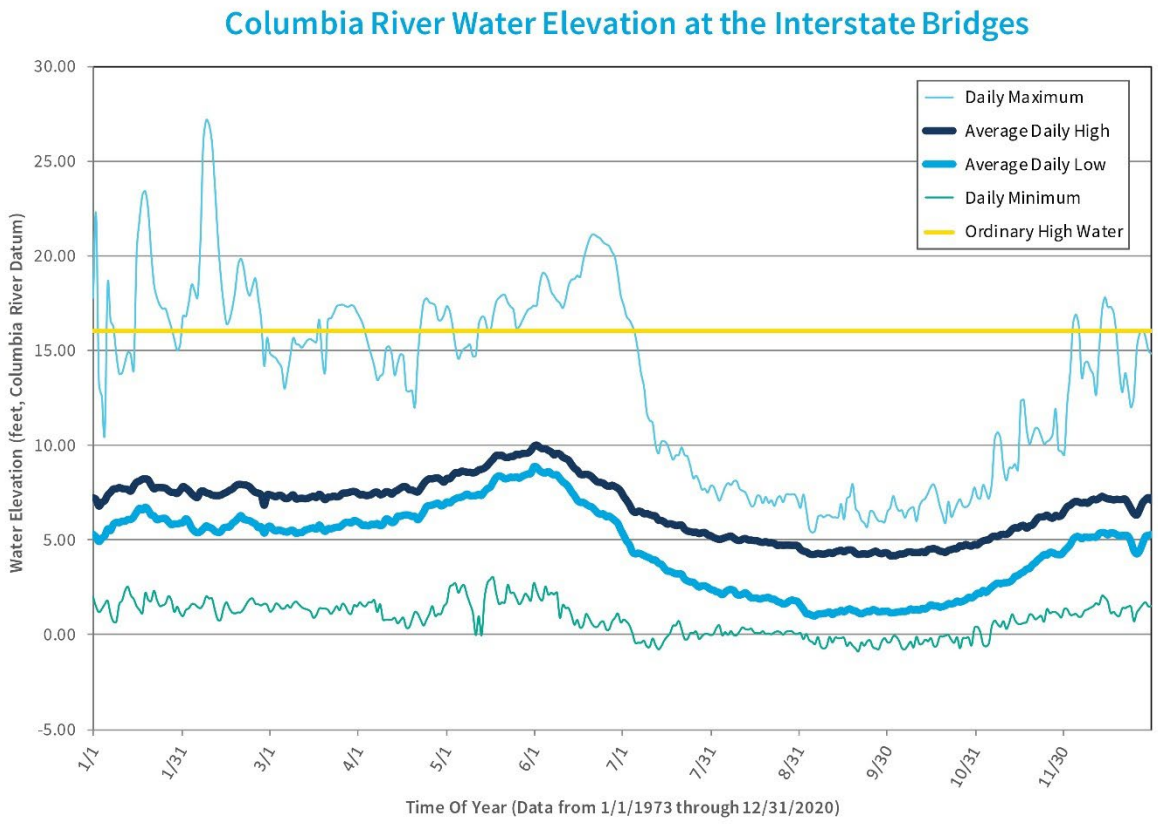
Between the I-5 bridges and the Celilo Falls BNSF railroad bridge 95 miles to the east, many shoreline land uses are dependent on the Columbia River. In general, the Columbia River shoreline is identified by local jurisdictions as a resource to be leveraged for river-dependent uses that are more in line with recreational, environmental, habitat, or economical purposes than with industrial marine, water-dependent uses. The intrinsic value of the Columbia River is largely in its natural beauty, especially within the National Scenic Area located roughly 50 miles east of I-5. The most significant land use control is the 85-mile-long Columbia River Gorge National Scenic Area, which protects the natural beauty of the gorge and severely limits industrial development outside of existing incorporated communities.

2.3.2 River Water Level at the I-5 Bridges

One of the critical factors influencing vertical clearance is river water level, which fluctuates daily and over the course of the year. Figure 2.3-1 summarizes the variability in water levels for the Columbia River at the I-5 bridges from 1972 through 2020. Included in the figure are daily maximum, daily

minimum, average daily high, and average daily low water levels. Appendix F contains the data used to develop this chart.

Figure 2.3-1. Columbia River Water Elevation at the Interstate Bridges (1972–2012)



The Columbia River generally follows a seasonal trend of lowest water levels in late summer, moderately higher than average water levels in the winter (except for occasional storm-induced high water), and the highest average water levels in May and June coinciding with peaks in spring snowmelt and rainfall. In general, the following river water level trends can be observed from the data collected over the past 50 years:

- The highest average daily high is approximately 10 feet above CRD and occurs in late May/early June. The lowest average daily low is approximately 2 feet above CRD and occurs in early September.
- The ordinary high water level of 16 feet above CRD was exceeded less than 1.2% of the time over the past 50 years. This is used as the “analysis level” for identifying vessels that would be impacted by different vertical clearances, as discussed in Section 2.17.

River levels at the I-5 bridges are influenced primarily by variations in runoff. However, the river level is tidally influenced between its mouth at the Pacific Ocean and the Bonneville dam. The tidal influence is less at high river flow conditions and greater during low flow conditions. According to NOAA Chart 18526, the diurnal range of the tide during low river stages is 1.8 feet at Vancouver. The range becomes progressively smaller with higher stages of the river.

2.3.2.1 Waterway Stages

According to records maintained by the National Weather Service, the following are the flood categories and river stages for the Columbia River downstream of the I-5 bridge:

- Action Stage – 15 feet above CRD
- Flood Stage – 16 feet above CRD
- Moderate Flood Stage – 20 feet above CRD
- Major Flood Stage – 25 feet above CRD

According to the Federal Emergency Management Agency National Flood Insurance Study for Clark County, Washington, the 100-year flood level is 26.12 above CRD (FEMA 2018).

The top five historical river crests (feet above CRD) for the Columbia River downstream of the I-5 bridges are:

1. 31.0 feet on June 13, 1948
2. 30.8 feet on June 1, 1948
3. 27.7 feet on December 25, 1964
4. 27.6 feet on June 4, 1956
5. 27.2 feet on February 9, 1996

The top four low water records for the Columbia River downstream of the I-5 bridges are:

1. -1.20 feet on January 7, 1937
2. -1.10 feet on November 8, 1936
3. -0.80 feet on July 30, 1978, and July 24, 1989
4. -0.74 feet on July 14, 2001

While many vessels will not transit during very high water stages, self-reported observations from marine contractors included reports of being very busy during the February 1996 flood event, when they had to perform many rescues and temporary repairs of vessels, docks, and moorings, and had frequent transits under the lift span of the I-5 bridges.

2.3.2.2 Potential Climate Change Impacts

Climate change could affect future Columbia River water levels, as described in Chapter 3 of the CRC FEIS. This was based on reviewing research conducted by the University of Washington's Climate

Change Impacts Group. Section 3.19 of the FEIS summarizes how the project might perform under potentially changing conditions predicted because of climate change. Updated information from the Climate Change Impacts Groups (Miller 2018) and other sources was also reviewed. Based on the published information, the impacts of climate change in the IBR program area that could be relevant to future Columbia River water levels and vessel clearance are projected as follows:

- Relative sea level rise in the Pacific Northwest will vary regionally based on uplift and subsistence. For 2100, the projected absolute sea level rise is 1.0 to 2.2 feet in the low scenario and 1.4 to 2.8 feet in a high scenario. For 2150, the projected ranges are 1.5 to 3.8 in the low scenario and 2.3 to 4.9 feet in a high scenario.
- Warmer winter temperatures in the Columbia River Basin will result in lower snowpack and higher winter base flows. Lower base flows are expected in the spring and summer months, and an increased likelihood of more intense storms may increase the chance of flooding. Average annual precipitation is likely to stay within the range of 20th century variability; however, there will be a shift in the amount and timing of seasonal precipitation, with a trend toward more winter precipitation.
- Seasonal shift in temperature and precipitation will likely impact base and peak flows and river water levels. Warmer, wetter winters will likely lead to higher winter base flows and river stages, while lower base flows and river stages will likely occur in spring and summer months.

There is uncertainty associated with these predictions, and the best available science does not provide specific predictions for how climate change impacts would change the daily or monthly average highs and lows at the bridge crossing. Further, while numerous studies have been performed on the impacts of climate change on the Columbia River, they have focused on hydrology. No known studies have evaluated the potential changes to the stage of the Columbia River, which is affected by river management and discharge as well as tide in the lower Columbia.

However, based on existing data regarding how Pacific Ocean tidal changes affect river water levels at the bridges, it is reasonable to expect that if sea levels rise as predicted, there would be a resulting increase in water levels at the bridge during low runoff periods that is less than the absolute increase in sea levels projected at the coast and little to no impact during the higher runoff periods. As indicated above, the climate change predictions, if accurate, suggest that average spring flows, which are historically the highest of the year, will be lower in the future; that average winter flows will be higher (peak average flows could shift away from the spring and toward the winter season); and that average summer flows, historically the lowest of the year, will be even lower in the future.

Because the best available science provides no quantitative predictions of how daily or monthly average flows could change, it is difficult to translate the general climate change predictions into precise conclusions regarding future vessel clearances. However, given that the average annual precipitation is not expected to change, this suggests that average annual runoff would be similar, and thus average annual river levels at the bridge would likely be similar to what they have been in the past 50 years. Sea level rise could have a minor impact on these water levels during low runoff periods.

Given the predictions in seasonal precipitation changes, however, any impact of sea level rise could be counteracted by low flows being even lower in the future. This combination could result in slightly

more vertical clearance during the spring and summer months compared to recent history, and slightly less during the winter months, at least during the days following storms or major precipitation events. However, these changes would not be expected to affect the ordinary high water level, which is the water level considered for evaluating vertical clearance available to vessels.

2.3.3 Natural Flow of the Waterway

Currents at the bridge location are generated by flows released at Bonneville dam. According to the Federal Emergency Management Agency Flood Insurance Study for Portland, Multnomah County, Oregon dated November 26, 2010, the average cross sectional velocity for the 100 year flood near the I5 bridge is 3.8 feet/sec (2.25 knots) (FEMA 2018). Note that this velocity is the average of the entire cross section. Localized velocities, especially near the center of the channel, could be greater. During low flow periods the current is affected by tides, such that slack tide can result in very little to no current. Currents used in the simulation effort are shown in Table 2.3-1. No current information was found for the Oregon Slough.

Table 2.3-1. Columbia River Currents

Designation	Discharge at The Dalles (KCFS)	River Gage @I-5 Bridge (CRD)	Current Magnitude (fps/knots)
Normal	140	2.8	1.84/1.09
Transition	400	14.5	3.65/2.16
10-Year	540	19.1	4.35/2.58

Key:
CRD = Columbia River Datum
fps = feet per second
I-5 = Interstate 5
KCFS = 1,000 cubic feet per second

When traveling with a river current, vessels need to maintain a faster speed than the current to provide steerage. Consequently, at higher river velocities, speed over ground is increased and the required distance to negotiate turns becomes greater. Should the vessel need to stop for any reason, it must compensate for the river flow by backing down. If the vessel is towing a non-self-propelled barge or other vessel, the tow can lose control and the only chance to stop the tow would be to turn around. Barges being towed often have a tug alongside them while transiting under bridges and along other parts of the river to provide greater control.

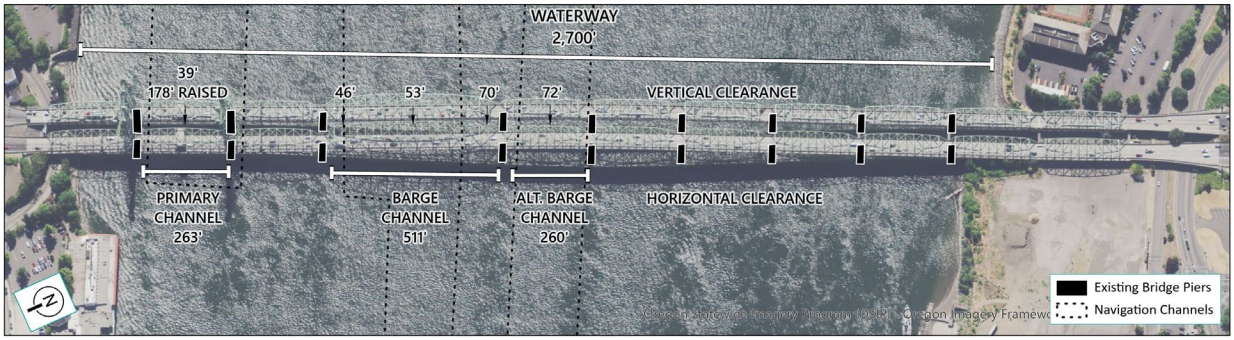
2.3.4 Waterway Width and Depth

2.3.4.1 Columbia River

The main Columbia River at the location of the I-5 bridge has a width of approximately 2,700 feet. The river is constrained by urban development with hardened banks. The width is relatively consistent up-

and downstream of the bridge for a considerable distance. The maintained federal channel widths and the overall river width are shown in Figure 2.3-2.

Figure 2.3-2. Columbia River Width



As noted previously, the channel depths maintained at the bridge by the USACE are either 15 or 17 feet. Available depth as shown by the most recent channel surveys completed by the USACE show water depths of 30 feet in the primary channel, 21 to 25 feet in the barge channels and depths of up to 48 feet outside the channels. Water shallower than 20 feet is limited to within 50 feet of the Washington shoreline and 300 feet of the Oregon shoreline (USACE 2021b).

Water depths in the UVTB and the Lower Columbia and Willamette project downstream of the bridge are currently less than the authorized depth of 35 feet. The most recent channel survey from the USACE in August of 2021 shows water depths of 20 to 30 feet downstream of the bridge for approximately 3,300 feet (USACE 2021c).

2.3.4.2 Oregon Slough

The Oregon Slough is a side channel of the Columbia River that separates Hayden Island and the Oregon shore. This waterway is also known as the North Portland Harbor, and this name is used on many maps, charts, and in other documents. Oregon Slough is used in this report for consistency with the name used on the bridge permit issued for the construction of the existing I-5 bridge and for the federal navigation project that is on portions of the waterway. However, North Portland Harbor is used in many prior documents, including other IBR program documents, and may be shown in figures and maps. The names should be used interchangeably.

The Oregon Slough at the location of the I-5 bridge has a width of approximately 950 feet. The waterway is constrained by a federal levee on the south bank and urban development and infrastructure on both shorelines. The river widens just upstream but is a relatively consistent width downstream to its confluence with the main Columbia River channel. The Oregon Slough has numerous floating home and recreational and commercial moorage facilities that constrain the channel both up- and downstream of the I-5 bridge. This restricts the available width of the waterway for navigation to approximately 350 feet just upstream with even narrow widths available further east. These constraints are not generally present downstream of the BNSF bridge.

Water depths at the Oregon Slough are shown as approximately 8 to 10 feet at the I-5 bridge on North American Oceanic and Atmospheric Administration (NOAA) charts (NOAA 2020). Water depths vary considerably up- and downstream of the bridge, with depths of 40 feet or more downstream near the Port of Portland berths and shoaling at the upstream confluence with the Columbia, with depths as shallow as 3 to 4 feet. There are no available USACE surveys of the waterway at the existing bridge as it is not a federal project.

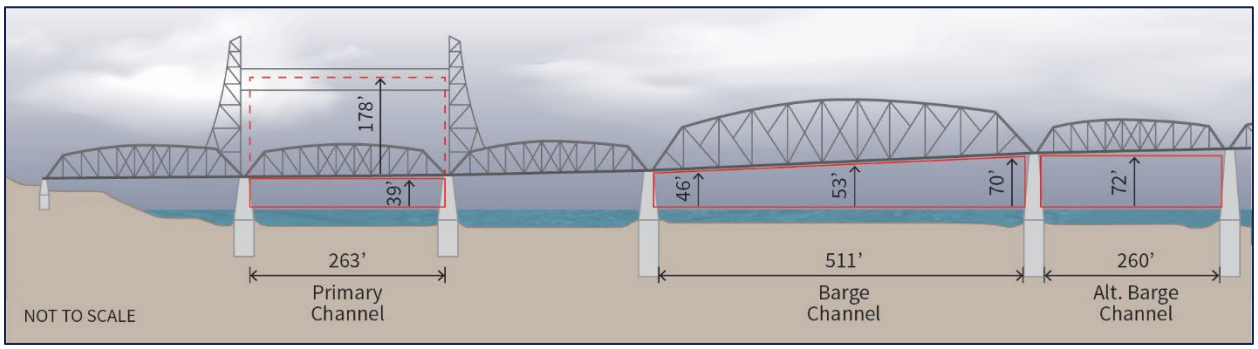
2.3.5 Channel and Waterway Alignment

There are three bridges crossing the main channel of the Columbia River in the program area: the northbound and southbound structures of the I-5 bridges and the BNSF railroad bridge.

Under the I-5 bridges, vessels that are restricted to the navigation channel (the majority of commercial vessel traffic) pass through one of three designated federal navigation channels: the primary channel, the barge channel and the alternate barge channel (see Figure 2.3-3).

- The primary channel corresponds with the bridges' lift spans and has a horizontal clearance of 263 feet and a vertical clearance of 39 feet in the closed position and 178 feet in the raised position.
- The barge channel lies under the wide spans of the bridges and has a horizontal clearance of 511 feet and a vertical clearance ranging from 46 feet to 70 feet.
- The alternate barge channel occupies the span directly to the south of the wide span and has a horizontal clearance of 260 feet and a vertical clearance of 72 feet.

Figure 2.3-3. Existing I-5 Columbia River Navigation Clearances



The third bridge in the program area—the BNSF railroad bridge—is located approximately 1 mile downstream (westerly) from the I-5 bridges and provides unlimited vertical clearance through a 200-foot-wide movable swing span. It provides a vertical clearance of 39 feet in the closed position. There is only a single federal channel corresponding with the swing span. The vertical clearance of 39 feet is generally available on the fixed spans across the width of the bridge outside the federal navigation channel.

The most direct vessel route through this river section is through the I-5 bridges' primary channel lift spans and through the BNSF bridge's swing span. This route is relatively straight and is preferred

during times of high velocity river flow and for vessels with limited maneuverability when traveling downstream regardless of vessel height. Vessels that require a vertical clearance over 39 feet necessitate the lift spans and swing span to open to complete the transit. The Code of Federal Regulations (CFR) stipulates that the I-5 draw shall not be opened Monday through Friday from 6:30 a.m. to 9 a.m. or from 2:30 p.m. to 6 p.m. (CFR Title 33 Chapter I Subchapter J, Part 117 § 117.869).

Vessel operators can avoid the need for a bridge lift by utilizing the I-5 bridges' barge or alternate barge channels as vertical clearance and vessel maneuverability allows. Vessels are generally prohibited from requesting a lift span when they can pass without a lift (CFR Title 33 Section 117.11). The use of these channels requires a more complex maneuver than does the route through the primary channel and requires the vessel to navigate a relatively complex "S" curve path between the I-5 bridges and the BNSF bridge to pass through the BNSF swing span. The alternate barge channel (the southernmost channel) requires a more pronounced maneuver than the barge channel. These routes are generally shown in Figure 2.3-4 and are designated as the barge channel route and the alternate barge channel route. The channel locations would be modified to accommodate the proposed vertical clearance locations and location of the bridge piers. Proposed navigation channels are shown in Figure 2.3-5.

Figure 2.3-4. Existing Columbia River Navigation Channels

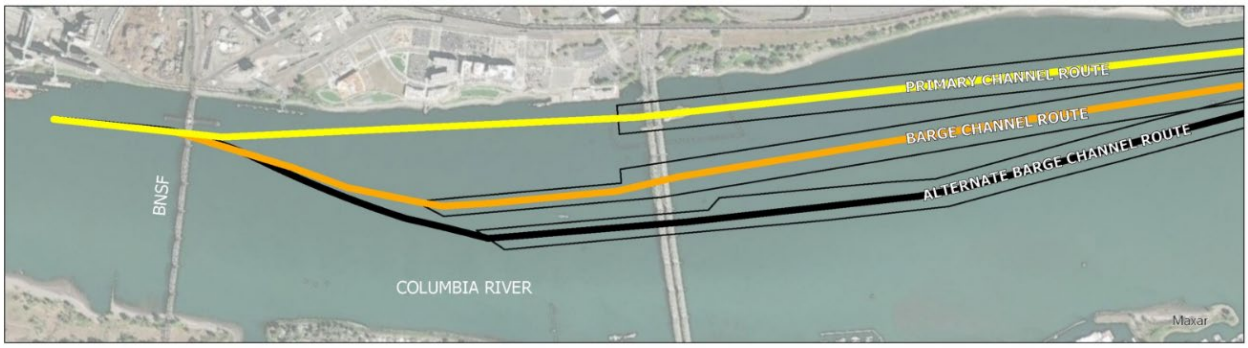


Figure 2.3-5. Proposed Columbia River Navigation Channels

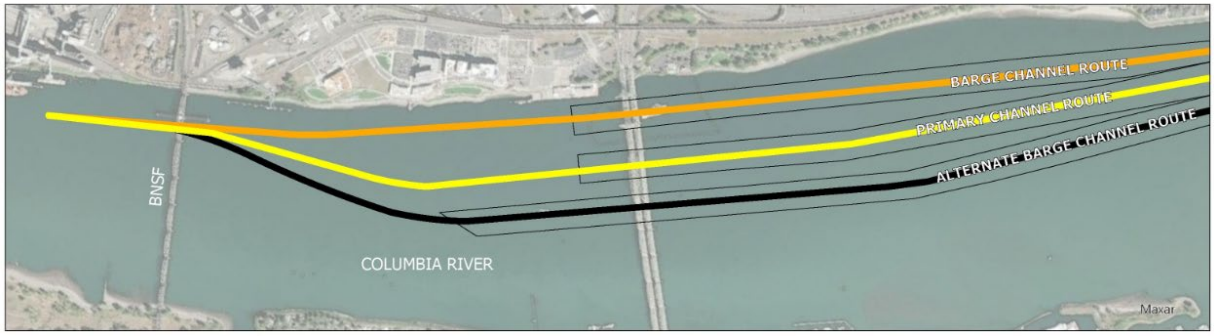


2.4 Emergency Operation, National Defense and Channel Maintenance Vessels

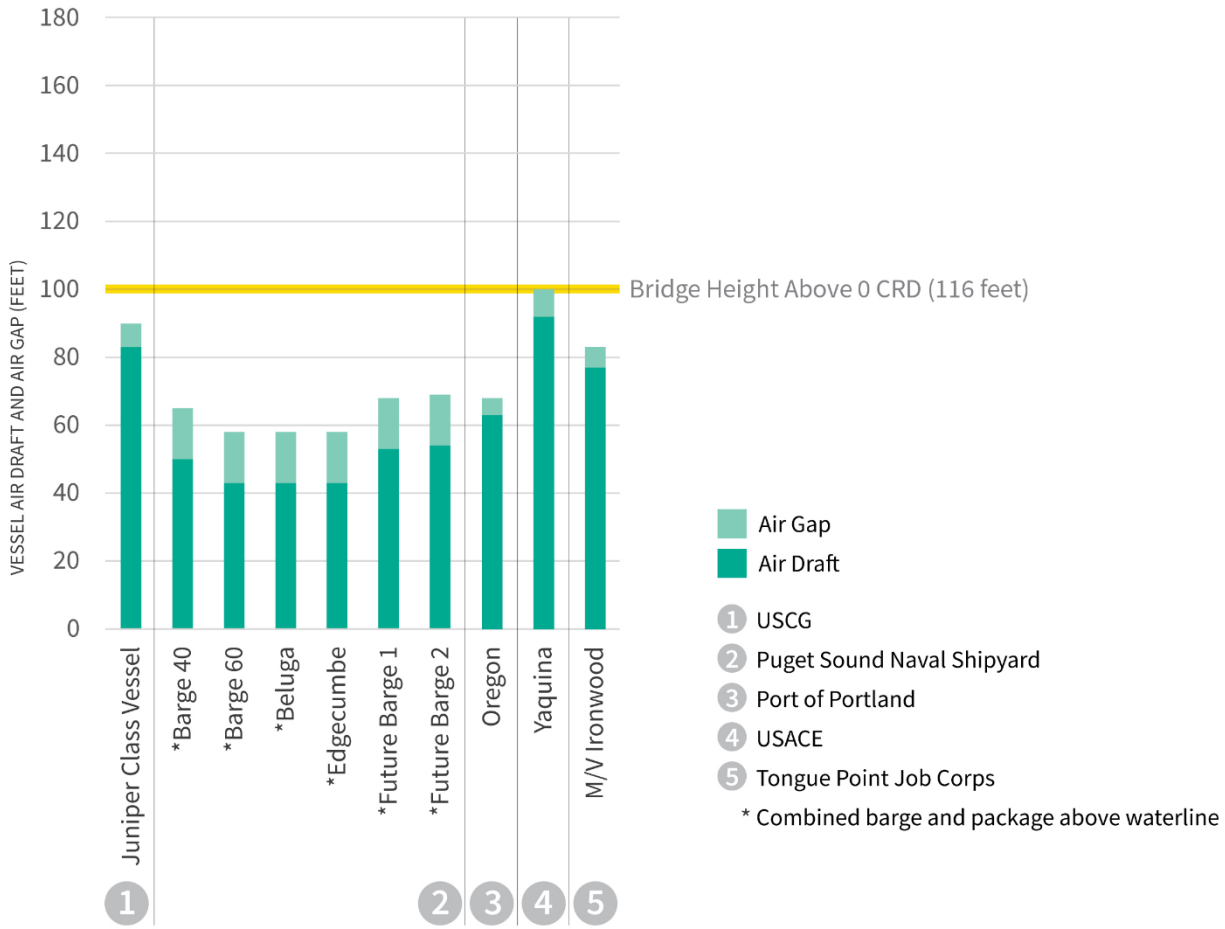
Vessels operated by the USACE, USCG, and U.S. Navy s, as well as training vessels from the Tongue Point Job Corps Maritime Training Program and a dredge operated by the Port of Portland operate on the rivers. These vessels are described below, and air drafts and air gaps from the river user survey are included on Figure 2.4-1. User and survey data on these vessels are included in Appendix B and C.

- The Port of Portland provided vessel characteristics for the *Dredge Oregon*. The port indicated an air draft of 63 feet with a desired air gap of 5 feet. They noted that the dredge utilizes "spuds" to hold itself on position and navigate within the channel. When in the stowed position for transit, the spuds are the highest point on the dredge at approximately 75 feet above the waterline. However, the port indicated that if the dredge were required to transit upriver from the Interstate Bridge, it would be reasonable to hire a derrick barge and crane to remove the spuds at the port's facility in the Swan Island harbor and place them on a barge, then reinstall them after the dredge has been towed upriver from the bridge. The port did not provide typical frequency of transit under the Interstate Bridge by month. They noted the dredge has transited under the I-5 bridge six times in the past.
- U.S. Navy Puget Sound Naval Shipyard (PSNS) in Bremerton, Washington, dismantles nuclear reactor compartments from deactivated nuclear submarines and cruisers. These compartments are then shipped via barge from Bremerton to the Port of Benton, where they are transferred to a large trailer for permanent disposal at the U.S. Department of Energy Hanford Reservation, approximately 7 miles from the Port of Benton. The U.S. Navy PSNS provided information on six freight barges, including two future barges (Barge 40, Barge 60, Beluga, Edgecumbe, Future Barge 1, and Future Barge 2) with air drafts ranging from 43 to 59 feet and desired air gaps of 15 feet. The vessels typically transit the bridge location during mid-March to mid-April and September through October. Shipment time and frequency will vary but could average two per year per vessel. U.S. Navy PSNS indicated that they use contract tugboats with the above vessels, and Tidewater holds the current contractor for the river portion of the trip.
- The USACE Portland District confirmed their hopper dredge (*Yaquina*) is the tallest USACE vessel that is expected to transit the bridge location. The *Yaquina* was surveyed as part of the CRC NIR, which noted a 92-foot air draft and an 8-foot desired air gap. The USACE confirmed that the dredge typically works during the in-water work window of August 1 to September 30; however, the dredge needs to be able to transit under the bridge at any time of year to address shoals.
- The USCG Marine Safety Unit (Portland) indicated that the information they provided in response to the Hood River-White Salmon Bridge Replacement river user survey was still accurate. For that project, the USCG provided information on a Juniper-class buoy tender. The vessel's primary mission is as a buoy tender; however, all USCG buoy tenders can perform other USCG missions, including search and rescue, maritime law enforcement, and marine environmental protection. The USCG indicated an air draft of 83 feet and air gap of 7 feet is

needed. The vessel is all-weather capable, and its frequency of passage depends on operations and situations.

- Tongue Point Job Corps Maritime Training Program did not respond to the request for information. They also did not respond to the request as part of the Hood River-White Salmon Bridge Replacement NIR. The CRC NIR indicated that Tongue Point uses the retired USCG *M/V Ironwood* buoy tender as a training vessel for students. The vessel was surveyed as part of the CRC NIR, which indicated an air draft of 77 feet and required air gap of 6 feet. Tongue Point reported one trip per month from May to August.
- The City of Vancouver, City of Portland, Clark County and Multnomah County operate small fire fighting, rescue and law enforcement vessels in the area. These vessels are small and would not be restricted.

Figure 2.4-1. 2.4 Emergency Operation, National Defense and Channel Maintenance Vessels Vessels Air Draft and Air Gap Results



Bridge lift data indicate that dredges accounted for an average of 3% of bridge opening events, ranging from a low of 0 (1989) to a high of 10% (2005). Bridge opening events for dredges averaged three to four per year between 2012 and 2020.

Other government vessels accounted for an average of 1% of bridge opening events, ranging from a low of 0% (there were several years when a government vessel did not request an opening, including 2000, 2002- 2004, 2014 and 2020 among others) to a high of 5% (1994). Government vessels that have required bridge openings include Puget Sound Naval Shipyard nuclear transporters, the USCG *Cutter Henry Blake*, and the *M/V Ironwood*.

Under the assumed conditions, the USACE dredge *Yaquina* would be able to pass under a bridge height of 116 feet in the vessel's current configuration more than 90% of the days of each month of the year. Because the dredge needs to be able to transit at any time of the year as necessary to address potential dredging needs, it is considered impacted by the proposed replacement bridges. The dredge would be essentially unaffected if only a 5-foot air gap is required (it could pass between 98% and 100% of the days in each month) or if the bridge height was 121 feet. The USACE requested a minimum 8-foot air gap for the *Yaquina*. With an 8-foot air gap, it could pass under the 116-foot bridge on more than 98% of the days each month of the year. Accordingly, for the purposes of this analysis, there is no substantial impact.

The USACE maintains the Columbia River navigation channel through dredging. Dredging keeps the navigation channel at its authorized depth and ensures that navigation features are maintained. As indicated above, the existing water depths at the I-5 bridge exceed the authorized depths without maintenance dredging. The CRC team conducted an analysis of capital and maintenance dredging needs associated with the proposed channels described above in January 2014 (CRC 2014). The report found that there would be no need for dredging to establish the channels and that there are no records of dredging within the navigation channels at the existing I-5 bridge for the past 30 years.

Future Vessels

A wide variety of vessel types and configurations can be used for dredging, including suction dredges, barges that use clamshell buckets, and ships equipped with suction equipment.

Equipment used for dredging downstream of the I-5 bridge location would not be constrained by the replacement bridges as it is located or based downstream of the I-5 bridges and does not need to navigate the bridge for other purposes (e.g., maintenance or refueling).

Navigation on the Columbia-Snake system extends nearly 230 miles along the Columbia River to Richland/Pasco/Kennewick, Washington, and also runs along 140 miles of the Snake River from the confluence at Pasco to Lewiston, Idaho. Along this channel, there are also numerous facilities such as docks, boat launches, marinas, intakes, outfalls, dams, and locks that may require regular or infrequent maintenance dredging, which will need equipment in the future to transit through the proposed replacement bridges. Equipment needed for dredging upriver of the BNSF railroad bridge at Celilo is constrained by its height and do not require further consideration.

The USACE typically conducts maintenance dredging yearly on the Vancouver to The Dalles project during the summer season. For 2020 the USACE reported an amount of 132,936 cubic yards (USACE 2021e). The USACE indicates that the dredge Yaquina typically completes this. There is no indication that the type and frequency of dredging will change in the future under current conditions. As discussed in Section 3, the Vancouver to The Dalles project is authorized to a depth of 27 feet but is only maintained to 17 feet. Should conditions change and the USACE undertake dredging of the channel to 27 feet, the capital dredging needs and ongoing maintenance needs would likely require different equipment than presently used. Considering the current channel use, existing facilities, available properties, and other factors, it is not likely that the channel would be extended to its authorized depth.

The USACE has indicated that there are no current plans for replacement of the Yaquina, but, based on the age of the vessel, it will likely require replacement during the life span of the replacement bridges. If the USACE were to replace the Yaquina, it is reasonable that the height of the proposed replacement bridges (if constructed) would be considered in the design specifications for the replacement dredge.

Dredging at berths and for other facilities is typically done by mechanical dredging or by small cutter section dredges due to the small volume of dredging needed. Mechanical dredging is most typically done by clamshell bucket operated by a crane from a barge, which are widely available. Future efforts would be expected to be similar and conducted by equipment that would not be constrained by the replacement bridges.

There is no evidence that the amount of dredging that occurs upriver of the proposed I-5 bridges is likely to be substantially different than in past years. No dredge equipment that would be constrained by the BNSF Celilo Falls rail bridge will be constrained by the proposed I-5 bridges; therefore, only dredge work between the existing I-5 bridges and the Celilo Falls Bridge is potentially impacted.

Government vessels include USCG, U.S. Navy, Tongue Point Job Corps Center, and other government-owned vessels, excluding dredges. As reported no government vessels using the Columbia River are identified as being height constrained by the proposed replacement bridges. There is no known reason to project an increase or change in the type of government vessels transiting upstream of the replacement bridges to change.

2.5 Federal Navigation Projects

The Columbia River and Oregon Slough include several federal navigation projects that are relevant to navigation within the project area. Table 2.5-1 provides a summary of the project details. There are numerous other federal navigation projects on the river including side channels, turning basins, small boat harbors, and anchorages that are not detailed here.

Table 2.5-1. Federal Navigation Projects

Project Name	Limits (RM)	Authorized Depth (feet)	Maintained Depth (feet)	Type of Project	Status
Mouth of the Columbia River	Offshore to RM 3	55	55	Channel	Operational
Columbia and Lower Willamette	RM 3 to RM 105.5	43 (to RM 105.5 and Oregon Slough RM 1.5) 35 (RM 105.5 to 106.5)	43	Channel	Operational Oregon Slough not maintained to 35 feet for entire length
Vancouver Upper Turning Basin	RM 106.5	35	35	Turning Basin	Operational Used infrequently
Vancouver to The Dalles	RM 106.5 to RM 189.7	27	17	Channel	Maintained for barge traffic
Barge Channel	RM 106.5 to 107.5	15	15	Channel	Operational
Alternate Barge Channel	RM 106.5 to 108	17	17	Channel	Operational
Oregon Slough – Upstream Entrance	Oregon Slough RM 5.8 to RM 109	10	10	Channel	Last maintained in 2001

2.5.1 Channel Details

Of the projects listed in Table 2.5-1, the Columbia and Lower Willamette, Vancouver Turning Basin, Vancouver to The Dalles (main or primary channel), barge channel, and alternate barge channel correspond with or are in proximity to the proposed bridge replacements. Figure 2.3-4 shows the existing channel configuration in the vicinity of the existing I-5 bridges.

The Columbia and Lower Willamette project ends just below the existing I-5 bridge. Deep-draft vessels utilizing the channel below the BNSF bridge do not typically use the channel between the two bridges, as there are no suitable berths and the waterway depths are not authorized or maintained to an adequate depth. Therefore, design vessels for the Lower Columbia and Willamette project are not addressed in this NIR.

The portion of the Columbia and Lower Willamette channel between the BNSF bridge and existing I-5 crossing and the Upper Vancouver Turning Basin (UVTB) are located just downstream of the existing I-5 bridge. Because the proposed replacement bridges will be located downstream (west) of the existing bridge, they will be located over the federal navigation projects. The channel was originally authorized in 1878 and the turning basin in 1962. The design vessel used by the USACE for these projects could not be determined. A design vessel was selected for the turning basin in the 2014 Ship Navigation Study (ODOT et al. 2014a), including future operations at the Lafarge facility near the BNSF bridge. The vessel is a small tanker with dimensions of 580 feet length overall, 101 feet beam, and drafts of 20 and 33 feet for ballasted and loaded conditions, respectively.

The Vancouver to The Dalles project begins just downstream of the existing I-5 bridge and was originally authorized by the Rivers and Harbors Act of 1937 with a depth of 27 feet for deep-draft vessels. The design vessel used by the USACE for this project could not be determined. No deep-draft vessel traffic currently uses this channel. The USACE maintains the channel to 17 feet based on current uses, and there are no deep-draft vessel facilities in operation upriver of the I-5 bridge. However, a design vessel was selected for this federal navigation project based on criteria discussed in the 2014 Ship Navigation Study (ODOT et al. 2014a). The vessel is a small product tanker with dimensions of 452 feet length overall, 75 feet beam, and a draft of 25 feet.

The Vancouver to The Dalles channel and the secondary channels located at the existing I-5 bridges are primarily used for shallow-draft barges being pushed by tugs or towboats. The specific design vessel used by the USACE for the project could not be determined. However, a design vessel was selected for this federal navigation project in the 2014 Tow Navigation Study (ODOT et al. 2014b) based on information on present vessels using the navigation channel through contacts with commercial shipping interests and operators. The primary limitation on vessels is dictated by the lock dimensions at the Bonneville dam. Many tugs and barges use the river and vary in size. For the simulation effort, a model tug and typical barges were selected based on equipment in use on the river under four different configurations. Table 2.5-2 lists the tug and barge details used.

Table 2.5-2. Tug and Barge Details

Vessel	Length Overall	Beam	Depth[1]	Other
Tug	95 feet	31 feet	11 feet 6 inches	2,800 horsepower
Grain Barge	275 feet	42 feet	16 feet 6 inches	120,000 bushel capacity

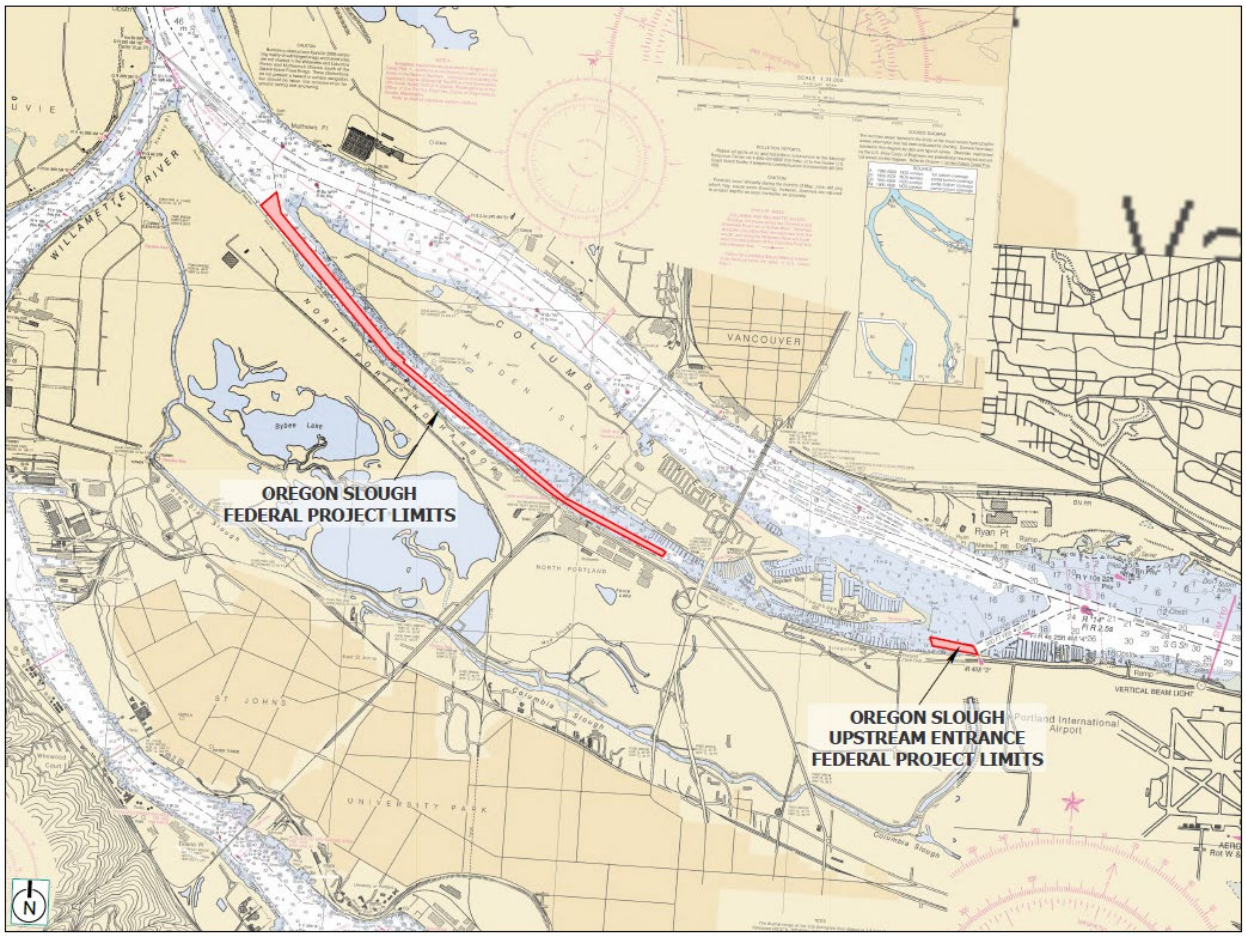
Note:
1. Depth is from top of deck to bottom of keel.

Navigation continues on the Columbia-Snake system beyond The Dalles. Vessels using that project are assumed to be the same as the Vancouver to The Dalles project.

On the Oregon Slough, the Columbia and Lower Willamette federal navigation channel does not extend to the existing I-5 bridge. Project limits extend for 1.5 miles, approximately 1,500 feet downstream from

the existing I-5 bridge. The Oregon Slough – Upstream Entrance project begins approximately 1.5 miles upstream of the existing bridge. Figure 2.5-1 shows the extent of the federal projects on the Oregon Slough. Design vessels for this project are not considered as the channel does not correspond to the bridge location. The USACE recently completed updated environmental documentation to maintain the Oregon Slough – Upstream Entrance to its authorized depth, but the timing of this work is unknown. Since that effort is primarily to support existing navigation, no changes to vessel use or characteristics are anticipated as result of this project.

Figure 2.5-1 Oregon Slough Federal Project Limits



2.5.2 Proposed Channel Changes

The replacement bridges will result in the need to modify the federal project channel locations and the upstream extent of the Vancouver Upper Turning Basin. These changes will be subject to review and authorization by the USACE under a separate process established in Section 14 of the Rivers and Harbors Act of 1899, codified at 33 U.S. Code 408 (Section 408). A decision under Section 408 will be completed prior to the issuance of a Section 9 Bridge Permit by the USCG. The IBR program team will coordinate with the USCG to keep the agency informed through the review process. While these

changes will not be subject to USCG authority, they do have the potential to affect navigation and will be considered as part of this NIR. This section describes the proposed changes, shown in Figure 2.3-5, above.

To maintain the current bridge in an operational condition during construction, the replacement bridges will be placed downstream of the existing bridges. This overlaps with the UVTB, which will be shifted west. No specific definition of the UVTB coordinates and dimensions was located other than an interim report that recommended dimensions of 800 by 2,000 feet. Drawings of the navigation project hydrographic surveys show the dimension to be approximately 800 by 2,250 feet. Based on the information available, it is estimated that the length will be reduced by approximately 200 feet resulting in an assumed length of 1,800 feet.

The three navigation channels (primary, barge, and alternate barge) will be renamed and some locations revised to correspond with the maximum vertical clearance provided by the replacement bridges and based on operational practices described by the towing companies.

The alternate barge channel is currently the southernmost channel. It is also referred to in the industry as the “High Span” and is almost exclusively used by upbound tows and tows with construction equipment that require the higher clearance but do not require using the lift span. Therefore, the current primary use of the alternate barge channel is by upbound tows, which are mostly empty. These tows are generally more controllable than downbound tows and can make the “S” turn needed to transition from the location of the BNSF bridge opening to the alternate barge channel alignment.

The barge channel, the middle of the three channels, is primarily reserved for downbound tows since they have less control, with currents pushing them downstream resulting in greater speed over the ground and less speed through the water. Therefore, these tows need the barge (also referred to in the industry as the “wide span”) navigation channel. This is because use of this channel requires less maneuvering to move toward the Washington shore to align with the BNSF railroad bridge.

Tows requiring air draft that is not available in the wide and high spans must use the lift span, which corresponds to the primary channel. The primary channel will be moved to the south and become the middle channel to correspond with the highest vertical clearance provided by the replacement bridges. The two flanking channels will be designated as barge channels. The barge channel to the north will have a minimum of 99 feet of vertical clearance and would accommodate the majority of commercial traffic on the waterway based on bridge height. The barge channel to the south would have a minimum of 113 feet of vertical clearance.

2.6 Present and Prospective Recreational Navigation

The Columbia River is an active recreational waterway. Recreational vessels are described below. User and survey data on these vessels are included in Appendix B and C. The majority of recreational vessel use consists of small power and sailboats that would not be impacted by bridge heights and widths. Only those vessels with the potential to be impacted are addressed in this section.

- Schooner Creek Boat Works (Schooner Creek) provided information on one sailboat, *Rage*. The vessel has a reported air draft of 90 feet and a desired air gap of 10 feet. *Rage* passes under the

Interstate Bridge typically one time per month in January, February, October, November, and December; five times per month in March and September; seven times per month in April and August; and 10 times per month May through July.

- A private individual provided information on their sailboat, *Make It So*. The boat has a reported air draft of 87 feet and a desired air gap of 10 feet. The boat passes under the Interstate Bridge typically once per month March through May and in September, and two times per month June through August. The CRC NIR indicated that *Make It So* was surveyed and has a surveyed air draft of 90 feet.
- The CRC NIR included information from Legendary Yachts Inc. and their sailboat, *Radiance*. The company confirmed that the information provided for the CRC report remained accurate which indicated a surveyed air draft of 85 feet with a desired air gap of 3 feet. The boat transits under the Interstate Bridge approximately two times per month from July through September. It is moored on the Columbia River in Vancouver. The company also indicated that their operation has been moved to a Vancouver location and that there are no vessels in or planned for production. They would utilize existing facilities (such as other vessel service locations) for any in-water needs.
- The CRC NIR provided information on 14 vessels surveyed at the Portland Yacht Club. The tallest of these vessels had an air draft of 74 feet. The report also provided information on vessels from the Rose City Yacht Club, where the tallest vessel had an air draft of 63 feet. See the CRC NIR pages 6-18 and 6-19 for additional information.

The 2012 CRC NIR identified a sailboat being constructed by Schooner Creek with 139-foot air draft and would not be able to pass under the proposed replacement bridge at any time within a calendar year without mitigation. Schooner Creek was contacted and did not provide any information on this potential vessel. Because no additional information was provided, it is assumed that this vessel was either completed and moved from the area or was never produced and thus would not be impacted by the proposed bridge height.

No recreational power vessels were found to be impacted under the assumed condition. Two sailboats (*Make It So* and *Rage*) were measured with an air draft of 90 feet. Under the assumed condition, the vessels would not be height restricted but it is included in this discussion because of the small margin of error.

Larger recreational sailboats with an air draft exceeding 90 or 95 feet would not be able to pass under the bridge under the assumed conditions. There are no known sailboats of this size in the area, and it is unlikely that this condition would change in the future due to the nature of the waterbody and vessel activity.

Sailboats accounted for an average of 28% of bridge opening events, ranging from a low of 13% (2001) to a high of 45% (2016). The data show that sailboats account for the greater percentage of bridge openings in more recent years than in the past.

Recreational sailboats and powerboats typically use the river more frequently during the peak recreational boating season which occurs between April and October. Sailboats that are affected by the

existing bridges generally had an air draft ranging from 50 to 90 feet, with an average of approximately 70 feet. The majority of the sailboats within the bridge opening data would be able to transit the bridge height options proposed.

Powerboat air drafts ranged from 20 feet to 25 feet and almost never required a bridge opening. There was at least one large private vessel (M/V Meduse) that required a bridge lift within the data.

Future Vessels

Most of the sailboat activity that transits the bridge is generated by residents living in or near the greater Portland area, defined as: Portland Metro Area (Clackamas, Columbia and Multnomah counties in Oregon and Clark and Skamania counties in Washington); adjacent Oregon counties surrounding the Portland Metro Area (Washington, Yamhill, Polk, Marion, Linn, Wasco, Hood River and Sherman Counties); and adjacent Washington counties surrounding the Portland Metro Area (Cowlitz, Lewis, Yakima and Klickitat Counties). Sailboats surveyed in 2021 had an average air draft of 44 feet compared to 66 feet from 2012 data. It is anticipated that sailboat activity and sizing would not likely change significantly from the existing situation.

2.7 Present and Prospective Commercial Navigation

Commercial vessels on the Columbia River include cruise vessels, tugs, tows and barges and marine contractors. In addition, this category addresses specialty fabricators that operate in the area. While these are not vessels they do utilize the waterway. Users and vessels are described below by each category. User and survey data on these vessels are included in Appendix B and C.

2.7.1 Cruise Vessels

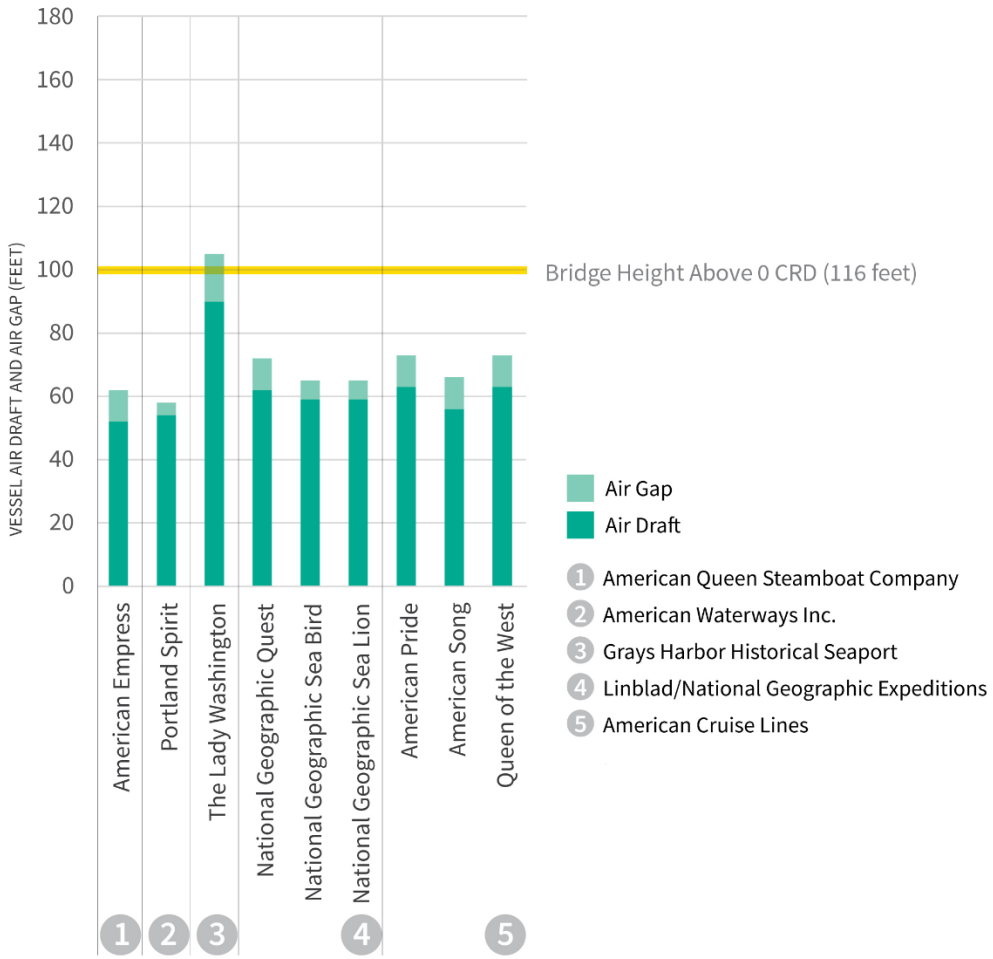
Several passenger cruise lines host tours up and down the Columbia and Snake Rivers. These vessels require frequent passage under the Interstate Bridge during the cruise season. Six passenger cruise lines were contacted, and three responded. Vessel characteristics by company are summarized below, and height clearances from the river user survey are provided on Figure 2.7-1below.

- American Cruise Lines completed the online survey for three vessels: the *American Pride, Queen of the West,* and *American Song*. The *American Pride* and *Queen of the West* have a reported air draft of 63 feet. The *American Song* has a reported air draft of 56 feet. All three vessels have a desired air gap of 10 feet. The vessels transit under the Interstate Bridge approximately 16 times per month during April through November.
- American Queen Steamboat Company did not respond to the request for information. The company did respond to the request as part of the Hood River-White Salmon Bridge Replacement NIR and indicated they have one passenger cruise vessel (*American Empress*) that travels on the Columbia and Snake Rivers. This vessel has an air draft of 52 feet and requires a 10-foot air gap. The Hood River-White Salmon NIR indicated that the *American Empress* passes under the existing Hood River-White Salmon bridge one to two times a week between March and December. Given the cruise route on the company website, this would likely be similar for the Interstate Bridge (https://www.americancruiselines.com/cruises/columbia-and-snake-

river-cruises). The American Queen Steamboat Company was not part of the river user outreach for the CRC NIR.

- American Waterways, Inc., provides passenger service on the Columbia River. The company provided information for a cruise vessel (*Portland Spirit*), which has an air draft of 48 feet and requires at least a 10-foot air gap. The company also indicated that they operated the *Columbia Gorge Sternwheeler*, which is similar in size to the *Portland Spirit,* and the *Willamette Star*, *Crystal Dolphin*, and the *Explorer*, which are much smaller. Frequency of transit was not provided. The CRC NIR indicated that the vessels average about 80 trips per month each on the Columbia River main channel and Oregon Slough from June through October, with fewer trips the rest of the year.
- Lindblad/National Geographic Expeditions provided confirmation regarding their vessels that operate on the Columbia River (*National Geographic Quest*, *National Geographic Sea Lion,* and *National Geographic Sea Bird*). The *National Geographic Quest* has a 62-foot air draft and requires an air gap of at least 10 feet. The *National Geographic Sea Lion* and *Sea Bird* both have air drafts of 59 feet with a 6-foot desired air gap. The *National Geographic Quest* transits under the Interstate Bridge approximately one time per month in September and three times per month in October. The *National Geographic Sea Lion* transits under the Interstate Bridge approximately three times per month in September and one time per month in October. The *National Geographic Sea Bird* transits under the Interstate Bridge approximately three times per month in September, four times per month in October, and one time per month in November.
- Grays Harbor Historical Seaport Authority did not respond to the request for information. They did provide information on two sailing ships (*Lady Washington* and *Hawaiian Chieftain)* during the Hood River-White Salmon Bridge Replacement NIR. Since that time, the *Hawaiian Chieftain* has been sold and is no longer in the area (Olympian 2021). The *Lady Washington* has a raised mast air draft of 90 feet and a stepped-down mast height of 65 feet with a required 15-foot air gap. The maneuverability of these vessels is limited because of their height and auxiliary sails. Grays Harbor Historical Seaport Authority is not currently operating tours due to the COVID-19 pandemic. It is assumed that future transits to upriver destinations could occur and would require transit under the Interstate Bridge. Vessel information for the *Lady Washington* was also included in the CRC NIR, but frequency of transit under the Interstate Bridge was not provided.
- UnCruise Adventures operates one passenger cruise vessel (*S.S. Legacy*) on the Columbia/Snake River system. The program team was not able to reach UnCruise to obtain vessel characteristics. According to its website, the company offers Columbia/Snake River cruises from Portland, Oregon, to Clarkston, Washington, September through December with an upstream destination of Richland, Washington (https://www.uncruise.com/destinations/columbia-river-cruises/columbia-river-itineraries). This route requires the transit of the Celilo railroad bridge (79-foot clearance), the Kalan railroad bridge (72.6-foot clearance), and others. Therefore, it is assumed that the air draft and air gap are less than 72.6 feet.

Figure 2.7-1. Cruise Vessels Air Draft and Air Gap Results



No passenger cruise vessels were identified that were unable to pass under the assumed conditions for the proposed bridge height.

Future Vessels

Cruise and passenger vessels include vessels that operate only on the Columbia and Snake Rivers, as well as those that offer seasonal itineraries. Included in this category are sightseeing boats and overnight cruise vessels.

Future passenger vessels are expected to remain at the heights of existing passenger vessels that transit the area. The cruise and passenger vessels that regularly operate in this area are constrained by other bridges; it is in the best interest of the operators to use vessels that can clear all of the bridges in the region. For example, the Sellwood Bridge in Portland has a vertical clearance lower than that proposed for the IBR program. To operate upriver of the Sellwood Bridge, vessels will necessarily be

able to clear the proposed I-5 bridges. The BNSF Celilo Bridge 95 miles upstream of the I-5 bridges has a vertical clearance significantly lower than the I-5 bridges, and bridges on the Snake River are even lower. Any cruise vessel operating up to Lewiston will be able to clear the proposed I-5 bridges.

2.7.2 Commercial Tugs, Tows, and Barges

This vessel group includes tugboats, towboats, and commercial barges. Tugboat and towboats are referred to generically as tugs. Crane barges associated with marine construction are included in the marine contractor category. Barges requiring tug or tow move up- and downriver with a variety of bulk and container cargoes. Most cargo moves from upriver origins to downriver destinations. Tugs can move without barges or with one or more barges. Barges in general use on the Columbia River for grain, petroleum and other typically uses are not generally included as they have lower vertical clearances than tugs. Some specialty barge information is included.

In the Columbia River, lock dimensions limit tows to 84 feet in width and 650 feet in length (up to four barges). Air drafts and air gaps for commercial tugs, tows and specialty barges are described below by company, and heights provided in the river user survey are presented on Figure 2.7-1.

- Bernert Barge Lines provided information on four towing vessels (*Kathryn B, Lori B, Diane B*, and *Mary B*) that transit the bridge location. The largest air draft for these vessels is approximately 54 feet (*Kathryn B*). The vessels pass under the existing Interstate Bridge up to eight times per month throughout the year. For each of these vessels, a 5-foot air gap is desired.
- Cadman, Inc., an affiliate of Lehigh Hanson (Heidelberg Group), operates one self-unloading aggregate hopper barge that transits the bridge location three times per month in January, four times per month in February through June, five times per month in July through September, four times per month in October, and three times per month in November and December. Its air draft is approximately 49 feet, with a desired air gap of 1 foot. The barge has no mechanical propulsion and requires a tug, which is provided by contract. The company indicated that the tug air draft is typically 52 feet.
- Mark Bernert Tugboat Company provided information via the online survey for one tugboat (*Claire B*). This vessel has a reported air draft of 48 feet with a desired air gap of 4 feet. The vessel transits under the existing Interstate Bridge four times per month March through October.
- SDS Lumber Company and SDS Tug & Barge (SDS) manufacture lumber, plywood, power, and pulp, as well as offering tug and barge services though the marine subsidiary. The company is located in Bingen, Washington. They did not respond to requests to verify or update vessel information. Information for three tugboats (*Dauby*, *Wallace E*, and *Bruce M*) was provided by SDS as part of the Hood River-White Salmon Bridge Replacement NIR. Based on that prior data, the greatest air draft is 56 feet with a desired air gap between 10 and 20 feet depending on the water level and conditions. SDS also transports vessels with spuds that can be lowered to a maximum height of 65 feet with a desired air draft of 15 feet. The CRC NIR reported about 10 trips per month all year for these vessels. The CRC NIR also noted the potential for shipments of loads on SDS barges as tall as 100 feet, but this information was not provided for the more

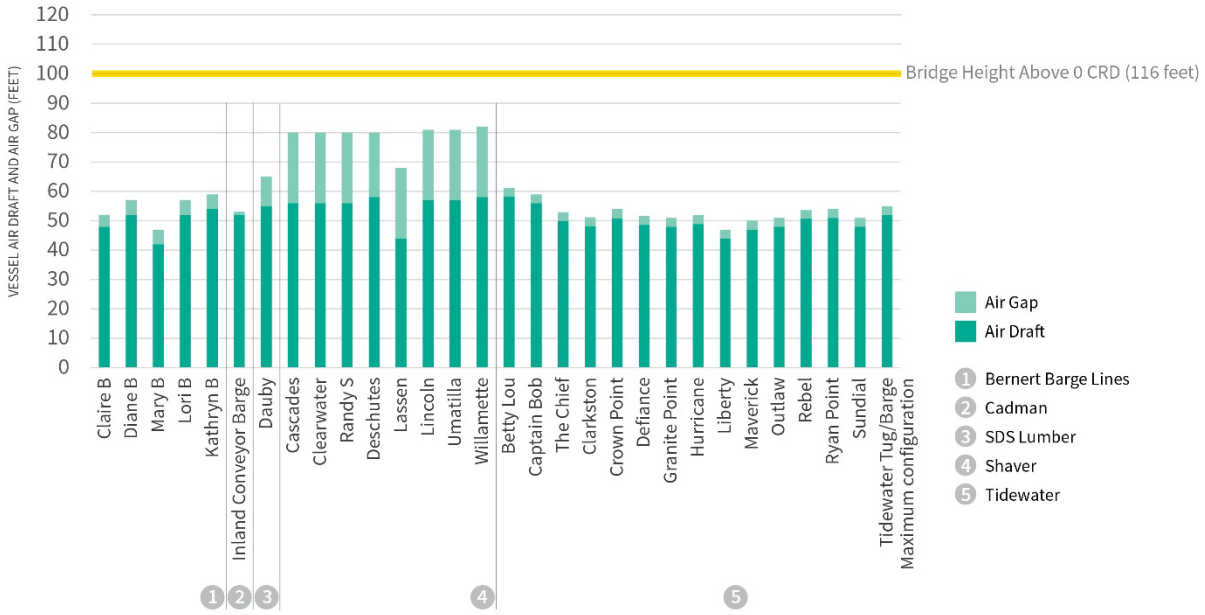
recent Hood River-White Salmon Bridge Replacement Bridge NIR and is not considered in the impact analysis.

- Shaver Transportation provided information on eight tugboats (*Cascades* [push knee], *Clearwater* [push knee], *Deschutes* [tractor tug], *Lassen* [push knee), *Lincoln* [push knee], *Umatilla* [push knee], *Willamette* [tractor tug], and *Randy S* [type not specified]). These vessels were notes as requiring a total clearance (air draft and air gap) of 80 feet. Air drafts range from 44 feet to 58 feet. The vessel data sheets indicated that tug assistance would be required during construction until the existing bridge is removed. The tugs transit under the existing bridge at all times throughout the year.
- Tidewater Barge Lines (Tidewater) provided vessel data sheets for 14 tugboats (*Betty Lou, Captain Bob, Chief, Clarkston, Crown Point, Defiance, Granite Point, Hurricane, Liberty, Maverick, Outlaw, Rebel, Ryan Point,* and *Sundial*). The maximum configuration of these vessels is a tug and four barges. On average, Tidewater vessels pass under the Interstate Bridge 70 times per month. The greatest air draft of these tugboats is 52 feet, with an air gap of 3 feet.

The following companies did not respond to the river user survey, and vessel information was not provided in prior reports. Information was obtained from publicly available sources. As the information was not verified through direct contact, vessel characteristics for this group are not included on Figure 2.7-1, and impacts are not assessed.

- The Brusco Tug and Barge Company website indicates that its Columbia River fleet provides towboat service on the Columbia, Snake, and Willamette Rivers for private customers and for the USACE to tow government-owned tank barges.
- Centerline Logistics (previously Olympic Tug and Barge and Harley Marine Services), according to their website, provides marine petroleum transportation services on the West, East, and Gulf Coasts of the U.S. The company website provides vessel specifications and indicates that two vessels operate in Oregon (the *Investigator* [barge] and *Lizzy Too* [tug]). The *Lizzy Too* has an air draft of 48 feet. The Hood River-White Salmon Bridge Replacement NIR noted that the *Investigator* has an air draft of 26 feet. The company website does not currently list an air draft for this vessel. The Hood River-White Salmon Bridge Replacement NIR also listed the *Willamette Champion* as a vessel that operates in the Portland area, but the current website does not include this vessel.
- Foss Maritime Company (Foss) provides a variety of tug services, including escort and ship assist, oceangoing cargo, and contractor support. For the Columbia/Snake River system, the company website indicates that they provide regional towing service. The CRC NIR indicated that Foss performs harbor-assist work and does not typically transit upriver of the I-5 bridge. Special projects in the past have required transit to the upper Columbia and Snake Rivers. Foss was reported as selling its Columbia River operations in 2013 (Oregonian 2013). Based on this information transit by Foss vessels would be infrequent.

Figure 2.7-2. Commercial Tugs, Tows, and Barges



No tugs or tows were identified that were unable to pass under the assumed conditions for the proposed bridge height.

Tugs and tows transiting this region fall into one of two categories: ocean tugs and barges that serve the metal fabricators at the Columbia Business Center, and tugs and barges that carry commodities on the shallow-draft river system between Portland/Vancouver and Lewiston.

River barges are sized to transit the locks and bridges in the Columbia-Snake River System. Tugs are higher than barges and are the more height-constrained component of this group. Tugs operating in the river system typically have a highest fixed point less than 55 feet high and are constrained by numerous bridges on the Columbia and Snake River system that have lower vertical clearances than the replacement bridges. Future river tugs are expected to remain within these height ranges. An example of this are three new tugs—the *Crown Point, Granite Point,* and *Ryan Point*—that were constructed for Tidewater after the analysis was completed for the CRC Project. As shown in Section 5, these tugs have a maximum air draft of 52 feet.

River barges are typically 150 to 273 feet long with a beam (width) of up to 42 feet. A standard tow consists of a tug with four barges lashed two abreast. This tow configuration can pass through the Bonneville lock, which has a lock chamber that is 86 feet wide and 675 feet long. Future river barges are expected to remain within these dimensions due to the lock restrictions.

Commercial tugs and barges have the highest share of river usage and transit year round accounting for approximately 54% of the bridge opening events across the 35-year study period. Their usage share ranged from a low of 25% (2005) to a high of 65% (2012). Tugs and barges generally ranges from 28 to

61 feet, and the tugs and barges are usually able to use the barge channel or alternate barge channel. Tugs and barges will request an opening of the I-5 bridge to provide sufficient vertical clearance or to make a straight course between the I-5 bridge and the BNSF bridge downstream. The largest share of these bridge lifts for tugs and barges occurs during the spring, when high rainfall and mountain snowmelt combine to increase the current and raise the river level at I-5. Twenty-four to 42% of bridge lifts for tugs and barges occurred in April, May, and June.

Future Vessels

Tugs and tows transiting this region fall into one of two categories: ocean tugs and barges that serve the metal fabricators at the Columbia Business Center, and tugs and barges that carry commodities on the shallow-draft river system between Portland/Vancouver and Lewiston.

River barges are sized to transit the locks and bridges in the Columbia-Snake River System. Tugs are higher than barges and are the more height-constrained component of this group. Tugs operating in the river system typically have a highest fixed point less than 55 feet high and are constrained by numerous bridges on the Columbia and Snake River system that have lower vertical clearances than the replacement bridges. Future river tugs are expected to remain within these height ranges. An example of this are three new tugs—the Crown Point, Granite Point, and Ryan Point—that were constructed for Tidewater after the analysis was completed for the CRC Project. As shown in Section 5, these tugs have a maximum air draft of 52 feet.

River barges are typically 150 to 273 feet long with a beam (width) of up to 42 feet. A standard tow consists of a tug with four barges lashed two abreast. This tow configuration can pass through the Bonneville lock, which has a lock chamber that is 86 feet wide and 675 feet long. Future river barges are expected to remain within these dimensions due to the lock restrictions.

2.7.3 Marine Contractors

The marine contractors category includes vessels such as crane barges, dredges, and other construction equipment transported by construction contractors on the Columbia River. Transits are not limited to a particular time of year or frequency, as construction work is typically performed on an as-needed or contract basis. Crane barges can conduct a wide range of water-related construction activities and are typically used by marine contractors. Crane barges are not motorized and are moved with tugs or tows. Spuds or anchors are used to keep barges stationary. During travel, the spuds are either raised to a level high enough to prevent the barge spuds from grounding or they are removed and lashed to the deck. The CRC NIR indicated most crane barges in the Columbia River travel with their spuds raised (as this requires the least amount of work), and when raised, the spuds are typically the highest points of the vessel.

Air drafts and air gaps for marine contractor vessels are shown below by company, and information obtained through the river user survey is presented in Figure 2.7-2.

- Advanced American Construction did not respond to the request for information. They also did not respond to the request as part of the Hood River-White Salmon Bridge Replacement NIR. The CRC NIR included information on five crane barges (*DB 125*, *DB 4000*, *DB 4041*, *DB 4100*, and

Paul Bunyan) and one tugboat (*Lindy Marie*). According to the CRC NIR, the barges have an air draft ranging from 78 to 92 feet (with spuds raised), and a 2-foot desired air gap. The *DB 4100* is the tallest crane, with a reported height of 92 feet with the spuds raised. The minimum crane gantry height for the *DB 125* is 51 feet, and for the *DB 4000*, *DB 4041*, and *DB 4100* is 35 feet. The *Paul Bunyan* is a spud barge, and the other barges are portable cranes on spud barges. The tugboat has a 35-foot air draft and a desired air gap of 5 feet. The vessels travel up and down the Columbia River a couple of times a month, all year. A review of the Advanced American Construction website confirmed the vessel characteristics identified above. The *Paul Bunyan* is not listed on the company's website. Therefore, it is unknown whether the *Paul Bunyan* is still part of their fleet. The website also includes descriptions of additional barges and tugs, but it is unknown whether those vessels transit the bridge location.

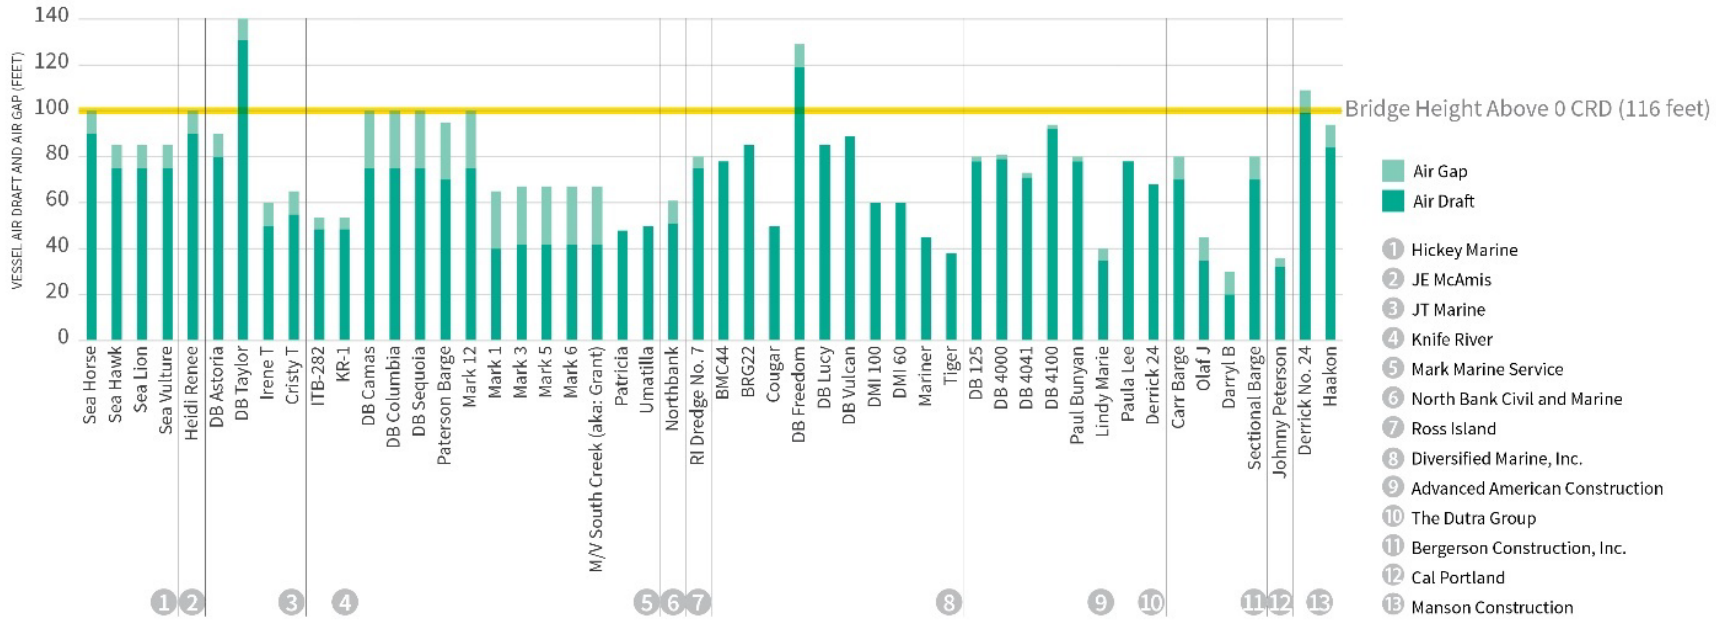
- Bergerson Construction did not respond to the request for information. They also did not respond to the request as part of the Hood River-White Salmon Bridge Replacement NIR. The CRC NIR included information on two barges (*Carr Barge* and *Sectional Barge*) and two tugboats (*Darryl B* and *Olaf J.*). The CRC NIR indicated that the two barges have air drafts ranging from 40 to 150 with the spuds raised. The air draft on the largest vessel with the spuds lowered is 78 feet and the crane lowered is 52 feet. The two tugboats have air drafts of 20 and 35 feet. All four vessels require at least a 10-foot air gap. The vessels transit the Columbia River as contracts require. The Bergerson Construction website does not provide information on their vessels.
- CalPortland Company did not respond to the request for information. The CRC NIR indicated that CalPortland operates a tugboat (*Johnny Peterson*) and a dredge (*Sanderling*), each with an air draft of 32 feet and a preferred air gap of at least 4 feet. The report further noted that the tugboat and dredge transits under the existing Interstate Bridge approximately eight times a month all year.
- Diversified Marine, Inc. (Diversified Marine) provided information on three derrick barges (*DB Freedom, DB Lucy,* and *DB Vulcan*), two spud barges (*BMC44* and *BRG22*), two barges (*DMI 100* and *DMI 60*) and three tugboats (*Cougar*, *Mariner*, and *Tiger*). The *DB Freedom* is the largest of the derrick barges, with an air draft of 119 feet with the crane lowered. The *DB Lucy* has a reported air draft of 85 feet (the CRC NIR noted an air draft of 73 feet with the crane lowered), and the *DB Vulcan* has an air draft of 89 feet (the CRC NIR noted that this height was with the crane lowered). The derrick barges have a desired air gap of 10 feet. The two spud barges (*BMC44* and *BRG22*) have air drafts of 78 and 85 feet, respectively, with spuds raised. The two barges (*DMI 100* and *DMI 60*) both have air drafts of 60 feet. Diversified Marine's three tugboats (*Cougar*, *Mariner*, and *Tiger*) have air drafts of 50, 45, and 38 feet, respectively. Diversified Marine did not provide any information related to frequency of transit. However, as part of the CRC NIR, they indicated that their vessels travel on the Columbia River as contracts are awarded and one trip a month all year is estimated for each vessel.
- The Dutra Group did not respond to the river user survey. They also did not respond to the request as part of the Hood River-White Salmon Bridge Replacement NIR. The CRC NIR included information on two crane barges (*Derrick 24* and *Paula Lee*). The CRC NIR indicated that the crane barges have the potential to work on the Columbia River. The highest point on the cranes

during transit is the A-frame. The *Derrick 24* has an A-frame height of 67 feet 4 inches, and the *Paula Lee* has an A-frame height of 77 feet 6 inches. The CRC NIR also indicated that the height of the A-frame above the waterline assumes the freeboard is half the hull height (halfway between the light- and full-loaded draft). Both vessels are still listed as part of the Dutra Group's fleet on the company website (http://www.dutragroup.com/equipment-aggregates-dredging-marine-construction.html?id=39).

- Hickey Marine Enterprises (HME) did not respond to the request for information. As part of the river user outreach for the Hood River-White Salmon Bridge Replacement NIR, HME provided information on four derrick barges (*Sea Hawk*, *Sea Horse*, *Sea Lion*, and *Sea Vulture*). HME indicated on the vessel data sheets that the *Sea Hawk*, *Sea Lion*, and *Sea Vulture* all have an air draft of 75 feet and a desired air gap of 10 feet, and the *Sea Horse* has a spud height of 90 feet and a desired air gap of 10 feet. The *Sea Horse* has a gantry height of 75 feet. Information on the gantry heights for *Sea Hawk*, *Sea Lion*, and *Sea Vulture* was not provided in the Hood River-White Salmon Bridge Replacement NIR river user survey. The CRC NIR indicated gantry heights of 28 feet, 34 feet, and 43 feet, respectively. The CRC NIR also indicated that trips primarily occur between October and March during the in-water work window, and the company estimated that their barges go upriver approximately six times per year.
- JE McAmis did not respond to the request for information. As part of the river user outreach effort for the Hood River-White Salmon Bridge Replacement NIR, JE McAmis provided information on one derrick barge (*Heidi Renee*). They indicated that the *Heidi Renee* is primarily used for dredging and marine construction and has an air draft of 90 feet (spuds up) and a desired air gap of 10 feet. The spuds can be lowered or removed (the data sheet for the Hood River-White Salmon Bridge Replacement NIR indicated that this is not ideal) for transit. The CRC NIR indicated a height of 12 feet with the spuds removed. The CRC NIR also noted that the company transits the river as required when contracts are awarded.
- JT Marine provided information on two tugboats (*Christy T* and *Irene T*), two crane barges, (*DB Astoria* and *DB Taylor*), and one towboat (*LeAnne T*). *Christy T* has an air draft of 55 feet and *Irene T* has an air draft of 50 with a desired air gap of 10 feet. *DB Astoria* has a height of 80 feet with spuds up and 30 feet with spuds removed. *DB Taylor* has an air draft of 90 feet with spuds and 75 feet with spuds removed. The *DB Taylor* can operate with a boom of 160 feet or 220 feet. The longer boom cannot be lowered to the cradle and has an air draft of 131 feet. A desired air gap of 10 feet was reported for both vessels. An air draft was not reported for the *LeAnne T.* JT Marine indicated that the vessels transit under the Interstate Bridge approximately 10 times per month, all year and one time per month all year under the Oregon Slough bridge.
- Kiewit Corporation confirmed that the vessel information provided for the CRC remained accurate. Six crane barges (*DB General, DB Alameda*, *DB Oakland*, *DB Olympia*, *DB Pacific*, and *DB Seattle*) were identified as having been upriver in the past. Air drafts for these barges range from 70 to 93 feet, with the *DB General* as the tallest vessel. Desired air gaps are 5 to 10 feet. The CRC NIR indicated that there is an optimal angle for the crane boom to be positioned while being towed. If the height is too tall to transit under a bridge, the vessel is moored near the bridge, the crane is lowered to pass under the bridge, and then the vessel is moored again, and the crane raised to the proper tow height.

- Knife River Corporation (Knife River) did not respond to the request for information. As part of the river user outreach for the Hood River-White Salmon Bridge Replacement NIR, Knife River provided information on two deck barges (*KR-1* and *ITB-282*), both with an air draft of 48.5 feet and a desired air gap of 5 feet. In the CRC NIR, Knife River provided information on the *KR-1* and indicated that the deck barge transits the area approximately 4 to 19 times a month all year.
- Manson Construction did not respond to the request for information. They also did not respond to the request as part of the Hood River-White Salmon Bridge Replacement NIR. The CRC NIR included information on two crane barges (*Derrick No. 24* and *Haakon*). The *Derrick No. 24 is* a crane barge with an air draft of approximately 99 feet and a desired air gap of 6 feet. The *Haakon* has an 84-foot air draft and a desired air gap of 5 to 10 feet. The height provided is for the gantry, and no information was provided regarding the ability to modify for lower clearances. The CRC NIR indicated that the *Derrick 24* had not been in the Columbia River system for 10 years but would go into the system if contracted to do.
- Mark Marine Services did not respond to the request for information. The company did respond to the request for the Hood River-White Salmon Bridge Replacement and the CRC Projects. The company provided information on different vessels for the two prior reports. It is not known whether the reported vessels differed due to the different locations of the projects on the Columbia River or if it were due to changes in their fleet. Vessel characteristics as reported in both prior reports is included here. For the Hood River-White Salmon Bridge Replacement NIR, Mark Marine Services provided information on nine barges (*DB Camas*, *DB Columbia*, *DB Sequoia*, *Paterson Barge*, *Mark 12*, *Mark 1*, *Mark 3*, *Mark 5*, and *Mark 6*) and one tugboat (*M/V South Creek*). Of these vessels, the highest air draft is 75 feet, and all desired air gaps are 25 feet. No information was provided in the Hood River-White Salmon Bridge Replacement river user survey regarding whether they can be modified for lower clearances. The CRC NIR indicated that the *DB Camas* spud height is 75 feet and can be lowered. The CRC NIR provided information on four crane barges (*DB Camas* and *DB Columbia*, as reported above, the *Amazon*, indicated as retired, and *Barge #7*, indicated as under construction). No vessel characteristics were provided for *Barge #7* in the CRC NIR or the Hood River-White Salmon Bridge Replacement NIR. The CRC report also provided information on two towboats, *Patricia* and *Umatilla*, with heights of 48 and 50 feet, respectively. The CRC NIR indicated that the company's busiest season is November through February, corresponding with the in-water work window. The company reported passing under the Interstate Bridge an average of one trip per month for the three crane barges and one round trip per year to the Oregon Slough, but the vessels access the slough from downstream and do not cross under the Oregon Slough bridge.
- NorthBank Civil and Marine provided information on one crane barge (*Northbank*), and the vessel data sheet indicated an air draft of 51 feet with the crane boom down in the travel position and a desired air gap of 10 feet.
- Ross Island Sand and Gravel (Ross Island) provided information on one dredge (*Dredge #7*) and one tug (*Rossisle*). Ross Island indicated that Dredge #7 requires a vertical clearance of 75 feet with its positioning spuds raised. The vessels transit under the Interstate Bridge two to four times per year.

Figure 2.7-3. Marine Contractors Air Draft and Air Gap Results



Construction equipment used by marine contractors accounted for an average of 17% of bridge opening events, ranging from no lifts (2013) to a high of 32% (1989 and 2000).opening events, ranging from no lifts (2013) to a high of 32% (1989 and 2000). Bridge transits by marine contractors are dependent upon their home location and the location of the construction project. Three marine contractors are located upriver of the I-5 bridges (including JT Marine, Mark Marine Services and SDS Tug & Barge). These contractors transit the I-5 bridges for downriver construction projects or to pick up supplies from downriver locations. Contractors that are located downriver of the I-5 bridges must transit the bridges for projects located upriver of the bridges.

Marine contractors reported they use the river on an as-needed basis all months of the year depending on the timing of the construction project. Air drafts for construction equipment ranged from 40 to 131 feet.

Marine contractor derrick barges make up the majority of the identified vessels that are impacted by the bridge heights studied due to the height of the crane elements. Contractors typically operate crane barges that conduct a wide range of water-related construction activities. FHWA regulations for bridges specify that special navigation clearances shall normally not be provided for floating construction equipment unless required for navigation channel maintenance (23 CFR 650.807(g)). Derrick barges are often used for dredging and could be used for maintenance or repair of navigation locks. No information was available to determine the status of the specific equipment related to these activities, and no equipment was eliminated from consideration specifically because of these regulations. The following vessels (arranged by the contractors) were considered to be potentially impacted.

Advanced American Construction

Under the assumed conditions, the *DB 4100* would not be able to pass under a bridge height of 116 feet in the vessel's current configuration. The *DB 4100* could pass at least 90 % of the days of each month of the year with a 10-foot air gap, and greater than 98% of days in all months of the year with a 5-foot air gap. The *DB 4100* would not be impacted under the assumed conditions for a bridge height of 121 feet. Accordingly, for the purposes of this analysis, there is no substantial impact at either height.

General Construction Company

Under the assumed conditions, the *DB General* would not be able to pass under a bridge height of 116 feet in the vessel's current configuration. However, when considering the seasonal variations in the river stages and the ability to use a smaller air gap, the *DB General* would be able to pass under a 116-foot bridge during much of the year. The *DB General* could pass under the replacement bridges more than 90% of the days in all the months of the year except the highest-flow months of May and June, when it could pass about 85% and 80% of the days, respectively. The *DB General* would not be impacted under the assumed conditions for a bridge height of 121 feet. The *DB General* also cannot go any farther up the river than the Bonneville dam due to the vessel's beam. Accordingly, for the purposes of this analysis, there is no substantial impact.

JT Marine

Under the assumed conditions, the *DB Taylor* would not be able to pass under a bridge height of 116 feet or 121 feet in the vessel's current configuration when outfitted with a 220-foot crane boom.

Diversified Marine

The *DB Freedom* has an air draft of 119 feet with the crane lowered and would not be able to pass under a bridge height of 116 feet or 121 feet in the vessel's current configuration. Their normal setup for transporting the vessel is to place the crane boom over the top of the tug placed at the stern of the barge. In that position it requires an air draft of up to 119 feet (depending on the tug used for moving the barge). When needed for transiting under obstacles with limited clearance, they have rotated the crane boom to the side of the tug, and lowered it to the level needed to pass under the obstruction. This requires that a crane operator be placed on the barge while in transit. Accordingly, for the purposes of this analysis, there is no substantial impact.

Manson Construction Company

Derrick No. 24 has an air draft of approximately 99 feet and a desired air gap of 6 feet and would be impacted under the assumed conditions for a bridge height of 116 feet. Based on water levels it could pass with a 5-foot air gap at least 90% of the days in all the months of the year except the highest-flow months of May and June, when it could pass at least 75% of the days. It could pass at least 80% of the days of the year, including at least 50% of the days during the high water months of May and June. It would also be impacted by a bridge height of 121 feet but the frequency of days that it would not be able to pass would decrease. Utilizing the air gap indicated by the owner would result in no impact for a bridge height of 121 feet. Information provided by the company indicates there are no plans to bring the vessel to the Columbia River. Accordingly for the purpose of this analysis, there is no substantial impact.

SDS Lumber Company

One reported possible future shipment made by SDS would be obstructed at some point in the year by the proposed 116-foot bridge. SDS has a barge that can ship loads as high as 100 feet. Under the assumed conditions, it could pass under a 116-foot bridge between 55% and 95% of days per month for 5 months of the year (July through November), between 25% and 37% of the days per month for 5 months of the year (December through April), and between 12% and 22% of the days in May and June. With a 5-foot air gap, it could pass more than 88% of the days each month except in May and June when it could pass between 72% and 78% of the days per month. A bridge height of 121 feet would reduce the days in which it would not be able to pass but would not eliminate the restriction. The future load is speculative and is not based on history or a specific future market and updated information was not provided by SDS. Accordingly, for the purposes of this analysis, there is no substantial impact.

Future Vessels

Bridge transits by marine contractors are dependent on their home location and the location of the construction project. Three businesses that provide marine contracting services or operate crane barges are located upriver of the I-5 bridge (JT Marine, Mark Marine Services, and SDS). These contractors transit beneath the I-5 bridge for downriver construction projects or to pick up supplies from downriver locations. Contractors that are located downriver of the I-5 bridges must transit the bridges for projects located upriver of the bridges.

As discussed previously in this report, the BNSF Celilo Bridge, located 95 miles upstream of the IBR program, has a lower vertical clearance than that proposed for the replacement bridges, and any marine construction project used upstream of the Celilo Bridge will not be height constrained by the proposed I-5 bridges. Therefore, the only marine construction projects that would be constrained by the proposed I-5 bridges are those located between the current I-5 bridge and the BNSF Celilo Bridge and that are performed by firms based downstream of the IBR program, and those located downstream of the proposed bridges that are performed by firms based upstream of the IBR program.

The volume of marine construction located between the I-5 bridges and Celilo Bridge in the future will be limited by the amount of property available for development and future construction activity. As discussed under the Future Land Use Analysis, most of this area is in the Columbia River Gorge National Scenic Area, which strictly limits the types of development that may occur. Downstream of the National Scenic Area there are a limited number of sites available for water-dependent development.

Future infrastructure projects between the I-5 bridges location and the Celilo Bridge that may require water-based construction equipment could include bridge replacements, construction of docks or other in-water construction, dredging, or work on The Dalles or Bonneville dams or locks. There are known projects, such as the planned replacement of the Hood River-White Salmon bridge over the Columbia River, and unplanned projects such as dam maintenance and repair, that will likely require floating construction equipment. Since these projects are still in the planning phases or are not currently anticipated, the type and size of this equipment needed cannot be determined. However, past projects can provide an indication of potential needs.

In 2019, emergency repairs were conducted on the Bonneville dam navigation lock by Advanced American Construction. Information published by the company noted that crane barge DB 125 was needed for the repair (AAC n.d.). As shown in Section 5, this vessels would be height constrained by the replacement bridges. Another recent project was The Dalles Dam Upstream Navigation Lock Gate project in 2016. The gate was fabricated by Greenberry at the Columbia Business Center and was transported by barge upstream, where shore-based cranes installed the gate. Photographs show the equipment in transit as being lower than the tug Dauby transporting it and would not be height constrained, as shown in Section 5 (Greenberry Industrial 2021).

Many, but not all, of the marine construction vessels discussed in Section 5 will be able to transit the proposed bridge, given the current figuration of the equipment. It is also important to note that 23 CFR 650.807(g) specifies that special navigation clearances shall normally not be provided for floating construction equipment unless required for navigation channel. Based on past trends and future land

use, future marine construction is not expected to exceed past averages and would not be expected to be height constrained by the replacement bridges. Equipment that, as currently configured, is not able to pass under the proposed I-5 bridges is not precluded from working on projects past the replacement bridges but may require a temporary or permanent modification to transit the bridge.

2.7.4 Fabricators

Fabricators were contacted individually by the program team to discuss their unique navigational needs and identify future business plans that might impact the size and/or type of vessels that transit the bridge location. A summary of the information provided by each company is included below. Additional details are included in Appendix B.

- Greenberry Industrial (Greenberry) is a general industrial fabricator and contractor. The company website indicates that their Vancouver, Washington, location fabricates and ships large tanks, pressure vessels, modules, bridge steel, and large structural components. Greenberry responded to the request for information and completed a vessel data sheet. The data sheet provides additional information on the type of fabricated materials they produce. They indicated that the vessels transporting their cargo have a maximum air draft of 136 feet, with a desired 1-foot air gap.
- Thompson Metal Fab is a heavy structural steel and plate fabrication company located in Vancouver, Washington. Thompson Metal Fab responded to the request for information and provided an extensive summary of their current and potential future operations, as well as information on the height and other characteristics of their past projects that have required a bridge lift. Thompson Metal Fab indicated that they need the same clearance currently provided by the bridge lift span (178 feet) to accommodate their operations. The total height (vessel, cargo, and air gap) of the example projects they provided that previously required a bridge lift ranged from 54 feet to 161 feet. Of the 40 projects included, six had heights above 116 feet, one had a height of 116 feet, and 33 had heights below 116 feet.
- Vigor Works, LLC (Vigor) is a heavy industrial fabrication company that serves the marine, hydroelectric, nuclear, oil and gas, and steel bridge industries. Vigor merged with Oregon Iron Works in 2014 (Vigor 2014) and Oregon Iron Works information was addressed in the 2012 CRC NIR. Vigor responded to the request for information and provided an overview of their current and potential future operations at three locations and around the Columbia Business Center. Vigor operates an aluminum fabrication facility at the former Christensen Yachts site in the Columbia Business Center. This facility will focus on aluminum ships including the construction of a landing craft for the U.S. Navy (Vancouver Business Journal 2019). They indicated that their products and equipment result in an air draft of 130 feet, and they recommend accommodating an air draft of 150 feet.

Due to lack of detail in the bridge tenders' logs, it is difficult to define the bridge lifts associated with metal fabricators located at the Columbia Business Center, which is located just upstream of the Interstate Bridge in Vancouver. However, discussions with the reveal that there is a shipment every year or two, consisting of structures for the oil industry (oil rig modules), local Pacific Northwest industries (structures for forest products plants and other local firms), USACE (lock gates, fish weirs

and other structures) and departments of transportation (mainly bridge structures). Not all these shipments require bridge openings or transits under the bridge. In addition, these firms are currently fabricating structures that support offshore energy programs (wind and tidal power).

Marine industries and fabricators ship products or have vessels transiting under the bridges on an as-needed basis all months of the year.

The tallest projected future shipments from Greenberry, Thompson Metal Fab, and Vigor would not be able to pass unrestricted under a bridge height of 116 feet or 121 feet. The lower reported shipments could pass under all of the studied bridges at least during some part of the year.

Users did not provide information on specific shipments that would be impacted but based the request on past shipments and potential future shipments. Thompson Metal Fab provided detailed information on past shipments from 1973 to 2020, including height of the shipment and air gap provided. The total height (vessel, cargo, and air gap) of the example projects they provided that previously required a bridge lift ranged from 54 to 161 feet. Of the 40 projects included, 19 would be height restricted by the replacement bridges in the assumed condition, and of these nine would be restricted under any stage.

Based on this information, the frequency and type of future shipments that could be impacted is unknown but could be impacted by a bridge height of 116 feet or 121 feet. It is also not known whether it is feasible to modify the way that future shipments are constructed, assembled, or shipped such that they could transit under the replacement bridges. Therefore, these users are potentially impacted by the replacement bridges.

Based on information provided by fabricators and a review of literature, some of the fabricated structures manufactured at the Columbia Business Center could be taller in the future than the tallest shipments in the past. Oil rigs are growing in dimensions in response to new technologies such as directional drilling of oil fields. However, the primary market for these rigs is Alaska, and this area has seen a significant reduction in crude oil production and changing conditions may affect the future demand for the type of drill rigs shipped in the past. These structures may require transiting heights in excess of 125 feet. Other structures, such as fish weirs and bridge trusses, are unlikely to change significantly in the future and would not be height restricted.

Most of the fabricated metal structures are transported by ocean barges bound for destinations located outside of the Columbia River, including Alaska, California and elsewhere. Ocean barges are larger than river barges, with lengths of 400 or more feet and a beam (width) of 100 feet or more. Ocean barges cannot transit through the Bonneville lock because their beam exceeds the width of the lock chamber. As a result, future fabricated metal operations in the affected region of the river are limited to the area downstream of the Bonneville dam.

2.7.5 Annual Cargo Movements

2.7.5.1 Columbia/Snake River System

The Columbia River originates in British Columbia, Canada, and flows for 1,175 miles to its mouth on the Pacific Ocean between Oregon and Washington. The Snake River is one of the main tributaries to

the Columbia River and originates in Wyoming. It flows approximately 868 miles to the confluence with the Columbia at Columbia RM 283. The navigable portion of Columbia/Snake River System begins at the mouth of the Columbia River and extends to the head of navigation in Lewiston, Idaho, at the confluence of the Snake and Clearwater Rivers, approximately 465 miles upriver from Astoria, Oregon, as shown in Figure 2.2-1. The navigable sections include a portion that supports deep-draft oceangoing vessels and a shallow-draft system supporting primarily shallow-draft barges being pushed by towboats or tugs.

The deep-draft navigation system provides for a 43-foot-deep by 600-foot-wide channel from inside the Columbia Bar to Portland, Oregon, and Vancouver, Washington, on the Columbia River—a distance of approximately 105 miles. This section of the channel, known as the Lower Columbia- Willamette, provides deepwater access to facilities at the Washington ports of Longview, Kalama, Woodland, and Vancouver and to the Oregon ports of Astoria, St. Helens and Portland, as well as to industrial facilities and private facilities located in this area. Approximately 60 million tons of cargo passed via the mouth of the Columbia River in 2019 (including both inbound and outbound directions).

The shallow-draft navigation system begins just downstream of the I-5 bridge (at RM 106.5). The Vancouver to The Dalles portion of this section was authorized as a deep-draft system (27 feet authorized depth) to serve oceangoing vessels common at the time. However, the USACE currently maintains the channel to 17 feet based on usage. The controlling depth for the rest of the shallow-draft system (from The Dalles to Lewiston, Idaho) is 14 feet. The section of the river from Vancouver to The Dalles handled approximately 8.4 million tons of cargo annually over a five-year average from 2013 to 2017 (USACE 2021a). More than 90% of this cargo passed through the locks at Bonneville, moving mainly from upriver ports to downriver ports (primarily grain moving down river and petroleum products moving upriver).

2.7.5.2 Oregon Slough

The lower entrance to the Oregon Slough is at Columbia RM 102.5, and the upper entrance (east) is at Columbia RM 108.8. The lower end is the location of several berths operated by the Port of Portland for deep-draft cargo vessels. These include auto berths (601 and 607) and container berths (603, 604, and 605). As reported by the USACE (2019), cargo volumes in 2019 were 330,981 tons. The Port of Portland uses this lower section for storage and staging of equipment associated with the *Dredge Oregon*.

The Port of Portland provided data on vessel calls for their existing berths on the Oregon Slough, as shown in Table 2.7-1. These berths are all deep water facilities and serve vessels using the deep-draft system downstream to the mouth of the river and do not transit upriver to the I-5 bridge location.

Table 2.7-1. Port of Portland Oregon Slough Vessel Call Data by Berth and Year

Berth	2016	2017	2018	2019	2020
601	64	60	57	68	66
603	0	2	1	3	1
604	0	1	5	4	0

605	0	5	23	10	49
607	71	45	71	39	12

Upriver of the BNSF rail bridge, the waterway is dominated by floating homes and recreational vessel moorage, with some commercial traffic associated with an existing marine contractor and shipyard located just downstream of the existing I-5 bridge. The BNSF railroad bridge on the waterway saw a total of 644 openings from January 2015 to July 2021, with an average of 92 openings per year (BNSF 2021). There are relatively few vessels moored between the two bridges and the openings are likely associated with the marine contractor and shipyard

2.7.6 Impacts to Commercial/Industrial Development

The replacement bridges will likely be in place for 100 years or more, and the NIR needs to consider potential impacts from prospective upstream commercial development that could result in different navigation on the waterway. Appendix A to this report assesses land uses along the Columbia River upstream of the I-5 bridge to evaluate the potential for development that could result in prospective navigation different than that currently using the waterway. The appendix includes an analysis of existing commercial and industrial development and land uses suitable for this type of development to identify their likelihood of creating additional navigation activities that could be impacted by the proposed replacement bridges.

The analysis in Appendix A concluded that both political and geographic constraints were the primary factors affecting commercial/industrial development along the waterway. Land use restrictions imposed by the Columbia River Gorge National Scenic Area, topography, transportation access parallel to shorelines (SR 14, Interstate 84 [I-84], and BNSF and Union Pacific railroads), and existing open spaces limited the areas for future water-dependent land uses. All the industrial uses between the BNSF bridge and BNSF Celilo Falls rail bridge are in urban areas and primarily within established industrial parks (e.g., Columbia Business Center, Port of Cascade Locks Industrial Park). There were no planned developments within the study area that would be served by marine transport that could be impacted by the proposed replacement bridge height.

Industrial Campuses Trend

Based on interviews and a literature review, most of the industrially zoned sites along the Columbia River that are owned by ports are being planned as industrial campuses that support light industrial and commercial uses and that will not generate marine traffic or include marine facilities (e.g., docks). This includes properties at the Columbia Business Center, Port of Cascade Locks, Port of Hood River, the Troutdale Reynolds Industrial Park, The Dalles, and Stevenson.

Existing Site Constraints

In many cases, the linear rights-of-way of SR 14, I-84, and the BNSF and Union Pacific railroads, on both sides of the river, can restrict lot depth, making the area less conducive to certain types of

development. Given the steep topography and limited area for placement of these rights-of-way, they often run along the shoreline, precluding industrial development.

Riverfront Trails

Many jurisdictions (such as Hood River, The Dalles, and Vancouver) have recreation trails and plans for future recreation trails and trail expansions along the river. Such trails can create a barrier to other marine-dependent uses of the Columbia River shoreline.

Redevelopment Potential of Industrial Sites with Existing Marine Structures

Redevelopment of sites that have existing marine traffic docking structures could be significantly easier and less expensive because redevelopment of such sites would have the potential to bypass, or have less arduous, environmental permitting requirements than required for new development.

2.7.6.1 Summary of Findings by Subarea

Within the program area, there are undeveloped and potentially re-developable sites along the Columbia River, which are zoned for industrial and other uses that could generate marine traffic that requires varying navigational clearances. Additionally, there are sites that have existing marine infrastructure, such as lumber mills, that could also be redeveloped with different water-dependent uses in the future and that could use the existing marine infrastructure. These sites are primarily located within incorporated jurisdictions.

This section summarizes the findings by subarea.

Clark County, Washington (Vancouver)

The water-dependent industrial sites within the jurisdiction of the city of Vancouver include industrial uses at the Columbia Business Center (metal fabricators include Thompson Metal Fab, Vigor and Greenberry, and JT Marine, a marine contractor), the Western Forest Products property, and the Lafarge property. Recreational water-dependent uses exist at the recreational moorage at Steamboat Landing Marina, Tidewater Cover Marina, and several docks associated with private residences.

It is uncertain whether all of the parcels in the Columbia Business Center will remain in industrial use over the long run. Some of the main fabrication buildings were built in the 1940s. If these areas are redeveloped, it could be as mixed use (residential, commercial and retail uses) like the area immediately to the west. A portion of the eastern shoreline of the Columbia Business Center is owned by Vigor, which has indicated that it will continue in long-term industrial use.

Only the uses at the Columbia Business Center are currently height constrained in the affected area in the city of Vancouver. The height-constrained uses include fabricated structures such as oil rig modules and fish weirs, among others, and marine equipment owned by JT Marine. Based on existing land use regulations, there are no vacant waterfront parcels that could be placed in industrial use.

The Steamboat Landing Marina and private moorages typically serve smaller powerboats and sailboats (up to 40 feet) and are not known to be height constrained. Tidewater Cover Marina has slips available for vessels ranging from 40 to 110 feet. Some recreational sailboats may experience height constraints, depending on the option under consideration.

Clark County, Washington (Camas)

There are two existing water-dependent sites within the jurisdiction of the city of Camas, including the Georgia Pacific Camas Mill and the city of Camas Boat Ramp. The Georgia Pacific Camas Mill has ceased operations of its marine facilities but they remain in place. It is likely that both sites could remain under marine uses in the future.

The Georgia Pacific mill site would not be constrained because it already has a height constraint imposed by the bridges that connect U.S. 14 to Lady Island.

The city of Camas leases a portion of the Columbia River shoreline to Mark Marine Service. The city is in the process of renewing the property lease for an additional five years beyond the current lease. Future use of this parcel could remain in industrial use or change to public access. Mark Marine Vessels are addressed earlier in this report.

Clark County, Washington (Washougal)

The waterfront industrial property in Washougal has been rezoned to highway commercial zoning and is undergoing a process of waterfront revitalization, focusing on mixed-use development (residential and commercial). This development encompasses the Port of Camas-Washougal marina, the site of the former Hambleton Lumber Mill, and the Port of Camas-Washougal's 6th Street property. These three properties are collectively referred to as the Washougal Waterfront.

Most of the moorage slips at the Port of Camas-Washougal marina are covered and are only usable by power boats, which are not height constrained. It is possible that some of sailboats at the marina could be height constrained by the bridge height options being studied. However, most of the sailboats are 50 feet or less in length, and sailboats of this size will not be height constrained by the IBR program.

Industrial development in Washougal is centered in the Port of Washougal's industrial properties at the eastern edge of the city. Heavy industrial zoning at this site accommodates uses such as bulk petroleum product terminals, plants, and storage facilities, which could generate marine traffic. However, a levee and recreation areas/trails parallel the river and separate the industrial site from the water, which inhibits marine industrial uses along the riverfront in Washougal.

Skamania County, Washington

The industrial waterfront properties in Skamania County have traditionally been used by the forest products industry, including the mill sites at Stevenson, Home Valley, and Underwood. As the forest product sector has declined, properties have been held by forest product firms for potential future reuse as a mill site or have been planned for redevelopment to resort or mixed-use development. The

proposed I-5 bridges do not impose a height constraint on shipping activities because log rafts or barges can easily pass under the bridge for destinations transiting downriver of the bridge.

The Port of Skamania owns a business park, cruise terminal, and boat launch at Stevenson. The port's property at Stevenson Landing is on the waterfront and has a cruise ship dock but does not offer waterfront access for water-dependent firms requiring barge service. Within the city of Stevenson, there is interest by the community to enhance recreational waterfront with public access.

Other land holdings in Skamania County provide space for commercial and industrial tenants but do not have direct access to the Columbia River (e.g., the Port of Skamania County's Cascades Business Park, the Lewis and Clark Business Park, and the Wind River Business Park).

Klickitat County, Washington

Most of the occupied industrial lots along the riverfront in Klickitat County are used by the timber industry, which generates cargoes (logs, wood chips, and aggregates, etc.) that are not height constrained. It is expected that the bridge will not have any impacts to shipping related to the timber industry. SDS operates a marine subsidiary from their location in Bingen. Vessels operated by SDS are addressed in Section 5.4.

There are some undeveloped industrial lots along the river in Klickitat County. The county's Industrial Park zoning allows for boat building, assembly, and fabrication of metal products, and additional manufacturing activities as uses permitted outright. However, many of the industrially designated lots are constrained by the railroad right of way, which creates shallow lots from the river and potentially limits large industrial structures on the site.

There are also vacant developable industrial lands at Dallesport Industrial Park. However, the BNSF railroad right of way cuts through the property near the river, leaving a narrow band of land adjacent to the river that is currently used by a barge terminal. It is unlikely that future uses would be height constrained at this location.

Multnomah County, Oregon (Portland)

There are many recreational marinas in the area between Hayden Island and Government Island that are used by both powerboats and sailboats. There are no known plans to change land uses in this section of the riverfront.

Multnomah County, Oregon (Fairview and Troutdale)

The industrially zoned sites in this area generate marine traffic that primarily consists of tugs and barges, which are not height constrained.

The Knife River aggregates terminal in Troutdale is not expected to change uses in the near future. Tugs and barges serving this facility are not height constrained.

Sundial Tug & Barge Works shipyard was closed by Tidewater in early 2011 because the vessel repair and construction business was cyclical and not a core business function. The facility is currently idle,

many of the marine facilities have been removed and the site could be sold or redeveloped. (Oregonian 2011)

The recently developed Troutdale Reynolds Industrial Park is located on the former 700-acre brownfield previously used by Troutdale Aluminum. The site's main tenants are Amazon and FedEx. The development does not include marine facilities, none are planned by the Port of Portland and shallow water would make development of marine facilities difficult.

Hood River County, Oregon (Cascade Locks)

There are undeveloped industrial lots along the river in the city of Cascade Locks. Some of these lots are zoned as light or heavy industrial and could be developed with marine uses. Other available lots in Cascade Locks have been identified for types of development that would not generate marine traffic, such as a business park serving non-water-dependent firms, or entertainment and recreational uses, potentially including a casino.

Cascade Locks is positioning itself as a sailboat racing destination. In general, there is a desire to attract the international sailing community, but the sailboats using this area are smaller and not height constrained by the proposed bridges.

Hood River County, Oregon (Hood River)

Activities that generate marine cargo are limited along Hood River's riverfront, due to the railroad tracks that abut the river for a large portion of the shoreline. In the Port of Hood River area, the emphasis is on recreational development and business park development rather than marine-based industrial uses.

Cruise ships that call Hood River are addressed in Section 5.4. The sailboats homeported in Hood River or calling on a transient basis at Hood River are typically less than 40 feet long and, as a result, are not constrained by the proposed height of the replacement bridges.

There are no known existing or future activities that would be height constrained in Hood River.

Wasco County, Oregon

Bernert Barge Lines and Mid Columbia Producers have barge terminals at the Port of The Dalles. The tugs and barges calling at these terminals are not constrained by the proposed height of the IBR program. The sailboats homeported at or visiting the port's marina are typically smaller and are not height constrained by the replacement bridges.

A new cruise dock was opened in The Dalles in September 2012 that provides a float to serve transient recreational boats, as well as a fixed pier for cruise ships.

Other industrial developments are focused on redevelopment of the Northwest Aluminum site, which offers approximately 120 acres for commercial and industrial development. This site does not provide riverfront access.

Summary of Redevelopment Opportunities

Based on the analysis in Appendix A, there are no known planned developments that would significantly increase navigation or require the use of vessels that would be height constrained by the proposed replacement bridges. Efforts are underway in upriver counties to reuse vacant or underutilized industrial waterfront parcels in forest products manufacturing (which is not height constrained) or in non-water-dependent uses, including commercial business parks, mixed-use residential/commercial developments, and tourist centers.
The sections below further summarize the 2012–2020 bridge lift data by vessel type.

2.8 Marine Facilities

The Columbia River near the program area has a high concentration of marine facilities. These include many marinas and services for recreational vessels, as well as a number of ship maintenance facilities. There is a higher concentration on Oregon Slough than on the main Columbia River channel. Recreational facilities are concentrated upstream of the I-5 bridges while cargo terminals are concentrated downstream. Figure 2.8-1 shows the location of the facilities within 3 miles and Table 2.8-1 contains details on the name, contact information and type of facility.

Figure 2.8-1. Marine Facilities within 3 Miles of the Interstate 5 Bridge

These facilities predominantly serve small recreational craft (power and sail). Except as noted below the facilities will not be directly or indirectly impacted by the replacement bridges.

There are three existing shipyards or vessel repair facilities within 3 miles of the program area: JT Marine, Schooner Creek Boat Works, and Diversified Marine.

JT Marine is located approximately 1.5 miles upstream of I-5 in the Columbia Business Center in Vancouver. JT Marine offers a full range of shipyard services including dry dock, vessel repair, new vessel construction and vessel deconstruction. Facilities include a 1,200 ton dry dock, 1,000 feet of dock space and overhead cranes (JT Marine 2021).

Schooner Creek Boat Works is located approximately .75 miles downstream of the program area on Hayden Island between the BNSF railroad bridge and the existing Interstate Bridge. Schooner Creek provides full service boat repair and manufacturing of small recreational and commercial vessels. Facilities include in-water docks, upland yard, and 35-ton and 70-ton travel lifts (Schooner Creek 2021).

Diversified Marine is located on Oregon Slough just downstream of the existing I-5 bridge. This yard offers repair, retrofit and construction of tugs, barges and commercial steel vessels. Vessels up to 100 feet wide and 300 feet long can be accommodated. Facilities include 100 ton and 700 ton dry docks (Diversified Marine 2021).

The Port of Vancouver's Terminal 1 facility is located on the north bank of the river just downstream of the existing I-5 bridges. This facility is partially within the bridge footprint and would potentially require portions of the existing dock and building to be removed. This site consists of a timber dock occupied by a vacant restaurant and hotel buildings. Currently, the timber dock and portions of an adjacent downstream concrete dock are used by river cruise vessels. Only a portion of the dock is anticipated to be impacted and would not impact the ability to use the dock for its current purpose. In addition, the Port of Vancouver has plans to remove the existing buildings on the dock and rebuild the dock with a modern structure and redevelop the upland elements (Port of Vancouver 2021).

Just downstream of the bridge on the Oregon side of the river is a facility that used to serve as a dock for a hotel that has since been demolished. This dock is not serviceable, and several abandoned vessels are located just offshore. This facility will likely be removed to accommodate the replacement bridges. Since it does not provide any marine services, the removal will not impact navigation or services.

On the Oregon Slough, the I-5 bridge is flanked by private moorage facilities for floating homes and recreational vessels. Portions of these facilities may be impacted by the replacement bridge over Oregon Slough, but details have not been determined (FHWA and FTA 2011). They do not provide any critical marine services such as fuel or repair activities and would not reduce available marine services on the waterway.

2.9 Local Service Facilities

The proposed bridge will not block access to any of the facilities noted in the prior section. The JT Marine facility is located upstream of the bridge and offers shipyard services. Vessels that are not able to transit under a bridge height of 116 feet would not be able to access the facility. Based on the size of the shipyard facility and information on past jobs provided on the companies' website, the shipyard primarily serves smaller vessels such as tugs, fishing vessels and barges. Vessels within these categories were not shown to be impacted by the proposed bridge. Larger shipyards such as Vigor on Swan Island are located downstream of I-5 and are available to serve larger vessels.

2.10 Alternate Routes

Alternate routes can provide vessels that are restricted from transiting the bridge location a way to avoid the restriction. The main Columbia River does not have an alternate route available. However, vessels that may be restricted by the proposed bridges over the Oregon Slough can use the main Columbia River as an alternate route, as it has greater horizontal and vertical clearances. Because of the existing clearances on the Oregon Slough bridge, there will be no change in the number of vessels that will need to use this alternative route.

2.11 Harbor Refuge

Harbors of refuge can play a critical safety role by allowing craft to seek shelter in protected waters during weather events or flooding .A harbor of refuge is defined as a naturally or artificially protected water area that provides a place of relative safety or refuge for commercial and recreational vessels traveling along the coast or operating in a region (USCG 2016). The Columbia River is not an open ocean or a coastal area and is therefore not subject to the same type of conditions that require harbors of refuge. Wind and wave conditions on the river do not affect vessels the same way as the conditions would in coastal areas near the mouth of the Columbia River.

Nearby marinas and the Oregon Slough can provide refuge for small craft during extreme weather events. There are several boating facilities located upriver from the project bridge, such as Donaldson Marina, Steamboat Landing, and the M. James Gleason Ramp, which can provide small craft refuge (OSMB 2007). The project would not block access to these sites, and small craft are not likely to be affected by changes to vertical or horizonal clearances. Commercial vessels are not generally impacted by weather conditions on the Columbia River and Oregon Slough and are too large to find refuge outside the channel. These larger vessels would either seek dock space or anchor as needed, should weather conditions dictate.

2.12 Waterway Bends

NOAA Chart 18526 (NOAA) shows the nature of the waterway and navigation channel within the project vicinity. This chart indicates that there are not bends in the waterway within .5 mile of the I-5 bridge. However, under the I-5 bridges, vessels pass through one of three channels: the primary channel, the barge channel, or the alternate barge channel. The primary channel lies under the bridges' lift spans and has a horizontal clearance of 263 feet and a vertical clearance of 39 feet in the closed position and 178 feet in the raised position.

The highest clearance of these alternate channels provides a vertical clearance of 72 feet. Typically, vessels require bridge openings either because they are too tall to pass under the alternate channel fixed spans or because the location of the primary channel provides a safer line for navigating between the I-5 bridges and the bridge opening in the BNSF bridge just downriver. The primary channel under the I-5 bridges lines up with the opening in the BNSF bridge, while the alternate channels under the I-5 bridges are located toward the center and south bank of the river, thus requiring vessels to make an S-curve maneuver between the I-5 bridges and the BNSF bridge opening.

2.13 Other Factors

Factors such as dockages, lightering areas, and existing bridges located within 0.5 miles of the proposed bridges may create hazardous passage through the proposed structure. There are not existing bridges within 0.5 miles of either crossing. However, BNSF railroad bridges are located approximately 1 mile downstream.

Marine facilities and dockages are addressed in Section 8. There are three facilities within 0.5 miles of the bridge. There are two facilities on the Oregon shoreline that do not impact navigation as they are located away from the navigation channel and areas where most navigation occurs. The Port of Vancouver's Terminal 1 is located just downstream of the I-5 bridges. The dock face is close the navigation channel and when cruise or other vessels are moored at the facility, they may come close to or infringe on the primary channel. This situation may require special consideration when vessels are transiting the primary channel.

According to USACE navigation project information and NOAA charts, there are no designated anchorages or lightering areas within the vicinity of either bridge on the main Columbia River or in the Oregon Slough. USCG regulations do not establish any regulated navigation areas proximate to the replacement bridge locations. Oregon Slough is subject to "Slow-No Wake" requirements by the State of Oregon which limits vessel speed within 200 feet of marinas and/or floating home moorages and 5 mph speed limit from west of the BNSF bridge east to the eastern entrance to the waterway from the Columbia River.

2.14 Hydraulic Conditions

Currents at the bridge location are generated by flows released at Bonneville dam. According to the Federal Emergency Management Agency Flood Insurance Study for Portland, Multnomah County, Oregon dated November 26, 2010, the average cross-sectional velocity for the 100 year flood near the I5 bridge is 3.8 feet/sec (2.25 knots) (FEMA 2018). Note that this velocity is the average of the entire cross section. Localized velocities, especially near the center of the channel, could be greater. During low flow periods the current is affected by tides, such that slack tide can result in very little to no current. Currents used in the simulation effort are shown in Table 2.14-1. No current information was found for the Oregon Slough.

Table 2.14-1. Columbia River Currents

Designation	Discharge at The Dalles (KCFS)	River Gage @I-5 Bridge (CRD)	Current Magnitude (fps/knots)
Normal	140	2.8	1.84/1.09
Transition	400	14.5	3.65/2.16
10-Year	540	19.1	4.35/2.58

Key:
CRD = Columbia River Datum
fps = feet per second
I-5 = Interstate 5
KCFS = 1,000 cubic feet per second

When traveling with a river current, vessels need to maintain a faster speed than the current to provide steerage. Consequently, at higher river velocities, speed over ground is increased and the required distance to negotiate turns becomes greater. Should the vessel need to stop for any reason, it must compensate for the river flow by backing down. If the vessel is towing a non-self-propelled barge or other vessel, the tow can lose control and the only chance to stop the tow would be to turn around. Barges being towed often have a tug alongside them while transiting under bridges and along other parts of the river to provide greater control.

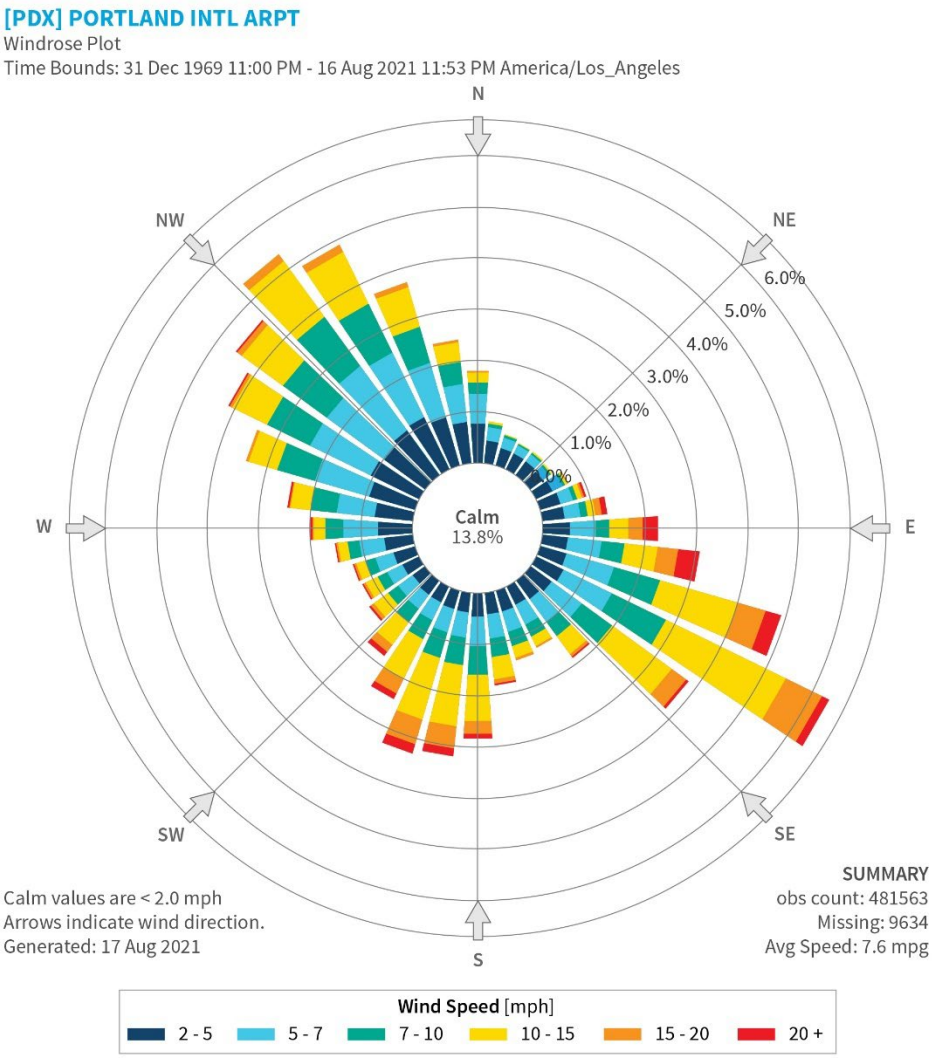
2.15 Atmospheric Conditions

2.15.1 Wind and Wave Environment

Wind forces on a vessel produce two impacts: a sideways drift and a turning moment. The degree to which wind affects a vessel depends on the relative direction of the wind, the ratio of wind speed to vessel speed, the depth to draught ratio, the vessel profile and whether the vessel is in a light or loaded condition. The impacts of waves and when they should be considered in navigation channel design is discussed at length in USACE EM 1110-2-1613, Chapter 5-2 and 6-4 (USACE 1995). For large ships and tows, waves must have a length of approximately half the length of the vessel. This would require swell waves that occur near the entrance of the river to the ocean. In the program area, the waves that would be present would be local wind-generated waves that have a much shorter wavelength than would be required to affect the vessel's behavior.

Winds from the bow are generally not a concern for wind speeds less than 10 times the vessel speed. However, winds become a greater concern as they increase or shift abeam. The maximum impact occurs when the wind direction is perpendicular to the ship's beam. Transiting in a strong wind or through a curve requires more skills and room for navigational tolerance than transiting in a light wind. Wind observations from the Portland airport weather station show that when strong winds occur they are predominantly from the northwest and southeast, in general alignment with the river and channel. Winds can occur from the south but are not the predominant direction (see Figure 2.15-1).

Figure 2.15-1. Portland Airport Windrose Plot



Source: Iowa State University (2021)

Wind waves are not a hazard to navigation in rivers except during storms (USACE 1980). Studies completed in the area have evaluated wave conditions (Coast & Harbor Engineering 2012). Waves in this stretch of the river are generated by passing ships and windstorm events. Waves of this size would not be expected to affect tugs and tows and larger commercial vessels due to their weight and length at the waterline, which serve to reduce the impacts of waves on the vessels. For smaller vessels, the specified air gap should provide adequate margins to accommodate vessel movements based on the height of waves in the area.

No wave information was found for the Oregon Slough. Because of the narrowness of the waterbody, the limited fetch, and the many shoreline restrictions, only very small waves would be expected in the area of the proposed replacement bridge and would not be expected to impact available vertical clearances.

2.15.2 Visibility

Fog, rain and transiting at night reduce visibility. The net result is that there is less time to react should a vessel need to maneuver quickly. Even with radar, vessels will travel slower than they normally would during periods of good visibility. This affects vessel steerage and maneuverability. In addition, knowing the bridge clearance and the vessel's height becomes extremely important because it may not be possible to simply "eyeball" whether the vessel will clear a bridge height. Users may want a greater air gap while transiting during these conditions. Fog is most prevalent in the area during the fall and winter when visibility can be reduced to 0.5 miles or less on four to eight days per month (DOC et al. 2021).

2.15.3 Guide Clearances

The USCG publishes bridge guide clearances for certain navigable waters of the U.S., and compliance with these guide clearances will ordinarily receive favorable consideration under the bridge permitting process as providing for the reasonable needs of navigation. According to the clearance guide[1] for the Columbia River from the BNSF railroad bridge at Vancouver (RM 105.6) to The Dalles, the horizontal navigational clearance is indicated as 450 feet, and the vertical navigational clearance is indicated as 135 feet as measured from a river stage of 600,000 cubic feet per second. Upriver of The Dalles, the horizontal clearance is indicated as 400 feet and the vertical clearance as 60 feet (based on 2% flowline). No guide clearance is provided for the Oregon Slough. The USCG notes that guide clearances are not intended to be regulatory, and greater or lesser clearances may be required or approved as necessary to meet the navigation needs at a particular location.

A bridge height of 116 feet or 121 feet would be less than the published guide clearance. The 400 feet of horizontal clearance would also be less than what is published in the guide clearance.

2.15.4 Other Natural or Human-made Conditions

There are no known natural or human-made conditions that affect navigation that are not addressed elsewhere in this NIR.

[1] https://www.dco.uscg.mil/Our-Organization/Assistant-Commandant-for-Prevention-Policy-CG-5P/Marine-Transportation-Systems-CG-5PW/Office-of-Bridge-Programs/Bridge-Guide-Clearances/

2.16 Additional Factors

Vertical clearance is just one of the factors that vessels transiting in a channel or under a bridge must consider when determining whether a passage can be accomplished safely. These factors are both operational and physical. The major operational factors considered by the USACE that affect the vessel transits in channels include the following:

> "Wind, wave, and current conditions; visibility (day, night, fog, and haze), water level (including possible use of tidal advantage for additional water depth), traffic conditions (one- or two-way, pushtows, cross traffic), speed restrictions, tug assistance and pilots, under keel clearance, and ice" (USACE 1984, 1995, 1999).

Physical factors affecting safe transit include vertical and horizontal clearance of human-made structures, as well as natural obstacles. For the I-5 bridge, the human-made physical factors include the bridge height and the width between piers. The proximity of, and channel alignment with, other human-made structures (such as other bridges) may also impact safe transit. Before proceeding into the details of vessel clearance, this section discusses operational factors because changes in the physical surroundings may result in users having to address the operational factors differently, even though the factors themselves do not change.

This navigation technical analysis does not include a discussion of operator skills or experience. Vessel operators are assumed to have sufficient training and qualifications to transit the Columbia River. This includes an understanding of the factors that affect their vessels, knowledge of the aids-to-navigation in the area, and knowledge of the presence of natural and human-made river obstacles.

From a navigation perspective, vessel operators consider the following when transiting between bridge piers:

1. Vessel size and maneuverability
2. Dredged channel width and distance to bridge piers
3. Operational factors
4. Risk of collisions
5. Vessel operator's experience

Bridge piers should be placed outside the top of the dredged channel's slopes. Any width greater than that increases the safety margin of the transit. The USACE Engineering Manual for shallow-draft navigation projects indicates that the span should be somewhat wider that than the designed width of the channel and depends on the alignment and velocity of currents, channel alignment approaching the bridge particularly from the upstream direction and impacts of the prevailing winds (USACE 1980).

To accommodate the proposed replacement bridges, the program proposes to modify the federal navigation projects authorized in the program. These changes will modify the way that vessels that are restricted to the channel navigate the area, and the potential impacts of those changes on navigation are discussed in this section. While the authority to modify these channels is through the USACE, the

changes are considered applicable to the preliminary navigation clearance determination to the extent that they affect navigation.

The analysis in this section is based primarily on vessel simulation efforts completed in 2014 by Waterway Simulation Technology, Inc., for the CRC Project. Simulation efforts were completed for deep-draft vessel use of the UVTB and the primary channel and for tug and tow use of the three navigation channels at the bridge location. The simulations were completed in support of the Section 408 process with the USACE to determine the impacts on navigation of the proposed channel modifications in accordance with EM 1110-2-1643 and EM 1110-2-1611. These manuals require that all proposed modifications to a new or authorized federal navigation channel be modeled for the final design, either with a physical model or ship and/or tow maneuvering model study, to ensure safe and efficient navigation. USACE ER 1110-2-1403 regulates this modeling. During the completion of this effort, the CRC Project was halted, and the simulation efforts were not finalized. All modeling was completed, and draft final reports were issued. The remaining tasks prior to finalization and submittal were limited to review by the USACE and an Independent Expert Panel Review process. The ship simulation studies and reports will be reviewed and finalized prior to issuance of Section 408 authorization by the USACE but the effort and reports completed to date provide a detailed analysis of navigation conditions suitable to support the IBR program NIR and preliminary navigation clearance determination.

Shallow-draft vessel navigation simulations were conducted based on the existing conditions and practices, interim conditions during construction based on the construction sequencing discussed in Section 8.5.1 and on the proposed conditions following construction. The shallow-draft vessel navigation simulations resulted in the following conclusions and recommendations:

Conclusions:

- The existing I-5 bridge spans and navigation channels are considered safe by the pilots, and this was demonstrated by the simulations.
- The pilots were able to make successful transits for all conditions without any accidents or collisions, under all conditions tested.
- The pilots were pleased with the navigation conditions with the proposed project.
- The proposed conditions for navigation will be better and safer than the existing conditions.
- Based on simulation results and pilot input, the proposed layouts of the navigation channels are safe for transits in this reach of the Columbia River.
- The proposed replacement bridges will aid in navigation and should be completed as soon as possible.
- The BNSF railroad bridge will continue to be critical and the most difficult location to transit this reach of the river.

Recommendations:

- Proposed Conditions (Post-Construction):

- The pile caps of the piers near the water level should have the corners marked with directional lighting since they extend out further into the navigation channel than the upper part of the pier.
- Mark the bridge piers on either side of each navigation span with red lights on the pier, lights on each corner of the wide portion of the pier near the waterline, three vertical green lights on the center of each navigation span, and buoys upstream and downstream of the piers on either side of a navigation channel, separated by approximately 200 feet to allow identification on radar during fog.
- Interim Conditions (During Construction)
- Provide all tows an assist tug with 2500- to 3000-horsepower (hp) Z-drive between the United Grain Terminal to upriver of the I-5 bridges.
- Develop guidance on the operation of the lift span so that pilots know what the operating rules will be.
- Provide tie-off or mooring facilities between the Junction Buoy and Ryan Point on both sides of the river.
- Restrict recreational and fishing boats from the construction area navigation channels; marked by buoys and enforced—there is no allowance for interfering traffic while the tows are maneuvering through this restricted area.
- Provide a point of contact during construction to provide information about the operations and location of equipment to pilots upon request using radio or phone and post conditions on the internet for access by towing companies and pilots.
- Operations will be suspended during fog.
- Construction equipment must be well lighted during night operations.
- Provide training for all pilots prior to beginning construction using the simulation models developed and improved to increase realism. Improve the empty tow models by making measurements of the tows in operations on the river and modifying the tow models to respond appropriately in the wind.

Because the Vancouver to The Dalles channel was authorized as a deep-draft (27-foot) channel, simulations were conducted for deep-draft vessel transits even though the USACE only maintains the channel for shallow-draft vessels and no deep-draft vessels currently navigate this stretch of the Columbia River. Since no deep-draft vessels pass under the I-5 bridge presently, simulations were conducted only in the proposed channel configuration and limited to the use of the UVTB and the primary channel. The deep-draft vessel navigation simulations resulted in the following conclusions and recommendations:

Conclusions:

- Two distinct scenarios for approaching the UVTB and performing a tug-assisted turn of the design ships (580 by 101 feet) were tested. The simulations showed that both scenarios were safe for the design ships using two 3,000-hp tractor tugs. These two scenarios were (a)

transiting directly through the BNSF railroad bridge into the turning basin and (b) coming off the Lafarge dock and driving into the turning basin.

- Both loaded and ships in ballast were tested and found to be safely turned in the UVTB and aligned for departure through the BNSF railroad bridge.
- The scenario in which the design ship departed the Lafarge dock (port-side-to) and backed through the BNSF railroad bridge with tug assist was not shown to be safe. However, restricted capabilities of the simulator visuals and tug operations limited the ability of the pilots to direct this maneuver; therefore, definitive evaluation was not possible based on the limited number of runs completed. The pilots did note that they do the backing through the bridge at other sites and that this is a common practice, and they did not expect that there would be a problem in real life if the ship beams were in the range of 88 to 96 feet rather than the test ship's beam of 101 feet.
- Transit of the deep-draft design vessel for the primary channel was shown to be safe for upbound and downbound transits. The controlling factor for these maneuvers was passing through the BNSF railroad bridge.
- The pilots thought that an assist tug should be used to slow a downbound ship after the I-5 bridge and then passing through the BNSF railroad bridge.
- Based on ship simulation results and input from the pilots, the proposed layouts for the primary channel and the UVTB are safe for navigation of the deep-draft design vessel.

Recommendations:

- Two 3,000-hp tractor tugs are recommended for turning the design ship in the UVTB.
- Navigation markers are needed to mark the southern (Oregon side) edge of the UVTB.
- For transits of deep-draft ships under the proposed I-5 bridge, navigation markers are needed above and below the two bridge piers bordering the primary channel. The channel upriver of the bridge should have un-gated buoys marking the channel bends.

Based on the results of the tug and two and ship simulation efforts the proposed channel modifications will increase navigation safety and will not impact the reasonable needs of existing and prospective navigation on the waterway.

The program team also conducted a focus group meeting with key members of the navigation community representing barge companies, a marine contractor and cruise vessels to explain the program and obtain feedback on the navigation conditions during construction and following completion of the I-5 bridges. The members attending indicated that conditions would improve with the project consistent with the findings of the simulation efforts. They also indicated that conditions during construction would present some difficult navigations conditions but could be addressed with careful planning and implementation of mitigation measures.

2.17 Impacts to Navigation

2.17.1 Temporary Impacts

2.17.1.1 Columbia River

The replacement bridges over the Columbia River must be constructed in stages because they occupy some of the same area occupied by the existing bridges and the need to maintain navigation. Over the existing navigation channel, the pier locations for the new bridges will be further apart than the existing bridges. Although vessels will navigate, temporarily, through a longer clearance envelope, it is not anticipated that this will create an adverse impact to navigation or safety levels that cannot be mitigated.

Due to an anticipated length of construction of several years, it is imperative to accommodate frequent users, such as tugs and tows, during construction. Most vessels that currently use the navigation channel would be able to continue to use the channel throughout most of the construction period. If necessary, it may be possible to temporarily restrict infrequent or recreational vessels.

During construction, the height and width of the navigation envelope will be reduced due to construction equipment and pier placement prior to removal of the existing I-5 bridges. A temporary construction navigation envelope (height and width of unobstructed clearance for navigation) will be maintained during construction with a minimum clearance of 75 feet (vertical) by 200 feet (horizontal)that meets the vessel clearance needs of the majority of waterway users including tugs and tows, passenger cruise vessels, and the majority of other vessel use on the waterway. However, there could be some temporary restrictions due to blockages from barges and cranes used to construct piers and lift bridge segments into place. Navigation on the river upriver of Bonneville is subject to yearly lock maintenance closures and anticipated closures for the bridge construction would be much shorter than what already occurs on the river. The length of the navigation channel underneath structures will temporarily increase when the new I-5 bridges are under construction and the existing I-5 bridges are still in use.

A potential construction staging sequence is presented in Section 2.18.2 that maintains the required temporary construction clearance envelope. The replacement bridges would not overlap the existing bridges' adjacent piers, enabling the piers of adjacent bridges to be constructed together, reducing construction time.

During construction, some of the new bridge piers, outside of the navigation channel, would not line up with the existing bridge piers. While the new crossing is under construction and the existing crossing is still operational, this would result in more obstacles in the river and more difficulty in navigation for vessels that may not utilize the main channel. Also during construction, the program will establish navigational haul routes on the river for the movement of construction materials and equipment.

The Tug and Two simulation discussed in Section 2.17.3 included simulation runs for different construction staging scenarios where were completed safely with no incidents. Under these scenarios the pilots often commented that even though they made the run successfully, there was no room for

error, misjudgment, or mechanical failures or for unexpected situations that might develop, and therefore, they considered these conditions unsafe. Providing an assist tug on the front of the tow gave the conning pilot control of the front of the tow and allowed the safe movement of tows through the temporary navigation channels in the construction zone with good control under all conditions. Additional recommendations are summarized in Section 2.17.3.

See Section 18 for discussion of construction methods and staging schemes to minimize and mitigate temporary navigation impacts.

2.17.1.2 Oregon Slough

The bridge(s) that will be built over the Oregon Slough will match or exceed, in height, the vertical clearance of the existing bridge over the harbor. Short duration in-water work windows and constructability issues suggest that the new structures over the Oregon Slough would most likely incorporate bridge elements that use prefabricated superstructure elements such as steel girders or precast segmental girders. These types of construction would eliminate the need for extensive supports in the Oregon Slough. However, some temporary restrictions may be necessary due to barges and cranes used to lift bridge segments into place and during demolition of the existing bridge. Since extensive temporary supports are not likely, the navigation clearance will not be significantly reduced from today's clearance envelope. In addition, the Columbia River provides for an alternative route that provides greater navigational clearance than what is provided on Oregon Slough. Therefore, navigation on Oregon Slough will not be adversely affected during construction.

2.17.2 Long-Term Impacts

The IBR program proposes to replace the existing lift span that is 178 feet above) CRD in the raised position with a fixed span providing 116 feet or 121 feet of vertical clearance and 400 feet of horizontal clearance. On average, about 2,600 commercial vessel trips occur each year, and more than 230,000 recreational activity days per year occurred in the Columbia River in Multnomah County. As described in earlier sections of this NIR the proposed bridge height accommodates the majority of users. With a 116-foot bridge, a total of eight vessels/users would be unable to pass with a 10-foot air gap when the river level is 16 feet above 0 CRD as shown in Table 2.17-1. A bridge height of 121 feet would reduce the number of impacted vessels/users to five.

Table 2.17-1. Vessels Restricted by a 116-foot Bridge Under Assumed Conditions

Vessel	Owner	Vessel Type	Air Draft (feet)	Trip Frequency
TBD (fabricator's tallest future shipment)	Greenberry Industrial	Barge with fabricated materials	136	Any time of the year

Vessel	Owner	Vessel Type	Air Draft (feet)	Trip Frequency
TBD (fabricator's tallest future shipment)	Vigor	Barge with fabricated materials	130	Any time of the year
TBD (fabricator's tallest reported shipment)	Thompson Metal Fab	Barge with fabricated materials	165	Any time of the year
DB Taylor	JT Marine	Marine contractor vessel	131	Up to 10 trips per month at all times of the year
DB Freedom	Diversified Marine	Marine contractor vessel	119	10 trips/year
DB 4100	Advanced American Construction	Marine contractor vessel	92	1–2 times per month, all months of the year
DB General	General Construction	Marine contractor vessel	93	Varies; can be any month of the year
Yaquina	U.S. Army Corps of Engineers	Hopper dredge	92	Twice a month October through July; 4 times a month August and September

As noted, these impacts are based on reasonable assumptions regarding river level and vessel air gap. While the impacted vessels would not have unrestricted, year-round access under the bridge height analyzed, some of those impacted vessels would be able to pass under that height, and lower bridge heights, for most or at least part of the year. This and other factors are important when considering the reasonable needs of navigation.

It is also worth noting that the identified navigation impacts all relate to restricting the frequency of passage; they do not adversely affect navigation safety, and they impact the passage of a very small portion of marine traffic. Of those impacted, a share could not pass for some days of the year and a smaller portion could not pass at any time, without mitigation. This is an important point for

permitting considerations, as described above. The USCG Bridge Administration Manual states that "the safety of navigation is a paramount consideration that cannot be compromised when addressing bridge program issues" (USCG 2004, Chapter 2 E.1). Navigation safety was an important factor when developing and screening alternatives during the CRC Project's NEPA process. As discussed in the ROD, under existing conditions "[m]arine vessels traveling this section of the Columbia River must navigate under one of the fixed spans or through the lift span of the I-5 bridges, and must also navigate through the swing span of the Burlington Northern Santa Fe (BNSF) railroad bridge one mile downstream. Navigation safety for these vessels, especially when traveling downstream (with the current), would be substantially improved with a replacement river crossing." While navigation safety is not part of the basic purpose and need for the project, navigation safety would benefit from the project as defined in the ROD.

The propose horizontal clearance would not result in any impacts vessels or river users.

2.17.2.1 Columbia River Bridges

To determine whether a vessel had the potential to be impacted by the proposed replacement bridges that are part of the IBR program, vessel air draft and air gap were compared to the proposed vertical clearance of the replacement bridges. A vessel was determined to be "impacted" if it could not pass under the replacement bridges with a 10-foot air gap (vertical clearance between the highest point of the vessel and the lowest point of the underside of the bridge) while the river water level is at 16 feet CRD or higher. This combination of air gap and 16-foot river stage is called the "assumed condition." The 16-foot river stage is known as the ordinary high water level and represents a near-worst-case analysis. The Columbia River level fluctuates in this area but is lower than 16 feet CRD more than 98% of the time. Since the river level fluctuates daily as well as seasonally, there can be months during the course of a year when a vessel that would be impacted at 16 feet CRD is not impacted at all. In addition, the inclusion of a 10-foot air gap in the analysis is a worst-case assumption of impacts because many vessels can safely pass with less air gap.

User heights were determined during the user identification and data-gathering phase of the work described in Section 1. Once vessel heights were confirmed, an impact analysis was conducted with a proposed bridge height of 116 feet. If a vessel was impacted based on the assumed conditions further analysis was done to determine the percentage of time it was impacted based on water levels or whether or conditions influenced its ability to transit under the proposed bridge height. To consider the potential for design refinements to allow for increased vertical clearance an additional assessment was done for a bridge height of 121 feet.

While extensive work was performed to identify vessels that could be impacted by the bridge heights studied, there may be other vessels that have not yet been identified. Some local vessel owners may not have responded to the program's outreach efforts. Some vessels noted in the I-5 bridge logs could not be verified. Also, vessels from out of the area that have transited in the past may not be aware of the IBR program. Marine contractors from out of the area may come into the area if they are awarded a contract.

There are other factors besides vertical clearance that also affect safe passage, including horizontal clearance between bridge piers and channel configuration and alignment. Horizontal clearance was evaluated by comparing the propose horizontal clearance with the authorized navigation channel widths and channel widths from USACE engineering manuals. Channel configuration and alignment were assessed by evaluating previously completed ship and tug and tow simulation efforts.

2.17.2.2 Oregon Slough Bridge

The proposed replacement bridge(s) over the Oregon Slough will provide the same or greater vertical and horizontal clearances compared to the existing bridge. Limited information was provided by users on use of this waterway through the data-gathering phase. Because users of Oregon Slough are already constrained by the existing bridge and the Columbia River will provide an alternative route, no additional impacts to users will occur and a vessel-specific analysis of impacts was not conducted.

2.18 Potential Mitigation for Impacted Users

2.18.1 Mitigation for Unavoidable Short-term Impacts

Mitigation for temporary impacts on navigation will be addressed, in large part, by the construction methods and staging. The following sections describe several of many possible construction staging schemes that could be used to construct the bridges while maintaining sufficient clearance to minimize adverse impacts on navigation.

2.18.1.1 Main Span Columbia River

A construction staging scheme will be developed to provide a 200-foot-wide and 75-foot-tall navigation clearance envelop at nearly all times, which meets the vessel clearance needs of the tugs and tows, passenger vessels, and the majority of sailboat and construction equipment identified.

The construction staging and impacts on navigation will be generally as follows:

Phase I – Construct the new I-5 bridges to the west of the existing bridges. Figure 2.18-1 illustrates the construction sequence.

Stage 1 – Construct Piers 2, 3, and 4 for all bridges.

- Existing primary channel – In service, no navigation encroachment.
- Existing barge channel – In service, no navigation encroachment.
- Existing alternate barge channel – Out of service due to adjacent pier construction.

The alternate barge channel is out of service due to the adjacent construction of Pier 4. This may cause some inconvenience; however, both the existing primary and barge channels are in full service. The impact to vessel navigation is considered minimal. It may require more frequent operation of the lift span due the reduced clearance in the barge channel but that will not impact navigation.

Stage 2 – Construct Piers 6, 7, Spans at Piers 2, 3, 4, and 7 for all bridges.

- Existing primary channel – In service, some navigation encroachment.
- Existing barge channel – In service, no navigation encroachment.
- Existing alternate barge channel – In service, some navigation encroachment.

Both the existing primary and alternate barge channels have construction activity overhead, and vessels may experience some inconvenience. With the barge channel in full service, the impact to vessel navigation is considered minimal.

Stage 3 – Construct the remainder of the piers and spans: Pier 5, Spans at Piers 5 and 6 for all bridges.

- Existing primary channel – In service, some navigation encroachment.
- Existing barge channel – Out of service, significant navigation encroachment.
- Existing alternate barge channel – In service; existing piers are in line with new Pier 4, but vessels should be angling away from Pier 4 as they start to align with the BNSF railroad swing span.

Both the existing primary and alternate barge channels are in service. The existing primary channel has some overhead construction activity, but it is not anticipated to interrupt service. The construction of Pier 5 eliminates the use of the barge channel. Vessels that cannot (or choose not to) use the alternate barge channel may experience some delays, as the lift span restriction periods are still present.

At the conclusion of Stage 3, the new bridges are fully constructed.

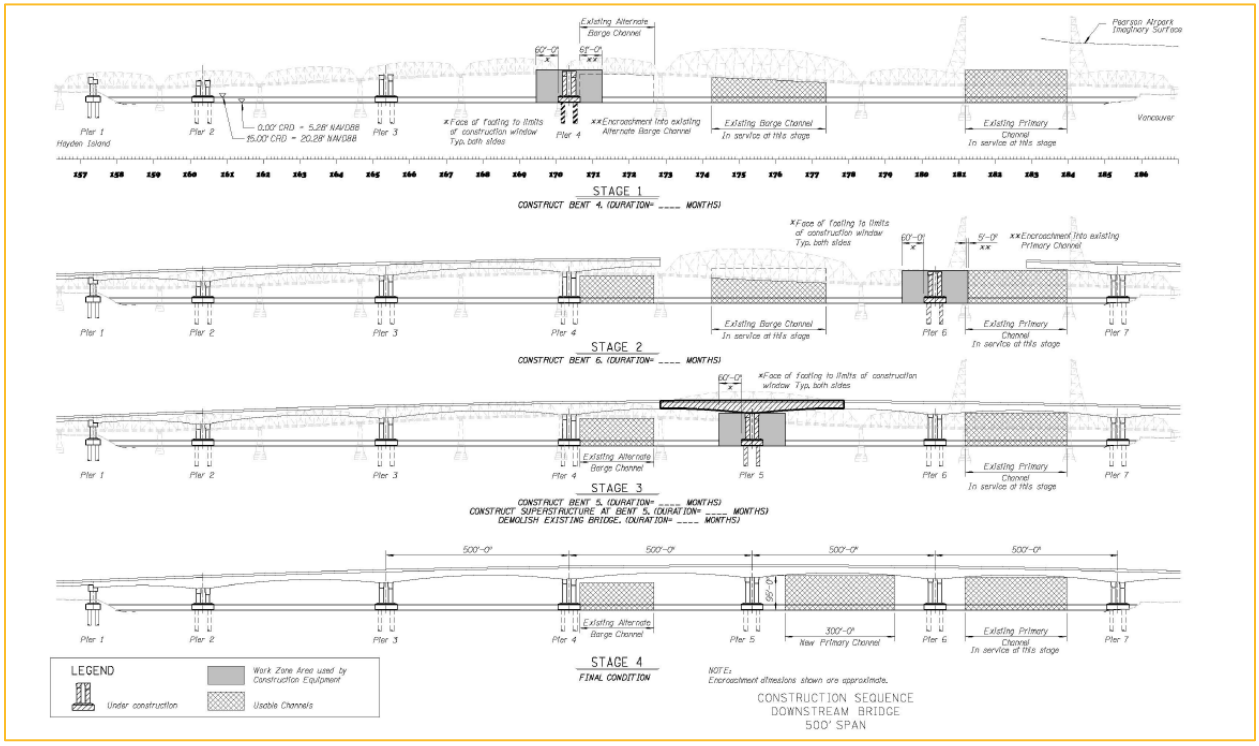
Phase II – Traffic switched to new bridges, remove existing bridges.

Stage 4 – Demolition and removal of existing I-5 bridges' piers between new Piers 5 and 6.

- Until the existing piers between the new Piers 5 and 6 are completely removed, the impact to vessel navigation is the same as construction Stage 3.
- Once the existing piers between the new Piers 5 and 6 are removed, the new primary channel is in full service and the existing channels can be removed from "official" service.

In summary, the locations of the proposed piers cause no apparent significant adverse impact to the route that vessel pilots must take to traverse this portion of the Columbia River during the construction of the permanent bridges. This is possible because all the in-water work could be completed at once without complicated staging.

Figure 2.18-1. Construction Staging



In addition to construction staging, communication of closures and clearance restrictions to users will be critical to reduce impacts on users.

Additional tugs may be needed to assist vessels through areas of reduced clearance, especially during times of high water. The USCG would review construction plans to determine potential impacts.

2.18.1.2 Oregon Slough

Construction staging schemes will be devised that minimize adverse impacts to navigation on Oregon Slough. Construction activities could temporarily reduce available clearances at due to the need for work bridges and platforms or from floating construction equipment and barges. The main Columbia River channel provides an alternate navigation route that can be used by vessels impacted by the reduced clearances. This results in an inconvenience due to the longer transit but will result in no impacts to navigation. Timing of the construction in Oregon Slough in relation to the main channel construction is unknown but is not expected to occur at the same time. It will be essential to communicate restrictions or temporary closures of the navigation channel and the availability of the alternate route to the marinas and moorages on the waterway as these are the primary users of North Portland Harbor at this crossing.

2.18.2 Mitigation for Unavoidable Long-Term Impacts

This section identifies potential mitigation measures for the affected users. Mitigation can include modifications to vessels, modification to cargo or how cargo is handled, the availability of alternative routes, transiting at lower water levels and other efforts. A prime consideration is the economic feasibility of the mitigation and whether users can adjust operations without economic loss. The mitigation measures identified herein are not final and would be subject to future decisions and agreements between the program and the affected users that would be finalized prior to issuance of the USCG bridge permit and/or construction of the project. Some of the mitigation measures identified are based on discussions with affected users that occurred for the CRC Project. Because the project was stopped those mitigation measures were never finalized nor was the mitigation undertaken. However, the mitigation that was identified and the status is included in the discussion below.

2.18.2.1 Avoidance and Minimization Overview

Avoidance and minimization measures typically precede the consideration or at least commitment of mitigation measures. Most of the impacted vessels could still pass at some time of the year although some would be too tall to pass at any time of year without mitigation. The 2012 CRC examined several bridge heights ranging from 95 to 178 feet in vertical clearance based on the findings in the ROD. The selected (at the time) bridge height of 116 feet had the most minimal impact to both vessel users and car traffic and thus was the preferred option moving forward. In addition, constructing a higher level bridge would not significantly reduce the number of impacted vessels or users.

Other minimization considered included modifying the “impact threshold,” as defined by river level and air gap. A less conservative air gap (5 feet rather than 10 feet) would reduce the number of impacted vessels to two pieces of floating construction equipment but would not change potential impacts to the three businesses.

2.18.2.2 Mitigation Timeline and Overview

The IBR program will further explore the mitigation measures with affected vessel owners and develop commitments as the program advances through the environmental review and design process. Mitigation discussions with affected owners and commitments to mitigation will advance through the re-evaluation and permitting processes. For each impacted vessel owner or business, mitigation discussions and documentation will include the following:

- Identify proposed clearance being discussed for mitigation.
- Describe the proposed mitigation for impacted users.
- Evaluate the viability of the mitigation.
- Develop statements from both parties to document status of mitigation discussions at key milestones.

The coordination and documentation would lead to specific mitigation commitments and mitigation work plans.

For this analysis, mitigation options are discussed for each vessel group rather than each individual vessel. Individual vessel mitigation requires understanding more about the specific vessel's operations, navigating constraints and vessel architecture, and is not generally included for each impacted vessel. However, there are several exceptions where this chapter describes mitigation specific to individual vessels. No recommendation is made at this time as to who would be responsible for funding or executing the mitigation. It is assumed that this would be determined as part of the negotiation process with impacted vessels and the permitting process.

The mitigation described below is for impacts associated with vessel transit on the Columbia River under the proposed I-5 bridges. No mitigation is identified for the proposed Oregon Slough bridges as no impacts were identified or concerns raised by river users. The vertical and horizontal clearances for the proposed bridges over Oregon Slough meet or exceed the clearance of the existing Oregon Slough bridge. In addition, users in the vicinity of the proposed Oregon Slough bridges are primarily recreational with clearance requirements that would not be impacted, and it is also possible to avoid the Oregon Slough bridges by utilizing the Columbia River. Oregon Slough bridges may be required to have navigation aids such as vertical clearance gages, lighting, or other navigation aids, as determined by the USCG through the bridge permit process.

Emergency Operation, National Defense and Channel Maintenance Vessels

The USACE hopper dredge Yaquina was the only federal vessel identified as being potentially impacted by the proposed replacement bridges. As discussed in Section 4, the USACE has indicated that a bridge height of 116 feet is adequate to allow the Yaquina to transit and none of the mitigation options are necessary. However, because this would not meet the assumed condition (minimum air gap of 10 feet), mitigation options are discussed here. Mitigation would not be necessary for a bridge height of 121 feet.

Mitigation Option 1 – Modify the mast structure and appurtenances.

Modifying the antenna and mast so that it could be lowered would reduce the air draft of the Yaquina. Everything higher than the crow's nest would need to be removed; the mast would then need to be outfitted with a hinge, then reinstalled. Whenever the Yaquina transits under the bridge, the mast could be unhinged and lowered either manually or electrically.

Mitigation Option 2 – Purchase a new dredge.

This option involves replacing the hopper dredge with one that has a smaller air draft than that required to pass under the bridge, considering the 16-foot river level and 10-foot air gap. To replace the Yaquina, the new dredge would, at a minimum, require the same capacity and capabilities as the existing dredge.

Mitigation Option 3 – Contract dredging to private dredges.

Contracting with private dredging contractors to perform upstream maintenance dredging that can be conducted with smaller dredges would eliminate the need for the Yaquina to pass under the new I-5 bridges. Due to occasional emergency situations, the contractors would have to be available on short

notice and have the properly sized hopper dredge. In addition, the USACE would need to have expedited contracting methods to select and contract with a contractor on short notice.

Mitigation Option 4 – Travel during times when river level permits.

The Yaquina's full height is 92 feet. With a 10-foot safety gap, up to a 14-foot river stage would allow safe passage for the vessel through the replacement bridges. The river stage is at or below 14 feet approximately 75% of the year, so trips could be scheduled based on historical river levels. However, this may not correspond with the times that dredging is needed.

Commercial Vessels

Marine Contractors

The analysis identified four contractor vessels as not being able to transit year round under the proposed bridge height of 116 feet or 121 feet. Marine contractors transit under the bridge while traveling to work sites. Of the vessels identified as being potentially impacted, some may not transit under the bridge in a given year, whereas others may transit multiple times. Given that there are numerous contractors and that marine construction services will continue to be needed on both sides of the bridge, acquisition of crane barges is not considered a mitigation option.

Ballasting the barge, while possible, will not provide enough additional air gap to make a significant height difference. Ballasting can be used when only a couple of feet are all that is needed to clear the bridge. Ballasting is usually performed on the end of the barge that supports the crane, so the height of the crane is lowered along with the freeboard.

Mitigation Option 1 – Remove the spuds.

Some crane barges have height limitations caused by traveling with raised spuds. The spuds need to be raised high enough to prevent grounding during transit, not only in the navigational channel but along the route to the desired destination. The spud heights are typically 70 to 90 feet. Removing the spuds prior to transit will reduce the vessel height to the next lowest point on the crane barge, typically a gantry or slightly elevated boom. A number of users indicated that it would take one-half to one day to remove the spuds and similar time to replace them. Removing spuds is an activity that is possible, although not always preferred by the operator, especially for those users that cannot self-remove them or need to travel only short distances. For instance, if the barge's own crane cannot lift the spuds out and lay them on the deck, another crane would be needed to perform this work. If the barge is not tied up to a dock or to shore when the spuds are removed, the barge will have to either anchor or have a tug assist it by holding the barge in place.

Mitigation Option 2 – Remove the boom.

If the boom tip is the highest point of the vessel, the boom can be removed prior to transit. This requires a considerable amount of work because all of the rigging needs to be removed, and another crane needs to be used to lift off the boom. If the boom is especially long and the barge it is removed from is too short, the boom may need to be transported on a separate barge.

Mitigation Option 3 – Remove the gantry.

If the gantry is the highest point of the vessel, it can be removed prior to the transit. It can take up to a week to lower the gantry and another week to raise it. It is a labor- and equipment-intensive activity and cannot be done frequently. It is not feasible for crane barges that need to transit under the bridge several times a month or more.

Mitigation Option 4 – Reconfigure the crane.

The crane gantry may be modified to reduce its height. The modification would require the services of a naval architect working with the crane barge owner to redesign the crane to ensure it can achieve the same lifting capacity and reach.

Mitigation Option 5 – Use mobile cranes mounted on barges upriver of the bridge.

If crane barges cannot transit under the bridge, it may be possible to transport a deck barge upriver, then load a land-based mobile crane from shore once the deck barge is upriver of the bridge. This is not a solution to getting an existing floating crane barge under the bridge, but rather an alternate method of getting equipment to work locations. Depending on the size of the mobile crane needed, there may be issues transporting the mobile crane over the highways and to the loading area.

Mitigation Options by Impacted Vessels

DB 4100 is constrained by the height of the spuds and mitigation Option 1 would be available for this vessel assuming an air draft of less than 10 feet cannot be accommodated or water levels are within 3 feet of the ordinary high water mark. Because of the limited time in which the vessel is height constrained, the ability to utilize a lesser air draft and the ability to remove or lower the spuds a small amount to accommodate a transit no specific mitigation for this vessel is anticipated.

The *DB General* is height constrained by the gantry and Mitigation Option 3 and 4 would be available to this vessel assuming an air draft of less than 10 feet cannot be accommodated or water levels are within 3 feet of the ordinary high water mark. Because of the limited time in which the vessel is height constrained and the ability to utilize a lesser air draft no specific mitigation for this vessel is anticipated. Another important consideration is that due to the width of this vessel it is not able to transit upriver of Bonneville dam in its present configuration and therefore is only constrained from a shorter stretch of the Columbia River system. The IBR program would not propose to undertake any mitigation of this vessel.

DB Freedom is constrained by height of the boom during transit. Mitigation Options 2 or 4 could be available for this vessel if it cannot operate as described earlier with the boom stationed temporarily to the side of the tug pushing the barge. The CRC program was working with the vessel owner to develop a plan for a temporary cradle to allow the vessel to transit more securely when placed to the side of the tug. Because of ability to transit in a manner that eliminates the height constraint no specific mitigation for this vessel is anticipated. The IBR program will consult with the vessel owner to confirm operating conditions and evaluate mitigation options if needed.

DB Taylor is constrained by height of the boom during transit when the longer of two booms available for this vessel is in use. Mitigation Options 2 or 4 could be available for this vessel. The CRC Project engaged in negotiations with the owner of this vessel. An analysis of options to retrofit the vessel was conducted and a solution was identified to allow the boom to be lowered further during transit by installing a new boom. A draft mitigation agreement to provide compensation in the amount equal to the estimated retrofit costs was presented to the vessel owner by the CRC. During the mitigation process the vessel owner made a decision to terminate negotiations and the agreement was never finalized.

Marine Industries and Fabricators

Occasional historical and anticipated future shipments from the three major upriver fabricators (Thompson Metal Fab, Vigor, and Greenberry) would not be able to pass under the bridge height of 116 feet under the assumed conditions year round. Increasing the bridge height to 121 feet would not change the impact. Discussions would be conducted with each fabricator to identify and evaluate mitigation options to address potential impacts to their operations and to reach formal agreement on mitigation prior to beginning construction of the project.

Negotiations with Thompson Metal Fab and Greenberry occurred in support of the CRC Project. The CRC Project worked separately with the two companies to identify appropriate mitigation strategies to allow them to continue to pursue current and future anticipated markets following construction of the bridge. Negotiations occurred under confidentiality agreements for the purposes of preserving proprietary company financial information. Work included the evaluation of potential business losses resulting from lost market opportunities, and also the consideration of opportunities and potential costs for relocation of their operations. The anticipated mitigation agreements would have resulted in payments to the companies that would be used by the companies at their business direction and control. One potential outcome would be a decision by the companies to relocate downstream of the bridge at a site of their choosing.

Vigor did not have any operations in the area at the time of the CRC Project that would have been impacted and no discussions occurred with them.

1. INTRODUCTION AND METHODOLOGY

1.1 Purpose

Federal law prohibits the construction of any bridge across the navigable waters of the U.S. unless first authorized by the U.S. Coast Guard. The Bridge Permit Application Guide (COMDTPUB P16591.3D) requires the development of Navigation Impact Report (NIR) to identify the current and prospective navigation on the waterway. This includes the potential for future navigation needs from the development of land uses along the waterway. This appendix includes an analysis of existing and potential commercial/industrial development and examines the likelihood of creating additional navigation activities that could be impacted by the proposed Interstate Bridge Replacement (IBR) program.

This appendix is an update of the work completed in support of the Columbia River Crossing NIR completed in 2012.

1.2 Subject Area

The geographical extent analyzed extends from the proposed new Interstate 5 (I-5) bridge to the BNSF Railway rail bridge at Celilo Falls. The geographical extent analyzed landward from the river is approximately 0.5 miles. Together, these geographical extents compose the "subject area." Land uses farther inland may generate marine traffic; however, those cargoes would be transported to waterfront facilities for transfer to barges or other vessels within the project area.

Locations upriver of the BNSF Railway rail bridge at Celilo Falls would not be expected to generate vessels or cargoes that would be impacted by the I-5 bridges due to existing height (79 feet when raised) and width restrictions imposed by the Celilo Falls bridge and others located upstream (see Section 3.1 in the main report). Areas downstream of the I-5 bridge and the BNSF Railway would also not be expected to generate vessels or cargo that would be impacted by the I-5 bridge because most vessel transit is generated from upstream of the I-5 bridge. Furthermore, there is minimal cargo generation or transit from downstream locations that are not already limited by upstream height or width restrictions.

1.3 Data Sources

The land use assessment is an update to the land use assessment completed for the 2012 Columbia River Crossing NIR, Appendix A. Using aerial imagery, planning documents (e.g., Comprehensive Plans), and interviews with staff, the marine-dependent uses within each county were updated to reflect current land uses. This update relied on the following information:

- 2012 Columbia River Crossing NIR, Appendix A: Future Land Use Analysis, prepared by David Evans and Associates, Inc.
- Google Earth aerial imagery.

- Interviews: WSP USA Inc. interviewed city/county planning departments by telephone to confirm the key findings and identify potential concerns related to river traffic.

1.4 Land Use Assumptions

Comprehensive plan land use designations and policies and zoning and development regulations state what types of land uses can be set in each zoning area. Some uses are allowed "by right," which means they are permitted through a simple application process. Other uses are often referred to as "conditional" or "limited uses" and are subject to extra requirements and additional review. Base zone requirements, which developments may have to meet regardless of whether they are permitted outright, typically include dimensional regulations such as height and setbacks. Zoning overlays are additional designations that may further restrict uses or developments, such as requiring additional and potential mitigation related to floodplain, riparian, wetlands, and wildlife habitat. The land use permitting process ensures that development is compatible with the designated uses and standards of the zone.

In the subject area, zoning is typically industrial, residential, commercial, and open space/parks/recreation. Each jurisdiction typically will have variations in uses allowed in each zoning designation. For analysis purposes, the following assumptions are made regarding the various uses and their potential to generate marine-dependent uses:

- Industrial: Typically allows for varying levels of manufacturing and production. Marine-dependent uses can include ship building, metal fabricating, timber processing, and boat building. These sites may also have the capability of generating large objects, such as oil rigs.
- Commercial: These uses include restaurants, stores, and offices. Commercial uses may include commercial marinas; however, most commercial uses are unlikely to generate marine traffic. The marine traffic that could be generated by commercial uses is likely individually owned recreational boats, which could include sailboats, touring boats, or passenger (cruise) vessels.
- Residential: Residences with various tax lot sizes and accessory structures such as docks. The marine traffic that would be generated by residential uses is likely privately owned recreational boats. This could include sailboats.
- Open space/parks/recreation: Areas designated as open space/parks/recreation are typically used for habitat conservation and/or passive and active recreation. Public docks and marinas may be included with these uses for recreation purposes. Sailboats may use the docks and marinas.
- Zoning overlays: It is assumed that, depending on the local jurisdiction, floodplain, riparian, and other natural resource overlay standards may apply to all sites along the river.

1.5 Other Assumptions

There may be land uses outside of the project area, specifically agricultural, that may generate or be supported by marine traffic. However, because the goods would have to be transported by another

freight method to the riverfront, they could be accommodated by barge or shipped on boats that would not have any vertical clearance issues. Additionally, businesses outside of the area may provide service to the area. For example, marine contractors are likely needed upriver in the future for a variety of projects.

1.6 Site Suitability

Although lots may be zoned for use along the Columbia River, there may be additional factors that limit or leverage development potential. These include:

- Plotted tax lot size and dimensions can reduce development potential by limiting the necessary space to accommodate development and meet zoning setback requirements.
- Lots can be constrained by roads, freeways (such as Interstate 84 [I-84]), railroad (Union Pacific Railroad or BNSF line), or other public infrastructure (such as power lines). In addition, easements, particularly recreational trail easements, may create a buffer between a development and the riverfront.
- Regulated natural resources, such as wetlands or Endangered Species Act habitat, can prohibit development or make development cost-prohibitive because of the fees and mitigation requirements for environmental permitting, as well as local, state, and federal permitting (see following sections).
- Bathymetric and other river conditions may prohibit or restrict access to the navigable portions of the river from the shoreline.
- Sites with existing infrastructure, especially docks (see Section A.2.7), are more conducive to uses and redevelopment that may generate varying degrees of marine traffic. Depending on the development, these sites also would likely not be subject to as stringent environmental permitting requirements.

1.7 State and Federal Environmental Permitting Requirements

Water-dependent uses need access to the water, which typically involves a structure into the river. Depending on the type of development, where exactly development would occur in proximity to the river, and whether there is work below ordinary high water in the Columbia River, state and federal permits could potentially be required. This document does not cover whether the marine uses discussed require state or federal permits.

1.7.1 Columbia Gorge National Scenic Area

The Columbia River Gorge National Scenic Area (NSA) lies to the east of Portland, Oregon, and Vancouver, Washington. It stretches about 83 miles, from the Sandy River on the west to the Deschutes River on the east in Oregon, and from Gibbons Creek in Clark County to a line 4 miles east of Wishram in Washington. The NSA covers portions of six counties: Clark, Skamania, and Klickitat Counties in Washington, and Multnomah, Hood River, and Wasco Counties in Oregon.

The Columbia River Gorge Commission, a regional commission representing local, state, and national interests, was established in 1987 to develop and implement policies and programs that protect and enhance the scenic, natural, cultural, and recreational resources of the NSA, while encouraging growth within existing urban areas and allowing development outside urban areas consistent with resource protection.

To achieve the purposes of the Columbia River Gorge NSA Act, Congress called for preparation of a management plan that would treat the two-state, six-county area as a region. Congress established a two-tiered management approach for preparing the management plan. It divided responsibility between the U.S. Forest Service and the Columbia River Gorge Commission. The six Columbia River Gorge counties were authorized to implement the management plan through their land use ordinances.

The NSA is divided into three categories of land: urban areas, the special management area, and the general management area. Congress designated 13 cities and towns as urban areas: North Bonneville, Stevenson, Carson, Home Valley, White Salmon, Bingen, Lyle, Dallesport, and Wishram on the Washington side of the river and Cascade Locks, Hood River, Mosier, and The Dalles on the Oregon side. The urban areas are exempt from the management plan, but are eligible to receive federal funds authorized to implement it. Per the management plan, the urban areas are the primary focus for growth and economic development. In addition, the management plan states that new industrial development will not be allowed in the NSA outside the urban areas.

There are five established ports within the NSA: Skamania and Klickitat on the Washington side of the river and Cascade Locks, Hood River, and The Dalles on the Oregon side. All five of these ports are within the designated urban areas. Land use regulations regarding development and redevelopment of property in the NSA are promulgated through the Columbia River Gorge Commission's Land Use Ordinance (Chapter 350, Division 81). This code defines industrial and water-dependent uses. Any future expansions or development projects that would use the established ports as a water-dependent use would need to be within a designated urban area.

The NSA does not allow industrial development outside of the urban areas. It also confines development to the relatively small urban areas, thus limiting the amount of space for industrial uses and the additional services used to support industrial uses. In addition, less developed areas could lack the skilled labor necessary for an industrial use.

The NSA promotes recreation and water-dependent recreation and protects the resources of the Columbia River Gorge, which has ideal freshwater sailing conditions from spring through fall. As a result of these conditions, the Columbia River Gorge attracts sailors, including many from outside the area. Water levels are often highest during the sail season, and the number of sailboats visiting the gorge is anticipated to increase with additional waterfront developments and population changes.

1.7.2 Washington's Shoreline Management Act

Washington's Shoreline Management Act (SMA) was passed by the state Legislature in 1971 and adopted in 1972. The goal of the SMA is "to prevent the inherent harm in an uncoordinated and

piecemeal development of the state's shorelines." The SMA applies to the counties within the affected area as they have "shorelines of the state." Each jurisdiction prepares its own Shoreline Management Plan to be in compliance with the SMA. Preferred uses include single-family residences, ports, shoreline recreational uses, water-dependent industrial and commercial developments, and other developments that provide public access opportunities. Per the SMA, to the maximum extent possible, the shorelines should be reserved for water-oriented uses, including water-dependent, water-related, and water-enjoyment uses. The SMA emphasizes accommodation of appropriate uses that require a shoreline location, protection of shoreline environmental resources, and protection of the public's right to access and use the shorelines (Revised Code of Washington 90.58.020). The SMA supports the use of the Columbia River shoreline for water-dependent industrial uses. However, development must meet the SMA's "no net loss of shoreline ecological function" basis which can add costs for mitigation.

2. REVIEW OF LAND USES IN AFFECTED COUNTIES

The following sections identify the potential land uses existing and potential future capability to generate marine traffic. This review includes an evaluation of policies in comprehensive plans and zoning designations to ascertain long-term goals for river front tax lots. The jurisdictions evaluated include the six counties and cities located in the Columbia Gorge NSA on the Columbia River between the I-5 bridges and the BNSF Bridge at Celilo Falls, per Section 6.5 of the NIR:

- Washington
  - Clark County (Vancouver, Camas, Washougal)
  - Skamania County (North Bonneville, Stevenson, Home Valley)
  - Klickitat County (Bingen, Dallesport)
- Oregon
  - Multnomah County (Portland, Fairview, Troutdale)
  - Hood River County (Cascade Locks, Hood River)
  - Wasco County (The Dalles)

A summary of regulatory standards and any key issues/areas of concern are described for each jurisdiction.

2.1 Clark County, Washington (Vancouver)

This section describes the existing and expected future land uses along the riverfront in the city of Vancouver in Clark County.

2.1.1 Existing Uses

The shoreline in Vancouver contains a wide mix of uses, including heavy industry, residential, and recreational uses.

Port of Vancouver

The Port of Vancouver is located along the Columbia River's deep-draft channel that extends from the Pacific Ocean to just downstream of the I-5 bridge. Terminals downriver from the BNSF bridge are not included in this analysis because they would not likely contribute to changes in vessel traffic not captured by the upriver analysis. For example, the grain terminal includes facilities for the receipt of grain barges. These barges originate at barge-loading facilities upstream of I-5, upriver of the BNSF rail bridge include Terminal 1, the Vancouver Waterfront, and at the La Farge property. Terminal 1 is the eastern-most portion of the Port of Vancouver's waterfront development. The Port of Vancouver's master plan for Terminal 1 includes office, residential, and retail space and will have over 950,000 square feet of new mixed-use development. This includes removal the existing structures located on the dock. Terminal 1 will also include bike and pedestrian trails and a public dock for pleasure boats.

Per the master plan, Terminal 1 will not be devoted to cargo handling and thus would not involve changes to navigation for these types of vessels. Terminal 1 will continue to be made available to cruise vessels. Cruise vessels are addressed in Section 5 of the NIR. Terminal 1 is identified for potential partial acquisition by the program but adequate dock space should remain to support continued cruise vessel use.

La Farge Site

La Farge North America operates a cement handling facility on approximately 1.83 acres immediately east of the BNSF rail line. The site includes marine access and is presently the only facility that is accessed by deep-draft traffic above the BNSF bridge.[1] The deep-draft traffic that accesses the site does not use the Upper Vancouver Turning Basin and would not be impacted by the replacement bridges. No other deep-draft traffic passes above the BNSF railroad bridge.[2]

Vancouver Waterfront

The Vancouver Waterfront is a development located along the Columbia River between the BNSF rail bridge and the existing I-5 bridge. The 32-acre site extends across the Columbia waterfront and includes a variety of mixed-use, residential, and commercial space. The site includes an expansive open space that spans the entire site. The site does not include any marine facilities or land uses that would generate vessel traffic.

Columbia Business Center

The Columbia Business Center (CBC) is an industrial parcel located approximately 1.2 miles upriver from the I-5 bridges. To the west of the CBC is a mixed-use development, which includes residential housing, retail, and restaurants. To the east of the CBC is a city park with a boat ramp and an industrial waterfront site used by facilities operating out of the CBC.[3]

The CBC includes approximately 2.3 million square feet of space in 27 buildings and approximately 1.0 million square feet of open leasable space, as shown in Figure A.2-1. In 2021, it was reported that the CBC is essentially completely occupied with approximately 54,000 square feet of leasable area available.[4]

Figure A.2-1. Columbia Business Center

Source: CBC, https://columbiabusinesscenter.com/.

The CBC provides both barge and rail access. The BNSF mainline borders the north side of the property. Rail access within the CBC is provided by a private switching service, expediting transfer of goods on and off cars and reducing demurrage charges. The CBC has a barge slip accommodating river and ocean barges. The East Slip is 130 feet long with water depth at minus 10 feet Mean Low Low Water (MLLW). The East Slip is used to receive and ship fabricated steel products, construction materials, and supplies. The West Slip is not active and there are no plans to improve it. There is a dock located just to the west of the West Slip, which is used by JT Marine. JT Marine vessels and shipyard activities are addressed in the main body of the NIR.

The CBC area has the following water-dependent users:

Thompson Metal Fab, the largest tenant at the CBC, provides fabrication for a wide range of industrial uses including U.S. Army Corps of Engineers, oil and gas, nuclear, tank and vessel, marine and hydro, renewable energy, bridge and structural, and other high-tech industries. The oil rigs and some other structures (fish weirs for the U.S. ACE) are height constrained. Thompson Metal Fab has increased its presence at the CBC from approximately 200,000 square feet in 2006 to its current 717,762 square feet, which represents 30.8% of the net rentable area in the CBC. The 2011 expansion consisted of primary leasing two large older buildings (Buildings 40 and 41) and a large portion of the outside working area located between Building 40 and the Columbia River.[5]

[5] Source: Presale Report GS Mortgage Securities Trust, Series 2012-GCJ7, DBRS, May 2012, pages 17-22.

Vigor Industrial (Vigor) acquired Oregon Iron Works in 2014.[6] Vigor fabricates structures for the alternative energy industry in the Pacific Northwest (systems for tidal power and ocean-based wind energy systems), bridges and transportation equipment for state and local transportation projects, and structures for the U.S. Army Corps of Engineers (fish weirs, lock gates, and other products). Vigor leases approximately 75,000 square feet from CBC, including Building 33 and the laydown area immediately to the east of the building. Vigor owns property immediately in the CBC (a portion of the hatched area of Figure A.2-1), including Building 48 (approximately 50,000 square feet) and open working area south of the building.

Vigor also has a facility located east of the CBC that has approximately 180,000 square feet of manufacturing space. Vigor also has a lease with the city of Vancouver to use the 7-acre city boat basin at 901 SE Marine Park Way south of the facility (Figure A.2-2). The manufacturing site will be used to produce a new type of landing vessel for the U.S. Army.[7] There are no planned modifications at the site. The city of Vancouver also moors their emergency response vessel at the boat basin.[8]

Figure A.2-2. City Boat Basin 901 SE Marine Park Way

Greenberry Industrial (GI) is a full-service mechanical contractor, providing industrial fabrication and installation for various industries in the Pacific Northwest, as well as oil rigs and modules for the oil industry. GI's facilities[9] include 6 acres in Corvallis, approximately 150,000 square feet at the CBC, and a fabrication facility in Ferndale, Washington (approximately 8 acres). The oil rigs fabricated by GI are

[6] Oregon Iron Works (OIW) was acquired by Vigor Industrial (Vigor) in 2014., https://vigor.net/news-press/oregon-iron-works-vigor-merge-to-draw-larger-projects-and-more-jobs-to-the.
[7] http://choosewashingtonstate.com/vigor-to-built-new-landing-craft-in-vancouver/

[8] https://www.cityofvancouver.us/fire/page/vancouvers-quick-response-boat.

[9] Greenberry Industrial website http://www.greenberry.com/.

height constrained. GI's facilities at the CBC include a deep water, 3,000 ton loading dock and launch access for ocean-going vessels up to 400 feet.[10]

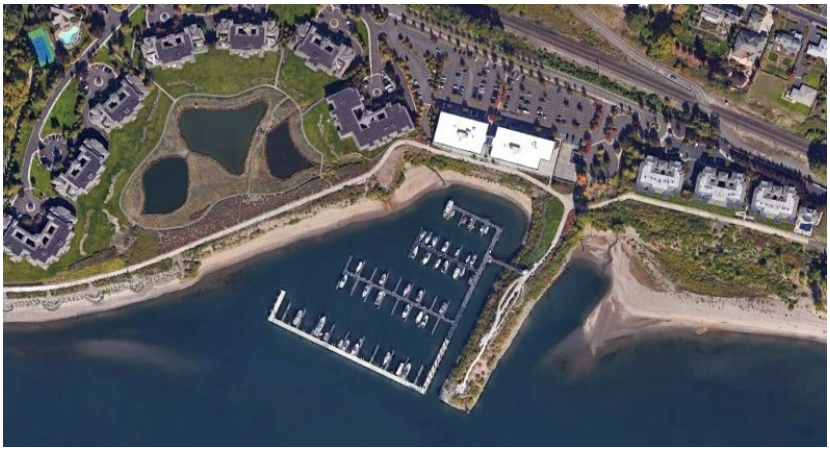
JT Marine operates a diverse array of services, including tug and barge service, shipyard services (providing mobile repair services for the tug and barge industry), and salvage services along the Columbia River. The company also acts as a marine contractor. JT Marine leases a portion of the west end waterfront from the CBC.

There are no known plans for redevelopment of the CBC.

Tidewater Cover Marina

Tidewater Cover Marina is a private marina located approximately 2 miles east of the I-5 bridge. The marina includes 87 slips, ranging in length from 40 feet to 110 feet.[11] Uplands adjacent to the marina are developed as residential condominiums and office and the city of Vancouver Columbia River Renaissance Trail.

Figure A.2-3. Tidewater Cove Marina



McCuddy's Steamboat Landing Marina[12]

McCuddy's Steamboat Landing Marina includes approximately 150 slips, ranging in length from 24 to 40 feet, and with some end-ties and side-ties for longer boats. The marina serves the general public and draws customers from across the county and beyond. However, many marina tenants are

[10] https://greenberry.com/facilities/vancouver-wa/.

[11] https://www.tidewatercovemarina.com/dmyxn64a4yh9qb52trjvvu6lstodjb.

[12] Clark County Shoreline Management Plan, Appendix D, BST Associates, page 35.

residents of the adjacent development. Sailboats that moor at the marina are typically too small to be height constrained by the proposed I-5 bridge (discussed in greater detail in Section 7.4.2 of the NIR).

Figure A.2-4. McCuddy's Steamboat Landing Marina

Western Forest Products

Western Forest Products U.S. LLC owns approximately 13 acres on the Columbia River within the City of Vancouver. Most of the site is used by Columbia Vista Corporation as a sawmill under a long-term contract. The facility has a barge dock for outbound shipment of lumber products and has capability to access log rafts.

The Vancouver Riverview Gateway Subarea Plan applies to the eastern section of Vancouver's riverfront. This plan does not include future changes of uses along the river. Within this plan there is one industrial site that is zoned industrial, corresponding with the sawmill location.

The waterfront site is zoned for heavy industry, and it is expected that heavy industrial use will continue through the long term.

Figure A.2-5. Western Forest Products Construction Property

2.1.2 Overview of Land Use Regulations

The Vancouver Comprehensive Plan does not include goals or policies specific to marine uses or land uses that would support further development of marine uses.

Much of the zoning along the Columbia River east of the I-5 bridges is residential interspersed with parks and open space uses that host waterfront trails. Where there isn't a waterfront trail, some of the residences have private boat docks. The industrially zoned tax lots discussed above in the CBC and along other portions of the river appear, from aerials, to be largely developed and provide support to marine uses. However, this does not preclude them from being further developed or redeveloped for additional marine uses. The industrial zoning classification can accommodate a wide range of uses. Additionally, the City Center zoning classification allows marinas, and the residential zoning classification includes marinas as a conditional use.

2.1.3 Key Findings

There are four existing water-dependent industrial sites within the jurisdiction of the city of Vancouver, including CBC, Vigor, Marine Park marina, and the Western Forest Products property. It is likely that these areas will continue in industrial use. Only the uses at the CBC are currently height constrained. This is detailed in the main text of the NIR.

In addition, there are two marinas (McCuddy's Steamboat Landing Marina and Tidewater Cover Marina) and several private docks associated with private residences. These marinas typically serve smaller powerboats and sailboats (up to 40 feet) and are not known to be height constrained. However, some recreational boats may experience height constraints depending on the option under consideration (this issue is discussed in greater detail in Section 7.4.2 of the NIR).

Based on existing land use regulations, there are no vacant waterfront parcels that could be placed in industrial use.

2.2 Clark County, Washington (Camas)

The following section describes the existing and expected future land uses along the riverfront in the city of Camas in Clark County.

2.2.1 Existing Uses

The existing commercial/industrial waterfront uses in Camas include a paper mill, a marine fabricator, a marina, and a boat ramp.

Georgia Pacific Camas Mill

Georgia Pacific's Camas mill, which encompasses 660 acres (including Lady Island), produces paper towel products. In 2018, Georgia Pacific reduced its operations at its facility in Camas. Georgia Pacific is demolishing 11 buildings in the Camas Business Center[13]. The sites listed below are reported as no longer supporting site operations and are currently not in use:

- A chip unloading dock that was used to receive hogged fuel and wood chips that are transferred via conveyor to an open storage area. Chips are also received by truck and rail. This dock is listed as 360 feet long with water depth of 12 to 15 feet at MLLW.
- A log lift that was used as a storage area for log rafts. This facility extends along both sides of Camas Slough and along the right bank of Columbia River to a point approximately 2.5 miles below the log lift; rafts being secured to timber and steel piling. This site is listed with water depth of 7 to 10 feet at MLLW.
- A petroleum receiving dock with a pipeline that extends from the wharf to storage tanks.
- The shipping dock has been used in the past to ship products by barge This dock is recorded as 366 feet long with a water depth of 12 to 15 feet at MLLW. There is a 30,000-square-foot warehouse located near this dock.

The Georgia Pacific site will likely be evaluated for changes in comprehensive plan designations, zoning, and shoreline designations as part of future updates to planning documents for Camas.[14] However, the Georgia Pacific site is height constrained by the bridges on U.S. 14 that provide access to Lady Island at Camas. The upstream span is fixed with a vertical clearance[15] of 37 feet and the downstream span is fixed with a vertical clearance of 69 feet. These clearances are less than the heights of the proposed I-5 bridge.

[13] Clark County Shoreline Management Plan, Appendix D, BST Associates, page 40.

[14] Personal conversation with Sarah Fox, Senior Planner Camas City Planner, City of Camas, August 2, 2021.

[15] National Oceanic and Atmospheric Administration chart 18531, Edition 24, December 2017.

Figure A.2-6. Georgia Pacific Camas Mill

City of Camas Ramp

The city of Camas owns a boat ramp located just to the south of their sewage treatment plant that has been leased to Mark Marine Service for more than 25 years. Mark Marine, which is engaged in marine construction, moors several company-owned vessels and barges at the site. The city is renewing the lease of the property for an additional five years.[16] There are no plans to improve the site. The city may consider using this site for another purpose (public access) in the future; however, changing uses would depend on future planning and funding for the proposed project. As a result, this site should be considered industrial use for the long term. Mark Marine was contacted as part of the river user survey and vessels are addressed in the main body of the NIR.

[16] Personal conversation with Sam Adams, Utility Manager, City of Camas, July 19, 2021.

Figure A.2-7. City of Camas Slip

2.2.2 Overview of Land Use Regulations

Much of the zoning along the Columbia within the jurisdiction of Camas is heavy industrial, but this is dominated by the Georgia Pacific paper mill. Other heavy industrial zoned lots appear to be undeveloped. The heavy industrial zoning classification includes boat building, boat repair and sales, metal fabrication, and assembly as uses permitted outright. The Camas Shoreline Master Program provides several economic policies in support of ensuring that land adjacent to the Columbia River is used for water-related uses, as provided below.

Shoreline Master Program Economic Development Element 3.5.2:

- Policy 3: New water-oriented industrial, commercial, and resource-based activities that will not harm the quality of the site's environment, adjacent shorelands, or water quality are encouraged along the shoreline. Limit or discourage uses that are nonwater-oriented and are not accessory to a water-oriented use.
- Policy 4: As an economic asset, the recreation industry should be encouraged along shorelines in a manner that will enhance the public enjoyment of shorelines, consistent with protection of critical areas and cultural resources.

However, according to the Trails and Open Space Plan, much of the area zoned heavy industrial area is identified as part of a proposed open space network, which includes a riverfront trail.[17]

[17] https://www.cityofcamas.us/sites/default/files/fileattachments/parks_and_recreation/page/18859/appendix_c_-_maps.pdf.

2.2.3 Key Findings

There are two existing water-dependent industrial sites within the jurisdiction of the city of Camas, including the Georgia Pacific paper mill and the Camas boat ramp. It is likely that both sites will remain in industrial.

Based on existing data and plans, it is anticipated that there will be no additional industrial uses developed in Camas. The heavy industrial zone does allow for some marine generating uses to be permitted outright.

The Georgia Pacific paper mill cannot be constrained by the proposed bridge because it already has a height constraint imposed by the bridges that connect U.S. 14 to Lady Island. Mark Marine Service vessels are addressed in the main body of the NIR.

2.3 Clark County, Washington (Washougal)

This section describes the existing and expected future land uses along the riverfront in the city of Washougal in Clark County.

2.3.1 Existing Uses

The existing waterfront sites on the shoreline of the city of Washougal include the Port of Camas-Washougal Marina, the Port of Camas-Washougal Sixth Street property, and the Port of Camas-Washougal Industrial Park (near the waterfront but not water-dependent).

Washougal Waterfront

The Washougal Waterfront consists of the Port of Camas-Washougal's Marina and Sixth Street property.

The Port of Camas-Washougal Marina has 356 moorage slips, ranging in length from 20 feet to 55 feet. Most of the moorage is covered and can only be used by powerboats, which do not have a height constraint. There are a few open slips that used by sailboats, which can be height constrained. In addition to the leased slips, the marina has 1,200 linear feet of transient moorage. The port also has a four-lane launch ramp with attendant floating docks.

The site of the former Hambleton Lumber Company, which consists of approximately 25 acres, is located directly east of the port's marina. In 2012, Killian Pacific purchased the 25 acres, of which 13.25 acres is now owned by the port.[18]

[18] https://parkerslandingwaterfront.com/.

The Sixth Street property, which includes around 14-acres, is located just east of the former Hambleton Lumber site.

Figure A.2-8. City of Washougal Waterfront

The Port of Camas-Washougal, in conjunction with a private developer (Killian Pacific), is seeking to redevelop the Washougal Waterfront. The site, Waterfront at Parker's Landing, will remain zoned as highway commercial and would be developed into a mixed-use waterfront project, featuring 13 mixed-use buildings (condos, offices, retail, and restaurants) as shown in Figure A-7.[19] There are currently no marine activities besides the marina at the Washougal Waterfront.

[19] http://portcw.com/index.php/projects/waterfront_revitalization/.

Figure A.2-9. Washougal Waterfront at Parker's Landing Proposed Master Plan

Port of Camas-Washougal Steigerwald Commerce Center

The Port of Camas-Washougal began development of the 310-acre Washougal Industrial Park in 1970. The industrial park has grown in use and currently averages above 90% occupancy rate[20]. To provide additional land for industrial development, the port is planning an area of undeveloped property east of and adjacent to the industrial park. The Steigerwald Commerce Center includes approximately 122 net acres.

The property is zoned as heavy industrial and entirely within city limits. Adjacent properties are designated as heavy industrial, industrial, and parks/open space.

A levee separates the industrial park from park and public access along the shores of the Columbia River. The levee presents significant engineering, procedural, and land ownership challenges to providing access to the Columbia River. In addition, the navigation channel is distant from the shoreline with shallow water providing a challenge to access for vessels. There are no users within the industrial park that use the Columbia River for navigation purposes, and there are no marine facilities associated with the industrial park.

[20]https://portcw.com/property/steigerwald-commerce-center/.

Figure A.2-10. Port of Camas-Washougal Industrial Park and Steigerwald Commerce Center

2.3.2 Overview of Land Use Regulations

The Washougal Comprehensive Plan Update (2016) does not include goals or policies specific to marine uses or land uses that would support further development of marine uses. It does have goals and policies related to increasing public access to shorelines for recreational purposes (parks and open space, Goal 4).

A large portion of Washougal's waterfront is zoned parks/open space, starting from the eastern edge of the urban growth boundary until 22nd Street. West of the open space is primarily residential and town center–core designations. Industrial uses abut the parks and open space to the north.

Selected goals of the Port of Camas-Washougal's to promote industrial development include:[21]

- Goal 2: Improve local economic opportunities by supporting the retention, expansion, and recruitment of preferred employers.

[21]https://mrsc.org/getmedia/d828a5e7-5a9f-43ca-b25b-27e71ff42596/s77p6c3w36CompScheme.pdf.aspx.

- Goal 3: Promote sustainable community prosperity by ensuring an ample supply of land, infrastructure, and facilities to meet the needs of potential employers.
  - Strategy 3.1 Maintain an ample supply of land and incubator space to meet the needs of preferred employers.
  - Strategy 3.2 Acquire additional property (that meet certain criteria).
  - Strategy 3.3 Consider the sale of property when doing so would better advance Goal 2.

Selected goals of the Port of Camas-Washougal's also promote mixed-use commercial development along the Washougal Waterfront, including:

- Goal 4: Lead a collaborative effort to develop a more vibrant, economically viable, and publicly accessible Columbia River waterfront.
  - Strategy 4.1 Work collaboratively with property owners, the public, and the Port's agency partners to develop a master plan for the future development and redevelopment of the Columbia River waterfront property for the area within the Port District. The master plan should provide sufficient flexibility to attract a range of employers.
  - Strategy 4.2 Prefer land uses and employers on the waterfront, that are water-dependent, -oriented, or - related.
  - Strategy 4.3 Manage marina operations, capital facilities, and lands in a manner that strives to generate sufficient revenues to offset marina operating expenses.
  - Strategy 4.4 Strongly support the provision of continuous public access along the Columbia River shoreline.
  - Strategy 4.5 Maintain Captain William Clark Park, the Parkersville Historic Park, Marina Park, and the boat launch facility as public recreation areas.

2.3.3 Key Findings

The Port of Camas-Washougal's Marina will remain an integral part of the Washougal Waterfront. Most of the moorage slips are covered and are not affected by height constraints from the proposed I-5 bridges. There may be use by sailboats at the marina that are height constrained, but most of the sailboat use is limited to boats up to 55 feet long, which would not be height constrained by the options under consideration. The port also has a four-lane launch ramp with attendant floating docks. However, the use of the boat ramp is generally by trailer-carried powerboats, which are not height constrained by the proposed bridge.

Industrial development in Washougal is centered in the Port of Washougal's industrial properties at the eastern edge of the city. The heavy industrial zoning designation allows uses that are permitted outright, such as bulk petroleum product terminals, plants, and storage facilities, which could generate marine traffic. However, the levee and recreation areas and trails that parallel the river create a buffer that inhibits marine uses along the riverfront in Washougal. Based on these conditions future marine facilities or activities are unlikely.

2.4 Skamania County, Washington

This section describes the existing and expected future land uses along the riverfront in Skamania County.

2.4.1 Existing Uses

Commercial/industrial waterfront properties in Skamania County include two former mill sites and property owned by the Port of Skamania County.

Stevenson Co-Ply Property

The Stevenson Co-Ply mill property, owned by Mountain View Property, was formerly owned by Wilkins, Kaiser & Olsen Inc. (WKO) and ceased operations in 1992.[22] The site has approximately 26 acres of uplands and is located inside the urban growth area of the city of Stevenson, but outside the city limits. It is zoned industrial (MG) by Skamania County. After its destruction by a fire in 2007. the site has been idle, and there are no current plans to redevelop this site. There are no marine facilities.

[22] Skamania County, Washington, MapSifter. https://skamaniawa-taxsifter.publicaccessnow.com/.

Figure A.2-11. Stevenson Co-Ply Property

Stevenson Waterfront

The vision for development on the Stevenson Waterfront, which includes Stevenson Landing, the Tichenor Building, and the Cascade Boat Launch, is based on fostering an active waterfront for recreation, a healthy economy, and a high quality of life.

Stevenson Landing, which is owned by the Port of Skamania County, is a cruise ship pier located on the Columbia River at river mile 150 of the Columbia River. The pier is 200 feet long, 15 feet wide and has a 55-foot-by-6.5-foot adjustable steel gangway. There are three sets of dolphins centered on gangway at various locations to allow for a range of docking possibilities. Cruise lines calling at Stevenson Landing include American Cruise Lines. American Queen Steamboat Company vessels used by these entities are addressed in the main NIR.

The Port of Skamania owns the Tichenor Building, which is located just upriver of Stevenson Landing and offers 29,000 square feet of flex-industrial space. It was built in 1992 and has experienced a successful transition from dependence on the forest products industry to a more diverse offering, serving a mix of light industrial and professional services. The Tichenor Building takes advantage of the views and amenities of the Columbia River, but it does not have facilities for water access for water-dependent businesses.

The Cascade Boat Launch is located in downtown Stevenson on the waterfront just east of the Tichenor Building. Trailer-carried power and sail boats and hand-powered craft use the boat launch. These craft are not height constrained and would likely be used locally and not transit through the IBR program area.

Figure A.2-12. Stevenson Waterfront

Home Valley

High Cascade Veneer (a subsidiary of WKO) began operating out of the former Stevenson Co-Ply peeler plant in Home Valley in the 1990s. The mill is no longer active, but WKO uses the property for storing lumber.[23] The site includes approximately 94 acres of upland area. The facility includes a barge dock, but the state of repair is unknown and access may be restricted by shoaling associated with the Wind River.

[23] Personal conversation with WKO Sawmill, July 20, 2021.

Figure A.2-13. Home Valley

Broughton Landing

The Broughton Lumber Company, which is located just west of Underwood, ceased operations in 1986 and has remained idle since. However, a plan was developed to create a destination resort called Broughton Landing. The property includes approximately 60 acres, and is inside the NSA of the gorge but outside any urban growth area. The plan calls for "a new resort comprised of approximately 250 new vacation homes, recreational amenities and retail areas serving resort guests, locals and visitors alike."[24] In 2008, petitioners appealed the decision to amend the plan allowing for this development. Ultimately, the court of appeals upheld the decision, but the proposed development has not progressed since this decision. Broughton Landing is divided by the railroad and State Route (SR) 14, creating three distinct sections. Most of the site does not have river frontage except a small portion on the far west side. This area, called Broughton Beach, is approximately 2.3 acres and is zoned for commercial recreation. The Broughton Landing Master Plan has a proposal for a pedestrian bridge spanning SR 14 and the railroad tracks to connect the beach area to other portions of the site. The site does not have any marine facilities and is unlikely to be developed for marine-dependent uses beyond recreational uses.[25]

[24] http://www.broughtonlanding.com/Overview/.

[25] Broughton Landing Master Plan, http://www.broughtonlanding.com/Documents_PDF/.

Figure A.2-14. Broughton Landing

2.4.2 Overview of Land Use Regulations

The Skamania County 2007 Comprehensive Plan Final does not include goals or policies specific to marine uses or land uses that would support further development of marine uses.

North Bonneville's riverfront is largely reserved for recreational uses or is under federal ownership because of the dam. Therefore, impacts to marine uses are not anticipated in this section of Skamania County.

However, in Stevenson, there are industrially designated lands identified along the southern portion of the riverfront (Stevenson Co-Ply). North of the industrial designations is a strip of commercial recreation, followed by commercially designated lots, one lot designated light industrial and then community commercial lots. Uses along the river include hotels, restaurants, and a kite-boarding school in the commercially zoned areas. The industrially zoned lots are used for timber-related activities. The entirety of Skamania County's southern border (approximately 90,204 acres)[26] is located within the Columbia River Gorge NSA. The NSA categorizes these areas into three categories: (1) urban areas, (2) special management areas, and (3) general management areas. Four urban areas, including North Bonneville, Stevenson, Carson, and Home Valley, are located within Skamania County. Urban areas within the NSA can grow over time and are the primary locations for any industrial or commercial uses that require vessel traffic. The NSA Management Plan limits

[26] Skamania County 2007 Comprehensive Plan, https://www.skamaniacounty.org/home/showpublisheddocument/1385/637122005286830000.

development outside of the urban areas while encouraging urban development to locate within these established urban designations.[27]

2.4.3 Key Findings

The industrial waterfront properties in Skamania County have been traditionally used by the forest products industry, including the mill sites at Stevenson, Home Valley, and Underwood. As the forest product sector declined, properties have been held by forest product firms for potential future reuse as a mill site or have been planned for redevelopment to resort or mixed-use properties. The proposed I-5 bridges do not impose a height constraint on shipping activities related to the forest products industry because log rafts or barges carrying logs, chips, or other forest products can easily pass under the bridges for destinations downriver of the bridges.

The Port of Skamania developed a business park, cruise terminal, and boat launch at Stevenson. The property at Stevenson Landing is on the waterfront and has a cruise ship dock but does not offer waterfront access for water-dependent firms requiring barge service. Within Stevenson, the movement is toward recreational waterfront with public access.

Potential impacts could occur from navigational height restrictions downstream affecting cruise vessels and sailboats. Impacts to vessels are addressed in the main body of the NIR.

The Port of Skamania County's other land holdings do not have direct access to the Columbia River (e.g., Cascades Business Park, the Lewis and Clark Business Park, and the Wind River Business Park).

2.5 Klickitat County, Washington

This section describes the existing and expected future land uses along the riverfront in Klickitat County.

2.5.1 Existing Uses

Klickitat County includes the small urban areas of Dallesport, Lyle, and Bingen.

Bingen

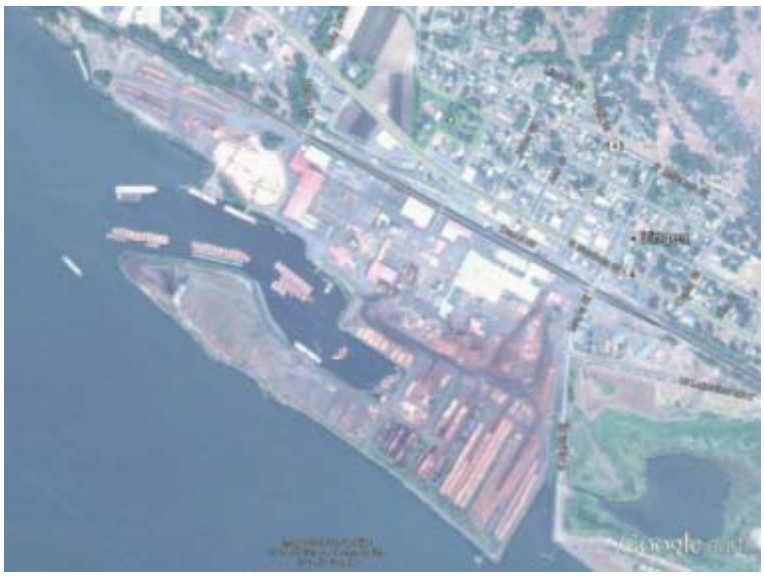
The SDS Lumber Mill and the Port of Klickitat County's Bingen Point Business Park are located in Bingen.

[27] Management Plan for the Columbia River Gorge National Scenic Area, August 2016, http://www.gorgecommission.org/images/uploads/amendments/Management_Plan_(as_revised_through_2016).pdf.

SDS Lumber Mill

The SDS Lumber Company mill site, located on the riverfront in Bingen, consists of approximately 170 acres (including uplands and in-water parcels). The mill produces lumber and plywood. The site includes a mooring area and approximately 30 acres of upland area for storage/staging of products. SDS can transload products from upland to barge, log yard, and ramp for raft/bundle preparation and load chips on barges.[28] It also has a construction fleet network with cranes up to 150 ton capacity. SDS vessels are addressed in the main NIR.

Figure A.2-15. SDS Lumber Mill



Bingen Point Business Park

The Port of Klickitat's Bingen Point Business Park, which is located just east of the SDS lumber mill, has 52 acres at Bingen Point available for light industrial and commercial uses. Bingen Point Business Park does not have direct access to the waterfront. Some of the key tenants at the business park are Insitu Group, Inc., which produces miniature unmanned aerial vehicles for military and commercial applications, and Zepher, a manufacturer specializing in defense and autonomous systems. There are no marine facilities or water-dependent tenants.

[28] SDS Lumber Mill. http://sdslumber.com/.

Figure A.2-16. Port of Klickitat Bingen Point Industrial Park

Bingen Marina

The Port of Klickitat owns the Bingen Marina, which includes a two-ramp boat launch, restrooms, and a parking area for boat trailers. Plans call for the development of additional facilities, including transitory and long-term moorage, a fuel dock, a pump-out facility, and other amenities.[29]

[29] http://www.portofklickitat.com/recreation/marina.asp.

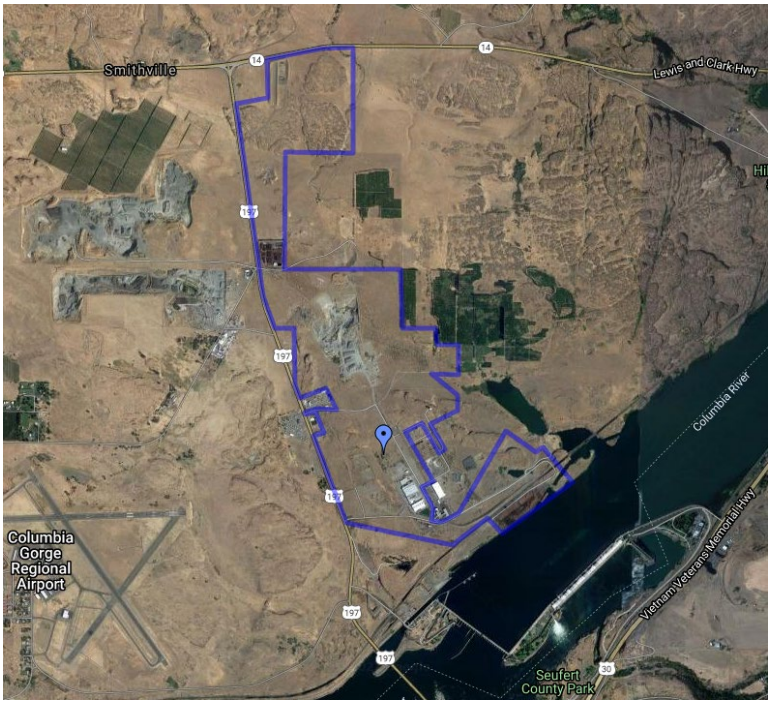
Figure A.2-17. Port of Klickitat Bingen Marina

Dallesport

The Dallesport Industrial Park is owned by the Port of Klickitat and covers approximately 660 acres east of U.S. Highway 197 and north of the Columbia River. Zoned for light and heavy industrial use, this site includes a barge terminal used for log exports immediately upstream of The Dalles Dam, which is operated by The Dallesport Log Yard. It was also used by an excursion boat that would tie up while passengers visited the Mary Hill Museum. However, this excursion boat activity has not occurred recently.[30] In addition, there is a privately owned property downstream of the dam that has dolphins and conveyor system for loading.

[30] PBPorts interview with Port of Klickitat.

Figure A.2-18. Port of Klickitat Dallesport Industrial Park



2.5.2 Overview of Land Use Regulations

The western portions of Bingen along Alpine Avenue are targeted for business, high technology, and light industry. The eastern portions along Parallel Avenue are targeted for moderate to heavy industry. Property north of Dow Road has been set aside for aggregate mining operations and future development. The Bingen Point Business Park is located along the Columbia River just outside Bingen, Washington, and across from Hood River, Oregon.

Waterfront zoning outside of White Salmon city limits includes suburban residential to the west and industrial park to the east in Bingen. From aerials, the industrial park area appears to be used for river-related and timber-related industry. Inside White Salmon, the western portion of the riverfront is designated as open space, and the eastern section is designated as the Riverfront Planned District. Not all the industrial lots are used for industrial activities; some are for residential uses, such as an RV park. Also, the railroad tracks constrain many of the industrial lots, making them shallow. Waterfront zoning in Lyle is almost entirely suburban residential.

The riverfront property in Lyle is undeveloped and the majority is owned by the Yakama Nation.

Zoning in Dallesport along the Columbia is almost entirely residential in the western portion with some areas of open space and industrially zoned areas to the east.

2.5.3 Key Findings

Most of the occupied industrial lots along the riverfront are used by the timber industry, which generates non-height-constrained cargoes (logs, wood chips, aggregates, etc.). The proposed bridge should not have any impacts to shipping related to the timber industry.

There are some undeveloped industrial lots along the river. Industrial park zoning allows for boat building, assembly, and fabrication of metal products and additional manufacturing uses as uses permitted outright. However, many of the industrially designated lots are limited by the railroad tracks that create shallow lots from the river, potentially limiting the possibility of large industrial structures on the site.

There are also vacant developable industrial lands at the Dallesport Industrial Park. However, the BNSF railroad right of way cuts through the property near the river, leaving a narrow band of land adjacent to the river that is currently used by a barge terminal. It is unlikely that future uses would be height constrained at this location.[31]

The aggregate terminal, approximately 2 miles east of Wishram, Washington, is operated by Pacific Northwest Aggregates, Inc., a produces sand, gravel, and other solid minerals used in road and other construction. The mining operations and marine facility operate on approximately 45 acres of Native American Lands property through a lease agreement. The facility includes a loading terminal used to load barges with material. Vessels transferring aggregates are addressed in the main NIR.

[31] Personal conversation with Mr. Marc Thornsbury, Executive Director, Port of Klickitat, September 11, 2012.

Figure A.2-19. Pacific Northwest Aggregates

2.6 Multnomah County, Oregon (Portland)

This section describes the existing and expected future land uses along the riverfront in Multnomah County in the city of Portland, upriver from the BNSF rail bridge.

2.6.1 Existing Uses

The portion of Portland east of the BNSF rail bridge has several waterfront uses, including marinas and houseboat communities.

Hayden Island to Government Island

There are several marinas and floating home communities in the area from east Hayden Island to Government Island, but there are no industrial uses on the riverfront east of the I-5 bridges up to the city of Fairview (see Section A.2.7).

2.6.2 Overview of Land Use Regulations

Zoning along the Columbia River east of the I-5 bridges is primarily open space that accommodates a riverfront multiuse trail. There are additional small pockets of residential zoning and areas of commercial zoning close to the bridges and on Hayden Island. There are two areas designated industrial: one on the south side of Hayden Island and one just north of 33rd Road and Marine Drive. The lots along Marine Drive are shallow in depth because they are between Marine Drive and the River. There are numerous private marinas, especially closer to the I-5 bridges. In addition, there are marine-related uses such as watercraft rentals and sales.

Manufacturing and warehouse and freight movement are permitted outright in the industrial zone.

2.6.3 Key Findings

There are many recreational marinas that are used by both powerboats and sailboats. Sailboats that are affected by the existing I-5 bridges generally had an air draft ranging from 50 to 90 feet, with an average of approximately 70 feet and are not height constrained by the replacement bridges. In 2012, there were only 48 sailboats that were 46 feet or longer that could be height constrained at 95 feet. Powerboats have an air draft that ranging from 20 feet to 25 feet and can use Oregon Slough, thus never requiring a bridge opening.

2.7 Multnomah County, Oregon (Fairview)

This section describes the existing and expected future land uses along the riverfront in Multnomah County in the city of Fairview.

2.7.1 Existing Uses

There are two barge terminal sites in Fairview.

CalPortland Blue Lake Aggregate Yard

CalPortland owns and operates the Blue Lake Aggregate Yard, a distribution facility that stocks crushed rock, washed rock, concrete sand, and dredged sand. The Blue Lake Aggregate Yard is barged to the terminal from other sites, unloaded, and then trucked to construction sites in northeast Portland.[32] The facility is served by tugs and barges that are addressed in the main NIR.

[32] CalPortland. https://www.calportland.com/locations/oregon/blue-lake-aggregate-yard/.

Figure A.2-20. CalPortland Blue Lake Aggregate Yard

Chinook Fairview – Sundial Chip Reload

Chinook Fairview owns the former Georgia Pacific West chip reload terminal in Fairview. The facility ships and receives chips by barge.

Figure A.2-21. Chinook Fairview Terminal

2.7.2 Overview of Land Use Regulations

Metro owns a large portion of land on the north side of Fairview, including Blue Lake Park, Chinook Landing Marine Park, and the Columbia River open space. Part of a 40-mile-loop trail is planned to go along the Columbia River in this area. There is also an area designated general industrial, and as noted above, there are two marine-development uses in Fairview.

The Fairview Comprehensive Plan (2004) encourages private landowners along the Columbia River to seek redevelopment options that would replace existing industrial operations with river- oriented

recreational, residential, and commercial development. The plan also recommends working with Metro to expand or develop recreational and commercial services and facilities at Blue Lake Park.

2.7.3 Key Findings

None of the existing industrial uses in Fairview would be height constrained by the proposed I-5 bridge. Although Columbia River industrial uses are permitted outright in the industrial zone, the Fairview Comprehensive Plan identifies trail planning and recreational uses for this area.

2.8 Multnomah County, Oregon (Troutdale)

This section describes the existing and expected future land uses along the riverfront in Multnomah County in the City of Troutdale.

2.8.1 Existing Uses

There is one barge terminal site in Troutdale and one former shipyard.

Sundial Marine Tug & Barge Works

The Sundial Marine site was formerly used as a ship and barge building and repair facility. The marine infrastructure is not operational with the exception of a spud barge.[33]

Tidewater operated the Sundial Tug & Barge Works at this site from 1970 until early 2011, when it closed operations. Tidewater decided to close the facility because the repair and construction business is cyclical, and Tidewater elected to focus on its core businesses of barge transportation and terminal operations. The Hickey Family Company currently owns the site, and there are no known plans to redevelop it.

[33] https://www.deq.state.or.us/Webdocs/Controls/Output/PdfHandler.ashx?p=9d2d4d6e-f45c-4464-80c7-501c9a3b561c.pdf&s=Staff-report.pdf.

Figure A.2-22. Sundial Marine Tug & Barge Works

Knife River Corporation Aggregates Terminal

Knife River Corporation operates an aggregates terminal in Troutdale. The facility consists of a ready-mix concrete plant with a dock and conveyor for sand and gravel delivery by barge and unloading-related facilities.[34]

[34] Oregon Department of Environmental Quality Permit Evaluation and Fact Sheet, 3/28/2012. https://www.deq.state.or.us/wqpr/3819_2012040200772CS01.PDF.

Figure A.2-23. Knife River Aggregates Terminal

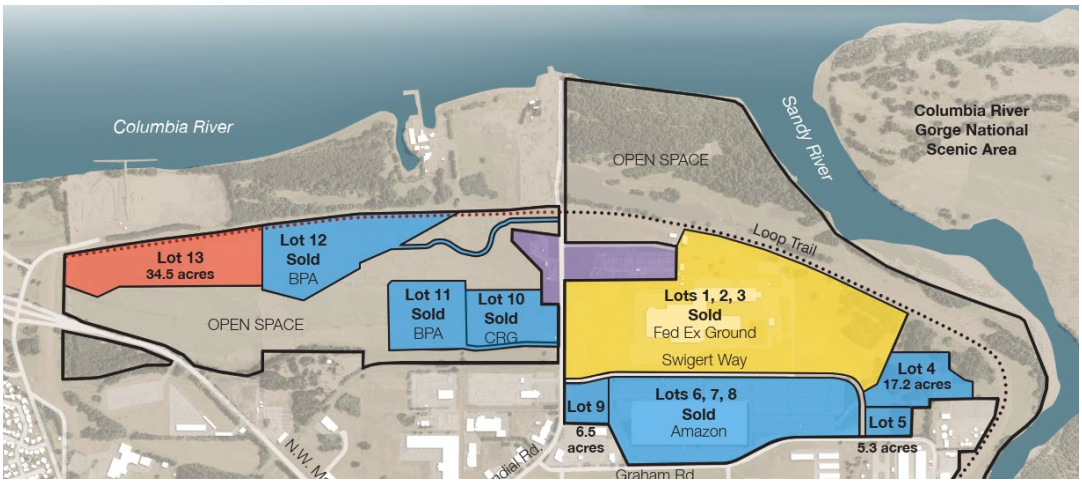
Troutdale Reynolds Industrial Park

The Port of Portland developed the Troutdale Reynolds Industrial Park, which is located on a 700-acre former brownfield site of the former Troutdale Aluminum Smelter.

Key tenets of the industrial park are FedEx and Amazon.[35] This development will respond to the need for large parcels of industrial land in the region. However, the development is not water-dependent, and significant shoaling from the Sandy River delta would make development of marine infrastructure very difficult. The Columbia and Sandy Rivers are designated open as space by the Port of Portland's master plan.[36]

[35] https://www.portofportland.com/trip.
[36] Ibid.

Figure A.2-24. Troutdale Reynolds Industrial Park



2.8.2 Overview of Land Use Regulations

Troutdale zoning along the river includes open space and general industrial uses. Some of the industrial lots are known to support uses that generate marine traffic. The general industrial designation allows for manufacturing, marinas, and marine industrial/marine service facilities to be permitted outright.

2.8.3 Key Findings

The industrially zoned sites generate marine traffic that primarily consists of tugs and barges, which are not height constrained. The Knife River terminal is not expected to change in the future. Sundial Marine is idle and could be sold or redeveloped. In either case, it is not expected that it will generate height constrained marine traffic.

2.9 Hood River County, Oregon (Cascade Locks)

2.9.1 Existing Uses

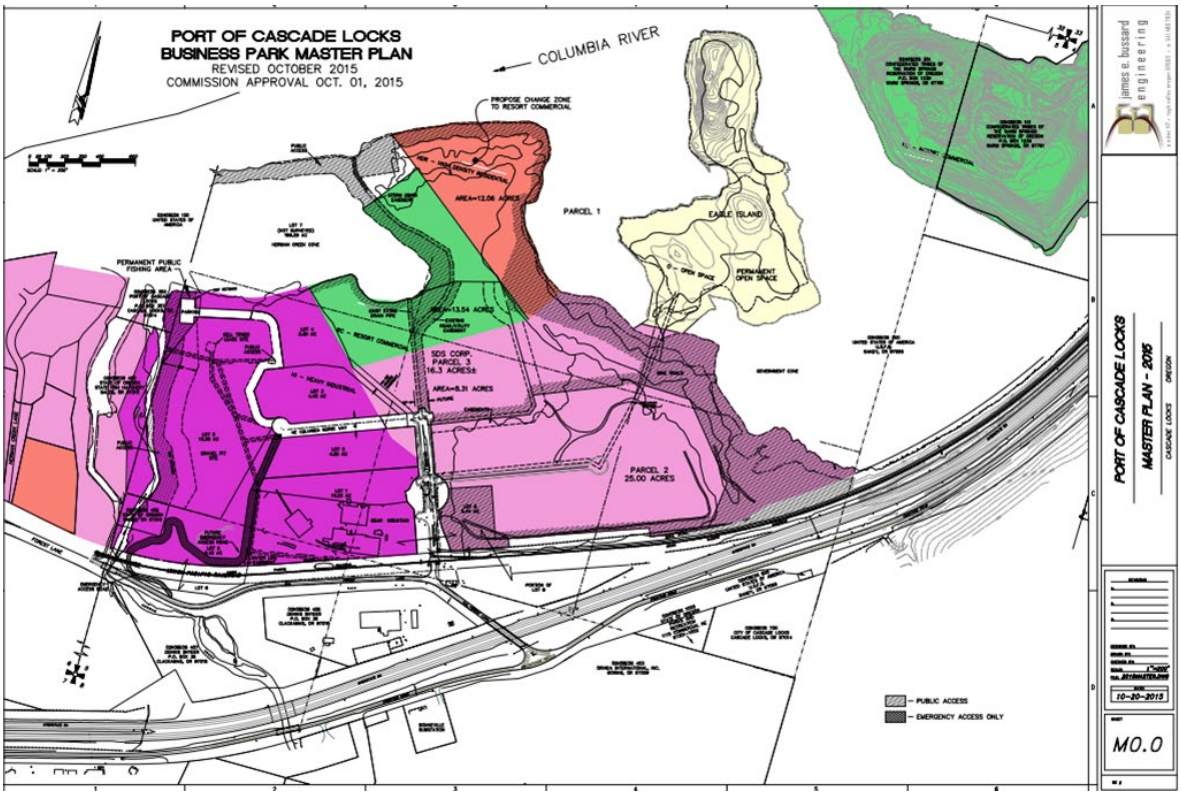
The Port of Cascade Locks operates an industrial park, marina, and a cruise facility.

Port of Cascade Locks Business Park

As shown in Figure A.2-25, the Port of Cascade Locks Business Park (North Point, Herman Creek Cove, and Lower Bench) is approximately 191 acres. There are currently vacant acres at North Point (17. 6

acres), Herman Creek Cove (4.25 acres), and Lower Bench (3.7 acres). The port listed the possibility of the development of an additional marina facility that could be located at the industrial park.[37]

Figure A.2-25. Port of Cascade Locks Business Park



Port of Cascade Locks: Herman Creek Business Complex

The Herman Creek Business Complex is located directly east of the business park and offers a variety of spaces for light industrial uses. The majority of the spaces advertised on the port's website are not available currently. There is no water access associated with the business complex.

Port of Cascade Locks Marina

The Port of Cascade Locks Marina has 36 slips. Cascade Locks is a well-established sailboat racing destination and is home to the Columbia Gorge Racing Association. The port identifies new

37 https://portofcascadelocks.org/documents/Final%20Adopted%20Port%20of%20Cascade%20Locks%20Strategic%20Business%20Plan%20December%202013%20sm.pdf.

recreational opportunities associated with sailing as part of their priorities in the 2016 Strategic Business Plan revisions, which may result in additional smaller, non-height-constrained vessels.[38]

Figure A.2-26. Port of Cascade Locks Marina

Port of Cascade Locks Cascade Locks Marine Park

The *Columbia Gorge Sternwheeler*, which is owned by the Port of Cascade Locks and operated by the Portland Spirit, is docked in the Cascade Locks Marine Park from May to October. The vessel provides daily passenger excursions. There is also a visitor center in the Cascade Locks Marine Park.

[38] Ibid.

Figure A.2-27. Port of Cascade Locks Marine Park

The port is working to further develop the northeast portion of the Marine Park to increase recreational opportunities. The improvements would enlarge the sailboat launching area, which currently hosts word-class sailing regattas.[39]

2.9.2 Overview of Land Use Regulations

Zoning along the Cascade Locks shoreline is largely open space to the west and heavy industrial, light industrial, public, resort commercial, and high on either side of Herman Creek. The eastern edge of the jurisdictional line is zoned resort commercial. The industrial designation allows manufacturing and production as a use that is permitted outright.

Within the urban area of Cascade Locks, the parcels zoned light industrial or heavy industrial are located at the northeast side of the city. There are two privately owned undeveloped heavy industrial zoned lots totaling 50 acres west of Herman Creek that are located on the Columbia River and are not constrained from water access by the railroad. Heavy industrial zoning could support land use activities that could utilize river navigation for receipt of raw material by water or shipment of finished goods. There is no marine infrastructure at the site with the exception of a series of dolphins that are of unknown condition and ownership. Steep slopes up to 60 feet in vertical relief are located along the river which would reduce the suitability of providing marine infrastructure to access the uplands.

There are three parcels identified by the Port of Cascade Locks for industrial development along the Columbia River. The three lots are zoned either light industrial, heavy industrial, high density residential, and resort commercial. Information from the Port of Cascade Locks stipulates that there are sections of these properties available for rezoning. The Cascade Locks Resort and Casino is potentially planned for adjacent lots to the south.

[39] https://portofcascadelocks.org/recreation-projects/

Based on the port's website,[40] there is availability to construct an industrial park in this area with water access. Figure A.2-25 shows the lots along the river that area available for industrial development. Existing uses south of these lots include Bear Mountain Forest Products, which has been producing premium quality forest products in Oregon since 1988, and SDS lumber. The Warm Springs Resort and Casino was a planned development south and adjacent to the available industrial lots in this area but the status of this project is unknown.

2.9.3 Key Findings

There are undeveloped industrial lots along the river. These lots have been identified for potential development that would likely not generate marine traffic, including business parks and entertainment and recreational uses.

The Cascade Locks community is positioning itself as a sailboat racing destination. In general, there is a desire to attract the international sailing community, but the sailboats using this area are typically small and are not height constrained.

The Port of Cascade Locks also homeports the *Columbia Gorge Sternwheeler* during the tourist season, but this vessel is not height constrained by the proposed I-5 bridge options.

2.10 Hood River County, Oregon (Hood River)

2.10.1 Existing Uses

The Port of Hood River operates a Business Park, marina, and a cruise facility.

Port of Hood River Business Park

The Port of Hood River owns most of the waterfront properties in Hood River. The goal of the port's Waterfront Development Strategy emphasizes preservation of and support for local light industrial businesses. In addition to job retention and business development, other Waterfront Development Strategy goals include quality development in a collaborative process, and ensuring compatibility with existing and future recreational activities. There are no marine facilities and there is no direct access to the riverfront for barge or other terminals within the business park.

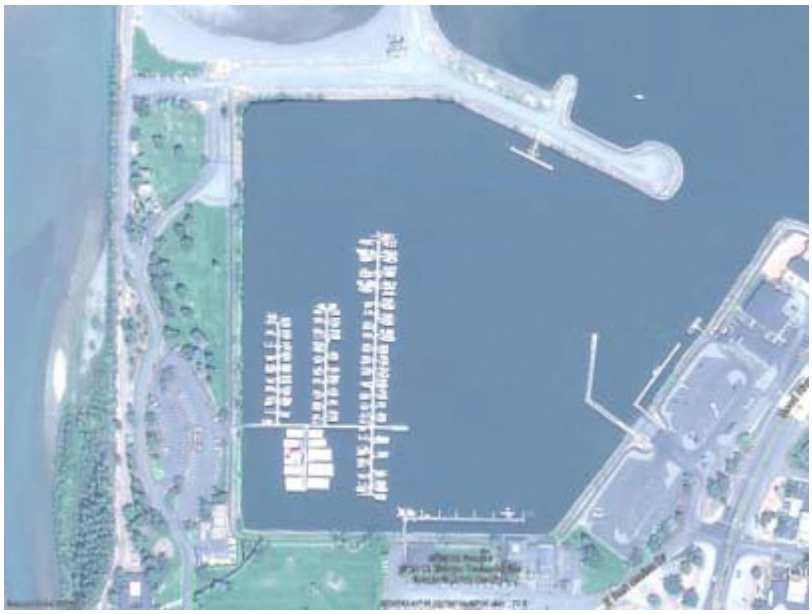
40

Figure A.2-28. Port of Hood River Business Park

Port of Hood River Marina Park

The port's marina offers moorage for over 160 vessels, with slip sizes ranging from 20 feet to 40 feet. The marina has a short-term transient dock available for travelers at river mile 169. The boats homeported or calling on a transient basis are typically less than 40 feet long, and as a result are not height constrained by the proposed I-5 bridge. Small cruise ship vessels that call Hood River in the spring and fall seasons, including: InnerSea Discoveries (*The Legacy*), Lindblad Expeditions (*Sea Bird* and *Sea Lion*), and Portland Spirit (*Columbia Gorge Sternwheeler*), among others. The dock on the north side of the marina is reserved for small cruise ship vessels. Vessels moored at the Port of Hood River are addressed in the main NIR. Other uses of the marina include kayaking, small sailing craft, community education sailing classes, and Hood River Yacht Club activities.

Figure A.2-29. Port of Hood River Marina



2.10.2 Overview of Land Use Regulations

Zoning along the Hood River shoreline consists of open space, Columbia River recreation/commercial, and light industrial. The eastern edge of the jurisdiction along the shoreline and directly adjacent to the Hood River bridge is general commercial zoning. The city of Hood River defines light industrial as industrial service (e.g. corporate laundry and cleaning, etc.), research and development, manufacturing, processing, fabrication, packaging, assembly of goods, and warehousing. The use of Columbia River recreation/commercial zoning along the shoreline is intended to be consisted with visual and pedestrian access to the area. The Union Pacific railroad tracks run along the river, creating a barrier between the river and uses on the other side of the river. Past the railroad tracks (inland) are various uses, including general commercial, urban low density, open space, industrial, and light industrial. There are several light industrial parcels that abut the river, such as along Portway Avenue.

2.10.3 Key Findings

In the Port of Hood River area, the emphasis is on recreational development and business park development rather than marine-based industrial.

The cruise ships that call or could call on Hood River are addressed in the main NIR.

The sailboats homeported in Hood River or calling on a transient basis at Hood River are typically less than 40 feet long, and are not height constrained by the proposed I-5 bridge.

There are no known existing or future activities that would be height constrained in Hood River.

2.11 Wasco County, Oregon

Wasco County waterfront facilities are located at The Port of The Dalles.

2.11.1 Existing Uses

Waterfront uses include two barge terminals and a marina.

Bernert Barge Lines provides barge towing for the transport of commodities and containers on the Columbia, Snake, and Willamette Rivers. Bernert maintains a maintenance and fabrication facility in The Dalles that has a dock, crane, and shop with capabilities for marine repairs and general metalworking.

Mid Columbia Producers is a farmer-owned cooperative serving the grain producers of the mid-Columbia region. The cooperative owns offices and grain elevators on the riverfront where barges are loaded with wheat for transit downriver, primarily for export.[41]

The port sold all its developable land, with the exception of one 85 acre tract adjacent to the Columbia River. The port developed the site into the Chenoweth Business Park. None of the sites within the business park has water access and a waterfront trail is located between the lots and the river.[42]

[42] Port of The Dalles Strategic Business Plan, https://www.portofthedalles.com/files/405660130/2013+Port+of+The+Dalles+Strategic+Plan.pdf

Figure A.2-30. Barge Terminals in The Dalles

Port of The Dalles Marina

The port's marina has space for 62 boathouses and approximately 30 open moorage slips.[43] A boat launch is located adjacent to the marina to allow for easy haul outs with trailers. The marina provides a variety of services (fuel, power, public restrooms, picnic facilities, boat holding tank pump-out and potty dump station). The Dalles Yacht Club is located at the marina.

[43] Source: Port of The Dalles https://www.portofthedalles.com/the-marina.

Figure A.2-31. Port of The Dalles Marina

The Dalles Commercial Dock and Lewis and Clark Festival Park

The floating dock serves transient recreational boats, and the fixed pier serves cruise ships, similar to the vessels calling at Hood River.[44]

[44] http://www.ci.the-dalles.or.us/node/99.

Figure A.2-32. The Dalles Commercial Dock[45]

Former Northwest Aluminum Site (3313 W 2nd St.)

The Northwest Aluminum smelter ceased operations in 2000 and cleanup operations were largely completed by 2007. The site, which is approximately 120 acres and undeveloped, is now planned for commercial and industrial development. This site is not located on the river.

[45] Ibid.

Figure A.2-33. Former Northwest Aluminum Site (3313 West 2nd Street)

2.11.2 Overview of Land Use Regulations

The western shoreline of The Dalles has a significant amount of industrially zoned land along the riverfront. This designation includes shipyards and commercial docking facilities as use is permitted outright. In addition, manufacturing and fabricating are uses permitted outright. There are also pockets of commercial recreation and general commercial along the river. Some of the industrial sites support marine traffic generating uses.

The Dalles Comprehensive Land Use Plan, Volume I (May 23, 2011) specifies that riverfront property should be reserved for riverfront use (Goal 8) and that there should be provisions to accommodate future barge traffic (Goal 12).

2.11.3 Key Findings

In the western portion of The Dalles, there are numerous industrial lots along the river, some of which support industrial, marine-dependent uses. The lots could be redeveloped for marine-related. Closer to downtown, the tourism and recreation industry is anticipated to generate increased marine traffic.

A 2011 planning study[46] found that there is a shortage of commercial lands in The Dalles: “In order to capitalize on long-range economic and employment shifts, The Dalles will need to add to its existing supply of land for commercial uses within the urban growth boundary. Similar conversions of port

[46] The Dalles Comprehensive Land Use Plan, prepared by Winterbrook Planning, May 2011, Page 29

industrial lands along the riverfront can produce a mixed-use area to accommodate a slightly different market, including freeway commercial and recreational users."

Although current marine facilities in The Dalles do not have the capacity to support deep-draft vessels it is possible for them to reach the area as shown by past activities. The deep-draft navigation channel authorized by the U.S. Army Engineers terminates in The Dalles, but it is only maintained to a depth of 17 feet. Some deep-draft navigation has occurred in the past. One example being in 1938 when the freighter the *SS Charles L. Wheeler Jr.* became the first deep-sea vessel to travel past the Bonneville Dam up to The Dalles but deep draft navigation has never occurred on frequent basis to the Dalles.[47]

None of the planned development options in The Dalles would serve or require vessels that would be constrained by the bridge height.

[47] https://historylink.org/File/9883.

3. ANALYSIS SUMMARY

The project extent from the BNSF rail line in Vancouver to the Celilo Falls BNSF bridge covers a large portion of the Columbia River but overall few properties exist that currently have marine facilities available or have the potential for future facilities. The findings above highlight the political and geographic constraints the Columbia River waterfront has including:

- Columbia River Gorge NSA Designations
- Parallel transportation routes (SR 14, I-84, Union Pacific and BNSF railroads)
- Steep Topography
- Existing recreational and open space uses

Primarily industrial uses that generate or would generate marine vessel traffic are located within urban areas and typically within established industrial parks (e.g., CBC, Port of Cascade Locks Industrial Park). There are no known planned developments within the study area that would create additional navigation activities that would be impacted by the proposed bridge heights studied in the main body of the report.

Company: Diversified Marine

Vessel: *DB Freedom*

Company provided data sheets to the IBR Program. Data sheets are included below, followed by the information included in the CRC NIR.

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

Company/Owner Name: Diversified Marine, Inc.

Vessel Height Verification Sheet

By: Pete Geiger Date: 2 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Diversified Marine
   b. Name of contact: Kurt Redd
   c. Phone number (Office): 503.289.2662 (Cell):
   d. Email: kurt@dmipdx.com
   e. Address: 1801 N Marine Drive City: Portland
      State: OR Zip code: 97217
2. Vessel
   a. ID: b. Name: DB Freedom
   c. Type: Crane Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
      - Is a vessel specification sheet available? Yes
      - Configuration shown on the sheet: Crane Up
      - What is the lowest height configuration for transport? Crane down at ~ 34 Degrees above horizontal, spuds up and pinned

   b. What is the gantry configuration? Estimated gantry height: Not given
   c. Does the barge have spuds? Yes at least two forward. Spuds currently down
      - Height above waterline for travel? 85 Feet
      - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
      - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area.

4. Vessel Location

   a. Where is the vessel currently located? Columbia River North Portland Harbor

   b. Is it working on a job? Yes while tied up Is it tied up to shore? yes

   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	77.3 feet
Water Level:	16.0 feet
Top of Boom:	Measured while working = 201.4 feet (71 degrees off horizontal) Estimated at travel angle (34 degrees off horizontal) = 135 feet
Height of Boom Hinge Pin:	39.1 feet
Boom Cradle:	42.9 feet
Top of Spud:	Not surveyed – spuds in down position

6. Vessel Height

Kent - Thanks for taking my call today. Attached is the information submitted for the CRC program back in 2012. We would appreciate a review of this information to confirm that it remains accurate. We would especially want to know if any of the specifications have changed, if any of the fleet are no longer in service, if other vessels should be considered and whether you have any planned or potential projects that would result in the need to transit through the I-5 bridge area.

Feel free to contact me with any questions.

Marine Contractors

Company: JT Marine

Vessel: *DB Taylor*

Company provided data sheets to the IBR Program. Data sheets are included below, followed by the information included in the CRC NIR.

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

Company/Owner Name: JT Marine, Inc.

Vessel Name:
DB Taylor

Vessel Type:
Crane barge

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:Choose an item.

Vessel Category: Commercial

USCG Document Number:
514786

Primary Mooring Location *(waterway milepoint, if known)*:

Type and quantity of cargo, if applicable:

Length (overall; ft):
148

Beam (width; ft):

Vessel Height Verification Sheet

By: Pete Geiger Date: 12 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: JT Marine
   b. Name of contact: Waino Toristoja
   c. Phone number (Office): 360.750.1300 (Cell): 360.567.8382
   d. Email: waino@jtmarineinc.com
   e. Address: 2301 SW Hidden Way, #100 City: Vancouver
      State: WA Zip code: 98661
2. Vessel
   a. ID: b. Name: DB Taylor
   c. Type: Crane Barge d. USCG Document Number: 514786
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
   - Is a vessel specification sheet available? No
   - Configuration shown on the sheet: N/A
   - What is the lowest height configuration for transport? Crane down in cradle, spuds up and pinned

   b. What is the gantry configuration? Pinned Estimated gantry height: Not given

   c. Does the barge have spuds? Yes two midpoint. Spuds currently down
   - Height above waterline for travel? 80 Feet
   - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
   - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area. Can lift both spuds with own crane.

4. Vessel Location

   a. Where is the vessel currently located? Willamette River Sellwood Bridge

   b. Is it working on a job? Yes Is it tied up to shore? No

   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	65.3 feet
Water Level:	13.8 feet
Top of Boom[1]:	Measured while working = 192.7 feet (71 degrees off horizontal) Estimated height at travel angle: • 220 foot long boom: 131 feet • 166.6 foot long boom: 51 feet (limit is the gantry height)
Height of Boom Hinge Pin:	35.0 feet
Boom Cradle:	38.9 feet
Top of Spud:	62.4 feet – spuds in down position[2]

[1] Note: JT Marine reported that they use two different booms on the DB Taylor; one with a length of 220 feet and one with a length of 166.6 feet.

[2] JT Marine self reported that the height to the top of their spuds are 80 feet.

6. Vessel Height

Self-Reported		Surveyed[1]	
166.6 foot boom		220 foot boom	
Air Draft:	80 feet (top of spuds)	Air Draft:	131 feet
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet CRD	Water Level:	16 feet CRD
Total Height:	106 feet	Total Height:	157 feet

[1] Note: The surveyed air draft measurement shown is the estimated travel height based on the surveyed boom length.

image002.png
image003.png
image004.png

Brian,

I did just get a response on the upcoming planned activities from our Operating Project Managers.

The Yaquina looks to be the tallest USACE vessel that we expect to transit through the area. Annual O&M dredging's in water work window is 1 August to 30 September but we need to have the ability to address shoals at any time of year. I believe that's how we landed on the river level + Yaq height clearance in our formal letter to the CRC.

As far as future work goes, our contractors often move equipment and materials via barge to construction projects. For example recent gate replacements, JD AWS electrical building, etc along with the large cranes mobilized to handle these. The largest crane I've heard coming up river was "The General" which I think Kiewit now owns.

I am trying to verify the dimensions of "the General" as well as the largest items we've moved under contract (likely The Dalles or John Day Gates). Otherwise there is nothing planned that would be impacted by the bridge height.

Thanks, Jeff

Subject: [Non-DoD Source] Interstate Bridge Replacement Project - USACE vessels/Navigation needs

Jeff,

I am part of the team working on the Interstate Bridge (IBR) Program addressing the USCG permit. We are collecting information on vessel use of the Columbia River and are validating and updating the data provided by the USACE for the prior Columbia River Crossing Project.

The information at that time was provided by Marci Johnson. Would you be the best contact for validating the information? Specifically, I am looking to confirm information on the Yaquina, whether any other USACE vessels would be expected to transit through the area (either North Portland Harbor or the main channel) and whether there are any planned activities at upstream dams would require specific shipments under the bridge in the future.

Thanks in advance. Feel free to call or email if you have questions or need additional information.

FEB 23 2012

Ms. Heather Wills
Columbia River Crossing
700 Washington Street, Suite 300
Vancouver, Washington 98660

Dear Ms. Wills,

This letter is in response to the Columbia River Crossing (CRC), Interstate 5 (I-5) Project boat survey request for information regarding the Corps Dredges Yaquina and Essayons and our navigational needs upstream of the proposed new I-5 bridge project.

We determined that the proposed bridge height outlined in the Record of Decision would have serious impacts on our federal missions to maintain the navigation channel and provide emergency dredging upstream of the new bridge. After considering dredging requirements and potential future water release impacts to the Columbia River, we determined that the minimum prism needed for the new bridge is a height of 116 feet Columbia River Datum (121.4 NAVD88) for a width of 400 feet. A more detailed explanation of our requirements is enclosed.

We will forward a copy of this letter to Rear Admiral Keith Taylor, Commander 13th District United States Coast Guard, Jackson Federal Building, 915 Second Avenue, Seattle, WA 98174-1067, John McAvoy, FHWA, 610 East 10th Street, Vancouver, WA 98661; and Dave Hendricks, Multnomah County Drainage District No. 1, 1880 NE Elrod Dr., Portland, Oregon 97211.

We look forward to resolving these navigation concerns to ensure the CRC project does not have any unacceptable impacts to our federal projects. Please feel free to contact me at (503) 808-4500 or Ms. Marci Johnson of my staff at (503) 808-4765 or via e-mail at marci.e.johnson@usace.army.mil.

Sincerely,

John W. Eisenhauer, P.E.
Colonel, Army Corps of Engineers

U. S. Army Corps of Engineers Federal Navigation Channel Maintenance Needs
Columbia River Crossing (I-5 Interstate Bridge at Vancouver, WA)
February 2012

Summary:

Minimum prism needed for new bridge is height 116 feet Columbia River Datum (CRD) (equal to 121.4 feet NAVD88) for width 400 feet (channel width of 300 feet plus 50 feet on each side of the channel).

Authorized project:

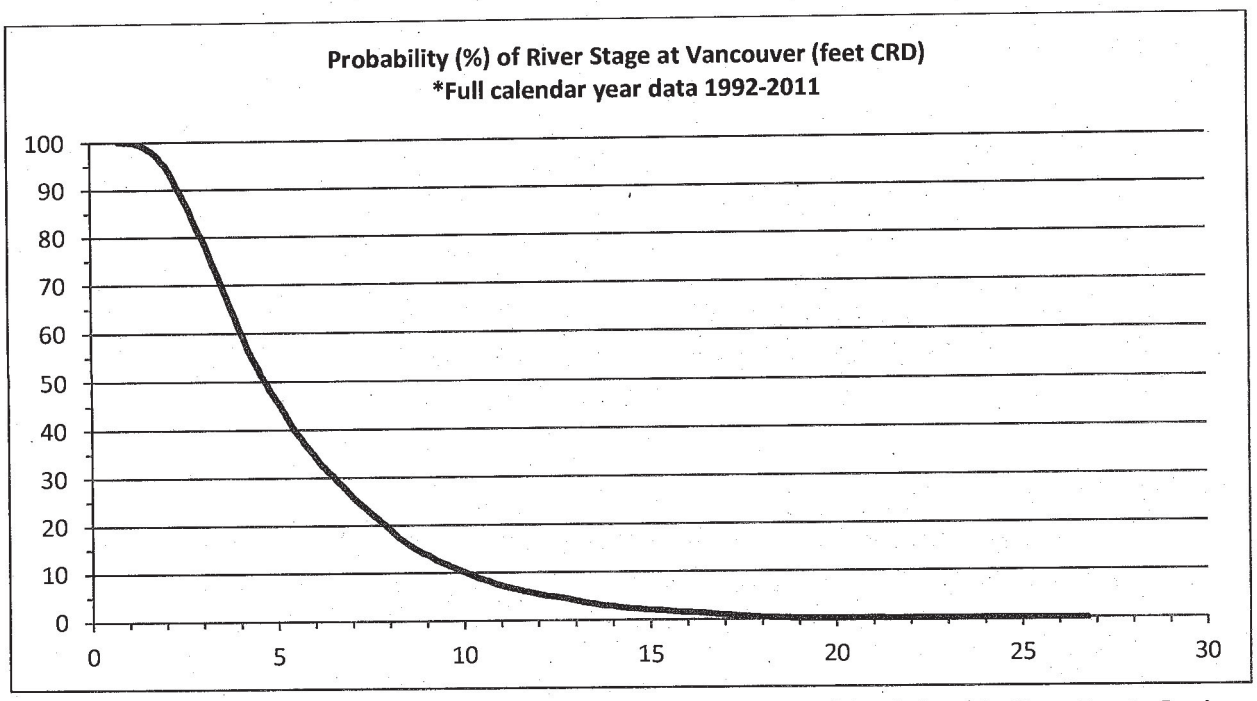
- The federal Navigation Channel immediately upstream of the Columbia River Crossing is authorized to 27 feet deep and 300 feet wide from Vancouver, WA, to The Dalles, OR. This channel supports the Columbia-Snake river system and transportation of 10 million tons of cargo annually. It is the largest wheat/barley export gateway in the U.S. and the third largest grain export gateway in the world.

Minimum bridge prism reasoning:

- The Corps' Dredge *Yaquina* performs annual channel maintenance dredging. The minimum prism needed for the new bridge is the vertical clearance required for this dredge to pass safely under the bridge at a specified river water level above CRD, and the horizontal clearance required for maintenance of the channel under the bridge.

Vertical clearance discussion:

- According to the USCG-licensed captains of the Dredge *Yaquina*, a 100-foot minimum vertical clearance from top of water to bottom of bridge is required (draft of 9 feet below the waterline gives a height of 92 feet above the waterline, plus an 8-foot minimum safety gap).
- The environmentally protective in-water work period as established by Federal and State agencies has changed in the past, and could continue to change as new species are listed, requiring work to be done during periods of higher river flow and stage.
- Year-round river flow levels must be considered as emergency operations could be required at any time. The probability of a river stage is shown below, using available data from the past 20 years.



- The uncertainty of future water levels must be considered. As part of the Columbia River Treaty Review, the Corps is collecting new data and performing studies to evaluate maintaining or potentially changing current levels of regulation for flood risk protection in this region of the Columbia River basin. The National Marine Fisheries Biological Opinion for the Federal Columbia River Power System also requires the Corps to spill water at its Columbia River dams to support salmon survival. These factors may lead to future operations resulting in elevated river levels (closer to ordinary high water) for longer durations compared with the past 20 years. Current Regulatory ordinary high water level at the Columbia River Crossing is 16 feet CRD (equivalent to 21.4 feet NAVD88).
- Bridge lift records show the lift height in feet above zero at the bridge pier elevation (39 feet CRD). Recent records show that the median lift for the Dredge *Yaquina* is 100 feet (equal to 139 feet CRD). The maximum lift shown was 136 feet (175 feet CRD). The minimum lift shown was 90 feet (129 feet CRD). Water levels shown on bridge records corresponding to these lifts ranged from 1 to 12 feet CRD.

Vertical clearance conclusion: A minimum vertical height of 116 feet CRD (121.4 feet NAVD88) is required. Year-round river level data from the past 20 years indicate that river levels were at or below 16 feet CRD approximately 98 percent of the time. Future river operations will likely increase river levels up to ordinary high water (16 feet CRD) for longer periods. Adding the 100-foot vertical clearance from waterline to bridge required for the Dredge *Yaquina* to 16 feet CRD yields a minimum vertical bridge height requirement of 116 feet CRD (121.4 NAVD88).

Horizontal clearance discussion:

- The Corps practices advanced width maintenance dredging (dredging up to 50-100 feet outside the channel width) to provide an area outside the channel for unstable side slope sloughing so that the full channel width remains clean.

Horizontal clearance conclusion: A horizontal width of 400 feet CRD is required at the vertical height specified above. This width includes the channel width (300 feet) plus 50 feet additional width on each side of the channel for advanced width maintenance dredging.

Marine Industries and Fabricators

Company: Greenberry

Company provided the following information to the IBR Program.

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

INTRODUCTION

The history of Thompson Metal Fab includes two major influences, the opening of the Interstate Bridge in 1917, and the opening of the Columbia Business Center *(originally Henry Kaiser's Vancouver Shipyard)* in 1942. Over the years, Thompson Metal Fab (TMF), the Columbia Business Center (CBC) and the Interstate Bridge will see their history evolve due to the changing needs of the region, rapid population grown, and dynamic industrial development. For these same reasons, their history also begins to connect, and their futures are tied together.

The original Thompson Metal Fab facility, shown in 2018. Thompson moved from this location and to Vancouver in the early 1970's. The old facility has since been demolished, making way for the brand new Meyer Memorial Trust building.

Original span of the Interstate Bridge opened 1917 – shown here in 1931.

The original Interstate Bridge (current day northbound span) was completed and opened in February of 1917. Upon completion of this span, travelers could go from Canada to Mexico on one complete roadway. This was not only a big accomplishment for the country, but it was also an opportunity for growth, specifically in southwestern Washington. At the time the bridge was opened, there were approximately 250,000 people in Portland, compared to the 12,000 in Vancouver. The new bridge would provide opportunity for dynamic population movement, economic growth, and forever connect not only two states, but two communities. To satisfy the needs of this expanding community, a second 'twin' span was eventually completed and opened in 1958.

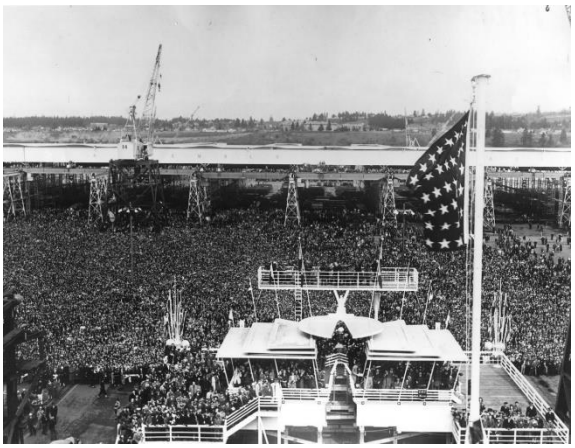
With a clearance of 72 feet, most river barges can pass under the bridge without impact when the drawbridge is closed. This is not the case with large industrial projects, like those manufactured currently by Thompson Metal Fab, or for large vessels, like the Liberty and Victory ships from the early 1940's. At full height, the current lift span can accommodate 178' from the water to the underside of the bridge. This "air gap" allows very large loads to pass upriver and downriver and has driven the development of upstream industrial areas such as the Columbia Business Center, originally known as Henry Kaiser's Vancouver Shipyard.

COLUMBIA BUSINESS CENTER *(former Kaiser Vancouver Shipyard)*

Building 40 and 41 of current day Thompson Metal Fab is shown prominently in the middle of this picture. At the time this picture was taken (circa early 1940's) the building and entire industrial area would have been known as Kaiser's Vancouver Shipyards.

[1943] Escort carriers at the Vancouver Shipyards (current day Thompson Metal Fab)

At nearly 200-acres, Kaiser's Vancouver Shipyard began production in early 1942 with an initial payroll of 38,000 workers. This facility, along with two in Portland, produced 752 ships during WWII and peaked at 97,000 workers in total. Many of these workers migrated from other parts of the country and is part of the reason why the Portland/Vancouver area saw such a big jump in population at this time. The development of these shipyards certainly contributed to the need for a new span (eventually built and completed in 1958) and the need to modify the original span, completed in 1960. For perspective on what these facilities were able to produce, the construction on the first Liberty ship took 131 days in 1941. By 1943, Kaiser workers were averaging a completed Liberty ship in 42-days and three ships were being completed each day. Record production for a completed ship was 10-days, although that production was bested by one of the Kaiser facilities in Richmond, CA *(4-days, 15-hours, 29-minutes)*.



75,000 people (largest crowd in Clark County's history) assembled on April 5, 1943 to witness first lady Eleanor Roosevelt christen the 'Alazon Bay' escort aircraft. Current day Thompson Metal Fab is seen prominently in the background.

drive opportunity to the Columbia Business Center as oil companies looked for fabricators to build "jacket liners" for new offshore wells. The facility could support the work on the massive infrastructure and the bridge was high enough to allow the jacket liners to be shipped downstream.

The 1960's and 1970's saw the construction of new dams on the Columbia River and Snake River in addition to the development of major oil fields in Alaska (i.e. Prudhoe Bay). Ongoing work on the US Interstate Highway System also provided opportunity for new bridges, including four highly visible bridges in Portland: Morrison Bridge (1958), Marquam Bridge (1966), Freemont Bridge (1973), and the Glenn L. Jackson Memorial Bridge (1982). These would be opened to accommodate a shifting population and to relieve pressure on traffic crossing the Interstate Bridge.

After the war ended and the need for shipbuilding diminished, learning how to leverage these 'abandoned' facilities for future industrial growth was important. The size of the facility at the Vancouver Shipyard was simply greater than most fabrication shops of the day. Even now, it remains one of the largest fabrication facilities on the West Coast. The sheer size of the building, access to a large yard, and location to a major waterway made the facility at the future Columbia Business Center an extremely attractive option for the large infrastructure needs that were coming.

The Portland/Vancouver Metro area became highly industrialized by the 1960's, driven by the ability of the Columbia Business Center and companies such as Thompson Metal Fab. This strong local economy centered around logging, pulp & paper products, and maritime transport on the Columbia River; and stimulated additional growth in the region. The California oil boom would also

Infrastructure for the California offshore oil fields being manufactured at the Columbia Business Center in 1967. Thompson Metal Fab would begin operations here a few years later in 1973.

THOMPSON METAL FAB

In 1937, "Pudge" Thompson opens 'Thompson Metal Fab' at 2405 Vancouver Avenue in Portland, OR. The opening of his facility comes 20-years after the opening of the Interstate Bridge while also pre-dating the second span by 20-years.

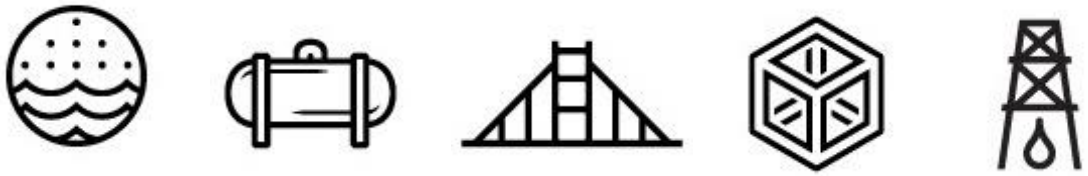
Original marketing display of the Thompson Ice Tongs

The origin story of Thompson Metal Fab is a humble one, especially compared to the work they do today. Pudge and his craftsmen manufactured lightweight metal products for the dairy and timber industries. One product, the Thompson Ice Tongs, held US patient #D206,091 and a quick Google search shows that the Thompson Ice Tongs are still selling online to this day. Thanks in part to the WWII war effort, expansion of TMF continued during the 1940's and 1950's; mirroring the growth of the community it served and the new industrial opportunities.

In 1973, after 36 years, Pudge Thompson sold his company to Harder Mechanical, whose story is like TMF's. Harder began as a small local plumbing contractor who was founded in 1934. A few years later they reinvented themselves so they could build housing for the workers at the Portland area shipyards during WWII. As the region continued to see growth, so did Harder who saw the acquisition of Thompson Metal Fab as a way to expand their capabilities and stake a claim on some of these emerging industries (i.e. hydroelectric dams). Shortly after the acquisition, the original Thompson Metal Fab facility (Portland, OR) was closed for good, and all operations were moved to the old Kaiser Shipyard in Vancouver, WA – a facility well suited to support the large projects Harder Mechanical would earn as they grew and expanded.

Thompson Metal Fab would transfer ownership again in the early 2000's with even more emphasis on how to maximize the capacity. The size of the facility requires TMF to be a diversified business and one with experience in multiple disciplines, including:

Marine/Hydro **Tanks/Vessels** **Bridges** **Modular/Structural** **Oil & Gas**



Since the early 1970's, TMF has completed countless projects while working over 10-Million man-hours *(estimated)*. The following list showcases some of the completed projects over the last 40+ years. In each case, transportation by barge was required (either by design or necessity), and in many cases the load passed under the Interstate Bridge.

Projects noted with (*) were not completed by Thompson Metal Fab but are on this list to showcase examples of other mega projects where a facility like Thompson's was required (Big shop, assembly yard, barge loading capabilities)

MARINE/HYDRO

<u>The Dalles Dam, Downstream Navigation Lock Miter Gates, Columbia River, WA/OR, USA [2011]</u>

Two Miter Gates were manufactured, where each gate measured 52' W x 106' L and weighed 1-Million pounds each. Due to navigational lock closures on the Columbia River, an aggressive fabrication and delivery schedule was required which required a fabricator with ample space and ability to load a barge. Picture to the right shows one gate getting ready to be loaded on the barge. Seen in the background is Parker Drilling Rig 272 & 273. Those rigs would ship just a few months after this load.

<u>Lower Monumental Dam, Downstream Navigation Lock Lift Gate, Snake River, WA, USA [2010]</u>

The finished weight of this structure was 1.5-Million pounds and would ship to the jobsite by barge in three segments. The final gate is 88' W x 84' H

<u>Ice Harbor Dam, Removable Spillway Weir, Snake River, WA, USA [2005]</u>

This removable spillway weir is designed to move juvenile fish more efficiently through the dam spillways. The unit measured 70' in width x 68' in height x 105' in length. It weighed 950-tons and is taller than Thompson's facility! The weir was completely fabricated at TMF and then transported by barge to Cascade General for repositioning before shipping to the jobsite on the Snake River.

Lower Granite Dam, Removable Spillway Weir, Snake River, WA, USA [2001]

The removable spillway weir is designed to move juvenile fish more efficiently downstream through the dam spillways. The weir was 83' wide x 61' deep x 115' long and weighed approximately 1,000-tons. The weir was completely fabricated at TMF and then transported by barge to Cascade General for repositioning before shipping to the jobsite on the Snake River.

Esperanza 124 MW Power Barge [1999]

Recently retrofitted in 2017 in Panama, it was originally fabricated in 1999 by Thompson Metal Fab, and transported to Cascade General in Portland, OR for final assembly and functional testing. The barge measured 105' wide x 30' deep x 284' long with a weight of 1,800-tons. The completed barge was loaded on a 400' L x 100' W barge for delivery to Cascade General.

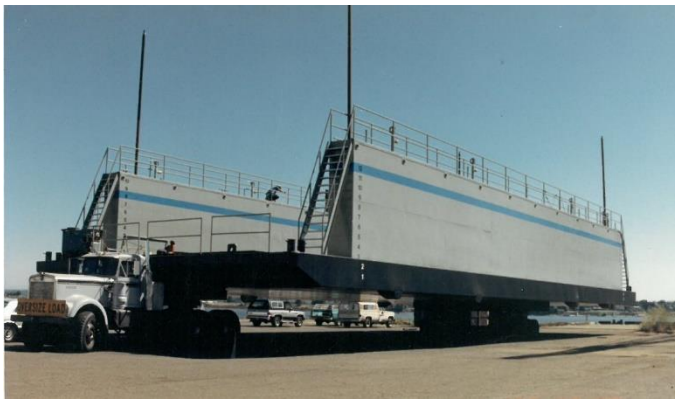
Golmar Explorer Ship Conversion [1997]

In 1997, Thompson fabricated multiple items for the infamous Golmar Explorer ship which was developed for the CIA and at the direction of Howard Hughes. By the mid-1990's the ship had changed hands a few times over and was in the process of being converted into an oil drilling vessel. TMF fabricated two double-bottom sections, four thruster tubs, vessel exhaust stacks, and manifold systems for this project. Completed components were transported by barge from TMF to Cascade General Shipyard.

John Day Dam, Upstream Navigation Lock Gate, Columbia River, WA/OR, USA [1991]
This gate was fabricated at the Columbia Business Center. The gate measured 28' deep x 80' high x 120' wide and weighed 105-tons. It was transported standing (80' high) for installation purposes.

Pacific Marine Hull Fabrication, Honolulu, HI, USA [1989]
TMF fabricated a 365-ton "SWATH" (Small Waterplane Area Twin Hull) excursion vessel. The fabrication consisted of twin cigar-shaped hulls that were 9' in diameter and 132' in length with vessel beams measuring 53'. Thompson's location adjacent to the Columbia River proved valuable for launching the vessel. After sea trials, the "Navatek" vessel headed to Hawaii. The vessel is still operating today.

Christensen Shipbuilders, Dry Dock, Vancouver, WA, USA [1987]
210' long dry dock was fabricated by TMF, including all walls, deck, ballast tanks and piping



Columbia River Barge Conversions [1979-1971]
Thompson converted barges to carry wood chips in support of the pulp and paper mills. The converted barges were fabricated to ABS and USCG standards. Projects were installed at our adjacent dock and barge facilities.

Alaska Ferry Conversion [1973]
Thompson Metal Fab supplied an exhaust funnel, solarium structure and modular subcomponents for the passenger ferry that travels the Inland Passage to Alaska. The existing ferry was cut in half and lengthened, with TMF fabricating all components for this major renovation. All items delivered by barge to the shipyard.

Other Examples Include:

- WSDOT Coleman Dock Improvements [2023] *
- Ballard Lock & Dam, Navigation Lock Center Miter Gates, Lake Washington, WA, USA [2022] *

- John Day Dam, 150-Ton Gantry Crane, Columbia River, OR/WA, USA [2022] *
- McNary Dam, Intake Bulkhead Gates, Columbia River, OR/WA, USA [2022] *
- Port of Alaska Petroleum & Cement Terminal Expansion, Anchorage, Alaska, USA [2021]
- Ward Cove Ferry Dock Expansion, Ward Cove, Alaska, USA [2020]
- WSDOT Mukilteo Dock Improvements, Mukilteo, WA, USA [2020] *
- The Dalles Dam, Upstream Navigation Lock Radial Gate, Columbia River, OR/WA, USA [2016] *
- Lower Granite Dam Expansion, Snake River, Washington, USA [1987]
- Revelstoke Dam, Columbia River, British Columbia, Canada [1984] *
- Bonneville Dam Expansion, Columbia River, Oregon, USA [1981] *
- Brownlee Dam Expansion, Snake River, ID/OR, USA [1980] *
- American Falls Dam Replacement, Snake River, ID, USA [1978] *
- Ice Harbor Dam Expansion, Snake River, Washington, USA [1976] *
- Grand Coulee Dam Expansion, Columbia River, Washington, USA [1974] *
- Mica Dam, Columbia River, British Columbia, Canada [1973] *
- John Day Dam, Columbia River, WA/OR, USA [1971] *
- Little Goose Dam, Snake River, Washington, USA [1970] *
- Lower Monumental Dam, Snake River, Washington, USA [1969] *

TANKS/VESSELS

<u>Phillips 66 Prefractioner Tower, Rodeo, CA, USA [2015]</u>

The 200-ton tower stretched 126’ Long and transitions from 10’-6” diameter at the smallest to 17’-0” at the largest. The vessel was manufactured in three separate sections before being married together at Thompson’s shop. The vessel shell and heads are made from clad plate which provides the necessary strength while also providing the required corrosion protection on the interior. For final acceptance, nearly 120,000 gallons of water was pumped into the vessel for a leak test. The vessel was pressurized over a period to ensure that all welds were water-tight.

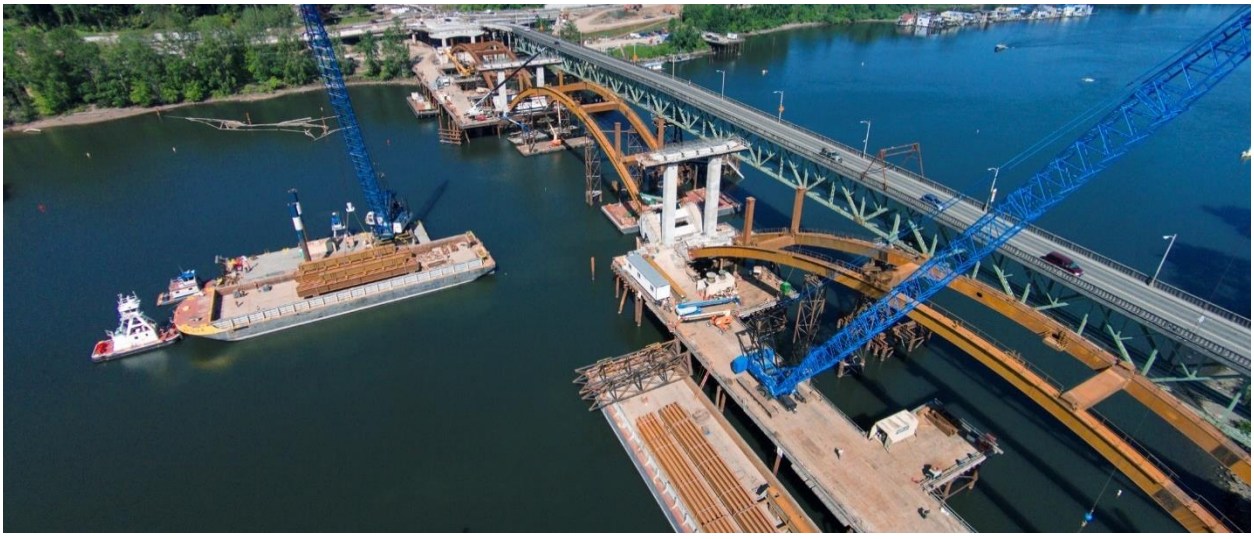
REC Solar Grade Silicon Project, Moses Lake, WA, USA [2007]

Thompson Metal Fab manufactured a total of 10 process vessels for the solar grade silicon industry. The project included four vessels which required barge transportation due to their size. Those vessels were 150" ID x nearly 120'-0" L and weighed over 200,000 LBS/ea. Vessels were barged to Pasco, WA and then shipped over the road to Moses Lake.

BRIDGE

Sellwood Bridge, Portland, OR, USA [2016]

Thompson's scope of supply included fabrication of all major bridge components: Arches, Arch Cross-frames, Vertical Spandrels, and the Bridge Deck Steel. Over 5,000-tons in total. The distinctive feature of the bridge are the three arches which cover 1,275' of the total 1,976' crossing. Each arch was fabricated in segments, with each segment 100' long. Because of the project's location on the Willamette River, steel was delivered to the jobsite with seven barge loads. Multiple barges can be seen here with incoming steel deliveries.



Bay Bridge Connector, Bay Area, CA, USA [2006]

TMF painted two orthotropic tub girders that were fabricated at the Columbia Business Center. Each weighed more than 1,600-tons and measured over 200' L x 80' W. Girders were transported by barge to the Bay Area for erection.

Richmond San Rafael Bridge, Bay Area, CA, USA [2004]

10,000 tons of structural bridge steel for the substructure was supplied for a seismic retrofit. Total fabrication took three years to complete. Larger components were transported by barge and direct to the jobsite.

Tri-Met Terry Moore Pedestrian Bridge, Portland, OR, USA [1996]

Fabricated at the Columbia Business Center, TMF painted the pedestrian bridge spanning HWY 26 near the HWY 217 junction. Completed sections were shipped by barge to a nearby location before being trucked to the jobsite.

1st Ave & Duwamish Bascule Bridge, Seattle, WA, USA [1996]

Completed truss sections for this project were fabricated at the Columbia Business Center, painted by Thompson, and assembled at the facility. Transportation to the jobsite in Seattle was done over the water, by barge.

Nimitz Freeway, Bay Area, CA, USA [1995]

This project consisted of (13) curved tub girders for the reconstruction of the Nimitz Freeway in the Bay Area. Girders were fabricated at the Columbia Business Center and painted by TMF. The total project weighed 6,000-tons with the largest girders weighing 450-tons; 50' W x 250' L. This project required four barges for delivery to jobsite..

I-90 East Channel Bridge, Seattle, WA, USA [1986]

Trapezoidal tub girders that varied from 98' to 198' in length and weighed between 60 and 200-tons each were fabricated at the Columbia Business Center and painted by Thompson Metal Fab. Girders were pre-assembled and completed sections loaded on a barge for transport to Lake Washington.

Other Examples Include:

- BNSF Bridge 58.8 Replacement, Home Valley, WA, USA [2019] *
- Wittpenn Bridge, Jersey City, NJ, USA [2017] *
- Sauvie Island Bridge, Portland, OR, USA [2004] *
- Glenn L. Jackson Bridge, WA/OR, USA [1982] *
- Freemont Bridge, Portland, OR, USA [1973] *

MODULAR/STRUCTURAL

Intel Expansion, Hillsboro, OR, USA [2010's - Present]

Expansion at the Intel facility in Hillsboro has been going on for some time and Thompson has supplied numerous modular structures in support of their effort. In 2020, TMF shipped the largest modules to date, buildings that were 44' W x 97' L x 16' H. Due to their size, the buildings could break apart in half, but still required a barge to get from TMF's facility to the jobsite as shipping over the road was not an option.

Caltrans, East Tie-In Project, Bay Area, CA, USA [2008-2009]

Thompson was selected by Caltrans (owner) to work with TY-Lin (designer), CC Myers (contractor) and DCCI (erector) to fabricate 3,100-tons of temporary steel to provide detour for the Oakland Bay Bridge at Yerba Vista Island. Thanks to the size of their facility TMF could meet the 'expedited' schedule requirement for this project. Major components required four barge loads from TMF's facility to the job-site in California. Project was completed in 2009.

OHSU Tram, Portland, OR, USA [2006]

TMF fabricated the center support tower, the lower station, and the upper station for the tram project. The major components were transported by barge from TMF to the jobsite in Portland, OR where they were offloaded and erected.

The team at Thompson Metal Fab standing in front of base of the iconic Portland Aerial Tram mid-tower. The tram is located at the OHSU hospital in Portland and spans across I-405. The tower base is over 40' high as shown in this picture.

Alaska Gold Mining Project, Nome, Alaska, USA [2005]

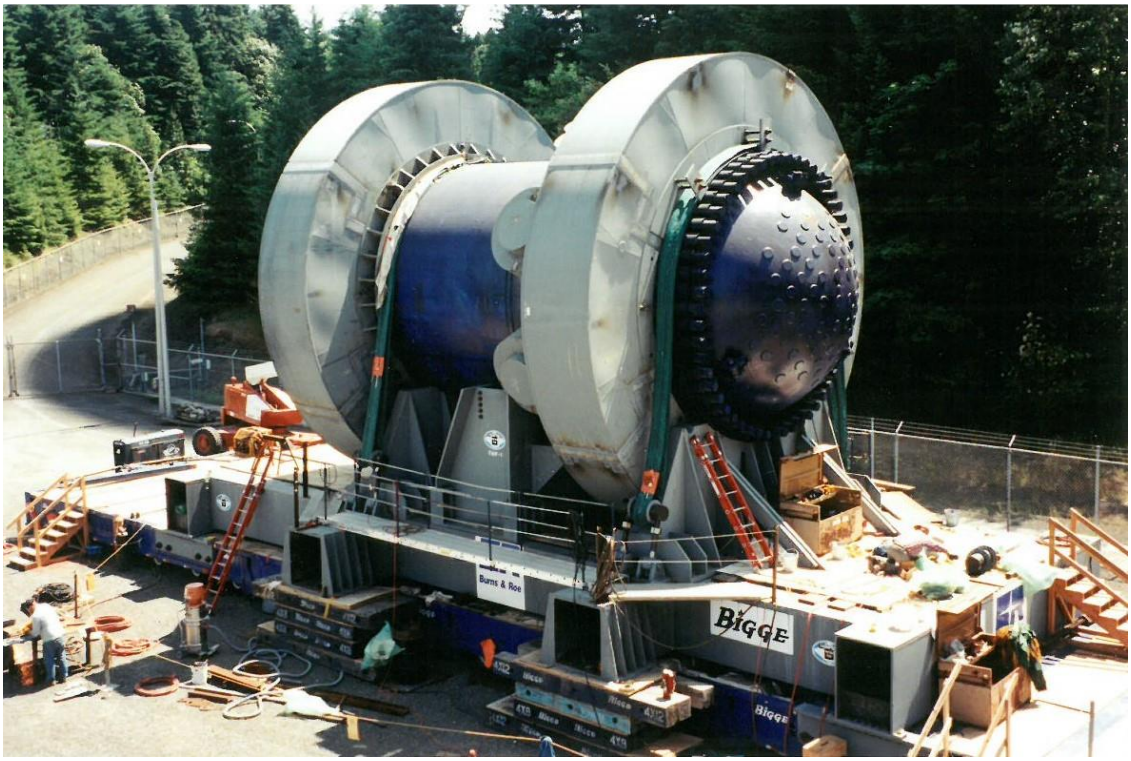
Thompson fabricated hoppers, grizzly grates, ball mill chutes, structural supports, modification of the ball mill, and other mining equipment for this project. TMF's facility was used for the marshaling yard and the load out point for all equipment and structures. Delivery was made via barge to Nome, AK.

Boeing Delta IV Launch Table, Vandenberg AFB, CA, USA [2003]

The 98' long x 33' high x 46' wide launch table weighed 580-tons. The project also included large flame deflector components which weighed up to 120-tons. The launch table and flame deflectors were fully assembled at the TMF facility and transported by barge to Vandenberg Air Force Base in California. It was then off-loaded an installed at the launch site.

PGE Decommissioning Trojan Nuclear Reactor Project, Rainier, OR, USA [1998]

TMF fabricated a 120-ton transport structure and 5" THK shielding enclosures. The completed structures were shipped by barge to the jobsite where the decommissioned reactor was loaded. The entire load was then shipped by barge to the final storage location at Hanford – Richland, WA.



Powell River Paper Company, British Columba, CANADA [1991]

Thompson supplied the fabricated steel for a Chlorine Dioxide Module that measured 35' wide x 76' high x 35' long. This module weighed 350-tons and was transported by barge in the vertical position from TMF's facility in Vancouver, WA to the Power River Paper Company in British Columbia, Canada.

Georgia Pacific Wood Chip Material Handling System, Toledo, OR, USA [1973]

TMF fabricated six 280' tube conveyor sections and all support towers for this project. The completed structures were transported by barge to Toledo, OR and installed.

Other Examples Include:

- Data Centers, The Dalles, OR, USA [2010's – Present] *
- Data Centers, Hermiston, OR, USA [2010's – Present] *
- Pre-Heater Tower, Richmond, British Columbia, CANADA [1997]
- Portland Expo Center, Portland, OR, USA [1995]
- Bulk Material Handling System, Sacramento, CA, USA [1993]
- Newport Bay Floating Restaurant, Portland, OR, USA [1986]

OIL & GAS

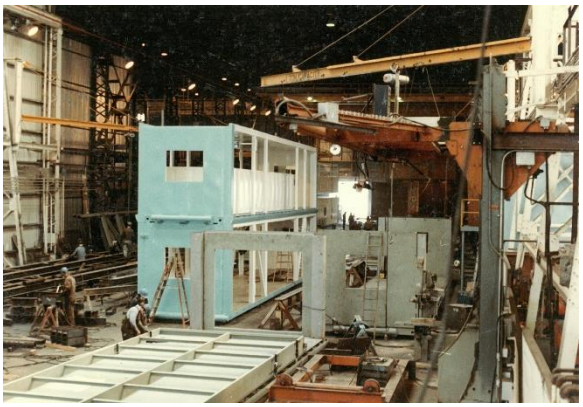
The turnkey modular service TMF offers today reflects what kicked off in the 1980's. By that point work at Prudhoe Bay was ongoing, but the infrastructure needed to support the development was still in process. In 1984, Thompson supported ARCO by manufacturing two 96-room housing modules. Each module was 40' wide x 46' high x 80' long. In addition, two Utilidor Modules were manufactured *(each 10' W x 22' H x 24 L)*. In 1985, more infrastructure was sent to ARCO; these 'bases' were 33' wide x 100' long x 10' high. Thompson also supported Conoco's Milne Point unit in 1985 with the supply of (10) module bases and (11) skids. These structures weighed anywhere from 20 to 270 tons each, with a max dimension of 64' W x 123' L x 12' H. Manufacturing structures of this size and delivering complete to the jobsite seems strange in the lower-48, but given the expanse of the North Slope, it's well suited to receive large infrastructure without other physical limitations to navigate. Additionally, with as fast as the development was happening, there was a value placed on 'set it and leave it' projects; things that could be installed and immediately put-to-use.

Massive platforms for the Alaska oilfields being fabricated at Thompson Metal Fab in the mid-1980's. The platforms nearly took up the entire width of a bay (80')

The platforms (seen left) were delivered by barge to Alaska where high capacity trucks and dollies (shown above) off loaded the structures for delivery to the jobsite.

Thompson's experience in supplying the oil fields eventually led to connections with the drilling contractors. The drilling contractors work on behalf of the owners to drill production wells and test holes as part of the exploration process. Drillers operate large equipment (known as rigs) to drill the holes. Thompson's first experience with rigs started in the late 1980's with Pool Arctic *(now Nabors Drilling)* who was a drilling contractor working on Alaska's North Slope. At one point, Pool Arctic operated the largest fleet of drill rigs on the North Slope. When TMF began working for Pool, they were looking to expand their fleet to meet market demand. This required retrofitting current rigs due to advances in equipment technology and drilling conditions that surpassed the capability of their rigs. Retrofitting works the same way as a new-build, only backwards. In a retrofit, the rig is placed on the barge and then shipped to a location large enough to receive it over the water and with enough yard space to accommodate the work. There are very few facilities on the West Coast who can accommodate this. Retrofits are just as attractive to TMF as new-builds. During a retrofit it is not unusual for some level of "rigging down" to happen and for structures to be placed in the shop. In that circumstance, it is very attractive to contractors to work with a facility large enough to handle these structures and keep them under the roof and out of the elements.

AADCO merged with Pool Arctic in 1983 and provided the rig shown above as part of the merger. This rig would be retrofitted by TMF.



Modular fabrication at Thompson Metal Fab for a Pool Arctic retrofit. The modules shown here represent the scale of a 'truckable' module, typically 12' H x 10' W x 40' L

Traditionally, drill rigs are built by manufacturing a series of truckable modules. These modules are fully assembled at the manufacturer's yard for verification, testing, and commissioning. Upon approval, the rig is completely disassembled for transportation to the jobsite. "Rigging up" is the process by which all these truckable modules are then reconnected together and recommissioned. Depending on the size of the rig, it is not unusual for 200 truckloads to be needed to move from the manufacturing location to jobsite. The process of putting a rig back together in remote locations can take months and cuts into production time. The ability to offer a turnkey service and integrate work in Thompson's shop and in their yard ultimately saves money in the long run – and contractors and owners have come to expect the capacity TMF can offer. During the early development of Prudhoe Bay in the Arctic, machinery and field services were limited and getting the required equipment to the jobsite required creative solutions. Field work is expensive and risky; and often there is limitations to what can be performed. Thompson can build larger modules for delivery, which provides a distinct advantage by minimizing costs in the field and minimizing risk.

Parker Drilling was one of the first contractors who recognized that one solution to the problems on the North Slope was to simply to deliver a *bigger* rig. A bigger rig would be capable of holding more robust equipment which would allow for drilling longer, bigger holes for greater production. The benefit of drilling longer holes is that you do not need to move the rig from pad to pad as frequently; you can cover a lot more ground from just one spot. They understood the importance of downtime and the full capacity of what TMF could offer with regards to turnkey modular fabrication. The design for Parker Drilling's Rig 245 swapped out the multiple, smaller, truckable

A large module for Parker Drilling Rig 245 moving from TMF's shop to their yard for assembly. Seen in the background is the mast and substructure of this massive drilling rig.

Rig 245 shown here at the assembly yard. When fully raised, the mast hangs high in the Vancouver, WA skyline.

modules and consolidated them into fewer 'mega modules.' Less modules simply take less time to put back together in the field. What could be 4-6 months in field work could now be up and running in weeks. Also, by eliminating trucks, the risk of loads being damaged during transport is reduced dramatically. Parkers' vision of 'mega modules' required a facility that offered a few things: a big shop, big yard, skilled workforce, access to water for shipping, and a logistically friendly location.

Parker Drilling Rig 245 being 'rigged up' at Thompson Metal Fab's yard. This yard space is immediately adjacent to the manufacturing facility and to the roll-on/roll-off barge slip. The ability to offer turnkey projects and delivery via water has given Thompson Metal Fab an advantage in the marketplace.

Drilling equipment has long been manufactured in Houston, Louisiana, and other Gulf state locations. These facilities manufacture the truckable modules and often the large offshore platforms. They certainly have the shop, yard, workforce, and access to water – but they do not have a strategic location to Alaska when it comes to logistics. To get a barge from the Gulf to the North Slope requires passage through the Panama Canal just to get from one side of the continent to the other. The added time for shipping and the added cost of voyage does not justify the mega module concept. What is needed is a manufacturer in the Pacific Northwest. TMF's location at the old Kaiser shipyard in Vancouver, WA provides the space and direct access to a deep-water barge slip with roll-on/roll-off access. The combination of a heavy-industrial construction facility and a support yard with marine transportation capability is an important asset to the region's industrial job base and has potential to attract large job producing projects. This capability has enabled TMF to stay competitive in a business that has largely moved overseas.

Becoming a proven West Coast manufacturer of drilling equipment gave drilling contractors an option that was not there previously. By entering the market, engineers could now extend the limits of their design and present solutions that were attractive to both contractors and owners who were seeking to replicate what Parker did with Rig 245, the first mega-rig on the North Slope. Among the design variables that has always been taken into consideration are the shipping clearances between our facility and the North Slope of Alaska. In that distance, there are three bridges which loads must pass under: The Interstate Bridge, the Lewis & Clark Bridge, and the Astoria-Megler Bridge. Of those three, the Interstate has the lowest total clearance, but is currently sufficient to meet the requirements of transporting mega modules.

Doyon Drilling Rig 25 shown on the barge in the foreground. Due to the size of the rig and its six mega-modules, two barges were required for delivery to Alaska's North Slope. The background shows the remaining modules for Rig 25, in addition to Parker Drilling's AADU Rigs (Rig 272 and Rig 273)

Thompson's greatest competitive advantage in earning business with the drilling contractors is their ability to ship completed, commissioned, turn-key 'mega modules' to the jobsite. If that advantage is eliminated, they will be priced out of the market. In addition to competing against the Gulf states, they actively compete with Canadian shops in Alberta. Because of the exchange rate, those facilities have a 30% pricing advantage, all other things being equal. That is the magnitude of the shipping advantage they have at Thompson. Contractors are willing to pay a

Picture of the Interstate Bridge in 2011 showing both the original Northbound span (background) and the second span (foreground) which opened in 1958 to traffic in both directions. In 1960, the second span was dedicated to Southbound traffic only. (Photo shows TMF manufactured drill rigs, AADU Rig 272 & 273 for Parker Drilling)

premium to avoid truckable modules manufactured in interior Canada or in the Gulf. It is the Contractor's advantage in the long term to have mega modules as their risk is lower, their down time is lower, field erection and trucking costs diminish, etc. Please note, these mega modules can only have their loads diminished so much (because of shipping clearance issues, etc.) before the concept no longer makes sense and the design is forced back to a more traditional build plan.

PROJECT EXAMPLES:

Hilcorp Innovation Rig, North Slope, Alaska, USA [2016]

The Innovation Rig is the next generation of drilling equipment. At nearly 1.5-Million LBS of steel, this rig consists of multiple modules and was built up to 50' H in TMF's shop before moving to their yard for final fit-up. At 9-months, this was the fastest rig build in Thompson's history, a true testament to their size and capability.

Parker Drilling AADU Rig 272 & 273, North Slope, Alaska, USA [2011]

Each drilling rig was comprised of three main modules. The Mud Modules weigh 600-tons, the Drill Modules weigh 700-tons, and the Utility Modules weigh 460-tons. The Mud and Utility Modules are 48' wide x 55' high x 99' long. The Drill Module is 76' high with the mast in the lay-down position.

Doyon Drilling Rig 25, North Slope, Alaska, USA [2010]

4-million LBS of steel and aluminum fabricated for Rig 25, a project where TMF also acted as the General Contractor. TMF managed all rig-up activities including mechanical, electrical, and functional checkout. This rig consisted of six primary modules: Power Complex (550-tons, 56' L x 40' W x 42' H); Drill Complex (560-tons, 96' L x 37' W x 40' H); Pipe Complex (560-tons, 68' L x 47' W x 25' H); Mud Complex (550-tons, 68' L x 40' W x 49' H); Pump Complex (560-tons, 64' L x 40' W x 52' H); Casing Complex (500-tons, 60' L x 56' W x 40' H). The 26' x 25' Mast extends to 148' L.

Parker Drilling/British Petroleum Liberty Rig, North Slope, Alaska, USA [2009]

This drilling rig shipped from our facility to the North Slope of Alaska in July 2009. TMF furnished approximately 5.5-milion pounds of fabricated steel. The rig was the world's largest land-based rig at the time of manufacturing and consisted of three large modules. The Drill Module was 58' W x 98' H x 68' L, weighing 900-tons. The Pipe Barn module was 158' W x 45' H x 170' L, weighing 2,560-tons. The Drill Service Module was 50' W x 48' H x 177' L, weighing 2,600-tons.

Pool Arctic Rig 6, North Slope, Alaska, USA [1998]

The Rig 6 project was a retrofit of the existing rig and included all new structural framing in addition to new mechanical components for the moving system. At the time of manufacturing, it was reported by the tire manufacturer to be the largest rubber tire vehicle in the world. Nicknamed 'Radio Flyer', this backbone of this rig is twin 6' x 10' box girders which support the drill floor and mast, and transfers load to the substructure.

Nordic Calista Rig 3, North Slope, Alaska, USA [1998]

In 1998, TMF completed and delivered Modular Mobile Oil Drilling Rig 3 to Nordic Calista. The rig includes 850-tons of fabricated steel, it measures 45' wide x 78' high x 110' long. The rig was transported by barge to the North Slope of Alaska.

Parker Drilling Rig 245, North Slope, Alaska, USA [1990]

In 1990, TMF fabricated a self-propelled mobile oil drilling rig. The drilling module was 43' wide x 78' high x 150' long and weighed 3,000-tons. The utility module was 40' wide x 58' high and 130' long, weighing 1,500-tons. The cutting module is 30' wide x 30' high x 40' L, weighing 350-tons. The completed drilling rig was transported by ocean-going barge from TMF's facility to the North Slope.

ConocoPhillips Milne Point, North Slope, Alaska, USA [1987]

3,400-tons of fabricated modular steel structures were supplied to ConocoPhillips. This took three ocean-going barge loads to deliver to Alaska.

ARCO Operation Center Housing Expansion, North Slope, Alaska, USA [1985]

Modular superstructures (40' W x 65' H x 80' L) were fabricated along with bases and decking housing modules. Completed modules were loaded onto a barge and transported direct to the North Slope.

Other Examples Include:

- Cook Inlet Monopod, Cook Inlet, Alaska, USA [1970's] *
- Kenai Refinery, Alaska, USA [1969] *
- Maintenance on California refining facilities
- Maintenance on Washington refining facilities

With a structural height of 126', this pile template for a monopod in the Cook Inlet (Alaska) is one of the largest structures to ship from the Columbia Business Center in the last 40-years. Thompson Metal Fab manufactured piling for this project, delivered in 2014.

Taken in the early 1970's, the photo above shows Thompson Metal Fab shortly after closing the original facility in Portland and moving to Vancouver. Thompson added fiberglass roofing and walls to bays 5 through 9 to create an enclosed space. The land has been developed quite a bit in the last 40-years (including improvements to the roll-on/roll-off barge slip), but the building remains virtually the same.

LOCAL BENEFIT & LOOKING AHEAD

Because of Thompson's 40-year reputation, logistical advantage and modern quality programs required, they have a distinct benefit. Loss of that logistical advantage due to a diminished shipping clearance (or other) is not something they could replace. Earning this business is a tremendous benefit to Thompson, their employees, and their local community. For example, any one rig project is equivalent to one year of revenues, in addition to hundreds of direct high wage jobs, as well as work for hundreds of local small businesses.

Due to the magnitude of work, contractors often mobilize to Vancouver to manage the construction. This includes management, engineers, and other personnel to ensure that projects are delivered on time. This staff of people stay long-term in local hotels, rent from local citizens, spend entertainment dollars with local small businesses, and are an economic benefit. They not only employ the staff at TMF, but they also employ local electricians, machinists, painters, millwrights, pipe fitters, hydraulic operators, boilermakers, sheet metal workers, and other trades. This work also supports various apprentice programs which train the next generation of trade workers. Loss of this total benefit cannot be replaced.

Local businesses see boosts in revenues when major job producing projects are brought to the Columbia Business Center. Due to the nature of these large projects, stakeholders often move management teams to Vancouver to oversee manufacturing.

History has shown us that building a new link between Vancouver and Portland will bond our communities together and provide opportunity for economic growth and expansion. We also see that there is a correlation between the bridge, the growth of our community, and Thompson Metal Fab. The need for large-scale fabrication remains and markets that require TMF's services show no sign of slowing. There is potential for an industrial rebirth, one that mimics the industrial expansion of the 1950's through 1970's. While it is yet to be seen at the time of this writing, the federal government will at some point pass an infrastructure spending bill, which intends to replace our aging and deteriorating bridges, dams, and other critical works. Just as building these original structures kept generations of people working, so will the effort to replace these structures.

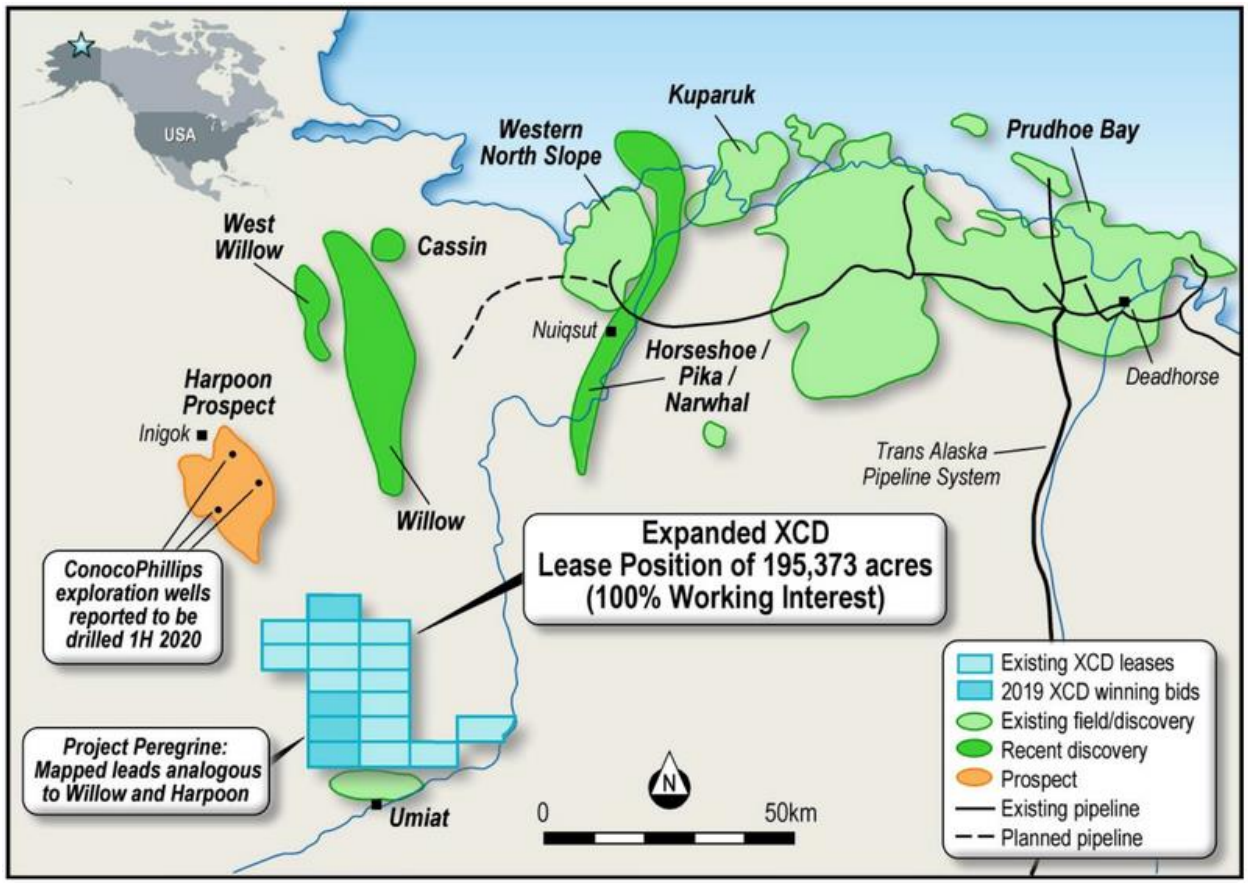
Thompson is encouraged by the commitment made to develop renewable energy sources. TMF has directly supported this effort for decades by manufacturing equipment that grows polysilicon crystals used in the development of solar panels. They have even been successful exporting domestically manufactured polysilicon equipment to countries such as China. Being a part of clean and renewable projects is something TMF does every day, thanks to the nature of their business. Steel is the most recycled material on Earth and steel products are 100% recyclable at the end of their useful life. Once produced, steel can be continually recycled into a new steel product without deterioration in product quality. Even the byproducts of steel work can be reused. Weld slag is used in cement, road construction, fertilizers, and hydraulic engineering. Process gasses are used to produce heat and electricity. Metal oxides can be recovered from steel making dust. Steel's inherent durability and recyclability make it an ideal fit for a circular economy. Allowing Thompson Metal Fab to continue producing steel products in the manner they do currently is a critical component in the continued development of clean energy and in effort to reduce America's carbon footprint.

As Thompson looks ahead to the future, they are currently tracking several projects and emerging markets which will certainly require a shop of their size and skill set. These projects will likely require delivery by barge and be of scale greater than or equal to what has been demonstrated. As noted, TMF has a competitive advantage with projects that require delivery by water and there is no other comparable, active facility with a roll-on/roll-off barge slip on the West Coast. Future opportunities include:

- ConocoPhillips – Willow expansion *(drill rigs, modules)*
- Oil Search – Pikka expansion *(drill rigs, modules)*

- Horseshoe Unit – Future North Slope Expansion *(drill rigs, modules)*
- Aerospace
- Offshore Wind and Wave power generators
- Burnside Bridge
- Golden Gate Bridge Seismic Retrofit
- West Coast Movable Bridges
- Hydroelectric Maintenance Projects
- Desalination in California
- Port of Nome - Expansion

Willow Expansion/Pikka Expansion/Horseshoe Unit



In many regards, the original Prudhoe Bay development has reached the end of its useful life. In 2020 original Owner, BP, sold their Prudhoe rights to ConocoPhillips and Hilcorp. Hilcorp is renowned for their ability to acquire 'legacy wells' and get a high level of production thanks to their ability to match modern technology with lean processes. What bigger companies might steer away from or flat out abandon due to high overheads, Hilcorp (a smaller independent company) can come in and still make profits for many years. The sale of Prudhoe and acquisition by Hilcorp signals the end of an era at Prudhoe, but it also marks the beginning of Alaska's next chapter in oil production.

In 2016, discovery wells were drilled in the Willow unit, owned by ConocoPhillips. The Willow unit is immediately west of Prudhoe and other large operating units but is on land that is largely under-developed. During the expansion of Prudhoe Bay facilities were tied into one another (Alpine, Kuparuk, Oooguruk, Milne Point, North Star, Endicott), man camps often shared, and roads and bridges integrated into one logistical network. Willow is far enough outside of this integrated network that relying on the existing infrastructure to support further expansion is not feasible. New piping systems would be needed, new roads would be required, new processing modules installed, and essentially a 'mini Prudhoe' would need to be built from scratch. After a successful exploration and appraisal season in 2018 it is estimated that Willow could contain up to 750-million barrels of oil and the infrastructure that would support Willow could produce approximately 100,000 barrels per day. Assuming full production each day of the year, Willow would be 'on-line' for 20-years.

This massive process module is being loaded out for delivery to the North Slope of Alaska in July 1990. This industrial equipment rivals the size of most downtown buildings and is representative of the equipment currently being requested for North Slope expansion projects. Due to scale and complex nature of work, this sort of equipment cannot be manufactured at the remote jobsite or accomplished at all in Alaska.

This massive process module is being loaded out for delivery to the North Slope of Alaska in July 1990. This industrial equipment rivals the size of most downtown buildings and is representative of the equipment currently being requested for North Slope expansion projects.

Flanked by existing units, Alpine and Kuparuk, sits Pikka. The Pikka unit is part of the Nanushuk Field which is estimated to hold as much as 1.5-billion barrels of oil. This is considered to be the biggest conventional onshore oil discovery in the US in the last 30-years. Upon full development, it is anticipated that Pikka will produce 120,000 barrels per day, and on some accounts up to 160,000 barrels per day. Conservatively, there is enough oil here to keep Pikka online for nearly 35-years.

Like Willow, there's just no infrastructure in Pikka despite being sandwiched by two existing fields. Early planning on Pikka included budgetary Requests for Proposal which were submitted by Pikka's Owner, Oil Search. One RFP requested multiple modules nearly 80' H x 200' L x 80' W, a fairly typical example of the infrastructure which is required.

Finally, early testing has been going on in the Horseshoe unit of the North Slope (south of the Willow and Pikka unit) and early indication is that Horseshoe will also be a high volume area, with volume of over 1-billion barrels. Combined with Willow and Pikka, the makings of a modern day Prudhoe Bay is in the works and could be a generational project.

Aerospace

Vandenberg Air Force Base is home to the US Air Force, United Launch Alliance, Space X, and now home of the Space Force, a branch of the US Air Force. Blue Origin is looking at Vandenberg as well and this will produce new opportunities for launch facilities. The western range is advantageous and continues to serve the needs of the industry. All these groups are getting a boost from "REACH" (Regional Economic Action Coalition). Currently, Vandenberg has the only Space Launch Complex (SLC) to launch for polar orbit. The Cape is working on a program for this, but currently the capability does not exist.

(Report from 'REACH' available for online viewing at https://reachcentralcoast.org/wp-content/uploads/Phase-0-Report.pdf)

Excerpt from the referenced report:

"Driven in large part by commercial enterprises, space is now a $425-billion industry that's expected to grow to $3-trillion over the next three decades…It's a huge opportunity and why REACH adopted building a thriving space enterprise as a core initiative in our 2030 plan."

This bold plan by the State in collaboration with all the stake holders will result in the construction of new facilities to support launch efforts at Vandenberg. Launch towers and/or mobile assemble buildings will be major projects that will require work on very large structures within this decade. The work on these facilities in the past been done by NW Oregon/SW Washington fabricators – including Thompson Metal Fab. This work requires facilities with large yard areas and heavy fabrication capabilities as well as a barge loading facility that is capable of supporting ocean going barges. There are very few of these types of facilities on the West Coast. The Columbia Business Center is one of those few spaces and represents a location that has both barge loading capabilities and the manufacturing capacity through groups like Thompson Metal Fab.

Pictures from Space Launch Complex-6 on April 26, 2021 show before and during launch of United Launch Alliance Delta IV Heavy rocket carrying a classified spy satellite. The launch table was manufactured by Thompson Metal Fab and delivered to the jobsite in 2003.

Past work in California dating back to the 1960's has been done at the Columbia Business Center. Jacket Liners for the Santa Barbara oil field were built at this location. Work for both Space Launch Complex 3 (SLC 3) and SLC 6 were done at Columbia Business Center. Much of this work required a full bridge raise to facilitate passage of the cargo on board a barge.

In addition to this planning at Vandenberg, Space X is now under contract for two more launches from there.

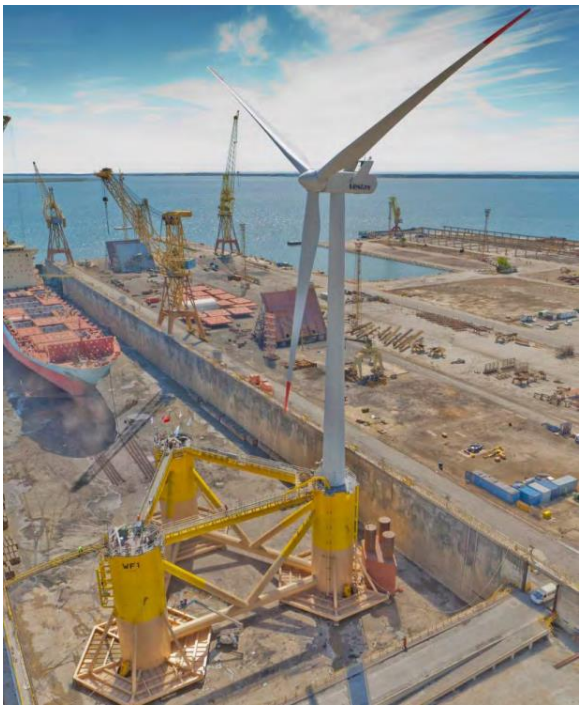
(https://www.noozhawk.com/article/defense_department_awards_contract_to_spacex_for_2_vandenberg_afb_launches)

Excerpt from NOOZHAWK Santa Barbara:

"The Department of Defense awarded Space Exploration Technologies a pair of missions that will involve two rocket launches from Vandenberg Air Force Base for the military's next-generation of space-based tools for warfighters….The announcement in the final hours of 2020 put the firm-fixed-price contract cost for SpaceX at $150,450,000…The first launch will occur in September 2022, and the second mission will take place no later than March 31, 2023, to complete putting the constellation in space, according to the award by the Space Development Agency in Washington, D.C."

SpaceX and United Launch Alliance have been awarded a 40%/60% split for launching DOD payloads. This award was made in August of 2020. For work at Vandenberg, SpaceX will have to add the capability of vertical integration of DOD payloads. This will require Space X to build a Mobile Service Tower (MST) or a similar structure to facilitate vertical integration of their vehicles. Currently SpaceX does all integration horizontally, installing satellites and rockets onto Falcon 9 and Falcon Heavy inside hangars near the company's launch pads. But some of the of the US Government's most sensitive and expensive intelligence-gathering satellites are designed to be mounted on their launch vehicles vertically. SpaceX officials have indicated that vertical integration capability is required of participants in the National Security Space Launch Phase 2 Launch Service Procurement.

Offshore Wind and Wave



Currently there are no independent organizations/companies willing to make the upfront investment into this emerging market. The land based wind industry grew because of federal tax credits that made it profitable, and without federal assistance it is unlikely that offshore systems will get the boost needed.

Recently, the administration under President Biden cited their plan to expand the use of off-shore wind farms in effort to develop renewable energy sources. The goal of the Biden Administration is to increase capacity of the current off-shore systems to power 10-Million homes by the year 2030. To meet that target, the administration intends to accelerate the permitting of projects along the coastlines and to open waters for development. $3-Billion in federal loan guarantees are available for offshore wind projects and for investing in the nation's port properties to support wind construction.

Mirroring this goal to develop offshore wind energy, the states of California and Oregon have introduced bills to develop wind energy along their coastlines. California bill AB525 sets a goal of 10GW of offshore wind by 2040,

3GW of which to be established by 2030. Oregon's HB3375 also sets a goal of 3GW by 2030. Oregon's effort is sponsored by a Republican (Rep. David Brock Smith) who has positioned the states bill as an opportunity to stimulate economic development and resiliency.

Currently there is not a facility on the West Coast that is set up to assemble these massive offshore wind systems. Thompson Metal Fab certainly has the capacity to manufacture the floating bases, and the facility/space to receive the wind towers and turbines. We also have the space to perform all assembly required. All opportunity to participate with this emerging market is gone however if the new bridge is not at a suitable height. Our current plan to participate with this emerging market is to manufacture the bases at TMF and float them downstream to a satellite yard where the towers and turbines can be assembled and installed on our bases. With that plan in place, we can utilize our current facility for all the heavy manufacturing, and provided that we are not impacted by the height of the I-5 bridge, we can ship these structures to wherever the assembly yard is located. The Biden administration keys in on one important factor, most coastal port properties are not currently set up to handle this massive manufacturing and investment in the properties must be made.

Most of the current facilities manufacturing offshore structures are on the American East Coast, or in the Gulf. Even though these facilities have the capacity, they are not well positioned to support the manufacturing of offshore systems for the West Coast. To reach the West Cost, all cargo must travel through the Panama Canal and the distance associated with voyage makes the transportation very expensive and further defines the reason why developing a manufacturer on the West Coast is so important.

Figure A-20 Vancouver

Image above comes from BOEM report in 2016 which evaluates various sites on the West Coast that would be suitable for the development of offshore wind power manufacturing. The far right shows the Columbia Business Center, and predominantly in middle is Thompson Metal Fab.

Thompson Metal Fab is one of possibly two manufacturers on the West Coast who has the size of facility, yard space and direct access to water to make our company a very attractive option for full-scale manufacturing of offshore systems. When you look at the total capacity of the Columbia Business Park, there is more than enough space and infrastructure to use our location in a dynamic way. If the new bridge does not at least accommodate this emerging market, it will be very difficult to develop the required infrastructure at all on the West Coast. Let us not lose what we currently have.

On March 3rd, 2016, the Bureau of Ocean Energy Management published a 256-page report that names the Columbia Business Park as a viable option for manufacturing offshore wind systems, but also notes that if the new height of the I-5 bridge is lowered below its current air gap it will severely restrict this type of manufacturing for any facility that is upstream of the bridge (i.e. Thompson Metal Fab).

To download a PDF file of the Environmental Studies Program report, go to the US Department of the Interior, Bureau of Ocean Energy Management, Environmental Studies Program Information System website and search for OCS Study BOEM 2016-011.

Images above comes from the 2016 BOEM report which shows the manufacturing and shipping capabilities of the Columbia Business Center for the wave power industry.

Burnside Bridge

The Burnside Bridge is scheduled for start of construction in 2024. There are two alternatives to the movable portion of the bridge: Replace the existing double-leaf bascule bridge with a vertical lift bridge – or – replace the bridge with a modern double-leaf bascule. The replacement of the approaches is difficult and would be best with a long span alternative. The option of a Tied-Arch, Cable-Stayed or Truss Span is attractive.

Image above shows the Sauvie Island Bridge being shipped to the jobsite via barge on the Willamette River and passing under the Burlington Northern RR Bridge in Portland, OR. Delivery of steel for the new Burnside Bridge would take a similar approach, due to the limited area for construction at the jobsite in downtown Portland, OR. Bridge steel coming from the Columbia Business Center would pass under the Interstate Bridge to reach the jobsite.

Due to congestion at the job site, moving the major spans into place will be done by water. Similar work has been done in the past on the Freemont Bridge, Sauvie Island Bridge and Sellwood Bridge.

Golden Gate Bridge Seismic Retrofit

The Golden Gate Bridge has an upcoming project that is one of the largest projects on a single bridge that is not new construction. The iconic towers on the Golden Gate Bridge will be retrofitted in addition to the deck steel between the two towers. This project was due to be completed by 2024 but has been delayed by other projects *(currently scheduled to be complete in 2023)*.

West Coast Movable Bridges

California has 36 movable (non-railroad) bridges. Of that group, four are in poor condition and 25 are in fair. Replacement will be recommended for some of these bridges and most will be shipped to the job-site by barge.

Oregon has the previously mentioned Burnside Bridge coming up. Additionally, the Rose Quarter Improvement project which will include the manufacturing of major steel spans.

Washington has 51 movable bridges (non-railroad). 10 are in poor condition and 34 are in fair condition. These bridges will be slow to replace due to budget issues but most of the poor condition bridges will be replace.

Hydroelectric Maintenance Projects

The current 2021 (fiscal year) budget work plan for the US Army Corps of Engineers is $2.7-Billion. Much of this work will be on the Columbia River system. Applicable work for TMF is as follows:

<u>Portland District</u>

- Bonneville Dam
    - Powerhouse 2, 65-Ton Tailrace Gantry Crane Replacement
    - Headgate Repair Pit Rehab
    - Powerhouse 1 Trash Racks
    - Fish Guidance Efficiency
- John Day Dam
    - Navigation Lock Downstream Gate Bearing Shoe Replacement
    - Trash Racks Replacement
- Cougar Dam:
    - Spillway Gate Rehab
    - Butterfly Valves

- Foster Dam:
    - Oil Spill Prevention
    - Oil Water Separator
    - Fish Weir Follow-on
- Detroit Dam:
    - Spillway Gate Rehab
- Dexter Dam:
    - Trash racks
    - Intake Gates
    - 25-Ton Intake Gantry Crane Replacement
- Green Peter Dam:
    - 180-Ton Bridge Crane Rehab
- Big Cliff Dam:
    - 40-Ton Intake Gantry Crane
    - Trash Racks and Gates Rehab

Seattle District

- Libby Dam
    - 75-Ton Intake Gantry Crane Rehab
- Albeni Falls Dam
    - Turbine Maintenance Platform
- Chief Joseph Dam
    - Intake Gates Rehab or Replacement
    - Turbine Maintenance Platform
    - 50-Ton Intake Gantry Crane Rehab
    - 18-Ton Tailrace Gantry Crane Rehab

Walla Walla District

- Ice Harbor Dam
    - Intake Gate Hydraulic System Upgrades
- Lower Monumental Dam
    - Turbine Maintenance Platform
- Lower Granite Dam
    - Turbine Maintenance Platforms

Desalination in California

California is always in a water crisis. They have new reservoirs planned that will require outlet works, gates, etc. Most of this work will ship by truck/train, but shipping over the water (by barge) will be the modular structures for new equipment in the planned Desalination facilities that California needs to sustain the population growth.

30-miles north of San Diego is the Claude "Bud" Lewis Carlsbad Desalination Plant, the largest effort in North America to turn salt water into fresh water. Each day 100-million gallons of seawater are pushed through semi permeable membranes to create 50-million gallons of fresh water that is piped to municipal users. Carlsbad, which became fully operational in 2015, creates about 10% of the fresh water the 3.1-million people in the region use, at about twice the cost of the other main source of water. This is a real issue for California and will require the state to build more of these desalination plants.

Wartime Efforts

Henry Kaiser's Vancouver Shipyard, shown in development in 1942. Eventually becoming the Columbia Business Center, this facility would become a strategic West Coast manufacturing facility.

It is important to plan for the unforeseen as well. Contingency comes in many forms; but let us not lose sight of the reason why the facility exists to begin with. Kaiser built the facility as part of the war effort in WWII. Because of the shipping clearances allowed when the drawbridge was at full height, the Vancouver Shipyards could produce Liberty and Victory war ships despite being upstream from the bridge. If that height is impacted by a fixed structure at a *lower* clearance, the ability for Thompson to support major wartime efforts is certainly diminished especially when compared to the capacity we could offer today. As noted previously, we are one of only a handful of facilities on the West Coast who has facility large enough to manufacture the structures we do and ship over the water. Reducing shipping clearances will certainly limit Thompson's ability to be a strategic West Coast manufacturer if a major wartime event occurs.

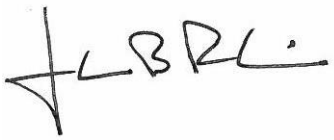
IN CLOSING

Thompson Metal Fab supports the new Interstate Bridge Replacement project. The region has outgrown the capacity of the current span and a new bridge is needed to reflect current and future needs. Innovations in transportation have changed the way people travel and move goods since 1917; and modern engineering, materials, manufacturing, and construction should allow for a beautiful, robust structure that will serve the needs for future generations. Currently the lift span on the Interstate Bridge is 178' at maximum clearance, any reduction

on a new span will have significant impact on TMF's industrial competitiveness. Less clearance will inhibit Thompson's ability to attract job-producing industrial projects to the region. Lower bridge clearance will also cause constraints for current and future energy infrastructure needs where TMF is counted on to be a major supplier to energy producers. Impacts to clearance could also affect the development of renewable energy sources, such as offshore wind. A facility, like that at Thompson Metal Fab in the current configuration, will be critical in the success of offshore wind programs on the West Coast. Additionally, users such as the US Army Corps of Engineers, will be impacted as they depend on TMF to deliver structures by barge to support our region's dams and ports East of I-5.

We recognize a new Interstate Bridge replacement needs to meet the requirements of all modern and future modes of transportation, and that requirement will most likely impact our historical, current, and future usage of river transit. However, Thompson also recognizes the importance of a new, safe, and modern bridge to the region, and is willing to work with the Interstate Bridge Replacement project team to preserve Thompson Metal Fab and hundreds of family wage jobs, while at the same time advancing a much needed new bridge to the future.

Sincerely,



John B. Rudi
Owner/President
Thompson Metal Fab

Clearance information assumes Zero (0) Datum. The Columbia River is typically 3' to 7' higher than Zero Datum. That measurement is not reflected in the example below. River height may significantly reduce the lift span clearance when seasonal river flows are above zero datum levels.*

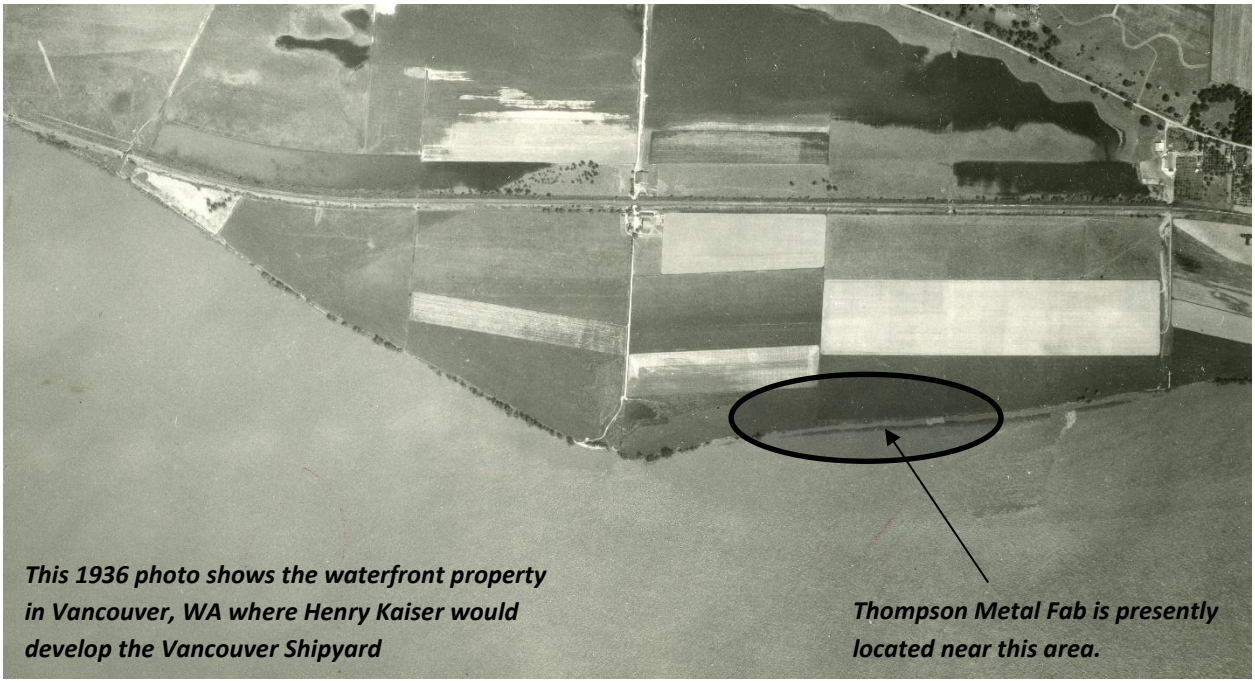
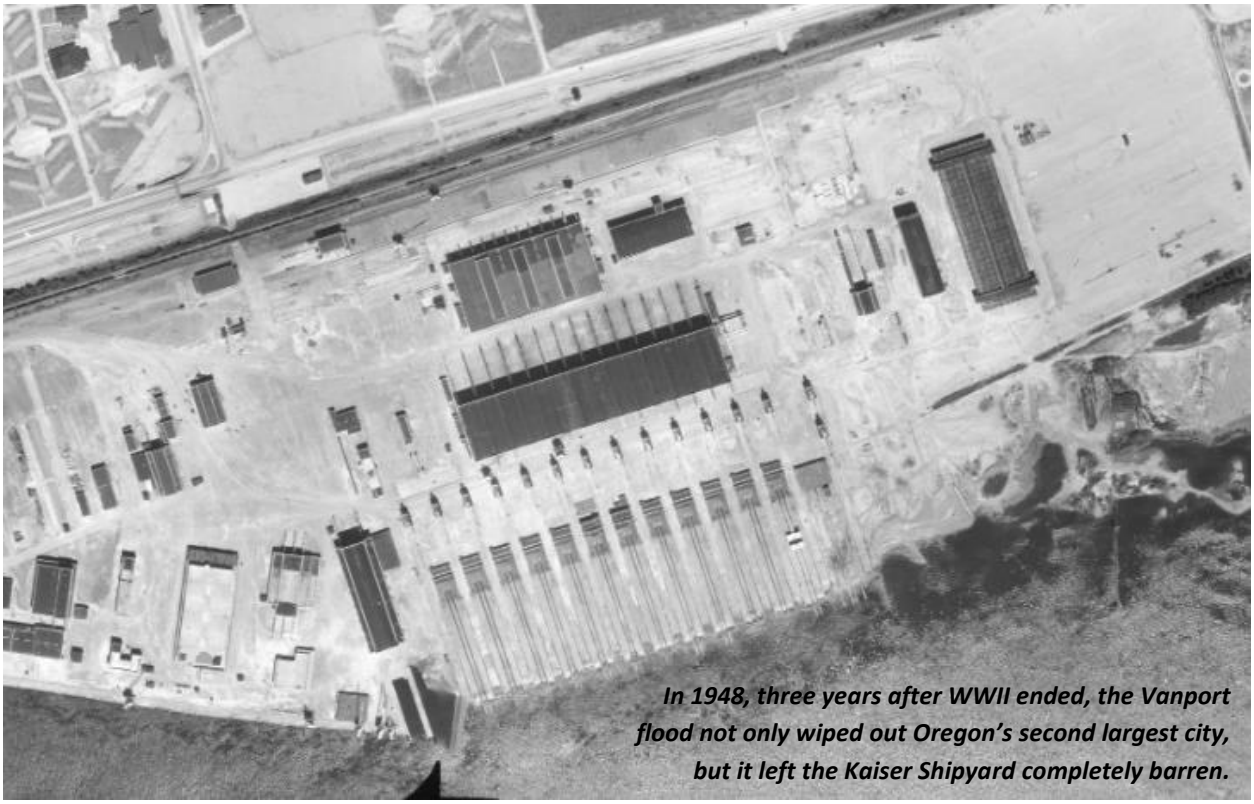
Bridge to be opened at Captain's discretion for loads under 72' high.



This 1936 photo shows the waterfront property in Vancouver, WA where Henry Kaiser would develop the Vancouver Shipyard

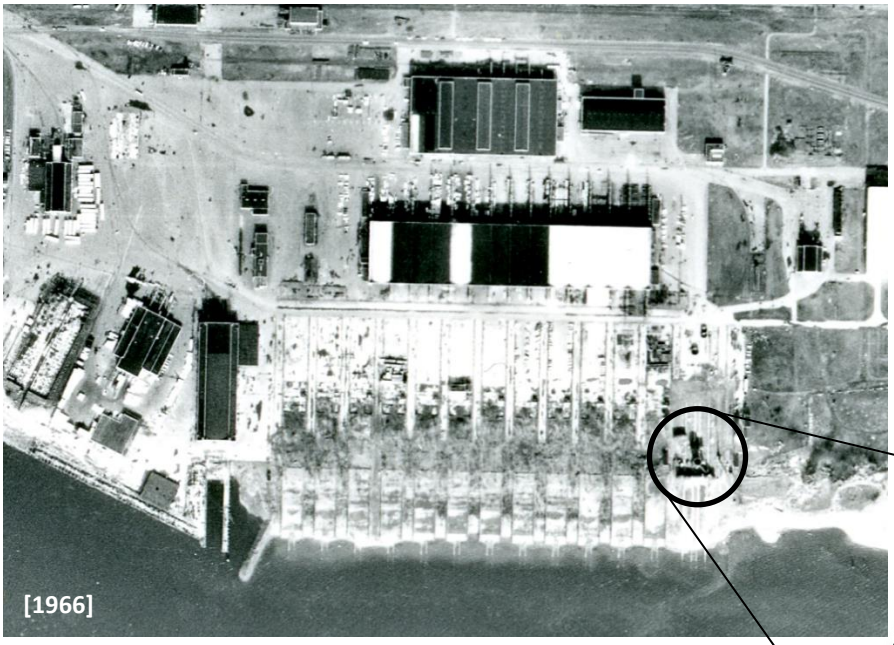
Thompson Metal Fab is presently located near this area.

In just a few years nearly 200-acres was redeveloped, providing Vancouver a major industrial waterfront facility. An active Kaiser Shipyard is shown here in 1943



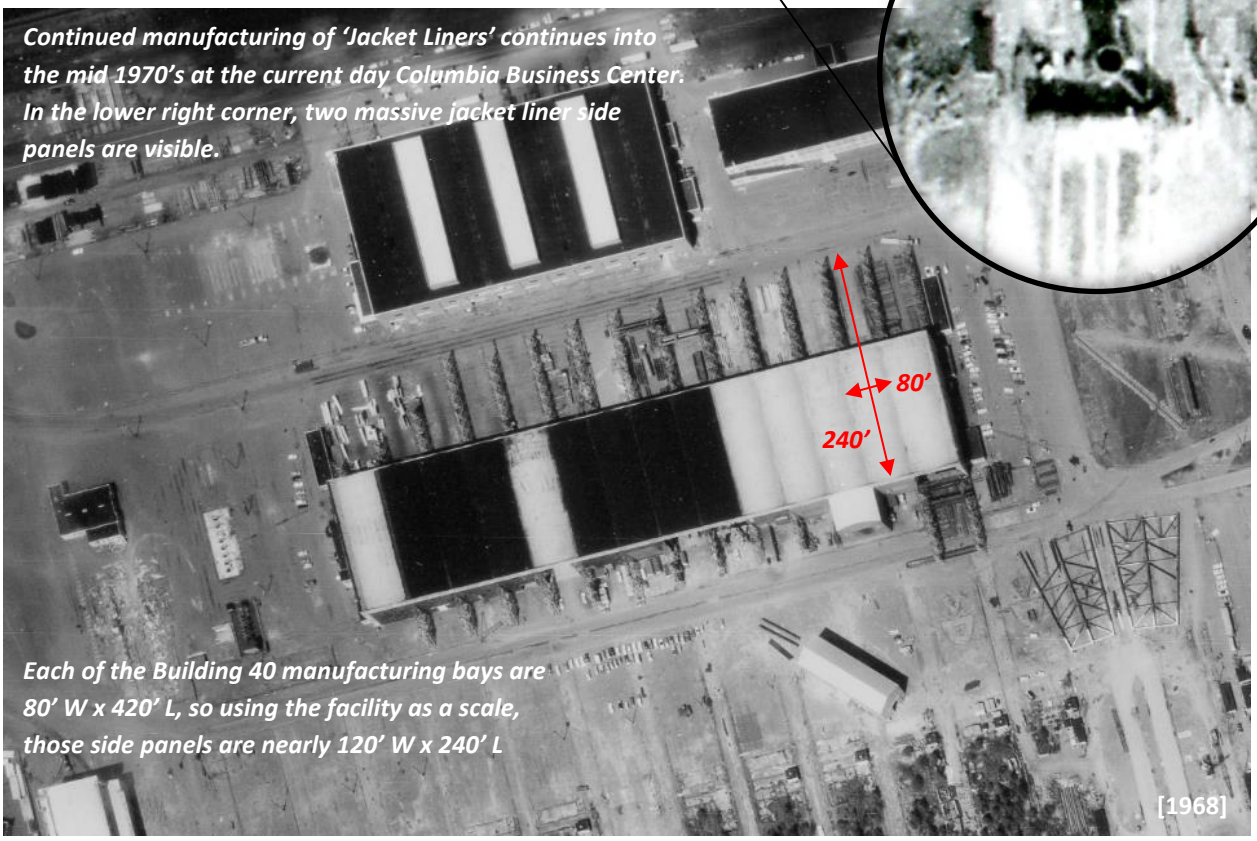
In 1948, three years after WWII ended, the Vanport flood not only wiped out Oregon's second largest city, but it left the Kaiser Shipyard completely barren.

By 1956, the facilities at the current Columbia Business Center are in full operation once more, leveraging the capacity to support the industrial needs of the time.



[1966]

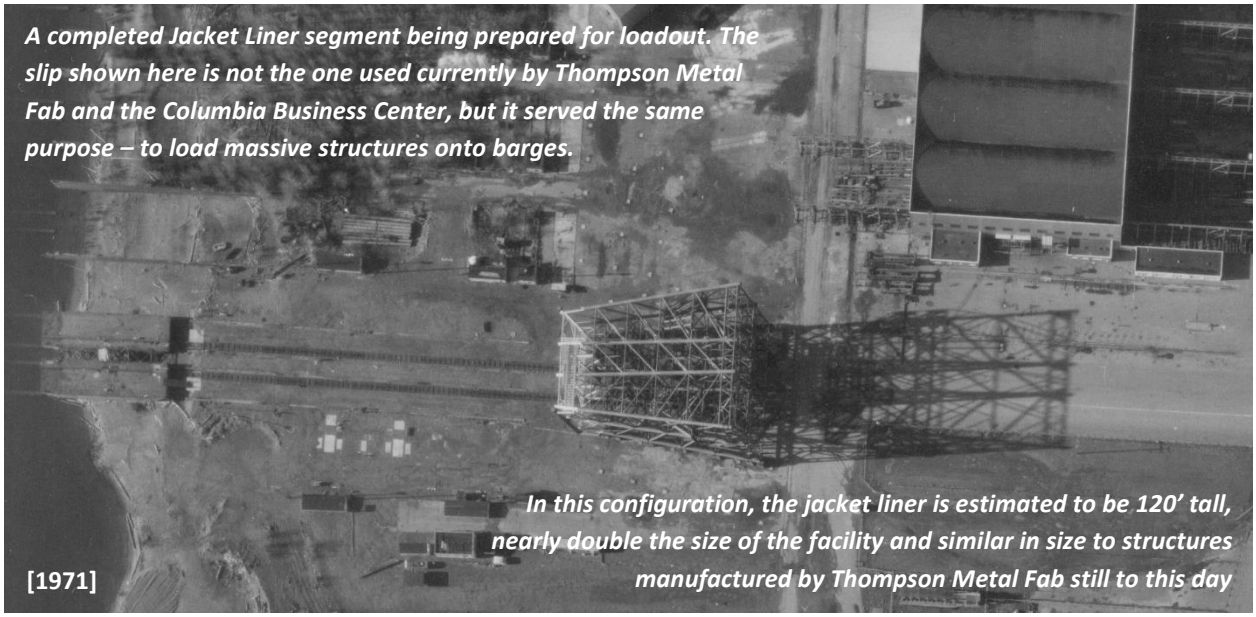
The development of offshore oil in California required the fabrication of massive infrastructure. Typically, offshore oil fabrication is done in the Gulf states, but with major oil production now on the West Coast those Gulf state areas could not lend support and a West Coast facility was required.



Continued manufacturing of 'Jacket Liners' continues into the mid 1970's at the current day Columbia Business Center. In the lower right corner, two massive jacket liner side panels are visible.

Each of the Building 40 manufacturing bays are 80' W x 420' L, so using the facility as a scale, those side panels are nearly 120' W x 240' L

[1968]



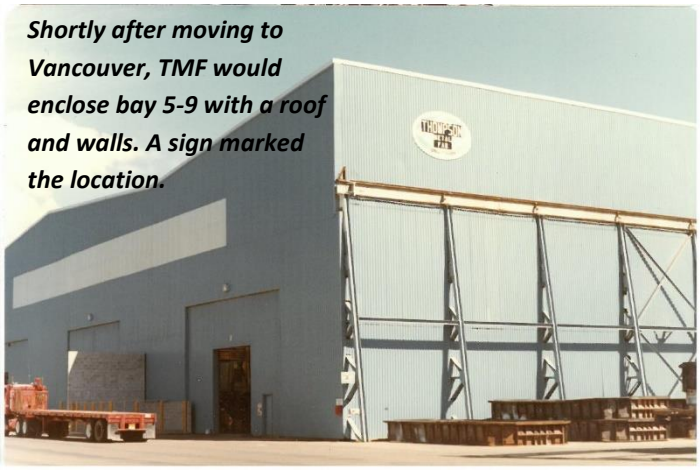
A completed Jacket Liner segment being prepared for loadout. The slip shown here is not the one used currently by Thompson Metal Fab and the Columbia Business Center, but it served the same purpose – to load massive structures onto barges.

In this configuration, the jacket liner is estimated to be 120' tall, nearly double the size of the facility and similar in size to structures manufactured by Thompson Metal Fab still to this day

[1971]

Roofing being extended to Building 40, Bay 10-12 (current Thompson Metal Fab).

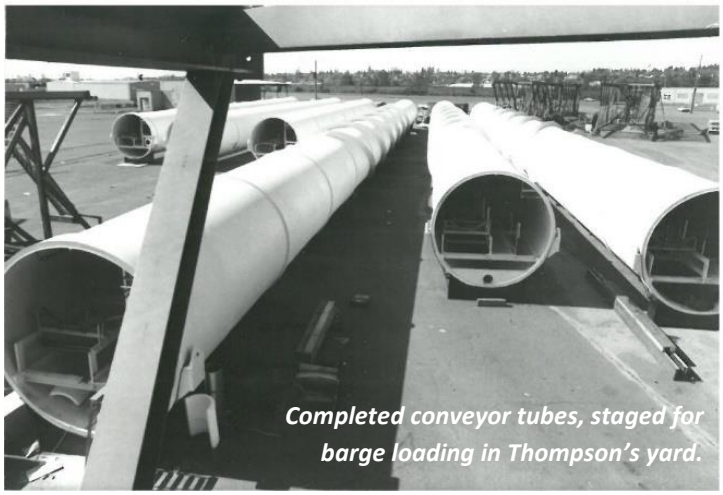
TMF Project Managers, early 1970's



Shortly after moving to Vancouver, TMF would enclose bay 5-9 with a roof and walls. A sign marked the location.

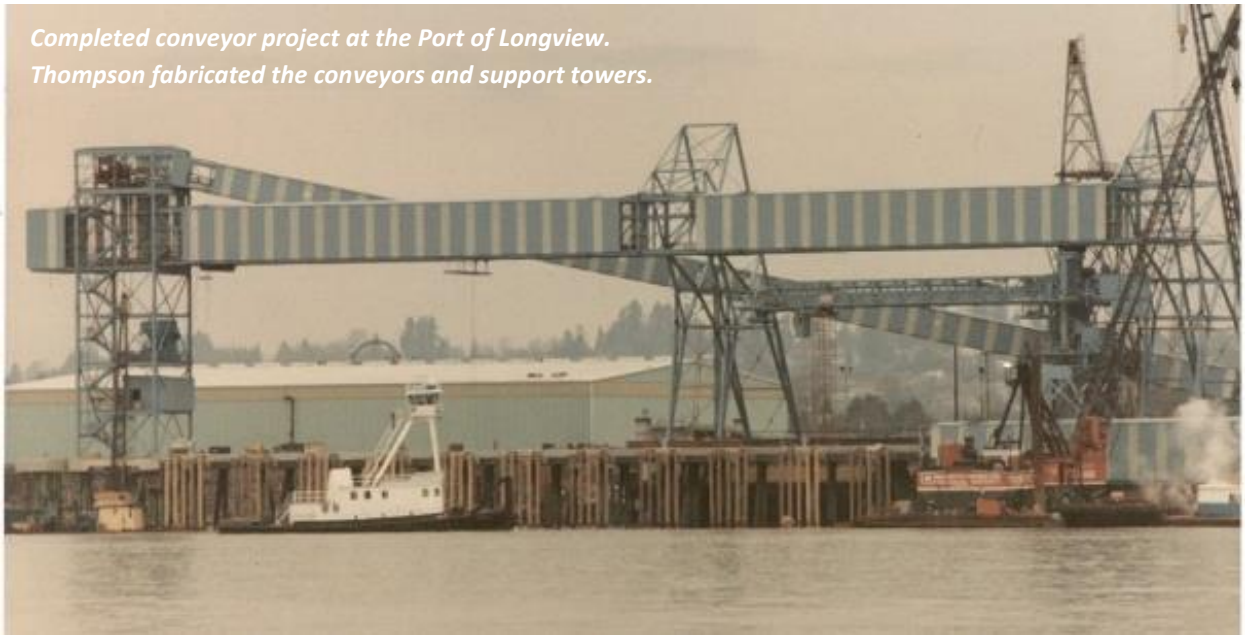
At 300' long, this conveyor nearly takes up the entire length of a bay at TMF

A barge is being loaded with conveyors for delivery to Bay Area, CA

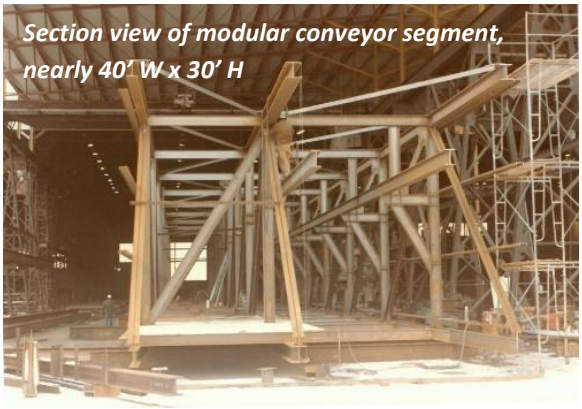


Completed conveyor tubes, staged for barge loading in Thompson's yard.

Conveyor systems and support towers were a major part of Thompson's first few decades at the Columbia Business Center. TMF's barge slip allowed for massive, modular deliveries to Ports, pulp & paper factories, and other industrial areas.



Completed conveyor project at the Port of Longview. Thompson fabricated the conveyors and support towers.



Section view of modular conveyor segment, nearly 40' W x 30' H

Conveyor being loaded on barge at Thompson Metal Fab.

There are numerous Ports on the Columbia River with large, developed properties and robust industrial activity. These Ports are critical to our region and are the hub for most incoming goods.

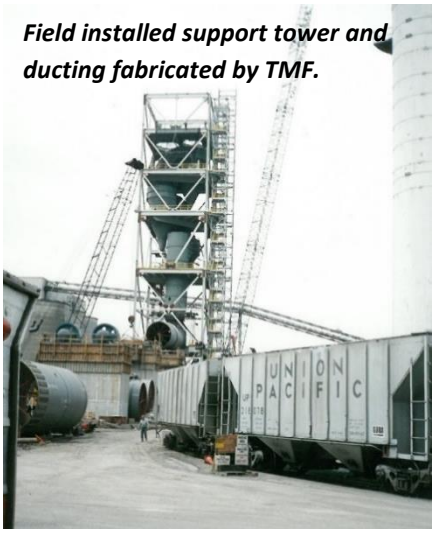
Conveyor systems are often used at Ports to quickly handle and transfer bulk materials. Thompson Metal Fab manufactured and delivered the massive conveyor system and support towers shown here and delivered to the Port of Longview.

Modular structures were loaded on a barge and erected in the field. Delivering modular units allows for quicker assembly in the field and easier integration of all mechanical components.

Conveyors come in many shapes and sizes, depending on the intended use. Shipping the structures pre-assembled saves on time and money in the long-run and is a value-add for Owners and other stakeholders. Shown here are additional examples of projects that were manufactured by Thompson and delivered all over the West Coast, from Toledo, OR to Sacramento, CA.

Heavy ducting for baghouses requires a facility like Thompson's. They can accommodate the size of the infrastructure in their shop and ship over the water by barge. The large duct section shown here is nearly 30' high and over 100' long.

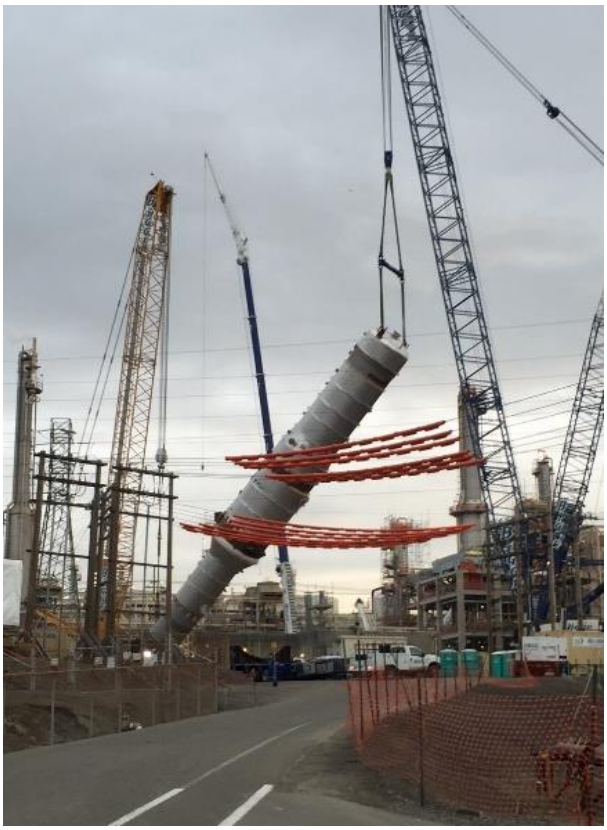
Structural tower inside Thompson's shop being outfitted with piping and ducting systems. This tower is well over 30' high.



Field installed support tower and ducting fabricated by TMF.

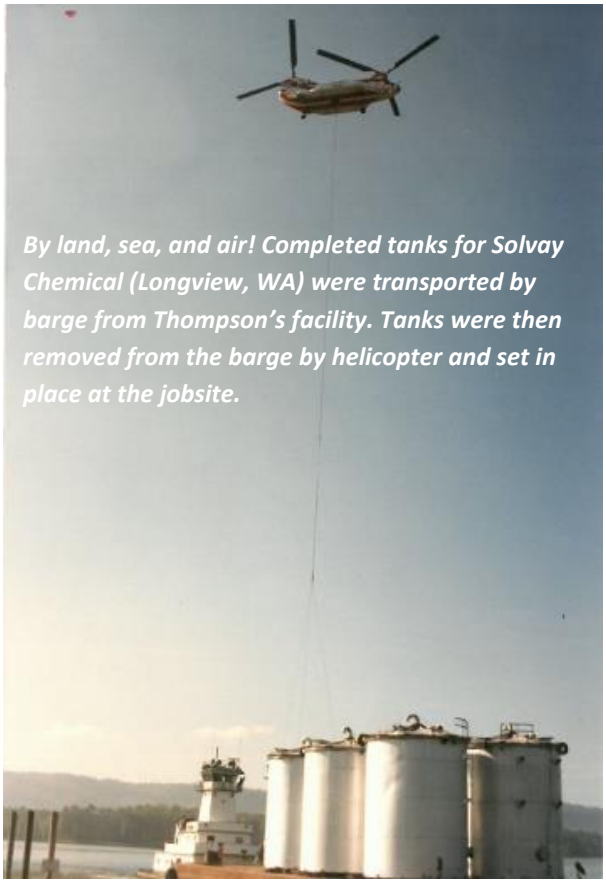
Baghouse components being loaded on a barge from Thompson Metal Fab's facility

Nearly touching the rafters, this giant structural building will soon be outfitted with mechanical items prior to load out on the barge. The size of Thompson's facility provides value to project owners who seek out modular, turn-key solutions for their infrastructure needs.



Refineries on the West Coast are typically located on coastal properties or are otherwise accessible by deep water ports. In addition to capacity expansion and improvements, these facilities have processing vessels and other equipment that wear out over time and need to be replaced.

Shown here at the Phillips 66 facility in Rodeo, CA, Thompson Metal Fab fabricated a "prefractioner" tower which was 17' diameter x 126' L. Too large and heavy to ship over the road, this vessel was delivered by barge and direct to the jobsite.

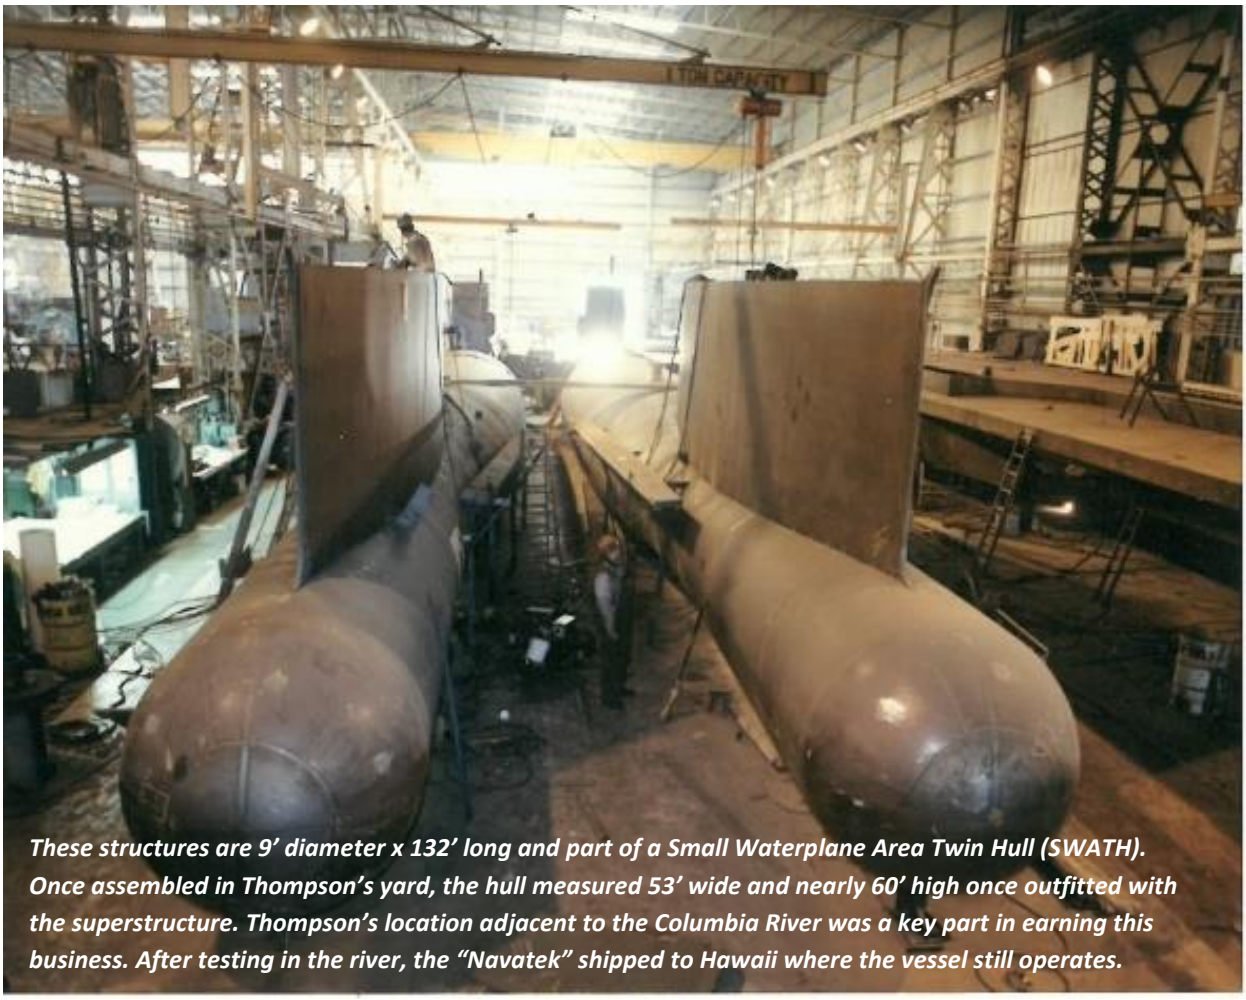


By land, sea, and air! Completed tanks for Solvay Chemical (Longview, WA) were transported by barge from Thompson's facility. Tanks were then removed from the barge by helicopter and set in place at the jobsite.

Process vessels and skids are being loaded on a barge from Thompson Metal Fab's facility. This load will be delivered to Alaska and used on the North Slope. These units are well over 20' and 40' long.

Large tanks for Amalgamated Sugar in Portland, OR. The tanks are used as part of their manufacturing process. Due to the size of the tanks, they were shipped by barge and then transloaded to a truck for final delivery.

Trunnions for the Interstate Bridge shown above in Thompson's shop. Their proximity to the bridge made TMF an ideal location when repairs were needed. Shown below are two Seattle area bridge projects that were completed at the Columbia Business Center, painted by TMF, and delivered to the jobsite by barge.



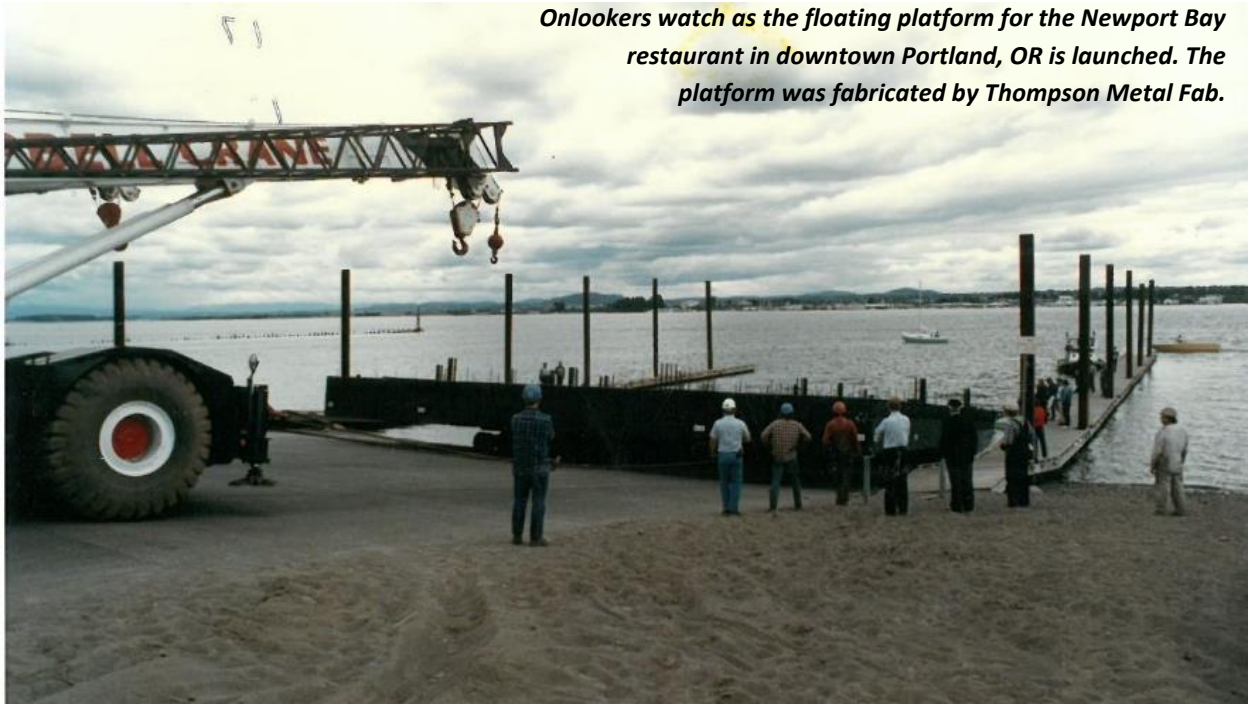
These structures are 9’ diameter x 132’ long and part of a Small Waterplane Area Twin Hull (SWATH). Once assembled in Thompson’s yard, the hull measured 53’ wide and nearly 60’ high once outfitted with the superstructure. Thompson’s location adjacent to the Columbia River was a key part in earning this business. After testing in the river, the “Navatek” shipped to Hawaii where the vessel still operates.

Barge load approaching the Interstate Bridge after leaving Thompson Metal Fab. TMF's massive facility is seen in the background.

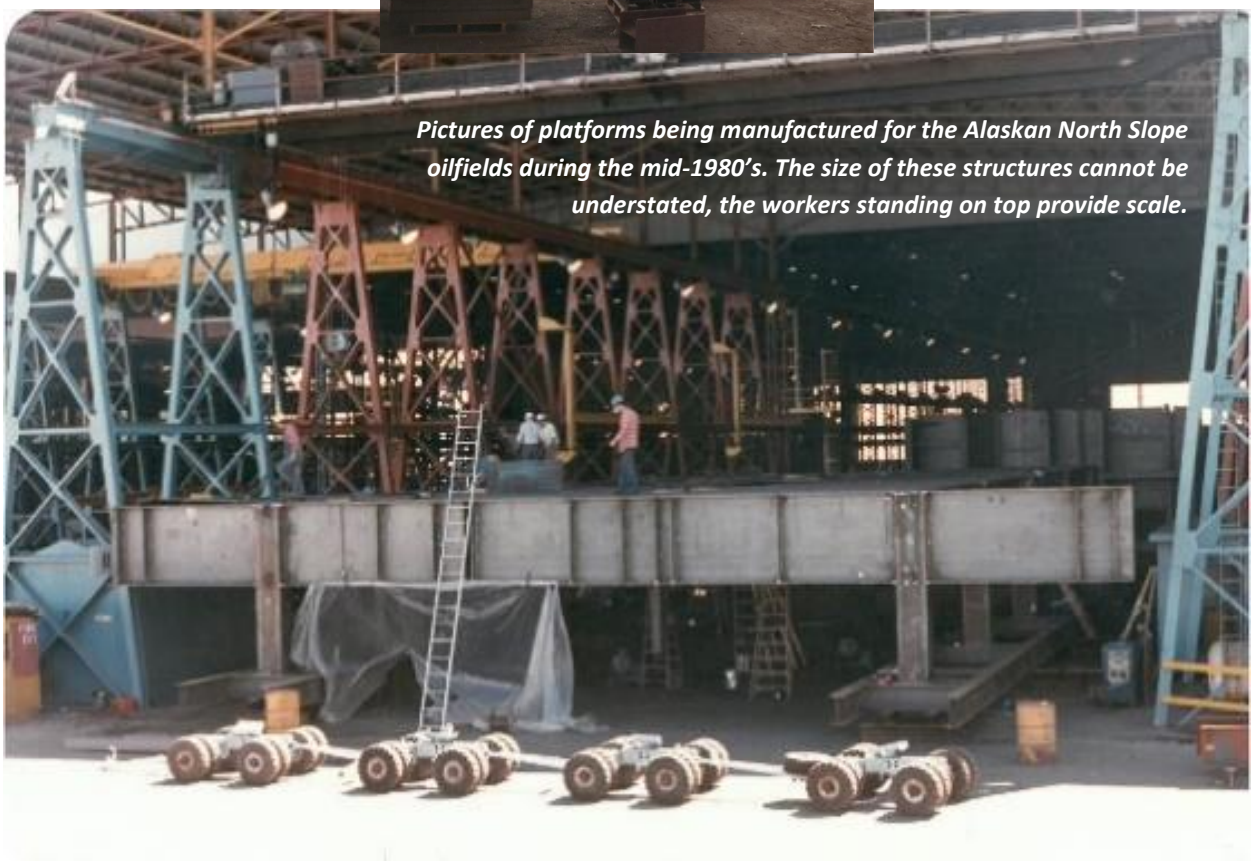
Shown above and below is a modular segment of the Power Barge fabricated by TMF. Segments were pre-fabricated in the shop before being assembled in Thompson's yard. The final assembly was 105' W x 30' H x 284' L

At left, large platform is being flipped inside Thompson Metal Fab's shop.

Thompson Metal Fab has a legacy of fabricating unique, complex, and often massive structures which require delivery by water.



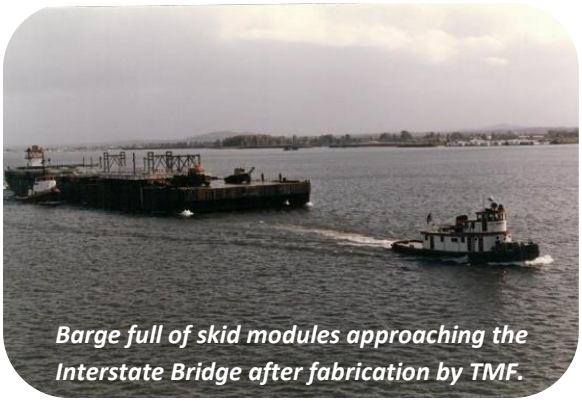
Onlookers watch as the floating platform for the Newport Bay restaurant in downtown Portland, OR is launched. The platform was fabricated by Thompson Metal Fab.



Pictures of platforms being manufactured for the Alaskan North Slope oilfields during the mid-1980's. The size of these structures cannot be understated, the workers standing on top provide scale.

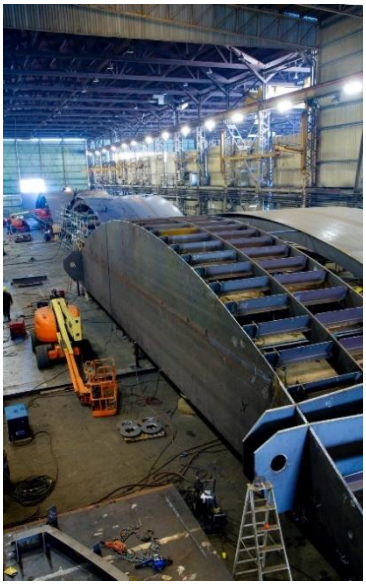
Shown below, load out of the cradle base that would carry PGE's Trojan nuclear reactor. TMF fabricated the base and the shielding enclosures.

Support towers nearing the Interstate Bridge. This load is headed for the Port of Sacramento upon completion at Thompson Metal Fab

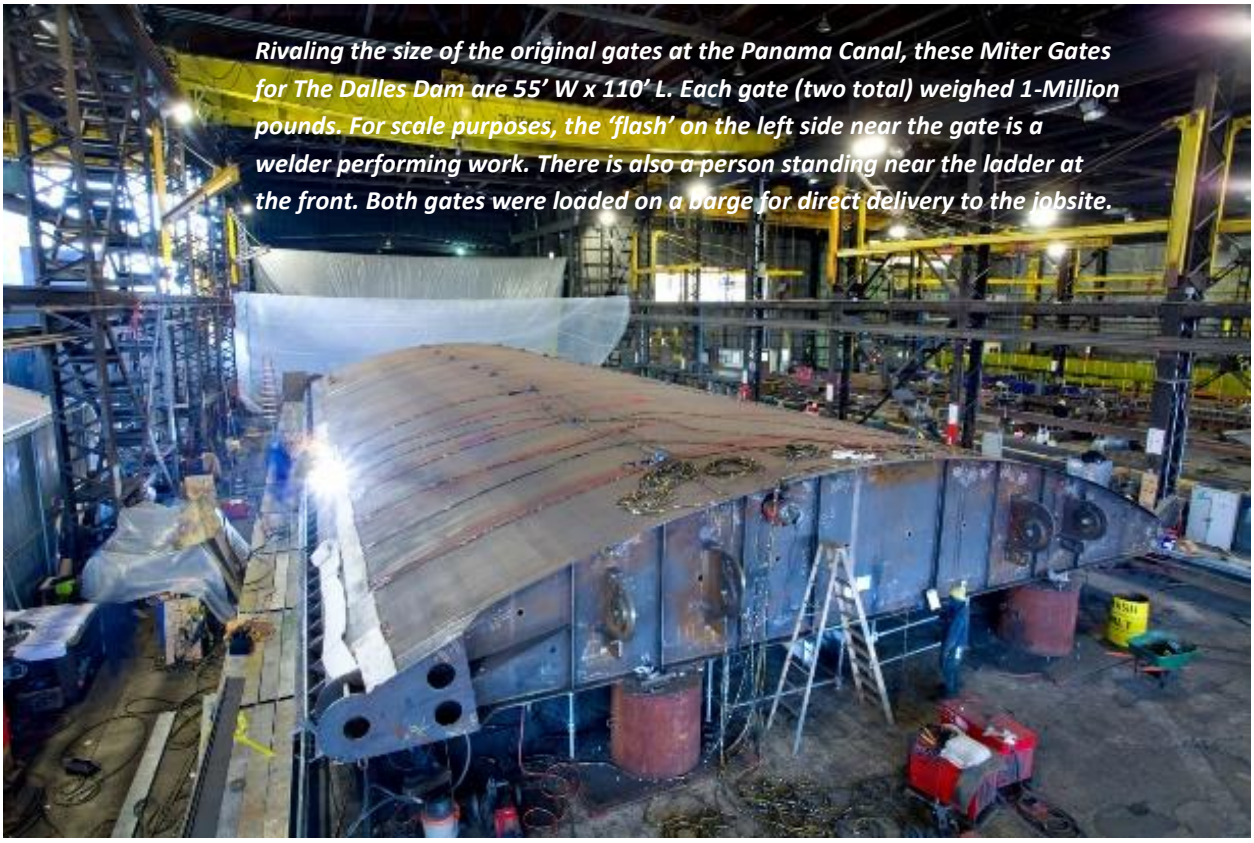


Barge full of skid modules approaching the Interstate Bridge after fabrication by TMF.

The lower segment of the iconic Portland Aerial Tram's tower is shown inside Thompson Metal Fab's shop. Including the bunking underneath, the tower is nearly 40' high and 30' wide. The completed tower can be seen at OHSU, spanning over I-405.



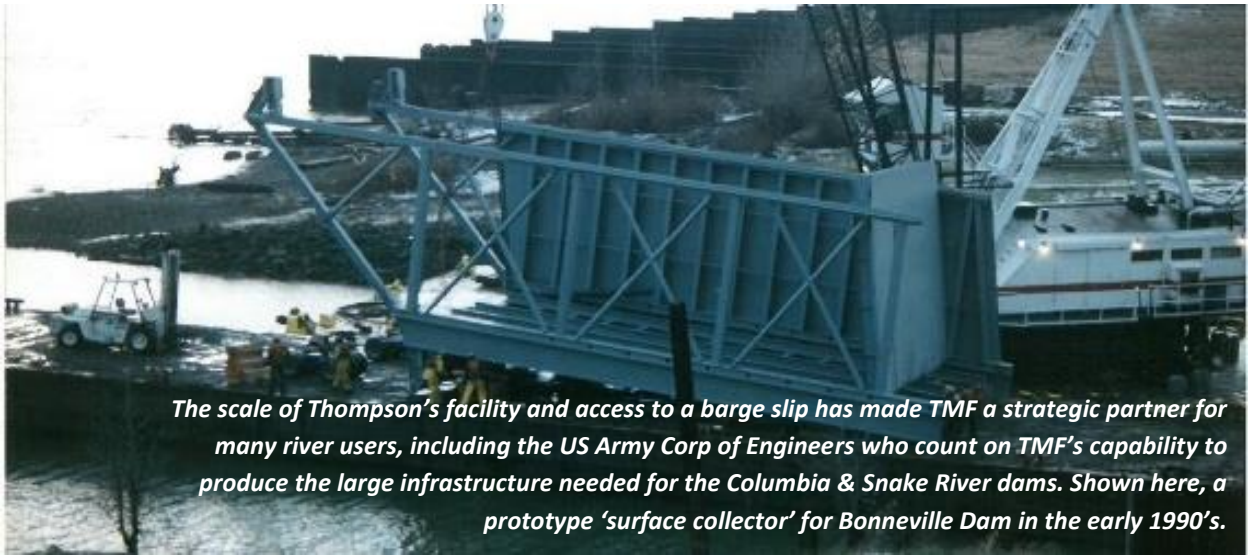
Fabrication of the Lower Monumental Dam Lift Gate is shown at left inside Thompson's shop. Due to its size (nearly 1.5-Million pounds) the gate was fabricated in three segments, loaded on a barge, and finished in the field by the General Contractor. The picture here shows the three segments be aligned for fit verification at TMF's yard. Final dimensions are 88' W x 84' H



Rivaling the size of the original gates at the Panama Canal, these Miter Gates for The Dalles Dam are 55' W x 110' L. Each gate (two total) weighed 1-Million pounds. For scale purposes, the 'flash' on the left side near the gate is a welder performing work. There is also a person standing near the ladder at the front. Both gates were loaded on a barge for direct delivery to the jobsite.

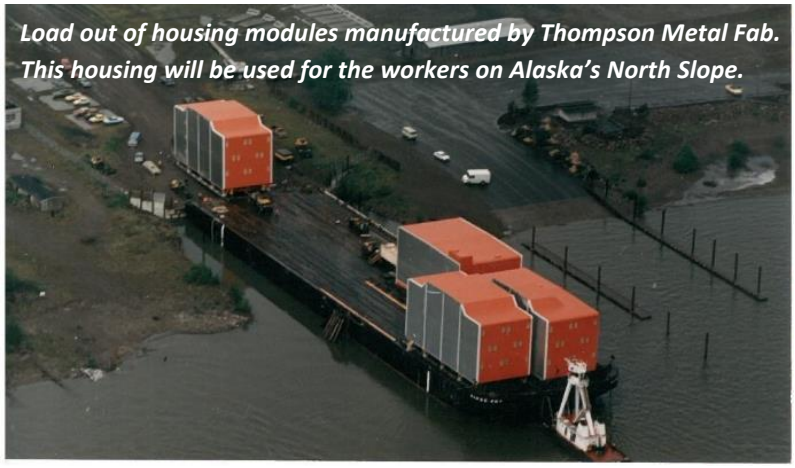
Many of the structures fabricated by TMF require the use of specialty moving systems for handling around the shop and for loading barges. Shown here, an SPMT (Self Propelled Modular Transporter) is used to move one of the Ward Cove Rection Dolphins from TMF's Bay 8 and out to the barge slip for loading. Each reaction dolphin is 30' x 30' x 12' H

Barge load out for the Ward Cove Ferry Terminal Expansion project. All structures were fabricated at the Columbia Business Center, including the Transfer Span and Reaction Dolphins which were completed by Thompson. The Transfer Span, shown near the back of the barge is 14' H x 140' L. These structures were delivered direct to the jobsite in Ketchikan, AK.



The scale of Thompson's facility and access to a barge slip has made TMF a strategic partner for many river users, including the US Army Corp of Engineers who count on TMF's capability to produce the large infrastructure needed for the Columbia & Snake River dams. Shown here, a prototype 'surface collector' for Bonneville Dam in the early 1990's.

Shown above and below are multiple barge loadings for a massive project at Lower Granite Dam in the mid-1990's. All structures were fabricated by Thompson Metal Fab and loaded out at the Columbia Business Center.



Load out of housing modules manufactured by Thompson Metal Fab. This housing will be used for the workers on Alaska's North Slope.

Enclosed modules to be used for a drilling rig, shown inside TMF's shop

Modular fabrication has long been a part of Thompson's history and success. The size of their facility at the Columbia Business Center allows TMF to offer large, turn-key, fully-operational modular systems which get used for housing, data centers, oil production/drilling, crude oil processing, technology, electrification, water treatment, chemical processing, fuel storage, pipe handling, and conveyor systems – among other uses. Remote jobsite locations and size of many of these structure require use of the barge slip, adjacent to Thompson's facility.

Example of processing modules being manufactured inside Thompson Metal Fab

Walls, roof, and equipment being installed on 44' x 97' skid shown below

Thompson's extensive experience with turn-key modular systems made it a valuable partner as a new market emerged for these products. Increase demand for technology pushed groups, like Intel, to expand their facilities. 'Cloud based' data storage requires facilities on the ground that can house servers. Increased online shopping (i.e. Amazon) requires warehouses and data centers. As the world becomes dependent on technology the demand for these custom, modular buildings has significantly increased.

Shown below in late 2019, this skid represents the largest non-oil related module manufactured by TMF. At 44' W x 97' L, this module is too large to ship over the road, and too big to be handled in the field.

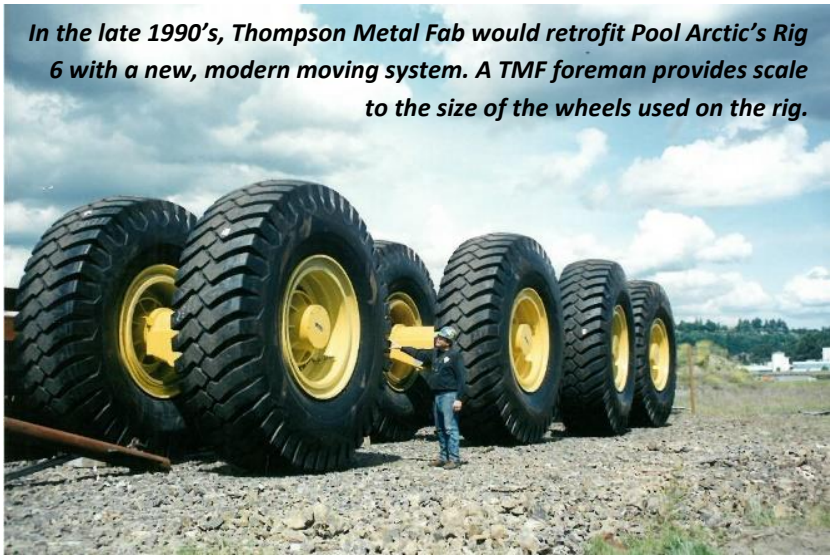
To accommodate field conditions, a shipping 'split' was engineered in the middle of the floor (shown) and in the roof trusses. The 44-ft mega module would ship via barge, and completely outfitted in two segments.

Two 44' x 97' modules were manufactured by TMF, each with a shipping split described above. Shown in the middle of this picture are two of the four total segments prior to barge loading.

Also shown is the BNSF Wind River Bridge. This was manufactured at the Columbia Business Center and would ship via barge completely assembled and installed in one-piece.

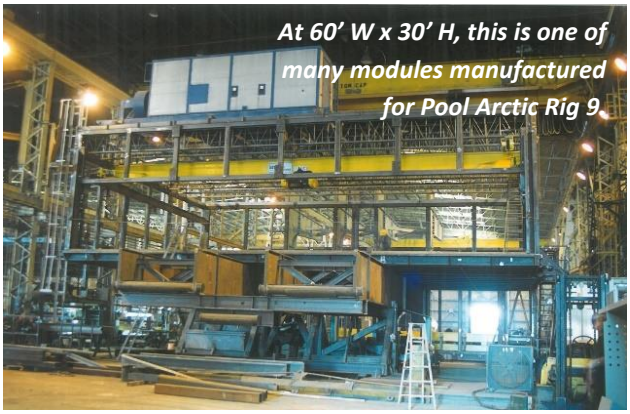
Pool Arctic Rig 3 Retrofit, performed by TMF

In the late 1990's, Thompson Metal Fab would retrofit Pool Arctic's Rig 6 with a new, modern moving system. A TMF foreman provides scale to the size of the wheels used on the rig.



Manufacturing Pool Arctic's Rig 9 inside TMF.

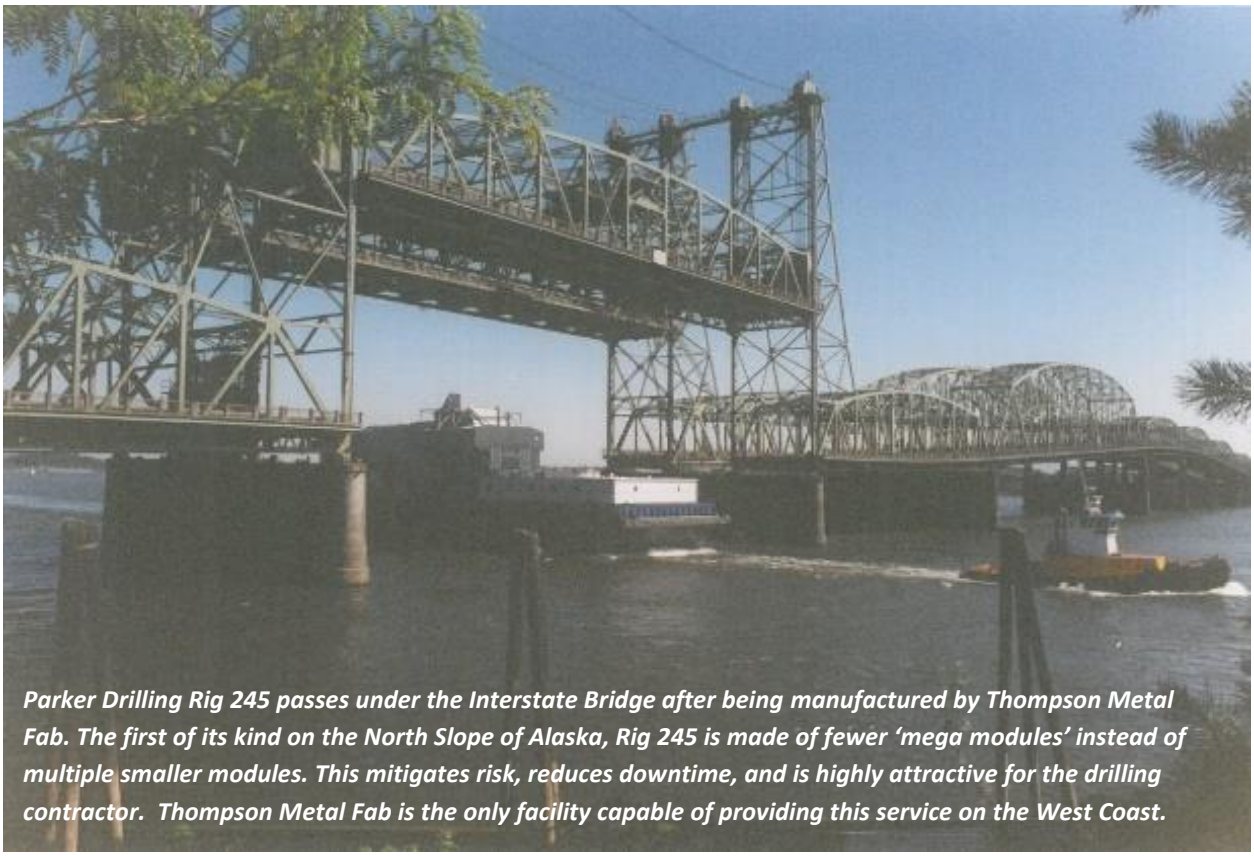
At 60' W x 30' H, this is one of many modules manufactured for Pool Arctic Rig 9.



Following some of its recent predecessors (i.e. Rig 245), Rig 9 would use the 'mega module' concept to reduce downtime on the North Slope

Over the last 30-years, 15 rig projects have been awarded to Thompson Metal Fab. Nearly 1/3rd of the rigs in Alaska have some connection to TMF.

Shown at right, Nordic-Calista's Rig 3 being 'rigged up' in Thompson's yard in 1997. This workover rig is used to restore production on exiting wells.



Parker Drilling Rig 245 passes under the Interstate Bridge after being manufactured by Thompson Metal Fab. The first of its kind on the North Slope of Alaska, Rig 245 is made of fewer 'mega modules' instead of multiple smaller modules. This mitigates risk, reduces downtime, and is highly attractive for the drilling contractor. Thompson Metal Fab is the only facility capable of providing this service on the West Coast.

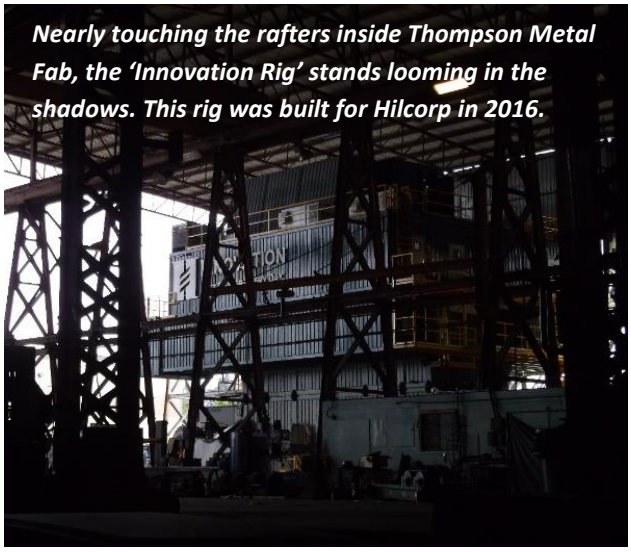
No, the picture to the right is not the inside of a 'big box' store, but it is the size of one! This is the inside of the Liberty Rig's Pipe Module (see above) and is where all production drill pipe is stored.

At the time it was manufactured, the Liberty Rig was the world's largest land-based drilling rig. Everything about this rig was supersized, including the mast shown here inside Thompson Metal Fab. Drill structures, like the one shown here, require special certification for manufacturing, and TMF is the only facility on the West Coast who holds that certification while also boasting a facility/yard of its size, in addition to roll-on/roll-off barge capabilities.

For new rig builds, drilling contractors traditionally manage the design and hire their own sub-contractors (structural, electrical, mechanical, etc.) For Doyon Drilling's Rig 25, TMF was hired as the General Contractor and managed all rig-build efforts on behalf of Doyon. As a result, Rig 25 becomes the rig built by Thompson as General Contractor.

Rig 25 is a sought after work-horse on Alaska's North Slope and is a dependable rig in Doyon's fleet. This picture shows a very proud Thompson team at the end of the project.

Shown above is the part of the substructure base for Rig 272. Its twin (Rig 273) was manufactured at the same time at TMF. Picture below shows the yard assembly of Rig 272, Rig 273, and Rig 25.



Nearly touching the rafters inside Thompson Metal Fab, the 'Innovation Rig' stands looming in the shadows. This rig was built for Hilcorp in 2016.

The Interstate Bridge looks on in the distance as Thompson Metal Fab manufactures three rig projects from their Columbia Business Center facility. Shipping clearance on Rig 272 & 273 (blue) would be nearly 160'.

Marine Industries and Fabricators

Company: Vigor

Company provided the following information to the IBR Program.

Vigor Works, LLC. is a Heavy Industrial Fabrication Company that serves the Marine, Hydro-Electric, Nuclear, Oil & Gas and Steel Bridge Industries. The wide variety of products produced by Vigor Works support private industry as well as Government Agencies (local, state, federal). Past and present projects completed from the Columbia Industrial Park include fully assembled final products: Bridges, Oil Field Modules/Platforms, Marine Vessels and other extremely large infrastructure type goods which have limited areas for fabrication due to water loadout/shipping and air draft restrictions.

Vigor Works (in and adjacent to the Columbia Industrial Park) are uniquely qualified and situated to support strategic and industrial needs, particularly our national infrastructure of dams, locks and bridges and marine vessels. The living wage trade jobs created by this work are critical to the health of the Vancouver/Portland area. Vigor currently supports ~1500 trade related jobs in the Portland Metro area which includes three separate locations in and around the Columbia Industrial Park.

Heavy investment in capital and people has occurred in all three Vancouver locations upriver of the I-5 bridge. By maintaining flexibility to pursue and provide ultra large product for customers, we can continue to pursue this type of work to support the jobs and economy of Vancouver. Our sites are unique due to their access to a large metro area with truck, rail and marine access.

The current bridge height has been important for commerce and shipments along the Columbia River for nearly a century and even more critically important since the war effort in the 1940s. In the late sixties and early seventies, offshore drilling rigs were constructed at this location and had to transit under the bridge. These offshore platforms required the bridge to be raised to its full height of 174 feet to allow them to pass under the raised span. More recently we have watched drilling equipment destined for Alaska being assembled in the Columbia Industrial Park that required 150 feet of clearance to be shipped down the river. Vigor consistently evaluates opportunities for product up to 110 feet in height. The additional height of blocking, transport barge freeboard and clearance margin, easily results in an air draft requirement of 130’ for these projects. Ideally, we recommend a height of 150 feet air draft.

Our other Portland facility located on Swan Island (Portland Shipyard) also engages in large fabrications and we have in the past, barged components to/from the Vancouver facilities. Our Marine Fabrication work has also resulted in portions of vessels being shipped via barge to Ketchikan and we are currently evaluating shipping product components to our Seattle Shipyard- the exact size of those products have not yet been determined. In the future, we would expect to ship product both upriver and down river.

The lower height of the bridge will limit Vigor Works’ ability to compete on some projects. The ability and direct access to shipping on the Pacific Ocean and subsequent trade routes to Alaska or the gulf coast and Mississippi River system (via the Panama Canal) is critical for our full and sustained operation. One recent project was delivered to New Jersey.

.

In summary:

The Bridge Height is now is 174 feet; this height has been needed as follows:

- 1960 to 1975 Drilling Platforms for the California Offshore Field.
- 1980 to 1995 Various loads from the Industrial Park to locations in Alaska and elsewhere.

- 2000 to 2012 Drilling Equipment for Parker Drilling assembled in the Park and shipped to Alaska.

Current:

- We are evaluating Vancouver for long term production related to partial or all construction for upcoming work. The final bridge height could impact the amount of work completed in Vancouver.
- We anticipate there will be some opportunity for future module or drill platform work associated with Alaska as equipment requires replacement.
- We expect, although do not know what the development of offshore wind will need for industrial shore side support.

Conclusion:

This Marine Highway is used by a multitude of users with traffic going both upstream and down. We ship goods from the industrial park upstream of the bridge to Swan Island Ship Yard and from the Swan Island Ship Yard to the industrial park. The I-205 Bridge upstream of the bridge has a clearance of 144 feet and downstream of the bridge we have clearance limited only at Astoria and that is 196 feet with the Lewis and Clark (Longview) bridge over 200 feet. We believe it is critical to our business and the viability of the river system used for commerce to keep the height of this bridge at least 150 feet.

APPENDIX C OTHER USERS INVENTORIED

Appendix C includes information collected and/or referenced for all users inventoried in the IBR NIR. Information was collected through direct outreach to river users and through an online survey. Notification of the request for information and a link to the online survey was provided in the following publications:

- The IBR website and social media platforms (digital)
- USCG Local Notice to Mariners (digital)
- Sea Magazine (digital and print)
- NW Yachting (digital and print)
- 48 North (digital)
- Oregonian (digital)
- Columbian (digital)
- DJC Oregon (digital)
- DJC Seattle (digital and print)
- Daily Astorian (digital and print)
- St Helens Chronicle (digital)
- Camas-Washougal Post Record (digital)
- Pacific Northwest Waterways Association (digital)
- Merchants Exchange Newsletter (digital)
- Lewiston Morning Tribune (print)
- Columbia River Steamship Operators' Association (email listserv)

USERS INVENTORIED

The following sections identify the river users inventoried for the IBR NIR, followed by all data received as part of the IBR outreach to river users, as well as data previously included in the CRC NIR. Where a user contacted did not provide information, only the data previously included in the CRC NIR is included.

Commercial Tugs/Tows/Barges

- Bernert Barge Lines
- Mark Bernert Tugboat Co.
- Cadman
- SDS Tug & Barge

Company provided an email confirmation of IBR data sheets. The CRC NIR did not include additional vessel survey information or images.

From: Jerry Grossnickle
To: River Navigation
Subject: Bridge Replacement Program
Date: Monday, May 17, 2021 9:07:09 AM

Greetings, Nicole & Team

On behalf of Bernert Barge Lines. Inc., I apologize for our tardy response to your request for vessel information. I reviewed the data sheets that you sent, and confirm their accuracy and that there are no additions that need to be made.

Thank you.

Jerry

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

Company/Owner Name: Bernert Barge Lines, Inc.

Vessel Name: Mary B

Vessel Type: Towing

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:Choose an item.

Vessel Category: Commercial

USCG Document Number: 516063516063

Primary Mooring Location *(waterway milepoint, if known)*:

BBL Dock at The Dalles
Shaver Dock at Rainier

Type and quantity of cargo, if applicable:

Barge loads of wood chips, logs, other commodities

Length (overall; ft):61.4

Beam (width; ft): 21.3

EXISTING VESSEL DATA SHEET

Push knee style tug boat

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:Yes

Twin Screw Conventional Tug Multiple Main & Flank Rudders, pushing up to 4 grain barges while transiting under the bridge.

Vessel Category: Commercial

USCG Document Number:
555059

Primary Mooring Location *(waterway milepoint, if known)*:
Willamette River mile 8.3

Type and quantity of cargo, if applicable:
Grain in barges, approximately 15000 tons per 4 barge tow

Length (overall; ft):
102 ft

Beam (width; ft):
30 ft

VESSEL DATA SHEET, CONT.

Draft (ft) - *depth of hull below waterline, fully laden*:

9.5 ft

Air Draft (ft) - *height of highest fixed point above waterline, unladen*:

56 ft

Air Gap (ft) - *desired clearance from highest fixed point to lowest part of bridge*:

24 ft

Safety Margin (ft) *horizontal clearance required by vessel to navigate through the bridge*:

450 ft

Transit speed under Interstate Bridge and Load Configuration:

8 knots

Pushing ahead on 4 barges – 2 x 2 – total barge width – 84 feet total length – 650 feet

Time of Year of Passage:

Year Round

Tug Assistance Required: No

Frequency of passage under Interstate Bridge main channel (typical per month):

Jan___12____ **Feb**_____12____ **Mar**___4_____ **Apr**__12_____ **May**___12_____ **June**___12____

Jul___12____ **Aug**____12____ **Sep**__12_____ **Oct**___12_____ **Nov**___12_____ **Dec**____12___

Frequency of passage under the North Portland Harbor Bridge (Oregon Slough):

Jan____0_____ **Feb**____2_____ **Mar**_____2____ **Apr**_____0____ **May**_____0____ **June**_____0____

Jul_____0____ **Aug**____0_____ **Sep**_____2____ **Oct**_____0_____ **Nov**_____0____ **Dec**_____0____

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

Company/Owner Name: Shaver Transportation Company

Vessel Name:
Clearwater

Vessel Type:
Push knee style tug boat

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:Yes

Twin Screw Conventional Tug Multiple Main & Flank Rudders, pushing up to 4 grain barges while transiting under the bridge.

Vessel Category: Commercial

USCG Document Number:
268312

Q18

Transit speed under Interstate Bridge and Load Configuration (if applicable)

7-10mph

Q19 **No**

Tug Assistance Required

Q20

Please identify any future vessel, cargo, and/or business plans that might require different vessels to transit under the bridge. If plans are available online, please provide a link to the online source or email the plans to rivernav@interstatebridge.org.

n/a

Q21

Is there anything else you would like to add about your vessel or business plans?

Its very rare that we use the lift span. Only special circumstances or during high water when we're unable to fit under green light widespan. If there was a bridge replacement it would be nice to make the transit a straight shot from KBM Interstate to KQ9049 Vancouver and eliminate the current S turn from I5 to KQ9049. Personally I think this project is a waste of time and would like to see a third bridge either on the east side or west side of town. This would actually alleviate some of the congestion we currently deal with. The proposed bridge will do nothing to solve the bottleneck issue in Portland.

Q22 **No**

Do you have another vessel?

Commercial Tugs/Tows/Barges

Owner: Tidewater

Vessels:

- Betty Lou
- Captain Bob
- Chief
- Clarkston
- Crown Point
- Defiance
- Granite Point
- Hurricane
- Liberty
- Maverick
- Outlaw
- Rebel
- Ryan Point
- Sundial

Company completed IBR data sheets and submitted characteristics for one vessel (Ryan Point) through the online survey. Data sheets also included characteristics for Ryan Point. Data sheets and survey response are included below. Vessel drawings provided for the CRC NIR are also included below.

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

Company/Owner Name: Tidewater

Vessel Name:
Betty Lou

Vessel Type:
Harbor

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:No

Vessel Category: Commercial
Push Tug

USCG Document Number:
259542

Primary Mooring Location *(waterway milepoint, if known)*:
Tidewater has mooring facilities along the Columbia and Snake Rivers located at Vancouver, WA, Pasco, WA, Boardman, OR and Umatilla, OR, and Wilma, WA (near Lewiston, ID).
Primary Mooring Location, Columbia River Mile 102. Vancouver

Type and quantity of cargo, if applicable:
Types are agricultural, liquid products, wood and paper, solid waste and special products cargo.
Quantity is up to 10,500 tons of cargo on an annual basis.

Length (overall; ft):
70

Beam (width; ft):
39.7

VESSEL DATA SHEET, CONT.

Draft (ft) - *depth of hull below waterline, fully laden*:

Push Tug-Line haul

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:No

Vessel Category: Commercial
Push tug

USCG Document Number:
514987

Primary Mooring Location *(waterway milepoint, if known)*:
Tidewater has mooring facilities along the Columbia and Snake Rivers located at Vancouver, WA, Pasco, WA, Boardman, OR and Umatilla, OR, and Wilma, WA (near Lewiston, ID).
Primary Mooring Location, Columbia River Mile 102. Vancouver

Type and quantity of cargo, if applicable:
Types are agricultural, liquid products, wood and paper, solid waste and special products cargo.
Quantity is up to 14,500 tons of cargo on an annual basis.

Length (overall; ft):
121.6

Beam (width; ft):
40.0

VESSEL DATA SHEET, CONT.

Draft (ft) - *depth of hull below waterline, fully laden*:

11.8

Air Draft (ft) - *height of highest fixed point above waterline, unladen*:

49.9

Air Gap (ft) - *desired clearance from highest fixed point to lowest part of bridge*:

3

Safety Margin (ft) *horizontal clearance required by vessel to navigate through the bridge*:

450

Transit speed under Interstate Bridge and Load Configuration:

8-10 mph down bound with loads, 4 loads

7-9 mph up bound with full tow- 3 empty and one loaded barge

Time of Year of Passage:

Could transit any day of the year, 24 hours of the day

Tug Assistance Required:No

Frequency of passage under Interstate Bridge main channel (typical per month):

Jan_____ Feb_____ Mar_____ Apr_____ May_____ June_____

Jul_____ Aug_____ Sep_____ Oct_____ Nov_____ Dec_____

Frequency of passage under the North Portland Harbor Bridge (Oregon Slough):

Jan_____ Feb_____ Mar_____ Apr_____ May_____ June_____

Jul_____ Aug_____ Sep_____ Oct_____ Nov_____ Dec_____

EXISTING VESSEL DATA SHEET

Please fill out the data sheet below. Note if the vessel is no longer in service or used on the waterway. If the vessel is still in service on the waterway, review and update vessel information and provide data where the field is blank. If you have new vessels that travel under the Interstate Bridge (main channel) and/or the North Portland Harbor Bridge (Oregon Slough), please use the following link to complete a waterway user survey: https://www.interstatebridge.org/rivernavigation. In addition, through the survey link, please note any future vessel or cargo plans you know of that might require different vessels to transit under the bridge.

3

Safety Margin (ft) *horizontal clearance required by vessel to navigate through the bridge*:
450

Transit speed under Interstate Bridge and Load Configuration:

Time of Year of Passage:
Could transit any day of the year, 24 hours of the day

Tug Assistance Required:No

Frequency of passage under Interstate Bridge main channel (typical per month): On the average (some months are higher, and others are lower), Tidewater vessels pass under the Interstate Bridge **70 times** per month. If you need this number broken down by vessel, please contact Jennifer Riddle for that information. Jennifer.Riddle@tidewater.com.

Jan_____ Feb_____ Mar_____ Apr_____ May_____ June_____

Jul_____ Aug_____ Sep_____ Oct_____ Nov_____ Dec_____

Frequency of passage under the North Portland Harbor Bridge (Oregon Slough):

Jan_____ Feb_____ Mar_____ Apr_____ May_____ June_____

Jul_____ Aug_____ Sep_____ Oct_____ Nov_____ Dec_____

Page 1: Introduction

Q1

Company Name

Tidewater

Q2

Contact Information

Name	**RANDY REINHOFER**
Email	**rv8aer@gmail.com**
Phone number	**12085820157**

Q3

Vessel Name (please complete one survey per vessel)

Ryan Point

Q4

Vessel Type

Tug

Q5

Specialized Vessel (e.g. limited maneuverability due to design or mode of operation. If yes, please describe)

No

Q6

Vessel Category

Commercial

Q7

USCG Document Number

Respondent skipped this question

Q8

Primary Mooring Location (waterway milepoint, if known)

Vancouver, WA

Q9

Type and quantity of cargo, if applicable

Barging wheat, petroleum, waste, pulp, etc.

Q10

Length (total feet)

104

Q11

Beam (width in feet)

38

Q12

Draft (feet) - depth of hull below waterline, fully laden

10'9"

Q13

Air Draft (feet) - height of highest fixed point above waterline, unladen

52'

Q14

Air Gap (feet) - desired clearance from highest fixed point to lowest part of bridge

30'

Q15

Safety Margin (feet) - horizontal clearance required by vessel to navigate through the bridge

Respondent skipped this question

Q16

Frequency of passage under Interstate Bridge (main channel)

January	**6**
February	**6**
March	**6**
April	**6**
May	**6**
June	**6**
July	**6**
August	**6**
September	**6**
October	**6**
November	**6**
December	**6**

Q17

Frequency of passage under the North Portland Harbor Bridge (Oregon Slough)

Respondent skipped this question

Q18

Transit speed under Interstate Bridge and Load Configuration (if applicable)

8-10 mph, various loading condition

Q19

Tug Assistance Required

No

Q20

Please identify any future vessel, cargo, and/or business plans that might require different vessels to transit under the bridge. If plans are available online, please provide a link to the online source or email the plans to rivernav@interstatebridge.org.

Respondent skipped this question

Q21

Is there anything else you would like to add about your vessel or business plans?

Respondent skipped this question

Q22	No
Do you have another vessel?

TANK CAPACITY TABLE: (CAPACITY GALS)

TANK	MAX	WORKING (95%)
Port bow	6112	5806
Starboard bow	6112	5806
Port stern	10488	9964
Starboard stern	10488	9964
Main Engine day tank	3960	3762
Generator day tank	789	750
Lube	2200	1980

Worst Case Discharge (BBLS)	Maximum Most Probable Discharge (BBLS)
956	95

FUEL
The Legend has four (4) diesel storage tanks. Two (2) are located in the bow - port and starboard and two are located in the stern - port and starboard. A main engine day tank supplies diesel to the main engines. A generator day tank supplies diesel to the generators. The ecology box is located on the starboard bow.

LUBE
The Legend has a lube oil storage tank located forward of the engine room, to the port side of the main engine day tank. The lube oil storage tank fill is a 2" deck hole in the lube oil tank cover (located aft and to port of center winch).

Detail transfer procedures are available in the Tidewater Operational Procedures notebook

Worst Case Discharge (BBLS)	Maximum Most Probable Discharge (BBLS)
1573	157

FUEL
The Chief has seven (7) tanks on each side of the hull. The #1 and #7 tanks are not used. The #4 tanks are used as day tanks for both the main and generator engines. The port and starboard systems are independent of each other. The fuel transfer pump is located in the port Generator Room.

LUBE
The Chief has a lube oil storage tank located on the aft bulkhead, center of the boat. The lube oil tank is a free drop tank. The tank fills from the header inside the ecology box at the stern of the main deck, center of house.

Detail transfer procedures are available in the Tidewater Operational Procedures notebook

TANK CAPACITY TABLE: (CAPACITY GALS)

TANK	MAX	WORKING (95%)
Port bow	7447	7075
Starboard bow	7447	7075
Port stern	10311	9795
Starboard stern	10311	9795
Main Engine day tank	3958	3760
Generator day tank	789	750
Lube	2200	1980

Worst Case Discharge (BBLS)	Maximum Most Probable Discharge (BBLS)
1011	101

FUEL
The Tidewater has four (4) diesel storage tanks. Two (2) are located in the bow - port and starboard and two are located in the stern - port and starboard. A main engine day tank supplies diesel to the main engines. A generator day tank supplies diesel to the generators. The diesel fuel header is in the starboard bow ecology box.

LUBE
The Tidewater has a lube oil storage tank located forward of the engine room, to the port side of the main engine day tank. The lube oil storage tank has a capacity of 2,200 gallons. The lube oil storage tank fill is on the bow - through a plug hole in the lube oil storage tank hatch (the hatch is painted black).

Detail transfer procedures are available in the Tidewater Operational Procedures notebook

Vessel Height Verification Sheet

By: Jennifer Rabby Date: 23 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Advanced American Construction
   b. Name of contact: Mike Johns
   c. Phone number (Office): 5053.445.9000 (Cell): 503.720.1108
   d. Email: mikej@callaac.com
   e. Address: 8444 NW St Helens Road City: Portland
      State: OR Zip code: 97231
2. Vessel
   a. ID: Serial No. 24626 b. Name: DB 125
   c. Type: Crane Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
   - Is a vessel specification sheet available? Yes
   - Configuration shown on the sheet: No
   - What is the lowest height configuration for transport? 51ft (spuds removed)

   b. What is the gantry configuration? Estimated gantry height: 51 feet

   c. Does the barge have spuds? Yes
   - Height above waterline for travel? 78 Feet
   - Can the spuds be removed for travel? Only for long distances upstream for big jobs; not for work in the Portland Harbor
   - Work and cost involved in removing spuds? ½-1 day
4. Vessel Location
   a. Where is the vessel currently located? AAC Dock in Portland
   b. Is it working on a job? No, but headed out soon Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? _____

5. Surveyed Measurements (measurements from Spec sheets)

Gantry Height:	51
Water Level:	
Top of Boom:	
Height of Boom Hinge Pin:	
Boom Cradle:	
Top of Spud:	78

6. Vessel Height

6. Air Draft (Height of the highest fixed point of the vessel above the waterline, unladen), feet: 20'

7. Air gap for vessel (desired clearance from the highest fixed point on the vessel to lowest part of bridge): 10'

8. Frequency of one-way passage underneath I-5 main channel (typical per month): Varies

   Jan ___ Feb ___ Mar___ Apr___ May___ Jun___ Jul___ Aug___ Sep___ Oct___ Nov___ Dec___

9. Frequency of one-way passage underneath I-5 main channel (other historic events): Varies

10. Frequency of one-way passage through North Portland Harbor (Oregon Slough) (typical per month): Varies

    Jan ___ Feb ___ Mar___ Apr___ May___ Jun___ Jul___ Aug___ Sep___ Oct___ Nov___ Dec___

11. Frequency of one-way passage through North Portland Harbor (Oregon Slough) (other historic events): Varies

12. Do you have a Business Plan (e.g. 10 or 20 year plan)? What does it say regarding vessels transiting under the I-5 Bridge or into North Portland Harbor (Oregon Slough)? May we have a copy? Yes. It does not address vessel traffic in this specific area.

13. Other miscellaneous

As a construction company predicting vessel traffic in a specific area is quite difficult as it is directly related to which contracts we are awarded.

   a. ID: b. Name: Betsy Ross
   c. Type: Crane Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
   - Is a vessel specification sheet available? No
   - Configuration shown on the sheet: N/A
   - What is the lowest height configuration for transport? Crane down at 66 ft, spuds removed

   b. What is the gantry configuration? Estimated gantry height: Not given
   c. Does the barge have spuds? Yes, two
   - Height above waterline for travel? 68 Feet
   - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
   - Work and cost involved in removing spuds? ½ day to day to remove spuds; need to tie up to a dock near the work area.
4. Vessel Location

a. Where is the vessel currently located? Astoria, OR

b. Is it working on a job? No Is it tied up to shore? yes

c. What is the best time to make a trip to the vessel? Prior to August

5. Surveyed Measurements (all measurements above water line)

Gantry Height:	N/A

Vessel Height Verification Sheet

By: Pete Geiger Date: 2 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Diversified Marine
   b. Name of contact: Kurt Redd
   c. Phone number (Office): 503.289.2662 (Cell):
   d. Email: kurt@dmipdx.com
   e. Address: 1801 N Marine Drive City: Portland
      State: OR Zip code: 97217
2. Vessel
   a. ID: b. Name: BMC44
   c. Type: Spud Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Spud Barge
      - Is a vessel specification sheet available? No
      - Configuration shown on the sheet: N/A
      - What is the lowest height configuration for transport? Spuds Up at 80 feet

   b. What is the gantry configuration? N/A Estimated gantry height: N/A

   c. Does the barge have spuds? Yes two. Midpoint at both ends. One Spud currently removed and one spud raised and pinned
      - Height above waterline for travel? 80 Feet
      - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
      - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area. Would need to be accompanied by a crane.

4. Vessel Location
   a. Where is the vessel currently located? Columbia River North Portland Harbor, tied up to dolphins about ¼ mile downstream of Diversified Marine's Facility
   b. Is it working on a job? No Is it tied up to shore? Yes
   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	Not Surveyed – No Crane
Water Level:	15.8 feet
Top of Boom:	Not Surveyed – No Crane
Height of Boom Hinge Pin:	Not Surveyed – No Crane
Boom Cradle:	Not Surveyed – No Crane
Top of Spud:	93.5 Feet

6. Vessel Height

Self-Reported (Top of Spud)		Surveyed (Top of Spud)	
Air Draft:	80 feet (Top of Spud)	Air Draft:	78 Feet (Top of Spud)
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet	Water Level:	16 feet
Total Height:	106 feet	Total Height:	104 feet

7. History Notes

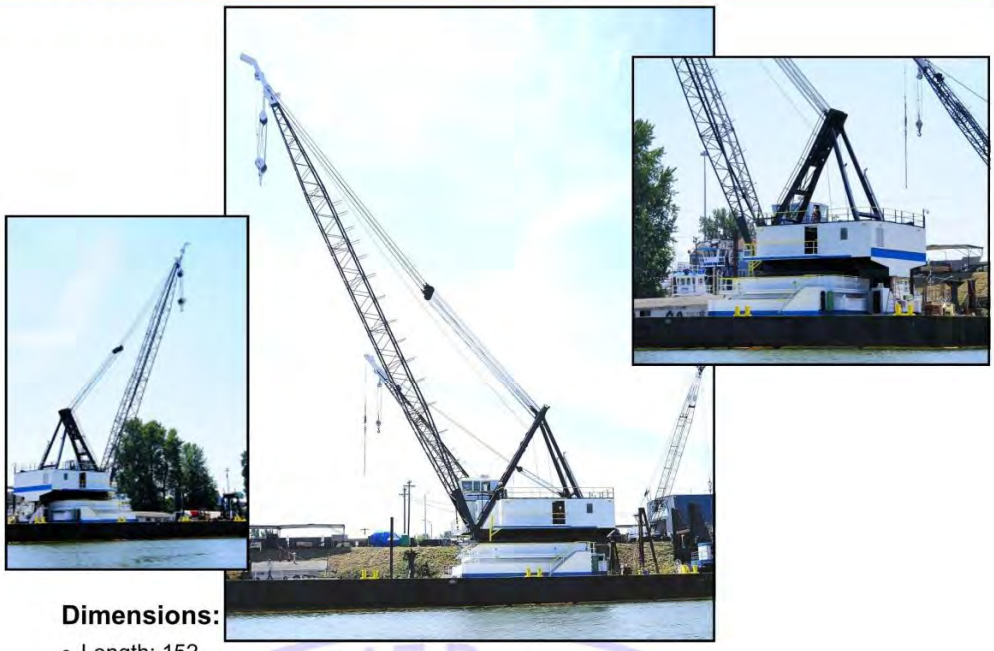
Vessel: DB Freedom

CRANE BARGE "DB FREEDOM"

Official No. 507476



Dimensions:

- Length: 152
- Beam: 60'
- Depth: 12"
- Draft: 4'
- Boom: 160' to main fall
- Boom: 172' to main whip line

Capacities:

- Fuel: 10,000 gallons
- Lift 123.5 tons off stern
- Lift: 87.4 tons @ 50' radius
- Lift: 81.2 tons @ 60' radius
- Lift: 67 tons @ 80' radius
- Lift: 25 tons @ 160' radius

Regulatory:

- American Hoist & Derrick Co American 305 Revolver
- Gross tonnage: 911 GRT

Machinery:

- Power: Diesel/Electric
- Generator: 375KW 480V
- Engine: C18

Auxiliaries:

- 3 drum 20,000#deck winch
- Twp (2) Aux hoist: 2 drum Skagit

Capabilities:

- Heavy Lifting
- Crane Service
- Salvage
- Pile Driving

2. Vessel
   a. ID: b. Name: DB Freedom
   c. Type: Crane Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
      - Is a vessel specification sheet available? Yes
      - Configuration shown on the sheet: Crane Up
      - What is the lowest height configuration for transport? Crane down at ~ 34 Degrees above horizontal, spuds up and pinned

   b. What is the gantry configuration? Estimated gantry height: Not given
   c. Does the barge have spuds? Yes at least two forward. Spuds currently down
      - Height above waterline for travel? 85 Feet
      - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
      - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area.

4. Vessel Location

   a. Where is the vessel currently located? Columbia River North Portland Harbor

   b. Is it working on a job? Yes while tied up Is it tied up to shore? yes

   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	77.3 feet
Water Level:	16.0 feet
Top of Boom:	Measured while working = 201.4 feet (71 degrees off horizontal) Estimated at travel angle (34 degrees off horizontal) = 135 feet
Height of Boom Hinge Pin:	39.1 feet
Boom Cradle:	42.9 feet
Top of Spud:	Not surveyed – spuds in down position

6. Vessel Height

Self-Reported		Surveyed (Top of Boom Estimated)	
Air Draft:	85 feet (Top of Spuds)	Air Draft:	119 Feet (Top of Crane)
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet CRD	Water Level:	16 feet CRD
Total Height:	111 feet	Total Height:	145 feet

      - Height above waterline for travel? 85 Feet
      - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
      - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area.

4. Vessel Location

   a. Where is the vessel currently located? Columbia River North Portland Harbor

   b. Is it working on a job? No Is it tied up to shore? Yes

   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	Not Surveyed – Obscured by drydock
Water Level:	16.0 feet
Top of Boom:	Measured at storage angle = 89.3 feet
Height of Boom Hinge Pin:	Not Surveyed – Obscured by drydock
Boom Cradle:	Not Surveyed – Obscured by drydock
Top of Spud:	Not surveyed – No Spuds – Anchors Only

6. Vessel Height

Self-Reported (Top of Spud)		Surveyed (Top of Boom)	
Air Draft:	85 feet (Top of Spud)	Air Draft:	73 Feet (Top of Crane Boom)
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet	Water Level:	16 feet
Total Height:	111 feet	Total Height:	99 feet

Owner: Diversified Marine
Vessel: DB Vulcan

CRANE BARGE "DB VULCAN"

Official No. 563327

Dimensions:

- Length: 101'
- Beam: 45'
- Depth: 8' 6"
- Draft: 3' 6"
- Boom: 113' to main fall
- Boom: 120' to main whip line

Capacities:

- Fuel: 4,500 gallons
- Lift: 60 tons @ 40' radius
- Lift: 38 tons @ 60' radius
- Lift: 14 tons @ 120' radius

Regulatory:

- RW Kaltenback Model YDH-9 Revolving Whirley
- Gross tonnage: 358 GRT

Machinery:

- Power: Diesel/Electric
- Generator: GE 125KW 230V
- Engine: Cat 3306

Auxiliaries:

- Four (4) 8000# anchors
- Aux hoist: 3 drum Skagit

Capabilities:

- Heavy Lifting
- Crane Service
- Salvage
- Pile Driving
- Clamshell Dredging
- Duty Cycle

Vessel Height Verification Sheet

By: Pete Geiger Date: 2 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Diversified Marine
   b. Name of contact: Kurt Redd
   c. Phone number (Office): 503.289.2662 (Cell):
   d. Email: kurt@dmipdx.com
   e. Address: 1801 N Marine Drive City: Portland
      State: OR Zip code: 97217
2. Vessel
   a. ID: b. Name: DB Vulcan
   c. Type: Crane Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
   - Is a vessel specification sheet available? Yes
   - Configuration shown on the sheet: Crane Up
   - What is the lowest height configuration for transport? Crane down at ~ 34 Degrees above horizontal

   b. What is the gantry configuration? Estimated gantry height: Not given
   c. Does the barge have spuds? No (Anchors Only)
   - Height above waterline for travel? N/A
   - Can the spuds be removed for travel? N/A
   - Work and cost involved in removing spuds? N/A
4. Vessel Location
   a. Where is the vessel currently located? Columbia River North Portland Harbor
   b. Is it working on a job? No Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	65.9 feet
Water Level:	16.0 feet
Top of Boom:	Measured at travel angle (34 degrees off horizontal) = 104.6 feet
Height of Boom Hinge Pin:	37.0 feet
Boom Cradle:	Not Surveyed – Obscured by tugs
Top of Spud:	Not surveyed – No Spuds – Anchors Only

6. Vessel Height

Self-Reported (Top of Gantry)		Surveyed (Top of Boom)	
Air Draft:	58 feet (Top of Gantry)	Air Draft:	89 Feet (Top of Crane Boom)
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet	Water Level:	16 feet
Total Height:	84 feet	Total Height:	115 feet

Owner: Diversified Marine
Vessel: DMI 60

RAMP/SPUD BARGE "DMI60"

Dimensions:

- Length: 60'
- Length (Ramps extended): 80'
- Beam: 24'
- Depth: 4'
- Draft: 1'
- Spuds: 85' x 12"

Regulatory:

- Gross tonnage: GRT 48

Machinery:

- Two (2) Pullmaster 12,000# hydraulic winches (raise and lower spuds)
- Pullmaster M25 to power ramps
- 50 HP self-contained power unit with biodegradeable hydraulic oil

Capabilities:

- Drilling support platform
- Salvage
- Floating Dock
- Bridge Inspections

Vessel Height Verification Sheet

By: Pete Geiger Date: 2 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Diversified Marine
   b. Name of contact: Kurt Redd
   c. Phone number (Office): 503.289.2662 (Cell):
   d. Email: kurt@dmipdx.com
   e. Address: 1801 N Marine Drive City: Portland
      State: OR Zip code: 97217
2. Vessel
   a. ID: b. Name: BRG 22
   c. Type: Spud Barge d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Spud Barge
   - Is a vessel specification sheet available? Yes
   - Configuration shown on the sheet: Spuds Raised; being pushed by tug
   - What is the lowest height configuration for transport? Spuds Up at 60 feet

   b. What is the gantry configuration? N/A Estimated gantry height: N/A

   c. Does the barge have spuds? Yes three. Center at either side and one at stern end at corner. Middle spuds dropped/set into riverbed and corner spud raised and pinned

   - Height above waterline for travel? 60 Feet
   - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
   - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area. Would need to be accompanied by a crane.

4. Vessel Location
   a. Where is the vessel currently located? Columbia River North Portland Harbor, tied up to dolphins about ¼ mile downstream of Diversified Marine's Facility
   b. Is it working on a job? No Is it tied up to shore? Yes
   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	Not Surveyed – No Crane
Water Level:	15.8 feet
Top of Boom:	Not Surveyed – No Crane
Height of Boom Hinge Pin:	Not Surveyed – No Crane
Boom Cradle:	Not Surveyed – No Crane
Top of Spud:	73.8 Feet

6. Vessel Height

Self-Reported (Top of Spud)		Surveyed (Top of Spud)	
Air Draft:	60 feet (Top of Spud)	Air Draft:	58 Feet (Top of Spud)
Air Gap:	10 feet	Air Gap:	10 feet

Marine Contractors

Company: The Dutra Group

Vessels:

- Derrick 24
- Paula Lee

Company did not respond to IBR request. Information below was included in the CRC NIR.

Marine Contractors

Owner: The Dutra Group

Vessel: Derrick 24

PB 100 YEARS

Telephone Conversation Memorandum

project: CRC - Data Verification job no. 80312 CS (use complete number) date: 7/3/12

from: Ralph Petereit talked to: Chris Petersen

indicate department, field office, etc., "for in-house" calls.
indicate agency or firm for other than "in-house" calls.

item discussed: Dutra Dredging Marine Equipment

information obtained: Dutra has 2 large derrick barges, the Paula Lee and Derrick 24. The Paula Lee has an 80' height and the Derrick 24 has a 70' height. This includes a few feet of clearance. Both barges are currently working in Southern California. To get to the Columbia River they would remove the spuds and lay them down on deck for travel up the coast. When they had a job in Lewiston they had to remove the A-frame / gantry and the height became 52'.

The ~~heir~~ highest point on both barges is the top of the A-frame / gantry. The boom lays flat and rests in a cradle. He has full size drawings that he can make copies of and send me. DB 24 has been to Lewiston twice. (1991+?)

Chris is currently in a Dr. Appointment and will call me back.

action required: Follow-up call to obtain drawings. Call Steve Lee in the equipment department.

distribution:

by: R. Petereit

The Derrick 24 (same name as Mansons Derrick 24 but they are different) has the following dimensions.

Width = 54 ft + tires
Length = 150 ft
Draft (light) = 5 ft
Draft (heary) = 9 ft
Distance between deck and A-frame = 60 ft 10 in
Hull height = 13 ft

The A-frame is the highest point on the derrick barge while being towed.

The Paula Lee has the following dimensions

Width = 68 feet + tires
Length = 250 ft
Boom length = 140 ft
Draft (light) = 5 ft
Draft (heary) = 10 ft
Hull height = 15 ft
Distance between deck and top of A-frame = 70 ft

As with the DB 24, the A-frame is the highest point on the derrick barge while it is being towed.

Kent - Thanks for taking my call today. Attached is the information submitted for the CRC program back in 2012. We would appreciate a review of this information to confirm that it remains accurate. We would especially want to know if any of the specifications have changed, if any of the fleet are no longer in service, if other vessels should be considered and whether you have any planned or potential projects that would result in the need to transit through the I-5 bridge area.

Feel free to contact me with any questions.

      State: WA Zip code: 98106
2. Vessel
   a. ID: b. Name: DB Alameda
   c. Type: Crane Barge d. USCG Document Number: 1075264
3. Vessel Configuration
   a. Identify vessel configuration: Crane barge
   - Is a vessel specification sheet available? Yes
   - Configuration shown on the sheet: Yes
   - What is the lowest height configuration for transport? 71 ft 2 in.

   b. What is the gantry configuration? Pinned Estimated gantry height: 71 ft 2 in
   c. Does the barge have spuds? Yes
   - Height above waterline for travel? Gantry height
   - Can the spuds be removed for travel? Yes
   - Work and cost involved in removing spuds? ½ - full day
4. Vessel Location
   a. Where is the vessel currently located? Portland
   b. Is it working on a job? Yes – Tri Met Bridge Is it tied up to shore? No
   c. What is the best time to make a trip to the vessel? NA

5. Measurements from Spec Sheet

D.B. GENERAL
700 TON FLOATING CRANE

SPECIFICATIONS

- Main Crane: Clyde 52
- Capacities: 700 tons @ 70′ radius over the stern
  500 tons @ 70′ radius fully revolving
  40 tons @ 243′ radius (auxiliary)
  25 tons @ 257′ radius (whip)
- Boom: 200′ to main fall (260′ available)
  230′ to auxiliary line (290′ available)
  245′ to whip line (305′ available)
- Barge Size: 300′ x 100′ x 18′
- Classification: ABS+A1, USCG
- Draft (std.): 8′-0″
- Spuds: Two 48″Ø x 90′ long
- Anchors: 6-point moorage
- Deck Loading: 2,000 psf uniform
- Bunkers: 50,000 gallons diesel fuel
  310,000 gallons fresh water

CAPABILITIES

- Heavy Lifting
- Piledriving
- Offshore Construction & Service
- Duty Cycle – Dredging
- Pipe Lay

Marine Contractors
Owner: General Construction
Vessel: D.B. Olympia

GENERAL CONSTRUCTION COMPANY

D.B. OLYMPIA
100 TON FLOATING CRANE

SPECIFICATIONS

- Main Crane: Dravo-Wellman 413
- Capacities: 100 tons @ 55′ radius over stern
  80 tons @ 50′ radius fully revolving
  15 tons @ 75′ duty-cycle
  15 tons @ 160′ radius
- Boom: 160′ to main fall (200′ available)
  165′ to main whip line (205′ available)
  Additional 50′ luffing jib available
- Barge Size: 150 x 60′ x 10′
- Classification: USCG
- Draft (std.): 4′-0″
- Spuds: Two 28″ square x 90′ long
- Bunkers: 6,000 gallons diesel fuel

CAPABILITIES

- Piledriving
- Duty Cycle
- Clamshell Dredging
- Heavy Lifting
- Crane Service

Vessel Height Verification Sheet

By: Ralph Petereit Date: July 10, 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: General Construction Co.
   b. Name of contact: Pat Boyd – Equipment Manager
   c. Phone number (Office): (206) 938-6758 (Cell): (206) 498-8815
   d. Email: PAT.BOYD@KIEWIT.COM
   e. Address: 3838 W. Marginal Way City: Seattle
      State: WA Zip code: 98106
2. Vessel
   a. ID: b. Name: DB Olympia
   c. Type: Crane Barge d. USCG Document Number: 1027118
3. Vessel Configuration
   a. Identify vessel configuration: Crane barge
   - Is a vessel specification sheet available? Yes
   - Configuration shown on the sheet: Yes
   - What is the lowest height configuration for transport? 70 ft 1.5 in

   b. What is the gantry configuration? Pinned Estimated gantry height: 70 ft 1.5 in

   c. Does the barge have spuds? Yes
   - Height above waterline for travel? Gantry height
   - Can the spuds be removed for travel? Yes
   - Work and cost involved in removing spuds? ½ - full day
4. Vessel Location
   a. Where is the vessel currently located? Lake Washington, WA.
   b. Is it working on a job? Yes – 520 Bridge Replacement Is it tied up to shore? No

c. What is the best time to make a trip to the vessel? None currently

Vessel Height Verification Sheet

By: Pete Geiger Date: 5 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Hickey Marine Enterprises/HME Construction
   b. Name of contact: Greg Speyer/Darrell Jamieson
   c. Phone number (Office): 360.695.4553 (Cell):
   d. Email: gregs@hickeymarine.com; darrellj@hickeymarine.com;
   e. Address: 6801 NW Old Lower River Road City: Vancouver
      State: WA Zip code: 98660
2. Vessel
   a. ID: b. Name: SeaHawk
   c. Type: Derrick Barge with Crane d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Boom lowered in travel postion; Spud Up on Pin
      - Is a vessel specification sheet available? On ProjectSolve
      - Configuration shown on the sheet: not shown, photo only
      - What is the lowest height configuration for transport? ~75 Feet (Spud on Pin)

   b. What is the gantry configuration? Assembled with Pins Estimated gantry height: Not given

   c. Does the barge have spuds? Yes, Two
      - Height above waterline for travel? Center (2) = 75 feet
      - Can the spuds be removed for travel? Only on very rare occasions
      - Work and cost involved in removing spuds? 4 hours to reset spuds. Need to find a site to harbor or tie up to. Spuds often need separate barge to transport them.
4. Vessel Location
   a. Where is the vessel currently located? Columbia River
   b. Is it working on a job? Yes but at HMI Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Anytime, Just need a few days advance notice.

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	44.0 feet
Water Level:	15.6 feet
Top of Boom:	77.0 feet (Travel angle ~17.5 degrees off horizontal)
Height of Boom Hinge Pin:	Not Measured
Boom Cradle:	Not Measured – No Boom Cradle
Top of Spud:	90.4 feet
Top of Deck:	Not Measured

6. Vessel Height

Self-Reported		Surveyed	
Air Draft:	75 feet	Air Draft:	75 feet
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet (CRD)	Water Level:	16 feet (CRD)
Total Height:	101 feet	Total Height:	101 feet

1. Company Name and/or Owner of Vessel and contact information
   a. Name of company: AME Hickey Marine Enterprises
   b. Name of contact: Greg Speyer & Darrell Jamieson
   c. Phone number (Office): 360.695.4553 d. (Cell): 360.772.4068
   e. Email: gregs@hickeymarine.com
   f. Address: 6801 NW Old Lower River Rd.
   g. City: Vancouver
   h. State: WA i. Zip code: 98660

3a. Vessel Name: Seahorse (Largest of 4) 3b. Vessel Type: Derrick Barge & Crane

3c. US Coast Guard Document Number: _____

4a. Length Overall (LOA), feet: 142 4b. Beam (width), feet: 60

5. Draft (depth of hull below waterline, fully laden), feet: 6.5'

6. Air Draft (Height of the highest fixed point of the vessel above the waterline, unladen), feet: 90' with spuds 75' gantry

7. Air gap for vessel (desired clearance from the highest fixed point on the vessel to lowest part of bridge): 10' They request 100' clearance when they go through bridges

8. Frequency of one-way passage underneath I-5 main channel (typical per month): Approx. 6x/yr. for all 4 vessels

   Jan ___ Feb ___ Mar___ Apr___ May___ Jun___ Jul___Aug___Sep___Oct___Nov___Dec___ Oct - March

9. Frequency of one-way passage underneath I-5 main channel (other historic events):____

10. Frequency of one-way passage through North Portland Harbor (Oregon Slough) (typical per month): None

    Jan ___ Feb ___ Mar___ Apr___ May___ Jun___ Jul___Aug___Sep___Oct___Nov___Dec___

11. Frequency of one-way passage through North Portland Harbor (Oregon Slough) (other historic events):_____ Rarely have a need to go through because they can get to either side without going through

Diversified Marine is in N. Portland Harbor but doesn't go above the I-5 bridge.

12. Do you have a Business Plan (e.g. 10 or 20 year plan)? What does it say regarding vessels transiting under the I-5 Bridge or into North Portland Harbor (Oregon Slough)? May we have a copy?

13. Other miscellaneous

They don't see a need for larger equipment. They have lengthened their spuds in the past. When they do that, they pull them out and barge them upstream.

- The gantry height (75') is the limiting factor. It is not adjustable. Other companies could have higher gantries.
- Bridge height of 125' at O'CRD would accomodate most users.
- Most of their work is in the Willamette Harbor. Also go up to Bonneville Dam (taking Seahorse + Sea Vulture there in March). Currently working in Longview & Pasco Dams and other facilities (grain elevators, petroleum docks) upstream for maint. Work on Columbia, Willamette, and Snake Rivers
- They can often "sneak" through the bridge high span rather than the lift span, depends on draft.
- They don't usually lower spuds, but can if the draft is good. Risk of losing spuds / bending them.
- March each year there is a shut down of the locks, so several barges (HME + others) going there

Vessel Height Verification Sheet

By: Pete Geiger Date: 5 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Hickey Marine Enterprises/HME Construction
   b. Name of contact: Greg Speyer/Darrell Jamieson
   c. Phone number (Office): 360.695.4553 (Cell):
   d. Email: gregs@hickeymarine.com; darrellj@hickeymarine.com;
   e. Address: 6801 NW Old Lower River Road City: Vancouver
      State: WA Zip code: 98660
2. Vessel
   a. ID: b. Name: SeaHorse
   c. Type: Derrick Barge with Crane d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Boom Down Near Cradle; Aft Spud Up on Pin
      - Is a vessel specification sheet available? On ProjectSolve
      - Configuration shown on the sheet: Crane Boom Up; Spuds Down
      - What is the lowest height configuration for transport? ~90 Feet (Aft Spud on Pin)

   b. What is the gantry configuration? Assembled with Pins Estimated gantry height: 75 Feet

   c. Does the barge have spuds? Yes, Three
      - Height above waterline for travel? Aft = 90 feet Center (2) = 79 feet
      - Can the spuds be removed for travel? Only on very rare occasions
      - Work and cost involved in removing spuds? 4 hours to reset spuds. Need to find a site to harbor or tie up to. Spuds often need separate barge to transport them.
4. Vessel Location
   a. Where is the vessel currently located? Columbia River
   b. Is it working on a job? No Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Anytime, Just need a few days advance notice.

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	88.7 feet
Water Level:	15.6 feet
Top of Boom:	65.1 feet
Height of Boom Hinge Pin:	Not Measured
Boom Cradle:	52.2 feet
Top of Spud:	104.0 feet
Top of Deck:	Not Measured

SEA LION

The Derrick Barge Sea Lion is a Manitowoc 60 Ton mounted crane on a 103' x 50'x 8' barge. Main draw-works power is provided by a Cummins diesel 300 HP She is set up with two winch controlled spuds. She was rebuilt in 1970. She has a minimum Height of 34.5' along with Minimum draft of 3' and Maximum draft of 5'. She has a 4,000 gallon fuel capacity which is separate from the hull. Clamshell Buckets available: 3 cy Yaun digging, 3.5 cy Esco digging, 3 cy Erie heavy duty digging, and 5 cy Yaun re-handle.

Spud Height 75' to water

Vessel Height Verification Sheet

By: Pete Geiger Date: 5 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Hickey Marine Enterprises/HME Construction
   b. Name of contact: Greg Speyer/Darrell Jamieson
   c. Phone number (Office): 360.695.4553 (Cell):
   d. Email: gregs@hickeymarine.com; darrellj@hickeymarine.com;
   e. Address: 6801 NW Old Lower River Road City: Vancouver
      State: WA Zip code: 98660
2. Vessel
   a. ID: b. Name: Sea Vulture
   c. Type: Derrick Barge with Crane d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Boom Elevated above Spuds; Bow Spud Up on Pin
   - Is a vessel specification sheet available? On ProjectSolve
   - Configuration shown on the sheet: not shown, plan view only
   - What is the lowest height configuration for transport? ~77 Feet (Bow Spud on Pin)

   b. What is the gantry configuration? Assembled with Pins Estimated gantry height: Not given

   c. Does the barge have spuds? Yes, Three
   - Height above waterline for travel? Bow = 77 feet Center (2) = 48 feet
   - Can the spuds be removed for travel? Only on very rare occasions
   - Work and cost involved in removing spuds? 4 hours to reset spuds. Need to find a site to harbor or tie up to. Spuds often need separate barge to transport them. Sea Vulture cannot reach its own spuds, necessitating a second crane.
4. Vessel Location
   a. Where is the vessel currently located? Columbia River

b. Is it working on a job? No Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Anytime, Just need a few days advance notice.

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	58.4 feet
Water Level:	15.6 feet
Top of Boom:	Measured while stored =185.8 feet (56 degrees off horizontal) Estimated at travel angle(17.5 degrees off horizontal) = 87.6 feet
Height of Boom Hinge Pin:	31.8 feet
Boom Cradle:	37.9 feet
Top of Spud:	90.7
Top of Deck:	Not Measured

6. Vessel Height

Self-Reported		Surveyed	
Air Draft:	77 feet	Air Draft:	75 Feet (Spud)

      State: CA Zip code: 95928
2. Vessel
   a. ID: b. Name: Heidi Renee
   c. Type: Spud Barge d. USCG Document Number: 1232925
3. Vessel Configuration
   a. Identify vessel configuration: Spuds Up on Pin
      - Is a vessel specification sheet available? No
      - Configuration shown on the sheet: not shown, photo only
      - What is the lowest height configuration for transport? ~81 Feet (Spud on Pin)

   b. What is the gantry configuration? N/A Estimated gantry height: N/A

   c. Does the barge have spuds? Yes, Two
      - Height above waterline for travel? Center (2) = 81 feet
      - Can the spuds be removed for travel? Only on very rare occasions
      - Work and cost involved in removing spuds? ½ day to full day to reset spuds. Need to find a site to harbor or tie up to. Need a crane to lift spuds.
4. Vessel Location
   a. Where is the vessel currently located? Tongue Point, Astoria, Columbia River
   b. Is it working on a job? No Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Prior August.

5. Surveyed Measurements (all measurements NAVD 88)

Vessel Height Verification Sheet

By: Pete Geiger Date: 12 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: JT Marine
   b. Name of contact: Waino Toristoja
   c. Phone number (Office): 360.750.1300 (Cell): 360.567.8382
   d. Email: waino@jtmarineinc.com
   e. Address: 2301 SW Hidden Way, #100 City: Vancouver
      State: WA Zip code: 98661
2. Vessel
   a. ID: b. Name: DB Astoria
   c. Type: Crane Barge d. USCG Document Number: N/A
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
   - Is a vessel specification sheet available? No
   - Configuration shown on the sheet: N/A
   - What is the lowest height configuration for transport? Crane down in cradle, spuds up and pinned

   b. What is the gantry configuration? Pinned Estimated gantry height: Not given

   c. Does the barge have spuds? Yes two foreward port and aft starboard. Both Spuds down
   - Height above waterline for travel? 80 Feet
   - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
   - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area. Cannot lift both spuds with own crane.

4. Vessel Location
   a. Where is the vessel currently located? Columbia River
   b. Is it working on a job? No Is it tied up to shore? Yes
   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	51.3 feet
Water Level:	14.8 feet
Top of Boom:	Measured while working = 111 feet (71 degrees off horizontal) Estimated height while traveling: 27 feet
Height of Boom Hinge Pin:	26.9 feet
Boom Cradle:	34.9 feet
Top of Spud:	53.9 – spuds in down position

6. Vessel Height

Self-Reported		Surveyed	
Air Draft:	80 feet (top of spuds)	Air Draft:	36.5 feet
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet CRD	Water Level:	16 feet CRD
Total Height:	106 feet	Total Height:	62.5 feet[1]

[1] Note: The spuds were in the down position when surveyed.

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: JT Marine
   b. Name of contact: Waino Toristoja
   c. Phone number (Office): 360.750.1300 (Cell): 360.567.8382
   d. Email: waino@jtmarineinc.com
   e. Address: 2301 SW Hidden Way, #100 City: Vancouver
      State: WA Zip code: 98661
2. Vessel
   a. ID: b. Name: DB Taylor
   c. Type: Crane Barge d. USCG Document Number: 514786
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
      - Is a vessel specification sheet available? No
      - Configuration shown on the sheet: N/A
      - What is the lowest height configuration for transport? Crane down in cradle, spuds up and pinned

   b. What is the gantry configuration? Pinned Estimated gantry height: Not given

   c. Does the barge have spuds? Yes two midpoint. Spuds currently down
      - Height above waterline for travel? 80 Feet
      - Can the spuds be removed for travel? Only in very special circumstances when they travel far upriver on the Columbia
      - Work and cost involved in removing spuds? 4 hours each spud to re-install; need to tie up to a dock near the work area. Can lift both spuds with own crane.

4. Vessel Location

   a. Where is the vessel currently located? Willamette River Sellwood Bridge

   b. Is it working on a job? Yes Is it tied up to shore? No

   c. What is the best time to make a trip to the vessel? Anytime just give him 1 day notice

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	65.3 feet
Water Level:	13.8 feet
Top of Boom[1]:	Measured while working = 192.7 feet (71 degrees off horizontal) Estimated height at travel angle: • 220 foot long boom: 131 feet • 166.6 foot long boom: 51 feet (limit is the gantry height)
Height of Boom Hinge Pin:	35.0 feet
Boom Cradle:	38.9 feet
Top of Spud:	62.4 feet – spuds in down position[2]

[1] Note: JT Marine reported that they use two different booms on the DB Taylor; one with a length of 220 feet and one with a length of 166.6 feet.

[2] JT Marine self reported that the height to the top of their spuds are 80 feet.

6. Vessel Height

Self-Reported		Surveyed[1]	
166.6 foot boom		220 foot boom	
Air Draft:	80 feet (top of spuds)	Air Draft:	131 feet
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet CRD	Water Level:	16 feet CRD
Total Height:	106 feet	Total Height:	157 feet

[1] Note: The surveyed air draft measurement shown is the estimated travel height based on the surveyed boom length.

Marine Contractors

Company: Knife River

Vessels:

- KR-1
- ITB-282

Company did not respond to IBR request. Information below for KR-1 was included in the CRC NIR. Information for ITB-282 was included in the Hood River-White Salmon Bridge Replacement NIR.

Marine Contractors

Owner: Knife River

Vessel: KR-1

River User Data Sheet By: _____ Date: 3-6-12

1. Company Name and/or Owner of Vessel and contact information

a. Name of company: **Knife River Northwest**

b. Name of contact: Dave Jensen

c. Phone number (Office): 503-944-3500 d. (Cell): 503-706-5117

e. Email: dave.jensen@kniferiver.com

f. Address: 12222 NW Marina Way

g. City: Portland

h. State: OR i. Zip code: 97231-2300

3a. Vessel Name: KR-1 3b. Vessel Type: Deck Barge

3c. US Coast Guard Document Number: 590980

4a. Length Overall (LOA), feet: 282' 4b. Beam (width), feet: 78'

5. Draft (depth of hull below waterline, fully laden), feet: 13.5'

6. Air Draft (Height of the highest fixed point of the vessel above the waterline, unladen), feet: 48.5'

7. Air gap for vessel (desired clearance from the highest fixed point on the vessel to lowest part of bridge): 5'

8. Frequency of one-way passage underneath I-5 main channel (typical per month):
Jan _4_ Feb _4_ Mar_6_ Apr_6_ May_8_ Jun_12_ Jul_16_Aug_18_Sep_18_Oct_12_Nov_4_Dec_4_

9. Frequency of one-way passage underneath I-5 main channel (other historic events):

10. Frequency of one-way passage through North Portland Harbor (Oregon Slough) (typical per month): N/A
Jan ___ Feb ___ Mar___ Apr___ May___ Jun___ Jul___Aug___Sep___Oct___Nov___Dec___

11. Frequency of one-way passage through North Portland Harbor (Oregon Slough) (other historic events): N/A

12. Do you have a Business Plan (e.g. 10 or 20 year plan)? What does it say regarding vessels transiting under the I-5 Bridge or into North Portland Harbor (Oregon Slough)? May we have a copy? Nothing formalized at this time. As the economy recovers, the frequency of trips under the bridge will increase – possibly twice as much.

13. Other miscellaneous

VESSEL DATA SHEET

Please fill out the data sheet below. Please complete a data sheet for each vessel in your fleet that transits under the Hood River – White Salmon Bridge. In addition, please note any future vessel or cargo plans that might require different vessels to transit under the bridge.

Company Name:

Vessel Name:

Current name: ITB-282

Vessel Type:

Deck Barge

Specialized Vessel *(e.g. limited maneuverability due to design or mode of operation. If yes, please describe)*:Choose an item.

Vessel Category: Choose an item.

Commercial

USCG Document Number:

596502

Primary Mooring Location *(waterway milepoint, if known)***:**

Sundial

Type and quantity of cargo, if applicable:

Aggregate

Length (overall; ft):

282

Beam (width; ft):

Vessel Height Verification Sheet

By: Ralph Petereit Date: July 21, 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Manson Construction Co.
   b. Name of contact: Randy Thorsen – Northwest Operations Manager
   c. Phone number (Office): (206) 762-0850 (Cell): (206) 793-2630
   d. Email: RTHORSEN@MANSONCONSTRUCTION.COM
   e. Address: 5209 E. Marginal Way City: Seattle
   State: WA Zip code: 98124
2. Vessel
   a. ID: b. Name: Haakon
   c. Type: Crane Barge d. USCG Document Number: 246141
3. Vessel Configuration
   a. Identify vessel configuration: Crane Barge
   - Is a vessel specification sheet available? Yes
   - Configuration shown on the sheet: Yes
   - What is the lowest height configuration for transport? Gantry Height

   b. What is the gantry configuration? Estimated gantry height: 84 ft
   c. Does the barge have spuds? Yes
   - Height above waterline for travel? 84 ft
   - Can the spuds be removed for travel? Yes
   - Work and cost involved in removing spuds?
4. Vessel Location
   a. Where is the vessel currently located? Gulf of Mexico
   b. Is it working on a job? Yes Is it tied up to shore? No
   c. What is the best time to make a trip to the vessel? None currently

5. Measurements from Spec Sheet

Gantry Height:	84 ft
Water Level:	
Top of Boom:	
Height of Boom Hinge Pin:	
Boom Cradle:	
Top of Spud:	

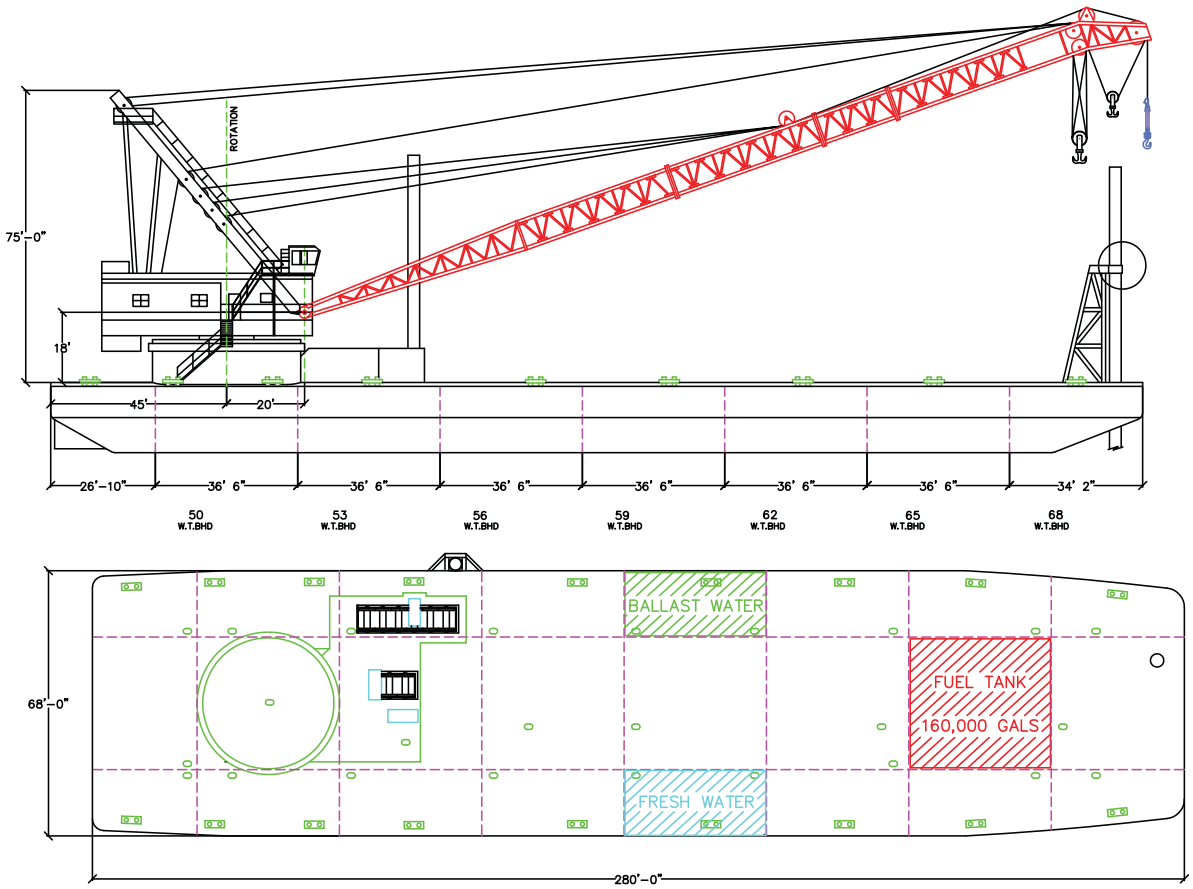
6. Vessel Height

Self-Reported		From Spec Sheet	
Air Draft:	84 ft	Air Draft:	84 ft
Air Gap:	5 – 10 ft	Air Gap:	10
Water Level:	16	Water Level:	16
Total Height:	106 ft	Total Height:	106 ft

7. History Notes

Date	Item
6/27/2012	Called and left message for Randy Thorsen – NW Ops Manager
7/9/2012	Called Randy, was told to send e-mail
7/9/2012	Sent-mail with information request
7/21/2012	Still no reply

Manson Derrick *Haakon*



Principal Characteristics	
Length Overall	280′-0″
Beam Overall (Without Spuds & Fenders)	68′-0″
Barge Depth at Main Deck	18′-0″
Mean Draft	9′-0″
Distance Deck to Boom Heel	18′-0″
Boom Length to Main	210′-0″
Boom Length Main to Whip	16′-0″
Spuds	Two
Clamshell Bucket Capacity (Cu Yards)	15 Cubic Yards

MANSON DERRICK "HAAKON"

Vessel Height Verification Sheet

By: Pete Geiger Date: 13 July 2012

1. Company Name and/or Owner of Vessel and Contact Information
   a. Name of company: Mark Marine
   b. Name of contact: Craig Mark
   c. Phone number (Office): 360.837.2677 (Cell): 360.772.0916
   d. Email: markmarine@ eathlink.net
   e. Address: 1498 SE 12th Street/PO Box 574 City: Washougal
      State: WA Zip code: 98671
2. Vessel
   a. ID: b. Name: DB Columbia
   c. Type: Derrick Barge with Crane d. USCG Document Number:
3. Vessel Configuration
   a. Identify vessel configuration: Crane Boom Elevated below Spuds; Port Spud Up on Pin
   - Is a vessel specification sheet available? No
   - Configuration shown on the sheet: N/A
   - What is the lowest height configuration for transport? ~75 Feet (Port Spud on Pin)

   b. What is the gantry configuration? Assembled with Pins Estimated gantry height: Not given

   c. Does the barge have spuds? Yes, Two
   - Height above waterline for travel? Port=75 feet Starboard = 75 feet
   - Can the spuds be removed for travel? Only on very rare occasions
   - Work and cost involved in removing spuds? 4 hours to reset spuds. Need to find a site to harbor or tie up to. Spuds often need separate barge to transport them.
4. Vessel Location
   a. Where is the vessel currently located? Columbia River
   b. Is it working on a job? No Is it tied up to shore? Yes

c. What is the best time to make a trip to the vessel? Anytime, Just need a few days advance notice.

5. Surveyed Measurements (all measurements NAVD 88)

Gantry Height:	51.8 feet
Water Level:	18.4 feet
Top of Boom:	63.9 feet
Height of Boom Hinge Pin:	30.7 feet
Boom Cradle:	53.5 feet
Top of Spud:	84.1 feet
Top of Deck:	Not Measured

6. Vessel Height

Self-Reported		Surveyed	
Air Draft:	75 feet	Air Draft:	66 feet (top of spud)
Air Gap:	10 feet	Air Gap:	10 feet
Water Level:	16 feet (CRD)	Water Level:	16 feet (CRD)
Total Height:	101 feet	Total Height:	92 feet

Good Morning Brian:

Ross Island Sand & Gravel Co. is indeed still a user of the Columbia with our dredging and marine construction operations. We pass through the Interstate Bridge two to four (2-4) times per year with our sand mining Dredge #7 pushed by the Tug Rossisle. Dredge #7 with it's positioning spuds raised requires a vertical clearance of 75' from the water surface.

See attached example photo.

Thank You for allowing our input. Ross Island is of course interested in what portions of the replacement project we can assist in with our marine construction cranes and barges.

ROSS ISLAND SAND & GRAVEL CO.

Subject: Interstate Bridge Replacement Program

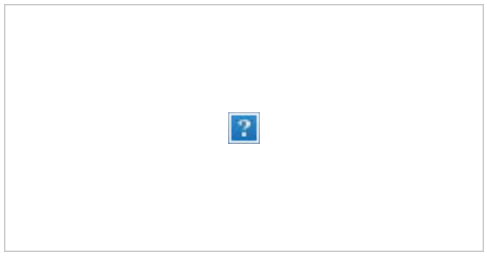
Mr. Steed,

I am part of the team working on the Interstate Bridge (IBR) Program for ODOT and WSDOT (https://www.interstatebridge.org/). I am reaching to you because Ross Island vessels were included in the Navigation Impact Report completed for the prior Columbia River Crossing project and we are validating and updating this data for the IBR program. We reached out to the contact listed in 2012 (Paul Godsil) but the email address was rejected. Can you provide a name and contact information for someone who can provide information your vessels and their use of the Columbia River at the I-5 bridge? Thanks in advance for your time and feel ree

to reach out if you have any questions specific to this request or the program in general.

Regards,

Brian



I-5 Bridge Replacement Program

Interstate 5 provides a critical connection between Oregon and Washington that supports local jobs and families, and is a vital trade route for regional, national and international economies. Beyond the concrete and steel of the existing bridge

INTRODUCTION

The history of Thompson Metal Fab includes two major influences, the opening of the Interstate Bridge in 1917, and the opening of the Columbia Business Center *(originally Henry Kaiser's Vancouver Shipyard)* in 1942. Over the years, Thompson Metal Fab (TMF), the Columbia Business Center (CBC) and the Interstate Bridge will see their history evolve due to the changing needs of the region, rapid population grown, and dynamic industrial development. For these same reasons, their history also begins to connect, and their futures are tied together.

The original Thompson Metal Fab facility, shown in 2018. Thompson moved from this location and to Vancouver in the early 1970's. The old facility has since been demolished, making way for the brand new Meyer Memorial Trust building.

Original span of the Interstate Bridge opened 1917 – shown here in 1931.

The original Interstate Bridge (current day northbound span) was completed and opened in February of 1917. Upon completion of this span, travelers could go from Canada to Mexico on one complete roadway. This was not only a big accomplishment for the country, but it was also an opportunity for growth, specifically in southwestern Washington. At the time the bridge was opened, there were approximately 250,000 people in Portland, compared to the 12,000 in Vancouver. The new bridge would provide opportunity for dynamic population movement, economic growth, and forever connect not only two states, but two communities. To satisfy the needs of this expanding community, a second 'twin' span was eventually completed and opened in 1958.

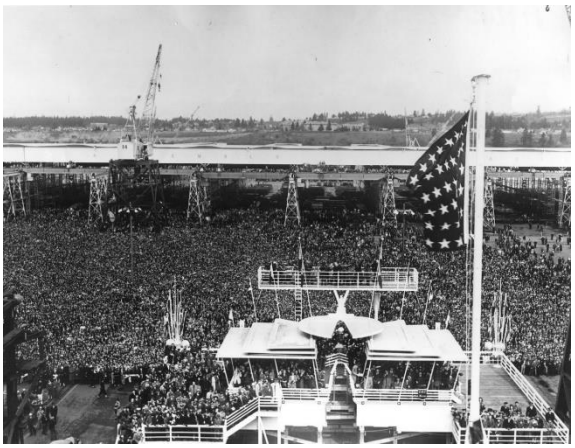
With a clearance of 72 feet, most river barges can pass under the bridge without impact when the drawbridge is closed. This is not the case with large industrial projects, like those manufactured currently by Thompson Metal Fab, or for large vessels, like the Liberty and Victory ships from the early 1940's. At full height, the current lift span can accommodate 178' from the water to the underside of the bridge. This "air gap" allows very large loads to pass upriver and downriver and has driven the development of upstream industrial areas such as the Columbia Business Center, originally known as Henry Kaiser's Vancouver Shipyard.

COLUMBIA BUSINESS CENTER *(former Kaiser Vancouver Shipyard)*

Building 40 and 41 of current day Thompson Metal Fab is shown prominently in the middle of this picture. At the time this picture was taken (circa early 1940's) the building and entire industrial area would have been known as Kaiser's Vancouver Shipyards.

At nearly 200-acres, Kaiser's Vancouver Shipyard began production in early 1942 with an initial payroll of 38,000 workers. This facility, along with two in Portland, produced 752 ships during WWII and peaked at 97,000 workers in total. Many of these workers migrated from other parts of the country and is part of the reason why the Portland/Vancouver area saw such a big jump in population at this time. The development of these shipyards certainly contributed to the need for a new span (eventually built and completed in 1958) and the need to modify the original span, completed in 1960. For perspective on what these facilities were able to produce, the construction on the first Liberty ship took 131 days in 1941. By 1943, Kaiser workers were averaging a completed Liberty ship in 42-days and three ships were being completed each day. Record production for a completed ship was 10-days, although that production was bested by one of the Kaiser facilities in Richmond, CA *(4-days, 15-hours, 29-minutes)*.

[1943] Escort carriers at the Vancouver Shipyards (current day Thompson Metal Fab)



75,000 people (largest crowd in Clark County's history) assembled on April 5, 1943 to witness first lady Eleanor Roosevelt christen the 'Alazon Bay' escort aircraft. Current day Thompson Metal Fab is seen prominently in the background.

drive opportunity to the Columbia Business Center as oil companies looked for fabricators to build "jacket liners" for new offshore wells. The facility could support the work on the massive infrastructure and the bridge was high enough to allow the jacket liners to be shipped downstream.

The 1960's and 1970's saw the construction of new dams on the Columbia River and Snake River in addition to the development of major oil fields in Alaska (i.e. Prudhoe Bay). Ongoing work on the US Interstate Highway System also provided opportunity for new bridges, including four highly visible bridges in Portland: Morrison Bridge (1958), Marquam Bridge (1966), Freemont Bridge (1973), and the Glenn L. Jackson Memorial Bridge (1982). These would be opened to accommodate a shifting population and to relieve pressure on traffic crossing the Interstate Bridge.

After the war ended and the need for shipbuilding diminished, learning how to leverage these 'abandoned' facilities for future industrial growth was important. The size of the facility at the Vancouver Shipyard was simply greater than most fabrication shops of the day. Even now, it remains one of the largest fabrication facilities on the West Coast. The sheer size of the building, access to a large yard, and location to a major waterway made the facility at the future Columbia Business Center an extremely attractive option for the large infrastructure needs that were coming.

The Portland/Vancouver Metro area became highly industrialized by the 1960's, driven by the ability of the Columbia Business Center and companies such as Thompson Metal Fab. This strong local economy centered around logging, pulp & paper products, and maritime transport on the Columbia River; and stimulated additional growth in the region. The California oil boom would also

Infrastructure for the California offshore oil fields being manufactured at the Columbia Business Center in 1967. Thompson Metal Fab would begin operations here a few years later in 1973.

THOMPSON METAL FAB

In 1937, "Pudge" Thompson opens 'Thompson Metal Fab' at 2405 Vancouver Avenue in Portland, OR. The opening of his facility comes 20-years after the opening of the Interstate Bridge while also pre-dating the second span by 20-years.

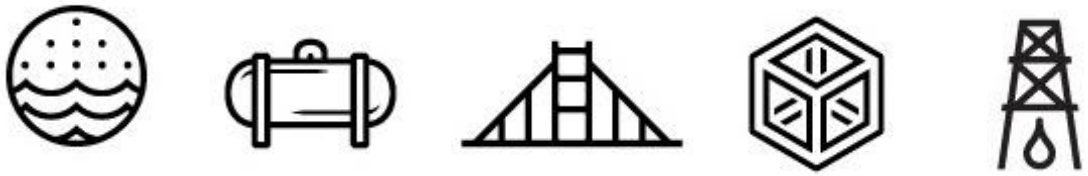
Original marketing display of the Thompson Ice Tongs

The origin story of Thompson Metal Fab is a humble one, especially compared to the work they do today. Pudge and his craftsmen manufactured lightweight metal products for the dairy and timber industries. One product, the Thompson Ice Tongs, held US patient #D206,091 and a quick Google search shows that the Thompson Ice Tongs are still selling online to this day. Thanks in part to the WWII war effort, expansion of TMF continued during the 1940's and 1950's; mirroring the growth of the community it served and the new industrial opportunities.

In 1973, after 36 years, Pudge Thompson sold his company to Harder Mechanical, whose story is like TMF's. Harder began as a small local plumbing contractor who was founded in 1934. A few years later they reinvented themselves so they could build housing for the workers at the Portland area shipyards during WWII. As the region continued to see growth, so did Harder who saw the acquisition of Thompson Metal Fab as a way to expand their capabilities and stake a claim on some of these emerging industries (i.e. hydroelectric dams). Shortly after the acquisition, the original Thompson Metal Fab facility (Portland, OR) was closed for good, and all operations were moved to the old Kaiser Shipyard in Vancouver, WA – a facility well suited to support the large projects Harder Mechanical would earn as they grew and expanded.

Thompson Metal Fab would transfer ownership again in the early 2000's with even more emphasis on how to maximize the capacity. The size of the facility requires TMF to be a diversified business and one with experience in multiple disciplines, including:

Marine/Hydro **Tanks/Vessels** **Bridges** **Modular/Structural** **Oil & Gas**



Since the early 1970's, TMF has completed countless projects while working over 10-Million man-hours *(estimated)*. The following list showcases some of the completed projects over the last 40+ years. In each case, transportation by barge was required (either by design or necessity), and in many cases the load passed under the Interstate Bridge.

Projects noted with (*) were not completed by Thompson Metal Fab but are on this list to showcase examples of other mega projects where a facility like Thompson's was required (Big shop, assembly yard, barge loading capabilities)

MARINE/HYDRO

<u>The Dalles Dam, Downstream Navigation Lock Miter Gates, Columbia River, WA/OR, USA [2011]</u>

Two Miter Gates were manufactured, where each gate measured 52' W x 106' L and weighed 1-Million pounds each. Due to navigational lock closures on the Columbia River, an aggressive fabrication and delivery schedule was required which required a fabricator with ample space and ability to load a barge. Picture to the right shows one gate getting ready to be loaded on the barge. Seen in the background is Parker Drilling Rig 272 & 273. Those rigs would ship just a few months after this load.

<u>Lower Monumental Dam, Downstream Navigation Lock Lift Gate, Snake River, WA, USA [2010]</u>

The finished weight of this structure was 1.5-Million pounds and would ship to the jobsite by barge in three segments. The final gate is 88' W x 84' H

<u>Ice Harbor Dam, Removable Spillway Weir, Snake River, WA, USA [2005]</u>

This removable spillway weir is designed to move juvenile fish more efficiently through the dam spillways. The unit measured 70' in width x 68' in height x 105' in length. It weighed 950-tons and is taller than Thompson's facility! The weir was completely fabricated at TMF and then transported by barge to Cascade General for repositioning before shipping to the jobsite on the Snake River.

Lower Granite Dam, Removable Spillway Weir, Snake River, WA, USA [2001]

The removable spillway weir is designed to move juvenile fish more efficiently downstream through the dam spillways. The weir was 83' wide x 61' deep x 115' long and weighed approximately 1,000-tons. The weir was completely fabricated at TMF and then transported by barge to Cascade General for repositioning before shipping to the jobsite on the Snake River.

Esperanza 124 MW Power Barge [1999]

Recently retrofitted in 2017 in Panama, it was originally fabricated in 1999 by Thompson Metal Fab, and transported to Cascade General in Portland, OR for final assembly and functional testing. The barge measured 105' wide x 30' deep x 284' long with a weight of 1,800-tons. The completed barge was loaded on a 400' L x 100' W barge for delivery to Cascade General.

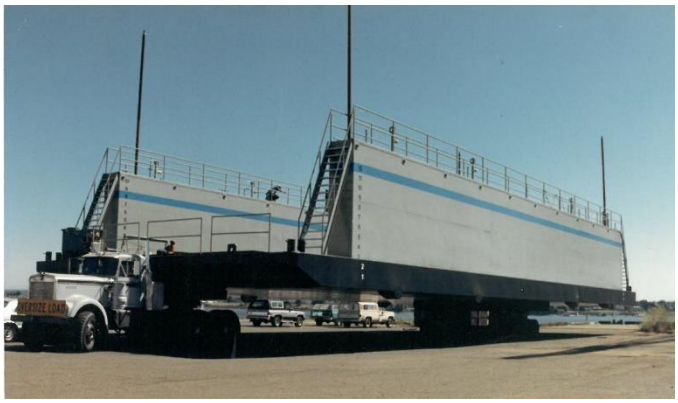
Golmar Explorer Ship Conversion [1997]

In 1997, Thompson fabricated multiple items for the infamous Golmar Explorer ship which was developed for the CIA and at the direction of Howard Hughes. By the mid-1990's the ship had changed hands a few times over and was in the process of being converted into an oil drilling vessel. TMF fabricated two double-bottom sections, four thruster tubs, vessel exhaust stacks, and manifold systems for this project. Completed components were transported by barge from TMF to Cascade General Shipyard.

John Day Dam, Upstream Navigation Lock Gate, Columbia River, WA/OR, USA [1991]
This gate was fabricated at the Columbia Business Center. The gate measured 28' deep x 80' high x 120' wide and weighed 105-tons. It was transported standing (80' high) for installation purposes.

Pacific Marine Hull Fabrication, Honolulu, HI, USA [1989]
TMF fabricated a 365-ton "SWATH" (Small Waterplane Area Twin Hull) excursion vessel. The fabrication consisted of twin cigar-shaped hulls that were 9' in diameter and 132' in length with vessel beams measuring 53'. Thompson's location adjacent to the Columbia River proved valuable for launching the vessel. After sea trials, the "Navatek" vessel headed to Hawaii. The vessel is still operating today.

Christensen Shipbuilders, Dry Dock, Vancouver, WA, USA [1987]
210' long dry dock was fabricated by TMF, including all walls, deck, ballast tanks and piping



Columbia River Barge Conversions [1979-1971]
Thompson converted barges to carry wood chips in support of the pulp and paper mills. The converted barges were fabricated to ABS and USCG standards. Projects were installed at our adjacent dock and barge facilities.

Alaska Ferry Conversion [1973]
Thompson Metal Fab supplied an exhaust funnel, solarium structure and modular subcomponents for the passenger ferry that travels the Inland Passage to Alaska. The existing ferry was cut in half and lengthened, with TMF fabricating all components for this major renovation. All items delivered by barge to the shipyard.

Other Examples Include:

- WSDOT Coleman Dock Improvements [2023] *
- Ballard Lock & Dam, Navigation Lock Center Miter Gates, Lake Washington, WA, USA [2022] *

- John Day Dam, 150-Ton Gantry Crane, Columbia River, OR/WA, USA [2022] *
- McNary Dam, Intake Bulkhead Gates, Columbia River, OR/WA, USA [2022] *
- Port of Alaska Petroleum & Cement Terminal Expansion, Anchorage, Alaska, USA [2021]
- Ward Cove Ferry Dock Expansion, Ward Cove, Alaska, USA [2020]
- WSDOT Mukilteo Dock Improvements, Mukilteo, WA, USA [2020] *
- The Dalles Dam, Upstream Navigation Lock Radial Gate, Columbia River, OR/WA, USA [2016] *
- Lower Granite Dam Expansion, Snake River, Washington, USA [1987]
- Revelstoke Dam, Columbia River, British Columbia, Canada [1984] *
- Bonneville Dam Expansion, Columbia River, Oregon, USA [1981] *
- Brownlee Dam Expansion, Snake River, ID/OR, USA [1980] *
- American Falls Dam Replacement, Snake River, ID, USA [1978] *
- Ice Harbor Dam Expansion, Snake River, Washington, USA [1976] *
- Grand Coulee Dam Expansion, Columbia River, Washington, USA [1974] *
- Mica Dam, Columbia River, British Columbia, Canada [1973] *
- John Day Dam, Columbia River, WA/OR, USA [1971] *
- Little Goose Dam, Snake River, Washington, USA [1970] *
- Lower Monumental Dam, Snake River, Washington, USA [1969] *

TANKS/VESSELS

<u>Phillips 66 Prefractioner Tower, Rodeo, CA, USA [2015]</u>

The 200-ton tower stretched 126' Long and transitions from 10'-6" diameter at the smallest to 17'-0" at the largest. The vessel was manufactured in three separate sections before being married together at Thompson's shop. The vessel shell and heads are made from clad plate which provides the necessary strength while also providing the required corrosion protection on the interior. For final acceptance, nearly 120,000 gallons of water was pumped into the vessel for a leak test. The vessel was pressurized over a period to ensure that all welds were water-tight.

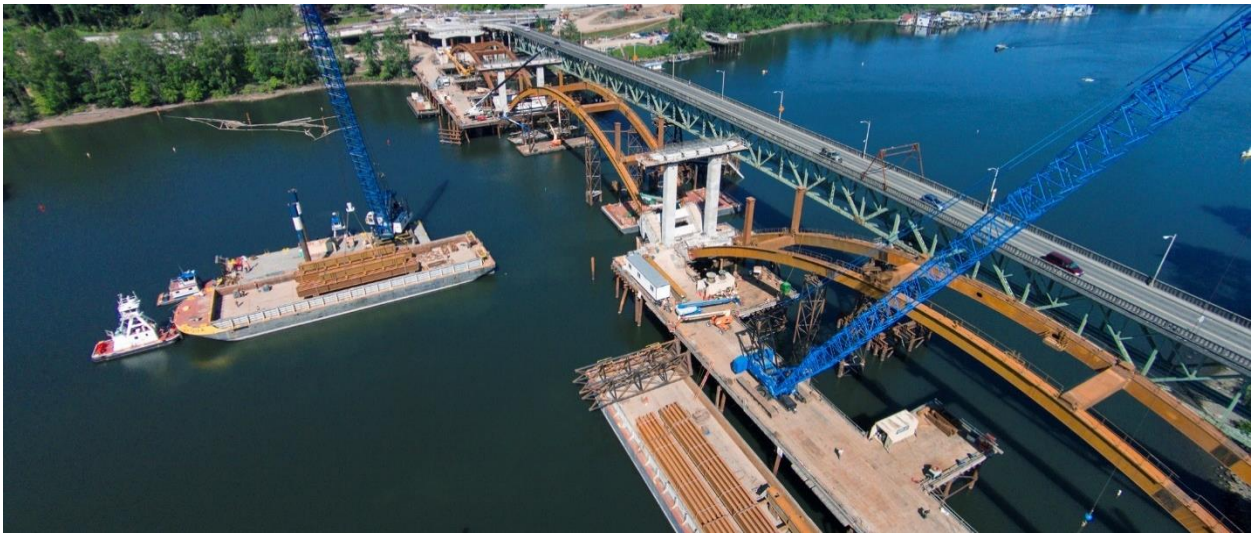
REC Solar Grade Silicon Project, Moses Lake, WA, USA [2007]

Thompson Metal Fab manufactured a total of 10 process vessels for the solar grade silicon industry. The project included four vessels which required barge transportation due to their size. Those vessels were 150" ID x nearly 120'-0" L and weighed over 200,000 LBS/ea. Vessels were barged to Pasco, WA and then shipped over the road to Moses Lake.

BRIDGE

Sellwood Bridge, Portland, OR, USA [2016]

Thompson's scope of supply included fabrication of all major bridge components: Arches, Arch Cross-frames, Vertical Spandrels, and the Bridge Deck Steel. Over 5,000-tons in total. The distinctive feature of the bridge are the three arches which cover 1,275' of the total 1,976' crossing. Each arch was fabricated in segments, with each segment 100' long. Because of the project's location on the Willamette River, steel was delivered to the jobsite with seven barge loads. Multiple barges can be seen here with incoming steel deliveries.



Bay Bridge Connector, Bay Area, CA, USA [2006]
TMF painted two orthotropic tub girders that were fabricated at the Columbia Business Center. Each weighed more than 1,600-tons and measured over 200' L x 80' W. Girders were transported by barge to the Bay Area for erection.

Richmond San Rafael Bridge, Bay Area, CA, USA [2004]
10,000 tons of structural bridge steel for the substructure was supplied for a seismic retrofit. Total fabrication took three years to complete. Larger components were transported by barge and direct to the jobsite.

Tri-Met Terry Moore Pedestrian Bridge, Portland, OR, USA [1996]
Fabricated at the Columbia Business Center, TMF painted the pedestrian bridge spanning HWY 26 near the HWY 217 junction. Completed sections were shipped by barge to a nearby location before being trucked to the jobsite.

1st Ave & Duwamish Bascule Bridge, Seattle, WA, USA [1996]
Completed truss sections for this project were fabricated at the Columbia Business Center, painted by Thompson, and assembled at the facility. Transportation to the jobsite in Seattle was done over the water, by barge.

Nimitz Freeway, Bay Area, CA, USA [1995]
This project consisted of (13) curved tub girders for the reconstruction of the Nimitz Freeway in the Bay Area. Girders were fabricated at the Columbia Business Center and painted by TMF. The total project weighed 6,000-tons with the largest girders weighing 450-tons; 50' W x 250' L. This project required four barges for delivery to jobsite..

I-90 East Channel Bridge, Seattle, WA, USA [1986]
Trapezoidal tub girders that varied from 98' to 198' in length and weighed between 60 and 200-tons each were fabricated at the Columbia Business Center and painted by Thompson Metal Fab. Girders were pre-assembled and completed sections loaded on a barge for transport to Lake Washington.

Other Examples Include:

- BNSF Bridge 66.4 Replacement, Cook, WA, USA [2020] *

MODULAR/STRUCTURAL

Intel Expansion, Hillsboro, OR, USA [2010's - Present]

Expansion at the Intel facility in Hillsboro has been going on for some time and Thompson has supplied numerous modular structures in support of their effort. In 2020, TMF shipped the largest modules to date, buildings that were 44' W x 97' L x 16' H. Due to their size, the buildings could break apart in half, but still required a barge to get from TMF's facility to the jobsite as shipping over the road was not an option.

Caltrans, East Tie-In Project, Bay Area, CA, USA [2008-2009]

Thompson was selected by Caltrans (owner) to work with TY-Lin (designer), CC Myers (contractor) and DCCI (erector) to fabricate 3,100-tons of temporary steel to provide detour for the Oakland Bay Bridge at Yerba Vista Island. Thanks to the size of their facility TMF could meet the 'expedited' schedule requirement for this project. Major components required four barge loads from TMF's facility to the job-site in California. Project was completed in 2009.

OHSU Tram, Portland, OR, USA [2006]

TMF fabricated the center support tower, the lower station, and the upper station for the tram project. The major components were transported by barge from TMF to the jobsite in Portland, OR where they were offloaded and erected.

The team at Thompson Metal Fab standing in front of base of the iconic Portland Aerial Tram mid-tower. The tram is located at the OHSU hospital in Portland and spans across I-405. The tower base is over 40' high as shown in this picture.

Alaska Gold Mining Project, Nome, Alaska, USA [2005]

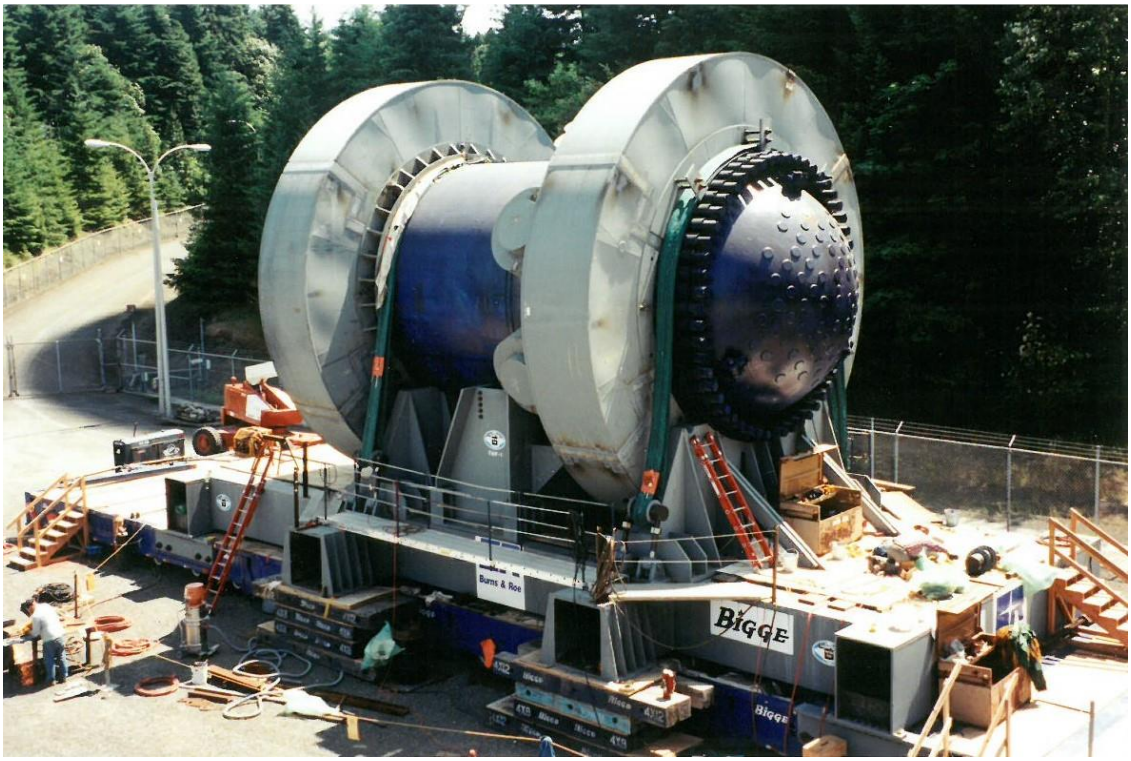
Thompson fabricated hoppers, grizzly grates, ball mill chutes, structural supports, modification of the ball mill, and other mining equipment for this project. TMF's facility was used for the marshaling yard and the load out point for all equipment and structures. Delivery was made via barge to Nome, AK.

Boeing Delta IV Launch Table, Vandenberg AFB, CA, USA [2003]

The 98' long x 33' high x 46' wide launch table weighed 580-tons. The project also included large flame deflector components which weighed up to 120-tons. The launch table and flame deflectors were fully assembled at the TMF facility and transported by barge to Vandenberg Air Force Base in California. It was then off-loaded an installed at the launch site.

PGE Decommissioning Trojan Nuclear Reactor Project, Rainier, OR, USA [1998]

TMF fabricated a 120-ton transport structure and 5" THK shielding enclosures. The completed structures were shipped by barge to the jobsite where the decommissioned reactor was loaded. The entire load was then shipped by barge to the final storage location at Hanford – Richland, WA.



Powell River Paper Company, British Columba, CANADA [1991]

Thompson supplied the fabricated steel for a Chlorine Dioxide Module that measured 35' wide x 76' high x 35' long. This module weighed 350-tons and was transported by barge in the vertical position from TMF's facility in Vancouver, WA to the Power River Paper Company in British Columbia, Canada.

Georgia Pacific Wood Chip Material Handling System, Toledo, OR, USA [1973]

TMF fabricated six 280' tube conveyor sections and all support towers for this project. The completed structures were transported by barge to Toledo, OR and installed.

- Portland Expo Center, Portland, OR, USA [1995]
- Bulk Material Handling System, Sacramento, CA, USA [1993]
- Newport Bay Floating Restaurant, Portland, OR, USA [1986]

OIL & GAS

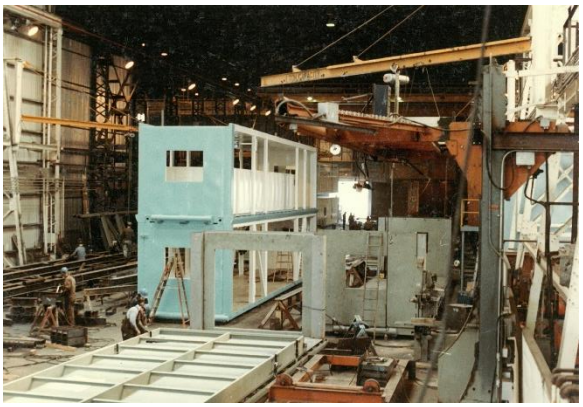
The turnkey modular service TMF offers today reflects what kicked off in the 1980's. By that point work at Prudhoe Bay was ongoing, but the infrastructure needed to support the development was still in process. In 1984, Thompson supported ARCO by manufacturing two 96-room housing modules. Each module was 40' wide x 46' high x 80' long. In addition, two Utilidor Modules were manufactured *(each 10' W x 22' H x 24 L)*. In 1985, more infrastructure was sent to ARCO; these 'bases' were 33' wide x 100' long x 10' high. Thompson also supported Conoco's Milne Point unit in 1985 with the supply of (10) module bases and (11) skids. These structures weighed anywhere from 20 to 270 tons each, with a max dimension of 64' W x 123' L x 12' H. Manufacturing structures of this size and delivering complete to the jobsite seems strange in the lower-48, but given the expanse of the North Slope, it's well suited to receive large infrastructure without other physical limitations to navigate. Additionally, with as fast as the development was happening, there was a value placed on 'set it and leave it' projects; things that could be installed and immediately put-to-use.

Massive platforms for the Alaska oilfields being fabricated at Thompson Metal Fab in the mid-1980's. The platforms nearly took up the entire width of a bay (80')

The platforms (seen left) were delivered by barge to Alaska where high capacity trucks and dollies (shown above) off loaded the structures for delivery to the jobsite.

Thompson's experience in supplying the oil fields eventually led to connections with the drilling contractors. The drilling contractors work on behalf of the owners to drill production wells and test holes as part of the exploration process. Drillers operate large equipment (known as rigs) to drill the holes. Thompson's first experience with rigs started in the late 1980's with Pool Arctic *(now Nabors Drilling)* who was a drilling contractor working on Alaska's North Slope. At one point, Pool Arctic operated the largest fleet of drill rigs on the North Slope. When TMF began working for Pool, they were looking to expand their fleet to meet market demand. This required retrofitting current rigs due to advances in equipment technology and drilling conditions that surpassed the capability of their rigs. Retrofitting works the same way as a new-build, only backwards. In a retrofit, the rig is placed on the barge and then shipped to a location large enough to receive it over the water and with enough yard space to accommodate the work. There are very few facilities on the West Coast who can accommodate this. Retrofits are just as attractive to TMF as new-builds. During a retrofit it is not unusual for some level of "rigging down" to happen and for structures to be placed in the shop. In that circumstance, it is very attractive to contractors to work with a facility large enough to handle these structures and keep them under the roof and out of the elements.

AADCO merged with Pool Arctic in 1983 and provided the rig shown above as part of the merger. This rig would be retrofitted by TMF.



Modular fabrication at Thompson Metal Fab for a Pool Arctic retrofit. The modules shown here represent the scale of a 'truckable' module, typically 12' H x 10' W x 40' L

Traditionally, drill rigs are built by manufacturing a series of truckable modules. These modules are fully assembled at the manufacturer's yard for verification, testing, and commissioning. Upon approval, the rig is completely disassembled for transportation to the jobsite. "Rigging up" is the process by which all these truckable modules are then reconnected together and recommissioned. Depending on the size of the rig, it is not unusual for 200 truckloads to be needed to move from the manufacturing location to jobsite. The process of putting a rig back together in remote locations can take months and cuts into production time. The ability to offer a turnkey service and integrate work in Thompson's shop and in their yard ultimately saves money in the long run – and contractors and owners have come to expect the capacity TMF can offer. During the early development of Prudhoe Bay in the Arctic, machinery and field services were limited and getting the required equipment to the jobsite required creative solutions. Field work is expensive and risky; and often there is limitations to what can be performed. Thompson can build larger modules for delivery, which provides a distinct advantage by minimizing costs in the field and minimizing risk.

Parker Drilling was one of the first contractors who recognized that one solution to the problems on the North Slope was to simply to deliver a *bigger* rig. A bigger rig would be capable of holding more robust equipment which would allow for drilling longer, bigger holes for greater production. The benefit of drilling longer holes is that you do not need to move the rig from pad to pad as frequently; you can cover a lot more ground from just one spot. They understood the importance of downtime and the full capacity of what TMF could offer with regards to turnkey modular fabrication. The design for Parker Drilling's Rig 245 swapped out the multiple, smaller, truckable

A large module for Parker Drilling Rig 245 moving from TMF's shop to their yard for assembly. Seen in the background is the mast and substructure of this massive drilling rig.

Rig 245 shown here at the assembly yard. When fully raised, the mast hangs high in the Vancouver, WA skyline.

modules and consolidated them into fewer 'mega modules.' Less modules simply take less time to put back together in the field. What could be 4-6 months in field work could now be up and running in weeks. Also, by eliminating trucks, the risk of loads being damaged during transport is reduced dramatically. Parkers' vision of 'mega modules' required a facility that offered a few things: a big shop, big yard, skilled workforce, access to water for shipping, and a logistically friendly location.

Parker Drilling Rig 245 being 'rigged up' at Thompson Metal Fab's yard. This yard space is immediately adjacent to the manufacturing facility and to the roll-on/roll-off barge slip. The ability to offer turnkey projects and delivery via water has given Thompson Metal Fab an advantage in the marketplace.

Drilling equipment has long been manufactured in Houston, Louisiana, and other Gulf state locations. These facilities manufacture the truckable modules and often the large offshore platforms. They certainly have the shop, yard, workforce, and access to water – but they do not have a strategic location to Alaska when it comes to logistics. To get a barge from the Gulf to the North Slope requires passage through the Panama Canal just to get from one side of the continent to the other. The added time for shipping and the added cost of voyage does not justify the mega module concept. What is needed is a manufacturer in the Pacific Northwest. TMF's location at the old Kaiser shipyard in Vancouver, WA provides the space and direct access to a deep-water barge slip with roll-on/roll-off access. The combination of a heavy-industrial construction facility and a support yard with marine transportation capability is an important asset to the region's industrial job base and has potential to attract large job producing projects. This capability has enabled TMF to stay competitive in a business that has largely moved overseas.

Becoming a proven West Coast manufacturer of drilling equipment gave drilling contractors an option that was not there previously. By entering the market, engineers could now extend the limits of their design and present solutions that were attractive to both contractors and owners who were seeking to replicate what Parker did with Rig 245, the first mega-rig on the North Slope. Among the design variables that has always been taken into consideration are the shipping clearances between our facility and the North Slope of Alaska. In that distance, there are three bridges which loads must pass under: The Interstate Bridge, the Lewis & Clark Bridge, and the Astoria-Megler Bridge. Of those three, the Interstate has the lowest total clearance, but is currently sufficient to meet the requirements of transporting mega modules.

Doyon Drilling Rig 25 shown on the barge in the foreground. Due to the size of the rig and its six mega-modules, two barges were required for delivery to Alaska's North Slope. The background shows the remaining modules for Rig 25, in addition to Parker Drilling's AADU Rigs (Rig 272 and Rig 273)

Thompson's greatest competitive advantage in earning business with the drilling contractors is their ability to ship completed, commissioned, turn-key 'mega modules' to the jobsite. If that advantage is eliminated, they will be priced out of the market. In addition to competing against the Gulf states, they actively compete with Canadian shops in Alberta. Because of the exchange rate, those facilities have a 30% pricing advantage, all other things being equal. That is the magnitude of the shipping advantage they have at Thompson. Contractors are willing to pay a

Picture of the Interstate Bridge in 2011 showing both the original Northbound span (background) and the second span (foreground) which opened in 1958 to traffic in both directions. In 1960, the second span was dedicated to Southbound traffic only. (Photo shows TMF manufactured drill rigs, AADU Rig 272 & 273 for Parker Drilling)

premium to avoid truckable modules manufactured in interior Canada or in the Gulf. It is the Contractor's advantage in the long term to have mega modules as their risk is lower, their down time is lower, field erection and trucking costs diminish, etc. Please note, these mega modules can only have their loads diminished so much (because of shipping clearance issues, etc.) before the concept no longer makes sense and the design is forced back to a more traditional build plan.

PROJECT EXAMPLES:

Hilcorp Innovation Rig, North Slope, Alaska, USA [2016]

The Innovation Rig is the next generation of drilling equipment. At nearly 1.5-Million LBS of steel, this rig consists of multiple modules and was built up to 50' H in TMF's shop before moving to their yard for final fit-up. At 9-months, this was the fastest rig build in Thompson's history, a true testament to their size and capability.

Parker Drilling AADU Rig 272 & 273, North Slope, Alaska, USA [2011]

Each drilling rig was comprised of three main modules. The Mud Modules weigh 600-tons, the Drill Modules weigh 700-tons, and the Utility Modules weigh 460-tons. The Mud and Utility Modules are 48' wide x 55' high x 99' long. The Drill Module is 76' high with the mast in the lay-down position.

Doyon Drilling Rig 25, North Slope, Alaska, USA [2010]

4-million LBS of steel and aluminum fabricated for Rig 25, a project where TMF also acted as the General Contractor. TMF managed all rig-up activities including mechanical, electrical, and functional checkout. This rig consisted of six primary modules: Power Complex (550-tons, 56' L x 40' W x 42' H); Drill Complex (560-tons, 96' L x 37' W x 40' H); Pipe Complex (560-tons, 68' L x 47' W x 25' H); Mud Complex (550-tons, 68' L x 40' W x 49' H); Pump Complex (560-tons, 64' L x 40' W x 52' H); Casing Complex (500-tons, 60' L x 56' W x 40' H). The 26' x 25' Mast extends to 148' L.

Parker Drilling/British Petroleum Liberty Rig, North Slope, Alaska, USA [2009]

This drilling rig shipped from our facility to the North Slope of Alaska in July 2009. TMF furnished approximately 5.5-milion pounds of fabricated steel. The rig was the world's largest land-based rig at the time of manufacturing and consisted of three large modules. The Drill Module was 58' W x 98' H x 68' L, weighing 900-tons. The Pipe Barn module was 158' W x 45' H x 170' L, weighing 2,560-tons. The Drill Service Module was 50' W x 48' H x 177' L, weighing 2,600-tons.

Pool Arctic Rig 6, North Slope, Alaska, USA [1998]

The Rig 6 project was a retrofit of the existing rig and included all new structural framing in addition to new mechanical components for the moving system. At the time of manufacturing, it was reported by the tire manufacturer to be the largest rubber tire vehicle in the world. Nicknamed 'Radio Flyer', this backbone of this rig is twin 6' x 10' box girders which support the drill floor and mast, and transfers load to the substructure.

Nordic Calista Rig 3, North Slope, Alaska, USA [1998]

In 1998, TMF completed and delivered Modular Mobile Oil Drilling Rig 3 to Nordic Calista. The rig includes 850-tons of fabricated steel, it measures 45' wide x 78' high x 110' long. The rig was transported by barge to the North Slope of Alaska.

Parker Drilling Rig 245, North Slope, Alaska, USA [1990]

In 1990, TMF fabricated a self-propelled mobile oil drilling rig. The drilling module was 43' wide x 78' high x 150' long and weighed 3,000-tons. The utility module was 40' wide x 58' high and 130' long, weighing 1,500-tons. The cutting module is 30' wide x 30' high x 40' L, weighing 350-tons. The completed drilling rig was transported by ocean-going barge from TMF's facility to the North Slope.

ConocoPhillips Milne Point, North Slope, Alaska, USA [1987]

3,400-tons of fabricated modular steel structures were supplied to ConocoPhillips. This took three ocean-going barge loads to deliver to Alaska.

ARCO Operation Center Housing Expansion, North Slope, Alaska, USA [1985]

Modular superstructures (40' W x 65' H x 80' L) were fabricated along with bases and decking housing modules. Completed modules were loaded onto a barge and transported direct to the North Slope.

With a structural height of 126', this pile template for a monopod in the Cook Inlet (Alaska) is one of the largest structures to ship from the Columbia Business Center in the last 40-years. Thompson Metal Fab manufactured piling for this project, delivered in 2014.

Taken in the early 1970's, the photo above shows Thompson Metal Fab shortly after closing the original facility in Portland and moving to Vancouver. Thompson added fiberglass roofing and walls to bays 5 through 9 to create an enclosed space. The land has been developed quite a bit in the last 40-years (including improvements to the roll-on/roll-off barge slip), but the building remains virtually the same.

LOCAL BENEFIT & LOOKING AHEAD

Because of Thompson's 40-year reputation, logistical advantage and modern quality programs required, they have a distinct benefit. Loss of that logistical advantage due to a diminished shipping clearance (or other) is not something they could replace. Earning this business is a tremendous benefit to Thompson, their employees, and their local community. For example, any one rig project is equivalent to one year of revenues, in addition to hundreds of direct high wage jobs, as well as work for hundreds of local small businesses.

Due to the magnitude of work, contractors often mobilize to Vancouver to manage the construction. This includes management, engineers, and other personnel to ensure that projects are delivered on time. This staff of people stay long-term in local hotels, rent from local citizens, spend entertainment dollars with local small businesses, and are an economic benefit. They not only employ the staff at TMF, but they also employ local electricians, machinists, painters, millwrights, pipe fitters, hydraulic operators, boilermakers, sheet metal workers, and other trades. This work also supports various apprentice programs which train the next generation of trade workers. Loss of this total benefit cannot be replaced.

Local businesses see boosts in revenues when major job producing projects are brought to the Columbia Business Center. Due to the nature of these large projects, stakeholders often move management teams to Vancouver to oversee manufacturing.

History has shown us that building a new link between Vancouver and Portland will bond our communities together and provide opportunity for economic growth and expansion. We also see that there is a correlation between the bridge, the growth of our community, and Thompson Metal Fab. The need for large-scale fabrication remains and markets that require TMF's services show no sign of slowing. There is potential for an industrial rebirth, one that mimics the industrial expansion of the 1950's through 1970's. While it is yet to be seen at the time of this writing, the federal government will at some point pass an infrastructure spending bill, which intends to replace our aging and deteriorating bridges, dams, and other critical works. Just as building these original structures kept generations of people working, so will the effort to replace these structures.

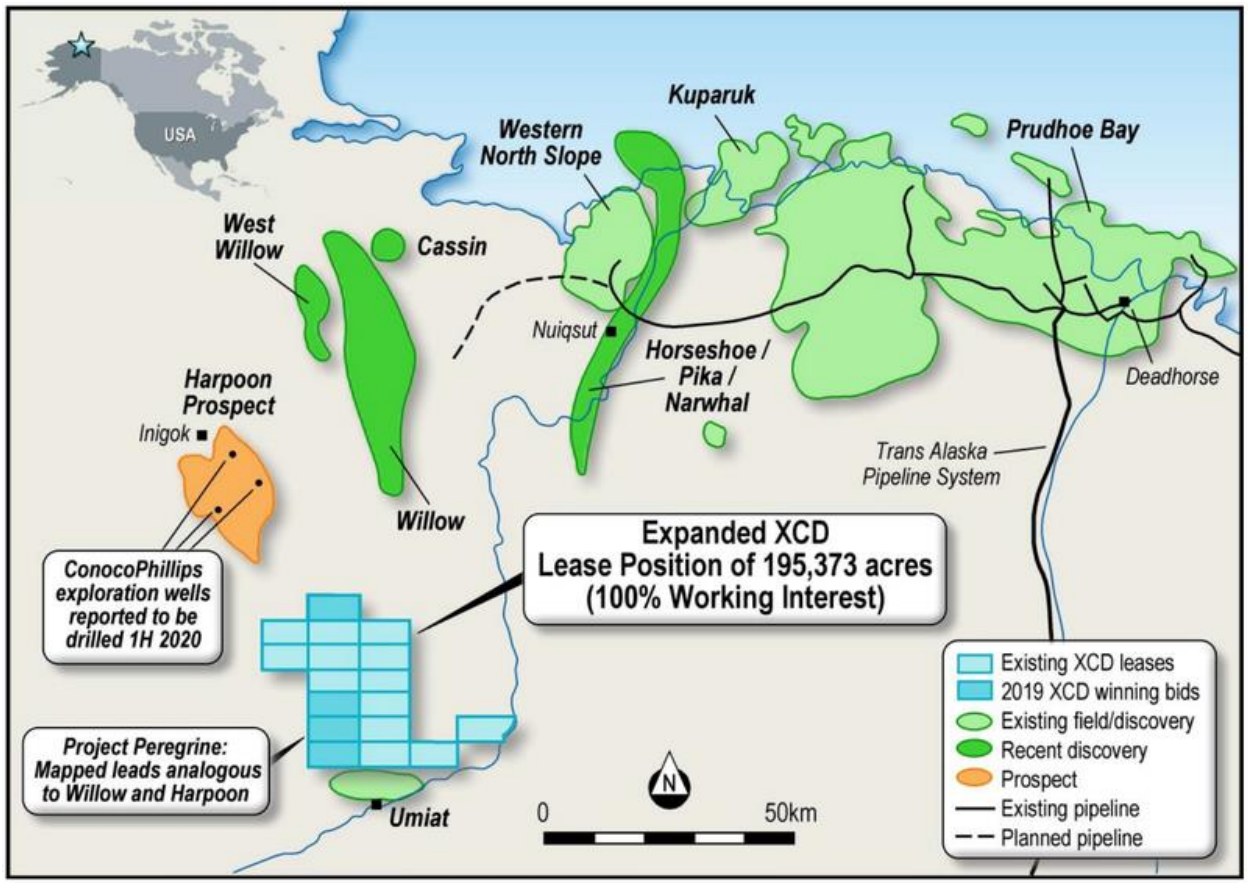
Thompson is encouraged by the commitment made to develop renewable energy sources. TMF has directly supported this effort for decades by manufacturing equipment that grows polysilicon crystals used in the development of solar panels. They have even been successful exporting domestically manufactured polysilicon equipment to countries such as China. Being a part of clean and renewable projects is something TMF does every day, thanks to the nature of their business. Steel is the most recycled material on Earth and steel products are 100% recyclable at the end of their useful life. Once produced, steel can be continually recycled into a new steel product without deterioration in product quality. Even the byproducts of steel work can be reused. Weld slag is used in cement, road construction, fertilizers, and hydraulic engineering. Process gasses are used to produce heat and electricity. Metal oxides can be recovered from steel making dust. Steel's inherent durability and recyclability make it an ideal fit for a circular economy. Allowing Thompson Metal Fab to continue producing steel products in the manner they do currently is a critical component in the continued development of clean energy and in effort to reduce America's carbon footprint.

As Thompson looks ahead to the future, they are currently tracking several projects and emerging markets which will certainly require a shop of their size and skill set. These projects will likely require delivery by barge and be of scale greater than or equal to what has been demonstrated. As noted, TMF has a competitive advantage with projects that require delivery by water and there is no other comparable, active facility with a roll-on/roll-off barge slip on the West Coast. Future opportunities include:

- ConocoPhillips – Willow expansion *(drill rigs, modules)*
- Oil Search – Pikka expansion *(drill rigs, modules)*

- Horseshoe Unit – Future North Slope Expansion *(drill rigs, modules)*
- Aerospace
- Offshore Wind and Wave power generators
- Burnside Bridge
- Golden Gate Bridge Seismic Retrofit
- West Coast Movable Bridges
- Hydroelectric Maintenance Projects
- Desalination in California
- Port of Nome - Expansion

Willow Expansion/Pikka Expansion/Horseshoe Unit



In many regards, the original Prudhoe Bay development has reached the end of its useful life. In 2020 original Owner, BP, sold their Prudhoe rights to ConocoPhillips and Hilcorp. Hilcorp is renowned for their ability to acquire 'legacy wells' and get a high level of production thanks to their ability to match modern technology with lean processes. What bigger companies might steer away from or flat out abandon due to high overheads, Hilcorp (a smaller independent company) can come in and still make profits for many years. The sale of Prudhoe and acquisition by Hilcorp signals the end of an era at Prudhoe, but it also marks the beginning of Alaska's next chapter in oil production.

In 2016, discovery wells were drilled in the Willow unit, owned by ConocoPhillips. The Willow unit is immediately west of Prudhoe and other large operating units but is on land that is largely under-developed. During the expansion of Prudhoe Bay facilities were tied into one another (Alpine, Kuparuk, Oooguruk, Milne Point, North Star, Endicott), man camps often shared, and roads and bridges integrated into one logistical network. Willow is far enough outside of this integrated network that relying on the existing infrastructure to support further expansion is not feasible. New piping systems would be needed, new roads would be required, new processing modules installed, and essentially a 'mini Prudhoe' would need to be built from scratch. After a successful exploration and appraisal season in 2018 it is estimated that Willow could contain up to 750-million barrels of oil and the infrastructure that would support Willow could produce approximately 100,000 barrels per day. Assuming full production each day of the year, Willow would be 'on-line' for 20-years.

This massive process module is being loaded out for delivery to the North Slope of Alaska in July 1990. This industrial equipment rivals the size of most downtown buildings and is representative of the equipment currently being requested for North Slope expansion projects. Due to scale and complex nature of work, this sort of equipment cannot be manufactured at the remote jobsite or accomplished at all in Alaska.

This massive process module is being loaded out for delivery to the North Slope of Alaska in July 1990. This industrial equipment rivals the size of most downtown buildings and is representative of the equipment currently being requested for North Slope expansion projects.

Flanked by existing units, Alpine and Kuparuk, sits Pikka. The Pikka unit is part of the Nanushuk Field which is estimated to hold as much as 1.5-billion barrels of oil. This is considered to be the biggest conventional onshore oil discovery in the US in the last 30-years. Upon full development, it is anticipated that Pikka will produce 120,000 barrels per day, and on some accounts up to 160,000 barrels per day. Conservatively, there is enough oil here to keep Pikka online for nearly 35-years.

Like Willow, there's just no infrastructure in Pikka despite being sandwiched by two existing fields. Early planning on Pikka included budgetary Requests for Proposal which were submitted by Pikka's Owner, Oil Search. One RFP requested multiple modules nearly 80' H x 200' L x 80' W, a fairly typical example of the infrastructure which is required.

Finally, early testing has been going on in the Horseshoe unit of the North Slope (south of the Willow and Pikka unit) and early indication is that Horseshoe will also be a high volume area, with volume of over 1-billion barrels. Combined with Willow and Pikka, the makings of a modern day Prudhoe Bay is in the works and could be a generational project.

Aerospace

Vandenberg Air Force Base is home to the US Air Force, United Launch Alliance, Space X, and now home of the Space Force, a branch of the US Air Force. Blue Origin is looking at Vandenberg as well and this will produce new opportunities for launch facilities. The western range is advantageous and continues to serve the needs of the industry. All these groups are getting a boost from "REACH" (Regional Economic Action Coalition). Currently, Vandenberg has the only Space Launch Complex (SLC) to launch for polar orbit. The Cape is working on a program for this, but currently the capability does not exist.

(Report from 'REACH' available for online viewing at https://reachcentralcoast.org/wp-content/uploads/Phase-0-Report.pdf)

Excerpt from the referenced report:

"Driven in large part by commercial enterprises, space is now a $425-billion industry that's expected to grow to $3-trillion over the next three decades…It's a huge opportunity and why REACH adopted building a thriving space enterprise as a core initiative in our 2030 plan."

This bold plan by the State in collaboration with all the stake holders will result in the construction of new facilities to support launch efforts at Vandenberg. Launch towers and/or mobile assemble buildings will be major projects that will require work on very large structures within this decade. The work on these facilities in the past been done by NW Oregon/SW Washington fabricators – including Thompson Metal Fab. This work requires facilities with large yard areas and heavy fabrication capabilities as well as a barge loading facility that is capable of supporting ocean going barges. There are very few of these types of facilities on the West Coast. The Columbia Business Center is one of those few spaces and represents a location that has both barge loading capabilities and the manufacturing capacity through groups like Thompson Metal Fab.

Pictures from Space Launch Complex-6 on April 26, 2021 show before and during launch of United Launch Alliance Delta IV Heavy rocket carrying a classified spy satellite. The launch table was manufactured by Thompson Metal Fab and delivered to the jobsite in 2003.

Past work in California dating back to the 1960's has been done at the Columbia Business Center. Jacket Liners for the Santa Barbara oil field were built at this location. Work for both Space Launch Complex 3 (SLC 3) and SLC 6 were done at Columbia Business Center. Much of this work required a full bridge raise to facilitate passage of the cargo on board a barge.

In addition to this planning at Vandenberg, Space X is now under contract for two more launches from there.

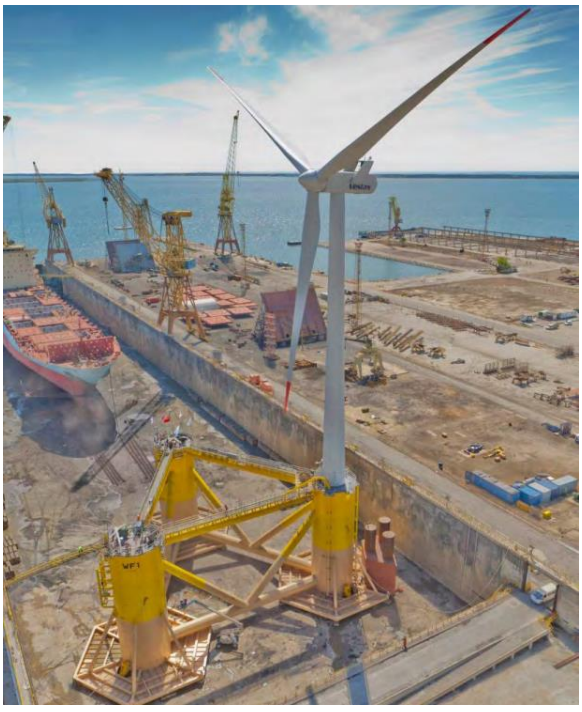
(https://www.noozhawk.com/article/defense_department_awards_contract_to_spacex_for_2_vandenberg_afb_launches)

Excerpt from NOOZHAWK Santa Barbara:

"The Department of Defense awarded Space Exploration Technologies a pair of missions that will involve two rocket launches from Vandenberg Air Force Base for the military's next-generation of space-based tools for warfighters….The announcement in the final hours of 2020 put the firm-fixed-price contract cost for SpaceX at $150,450,000…The first launch will occur in September 2022, and the second mission will take place no later than March 31, 2023, to complete putting the constellation in space, according to the award by the Space Development Agency in Washington, D.C."

SpaceX and United Launch Alliance have been awarded a 40%/60% split for launching DOD payloads. This award was made in August of 2020. For work at Vandenberg, SpaceX will have to add the capability of vertical integration of DOD payloads. This will require Space X to build a Mobile Service Tower (MST) or a similar structure to facilitate vertical integration of their vehicles. Currently SpaceX does all integration horizontally, installing satellites and rockets onto Falcon 9 and Falcon Heavy inside hangars near the company's launch pads. But some of the of the US Government's most sensitive and expensive intelligence-gathering satellites are designed to be mounted on their launch vehicles vertically. SpaceX officials have indicated that vertical integration capability is required of participants in the National Security Space Launch Phase 2 Launch Service Procurement.

Offshore Wind and Wave



Currently there are no independent organizations/companies willing to make the upfront investment into this emerging market. The land based wind industry grew because of federal tax credits that made it profitable, and without federal assistance it is unlikely that offshore systems will get the boost needed.

Recently, the administration under President Biden cited their plan to expand the use of off-shore wind farms in effort to develop renewable energy sources. The goal of the Biden Administration is to increase capacity of the current off-shore systems to power 10-Million homes by the year 2030. To meet that target, the administration intends to accelerate the permitting of projects along the coastlines and to open waters for development. $3-Billion in federal loan guarantees are available for offshore wind projects and for investing in the nation's port properties to support wind construction.

Mirroring this goal to develop offshore wind energy, the states of California and Oregon have introduced bills to develop wind energy along their coastlines. California bill AB525 sets a goal of 10GW of offshore wind by 2040,

3GW of which to be established by 2030. Oregon's HB3375 also sets a goal of 3GW by 2030. Oregon's effort is sponsored by a Republican (Rep. David Brock Smith) who has positioned the states bill as an opportunity to stimulate economic development and resiliency.

Currently there is not a facility on the West Coast that is set up to assemble these massive offshore wind systems. Thompson Metal Fab certainly has the capacity to manufacture the floating bases, and the facility/space to receive the wind towers and turbines. We also have the space to perform all assembly required. All opportunity to participate with this emerging market is gone however if the new bridge is not at a suitable height. Our current plan to participate with this emerging market is to manufacture the bases at TMF and float them downstream to a satellite yard where the towers and turbines can be assembled and installed on our bases. With that plan in place, we can utilize our current facility for all the heavy manufacturing, and provided that we are not impacted by the height of the I-5 bridge, we can ship these structures to wherever the assembly yard is located. The Biden administration keys in on one important factor, most coastal port properties are not currently set up to handle this massive manufacturing and investment in the properties must be made.

Most of the current facilities manufacturing offshore structures are on the American East Coast, or in the Gulf. Even though these facilities have the capacity, they are not well positioned to support the manufacturing of offshore systems for the West Coast. To reach the West Cost, all cargo must travel through the Panama Canal and the distance associated with voyage makes the transportation very expensive and further defines the reason why developing a manufacturer on the West Coast is so important.

Figure A-20 Vancouver

Image above comes from BOEM report in 2016 which evaluates various sites on the West Coast that would be suitable for the development of offshore wind power manufacturing. The far right shows the Columbia Business Center, and predominantly in middle is Thompson Metal Fab.

Thompson Metal Fab is one of possibly two manufacturers on the West Coast who has the size of facility, yard space and direct access to water to make our company a very attractive option for full-scale manufacturing of offshore systems. When you look at the total capacity of the Columbia Business Park, there is more than enough space and infrastructure to use our location in a dynamic way. If the new bridge does not at least accommodate this emerging market, it will be very difficult to develop the required infrastructure at all on the West Coast. Let us not lose what we currently have.

On March 3rd, 2016, the Bureau of Ocean Energy Management published a 256-page report that names the Columbia Business Park as a viable option for manufacturing offshore wind systems, but also notes that if the new height of the I-5 bridge is lowered below its current air gap it will severely restrict this type of manufacturing for any facility that is upstream of the bridge (i.e. Thompson Metal Fab).

To download a PDF file of the Environmental Studies Program report, go to the US Department of the Interior, Bureau of Ocean Energy Management, Environmental Studies Program Information System website and search for OCS Study BOEM 2016-011.

Images above comes from the 2016 BOEM report which shows the manufacturing and shipping capabilities of the Columbia Business Center for the wave power industry.

Burnside Bridge

The Burnside Bridge is scheduled for start of construction in 2024. There are two alternatives to the movable portion of the bridge: Replace the existing double-leaf bascule bridge with a vertical lift bridge – or – replace the bridge with a modern double-leaf bascule. The replacement of the approaches is difficult and would be best with a long span alternative. The option of a Tied-Arch, Cable-Stayed or Truss Span is attractive.

Image above shows the Sauvie Island Bridge being shipped to the jobsite via barge on the Willamette River and passing under the Burlington Northern RR Bridge in Portland, OR. Delivery of steel for the new Burnside Bridge would take a similar approach, due to the limited area for construction at the jobsite in downtown Portland, OR. Bridge steel coming from the Columbia Business Center would pass under the Interstate Bridge to reach the jobsite.

Due to congestion at the job site, moving the major spans into place will be done by water. Similar work has been done in the past on the Freemont Bridge, Sauvie Island Bridge and Sellwood Bridge.

Golden Gate Bridge Seismic Retrofit

The Golden Gate Bridge has an upcoming project that is one of the largest projects on a single bridge that is not new construction. The iconic towers on the Golden Gate Bridge will be retrofitted in addition to the deck steel between the two towers. This project was due to be completed by 2024 but has been delayed by other projects *(currently scheduled to be complete in 2023)*.

West Coast Movable Bridges

California has 36 movable (non-railroad) bridges. Of that group, four are in poor condition and 25 are in fair. Replacement will be recommended for some of these bridges and most will be shipped to the job-site by barge.

Oregon has the previously mentioned Burnside Bridge coming up. Additionally, the Rose Quarter Improvement project which will include the manufacturing of major steel spans.

Washington has 51 movable bridges (non-railroad). 10 are in poor condition and 34 are in fair condition. These bridges will be slow to replace due to budget issues but most of the poor condition bridges will be replace.

Hydroelectric Maintenance Projects

The current 2021 (fiscal year) budget work plan for the US Army Corps of Engineers is $2.7-Billion. Much of this work will be on the Columbia River system. Applicable work for TMF is as follows:

<u>Portland District</u>

- Bonneville Dam
    - Powerhouse 2, 65-Ton Tailrace Gantry Crane Replacement
    - Headgate Repair Pit Rehab
    - Powerhouse 1 Trash Racks
    - Fish Guidance Efficiency
- John Day Dam
    - Navigation Lock Downstream Gate Bearing Shoe Replacement
    - Trash Racks Replacement
- Cougar Dam:
    - Spillway Gate Rehab
    - Butterfly Valves

- Foster Dam:
    - Oil Spill Prevention
    - Oil Water Separator
    - Fish Weir Follow-on
- Detroit Dam:
    - Spillway Gate Rehab
- Dexter Dam:
    - Trash racks
    - Intake Gates
    - 25-Ton Intake Gantry Crane Replacement
- Green Peter Dam:
    - 180-Ton Bridge Crane Rehab
- Big Cliff Dam:
    - 40-Ton Intake Gantry Crane
    - Trash Racks and Gates Rehab

Seattle District

- Libby Dam
    - 75-Ton Intake Gantry Crane Rehab
- Albeni Falls Dam
    - Turbine Maintenance Platform
- Chief Joseph Dam
    - Intake Gates Rehab or Replacement
    - Turbine Maintenance Platform
    - 50-Ton Intake Gantry Crane Rehab
    - 18-Ton Tailrace Gantry Crane Rehab

Walla Walla District

- Ice Harbor Dam
    - Intake Gate Hydraulic System Upgrades
- Lower Monumental Dam
    - Turbine Maintenance Platform
- Lower Granite Dam
    - Turbine Maintenance Platforms

Desalination in California

California is always in a water crisis. They have new reservoirs planned that will require outlet works, gates, etc. Most of this work will ship by truck/train, but shipping over the water (by barge) will be the modular structures for new equipment in the planned Desalination facilities that California needs to sustain the population growth.

30-miles north of San Diego is the Claude "Bud" Lewis Carlsbad Desalination Plant, the largest effort in North America to turn salt water into fresh water. Each day 100-million gallons of seawater are pushed through semi permeable membranes to create 50-million gallons of fresh water that is piped to municipal users. Carlsbad, which became fully operational in 2015, creates about 10% of the fresh water the 3.1-million people in the region use, at about twice the cost of the other main source of water. This is a real issue for California and will require the state to build more of these desalination plants.

Wartime Efforts

Henry Kaiser's Vancouver Shipyard, shown in development in 1942. Eventually becoming the Columbia Business Center, this facility would become a strategic West Coast manufacturing facility.

It is important to plan for the unforeseen as well. Contingency comes in many forms; but let us not lose sight of the reason why the facility exists to begin with. Kaiser built the facility as part of the war effort in WWII. Because of the shipping clearances allowed when the drawbridge was at full height, the Vancouver Shipyards could produce Liberty and Victory war ships despite being upstream from the bridge. If that height is impacted by a fixed structure at a *lower* clearance, the ability for Thompson to support major wartime efforts is certainly diminished especially when compared to the capacity we could offer today. As noted previously, we are one of only a handful of facilities on the West Coast who has facility large enough to manufacture the structures we do and ship over the water. Reducing shipping clearances will certainly limit Thompson's ability to be a strategic West Coast manufacturer if a major wartime event occurs.

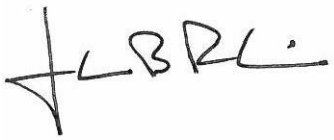
IN CLOSING

Thompson Metal Fab supports the new Interstate Bridge Replacement project. The region has outgrown the capacity of the current span and a new bridge is needed to reflect current and future needs. Innovations in transportation have changed the way people travel and move goods since 1917; and modern engineering, materials, manufacturing, and construction should allow for a beautiful, robust structure that will serve the needs for future generations. Currently the lift span on the Interstate Bridge is 178' at maximum clearance, any reduction

on a new span will have significant impact on TMF's industrial competitiveness. Less clearance will inhibit Thompson's ability to attract job-producing industrial projects to the region. Lower bridge clearance will also cause constraints for current and future energy infrastructure needs where TMF is counted on to be a major supplier to energy producers. Impacts to clearance could also affect the development of renewable energy sources, such as offshore wind. A facility, like that at Thompson Metal Fab in the current configuration, will be critical in the success of offshore wind programs on the West Coast. Additionally, users such as the US Army Corps of Engineers, will be impacted as they depend on TMF to deliver structures by barge to support our region's dams and ports East of I-5.

We recognize a new Interstate Bridge replacement needs to meet the requirements of all modern and future modes of transportation, and that requirement will most likely impact our historical, current, and future usage of river transit. However, Thompson also recognizes the importance of a new, safe, and modern bridge to the region, and is willing to work with the Interstate Bridge Replacement project team to preserve Thompson Metal Fab and hundreds of family wage jobs, while at the same time advancing a much needed new bridge to the future.

Sincerely,



John B. Rudi
Owner/President
Thompson Metal Fab

Clearance information assumes Zero (0) Datum. The Columbia River is typically 3' to 7' higher than Zero Datum. That measurement is not reflected in the example below. River height may significantly reduce the lift span clearance when seasonal river flows are above zero datum levels.*
