For ADA (Americans with Disabilities Act) or Civil Rights Title VI accommodations, translation/interpretation services, or more information call 503-731-4128, TTY 800-735-2900 or Oregon Relay Service 7-1-1.

Washington

Accommodation requests for people with disabilities in Washington can be made by contacting the WSDOT Diversity/ADA Affairs team at wsdotada@wsdot.wa.gov or by calling toll-free, 855-362-4ADA (4232). Persons who are deaf or hard of hearing may make a request by calling the Washington State Relay at 711. Any person who believes his/her Title VI protection has been violated, may file a complaint with WSDOT's Office of Equity and Civil Rights (OECR) Title VI Coordinator by contacting (360) 705-7090.

ABSTRACT

The Interstate Bridge Replacement (IBR) Program is a bridge, transit, and highway improvement project to address safety and mobility in the Interstate 5 (I-5) corridor between Portland, Oregon, and Vancouver, Washington. I-5 is the main interstate corridor on the West Coast of the United States (U.S.) from Canada to Mexico and one of only two roadway crossings of the Columbia River in the Portland-Vancouver metropolitan area. The IBR Program focuses on a 5-mile segment of the I-5 corridor that extends from approximately Victory Boulevard in Portland to State Route (SR) 500 in Vancouver.

The IBR Program is proposed by the Oregon and Washington State Departments of Transportation (ODOT and WSDOT), Southwest Washington Regional Transportation Council (RTC), Oregon Metro (Metro), Clark County Public Transportation Benefit Area (C-TRAN), and Tri-County Metropolitan Transportation District (TriMet). The Federal Highway Administration (FHWA) and the Federal Transit Administration (FTA) are the joint federal lead agencies for the IBR Program and are responsible for preparing the environmental documentation and overseeing the National Environmental Policy Act (NEPA) process.

The IBR Program is the renewal of the previously suspended I-5 Columbia River Crossing (CRC) project. The CRC project's NEPA process previously concluded with a 2011 Record of Decision and NEPA re-evaluations prepared in 2012 and 2013; however, the CRC project was suspended in 2014. In 2019, a bi-state legislative committee requested that ODOT and WSDOT reinitiate the CRC project, renaming it the IBR Program. In 2021 after the IBR Program was initiated, a third NEPA re-evaluation was prepared to evaluate the effect of changes in conditions and regulations since 2013, as well as potential design changes. FHWA and FTA determined that a supplemental environmental impact statement (SEIS) would be necessary to identify and disclose potentially new adverse impacts and mitigation associated with the IBR Program. Per 40 Code of Federal Regulations (CFR) 1506.13, this SEIS follows Council on Environmental Quality (CEQ) regulations that were in effect when the original Notice of Intent was published for the CRC project on September 27, 2005 (40 CFR Part 1506 as of 2005).

This Draft SEIS analyzes the transportation performance and potential impacts to the community and environment resulting from an updated No-Build Alternative and the proposed Modified Locally Preferred Alternative (Modified LPA). The IBR Program's Modified LPA is a modification of the CRC LPA and is the result of a multi-tiered screening process that included input from Program partners, tribes, and community members. The Modified LPA comprises a set of transportation components including a new pair of Columbia River bridges, a 1.9-mile light-rail transit (LRT) extension and associated LRT improvements from the Expo Center station in Portland to a new Evergreen Station in Vancouver, wider shoulders on I-5 from Victory/Interstate Boulevard in Portland to SR 500/39th Street in Vancouver, improvements to seven I-5 interchanges and I-5 mainline improvements, six new adjacent bridges across North Portland Harbor, active transportation improvements, integration of local bus transit service, and variable-rate tolling. There are several design options under evaluation for the Modified LPA, including three bridge configurations (double-deck fixed-span, single-level fixed-span, and single-level movable-span), site options for park and rides, one or two auxiliary lanes, alignment of the I-5 mainline in Vancouver, and the removal or inclusion of C Street ramps in Vancouver. The components of the Modified LPA are responsive to local agency policies and community priorities to support the mobility for people who walk, bike, roll, and drive throughout the study area. Based on a 2022 IBR Program cost estimate, the various components of the Modified LPA are expected to cost between $5 billion to $7.5 billion in year-of-expenditure dollars (YOE$).

Following publication of a Final SEIS, the federal lead agencies will issue an Amended Record of Decision, which would amend the 2011 Record of Decision.

FACT SHEET

Project Title

Interstate Bridge Replacement Program

Description

The Interstate Bridge Replacement (IBR) Program is a bridge, transit, and highway improvement project proposed by the Oregon and Washington State Departments of Transportation (ODOT and WSDOT), the Southwest Washington Regional Transportation Council (RTC), Oregon Metro (Metro), Clark County Public Transportation Benefit Area (C-TRAN), and Tri-County Metropolitan Transportation District (TriMet). The Program's purpose is to improve mobility in the Interstate (I-5) corridor by addressing present and future travel demand and mobility needs in the Program area. The Program area extends from approximately Victory Boulevard in Portland, Oregon, to State Route 500 in Vancouver, Washington, and includes the Interstate Bridge across the Columbia River. The Program is intended to address specific needs in the region through improvements to the following: travel safety and traffic operations on the Interstate Bridge and associated interchanges; highway freight mobility, interstate travel, and commerce; transit connectivity, reliability, and travel times; the availability of public transportation options in the study area; and the Interstate Bridge's structural integrity (seismic stability).

Date of Issue

September 20, 2024

Notice of Document Availability

An electronic copy of the Draft SEIS is available at no charge. Download an electronic copy here: www.interstatebridge.org

A printed copy and electronic copy of the Draft SEIS are available for viewing at the IBR Program office by appointment. To schedule an appointment:

Visit: SignUpGenius

Email: info@interstatebridge.org, or

Call: (360) 859-0494

Computers and internet access are available at various public libraries and meeting places throughout the Program area, as follows:

Washington Locations

Comment Period

September 20, 2024 – November 18, 2024

How to Submit Comments

Comments on the Draft SEIS will be responded to in the Final SEIS.

Written comments should not include any hyperlinks to outside materials or information. Any materials or information the commenter wishes to have considered should be included within the comment. Written comments on the Draft SEIS can be submitted through the online comment form at www.interstatebridge.org/DraftSEIS, by email to DraftSEIS@interstatebridge.org or by regular mail to the address below.

IBR Program Draft SEIS
c/o Chris Regan, IBR Program Environmental Manager
500 Broadway Street, Suite 200
Vancouver, WA 98660

Comments may also be submitted by leaving a voice message on the IBR Program's comment line at (866) IBR-SEIS (866-427-7347) (toll-free). Voice messages need to explicitly say "Draft SEIS" or "Draft Supplemental EIS" for them to be identified and addressed as comments on the Draft SEIS.

Comments can be submitted orally and in writing at a public hearing for the Draft SEIS. The dates and locations of the public hearings are detailed below.

Public Hearings

Public hearings will be held in Portland and Vancouver and virtually on the following dates and locations:

Tuesday, October 15, 2024
Clark College, Gaiser Hall 150
1933 Fort Vancouver Way
Vancouver, WA 98663
5:30-8:30 PM

Thursday, October 17, 2024
Portland Expo Center, Exhibit Hall E2
2060 N. Marine Drive
Portland, OR 97217
5:30-8:30 PM

Saturday, October 26, 2024
See www.interstatebridge.org for link
12:00-1:30 PM

Wednesday, October 30, 2024
See www.interstatebridge.org for link
6:00-7:30 PM

Subsequent Environmental Review

Following the Draft SEIS comment period and public hearings, the joint lead agencies will identify potential changes and refinements to the Modified LPA and proposed mitigation measures. Following refinements, the Program team will advance the engineering design and environmental analysis that will inform the Final SEIS and Amended Record of Decision.

ANTICIPATED PERMITS AND APPROVALS

Anticipated Federal, State, and Local Permits and Approvals

Permit or Approval	Issuing Agency
7460 permits for permanent and construction obstructions	Federal Aviation Administration
23 USC 129(a)(1)(E), Federal Tolling Authority	FHWA
Access revision report approval	FHWA
Design analysis approval	FHWA
Design approval	FHWA
Real estate acquisition review	FHWA
Right of way (interstate) approval	FHWA
Right of way (railroad) approval	BNSF Railway
Air quality conformity determination	FTA
Endangered Species Act Section 7 consultation	National Oceanic and Atmospheric Administration National Marine Fisheries Service (NOAA Fisheries), U.S. Fish and Wildlife Service (USFWS)
Magnuson-Stevens Fishery Conservation Management Act	NOAA Protected Resources Division
Marine Mammal Protection Act	NOAA Fisheries
National Historic Preservation Act Section 106	FHWA, FTA, National Park Service (NPS), Oregon State Historic Preservation Office (SHPO), and Washington State Department of Archaeology and Historic Preservation (DAHP)
Archaeological Resources Protection Act permit	NPS
Section 4(f) of the U.S. Department of Transportation Act of 1966 evaluation	FHWA, FTA
Section 6(f) of the Land and Water Conservation Fund Act documentation	FHWA, FTA, NPS
Bridge permit in accordance with the General Bridge Act of 1946	U.S. Coast Guard
Section 404 of the Clean Water Act (CWA)	U.S. Army Corps of Engineers (USACE)
Section 14 of the Rivers and Harbors Appropriation Act of 1899, as amended and codified in 33 USC 408 (Section 408)	USACE
Section 10 of the Rivers and Harbors Appropriation Act of 1899, as amended and codified in 33 USC 401 et seq.	USACE
Sole Source Aquifer Protection Act approval	U.S. Environmental Protection Agency
Migratory Bird Treaty Act	USFWS
Federal Lands to Parks program	U.S. General Services Administration, NPS
Approval of rail crossing, intersection, signals, and right of way encroachment permit	ODOT, WSDOT
Voluntary Cleanup Pathway approval	Oregon Department of Environmental Quality (DEQ)
CWA National Pollutant Discharge Elimination System construction stormwater permits	DEQ, Washington State Department of Ecology (Ecology)

Permit or Approval	Issuing Agency
CWA Section 401 water quality certifications	DEQ, Ecology
Air quality permits	DEQ, Ecology
Removal-Fill Permit	Oregon Department of State Lands (DSL)
Aquatic land use (aquatic lands lease) authorization	DSL
Oregon Fish Passage Act approval	Oregon Department of Fish and Wildlife
Archaeological Excavation Permit	Oregon SHPO, Washington State DAHP
Aquatic use authorization	Washington Department of Natural Resources
Hydraulic Project Approval	Washington Department of Fish and Wildlife
City of Portland local permits and approvals (design review/land use review, historic resources review, noise variance, improvements in right of way, building permit – site development, sign permit, trade permits, non-park use permit)	City of Portland
City of Vancouver local permits and approvals (public facilities master plan [hybrid approach], transportation development review, traffic impact analysis, shoreline substantial development permit, critical areas permit, noise permit, waiver of certificate of appropriateness, building permit, trade permits, temporary use permit, access closure, sign permit [temporary])	City of Vancouver
Right-of-way permit for any encroaching in public right of way or City easements, tree permit, design review	City of Gresham

SUMMARY

The following summarizes information from the Interstate Bridge Replacement (IBR) Program Draft Supplemental Environmental Impact Statement (SEIS), including Program background, the transportation problems the Program seeks to fix, the Modified Locally Preferred Alternative (LPA), and the key benefits and impacts. It concludes with a brief discussion of the next steps and methods by which the public can continue to be involved in the Program.

What is the IBR Program?

The IBR Program updates and supplements the Interstate 5 (I-5) Columbia River Crossing (CRC) project (approved in 2011) and focuses on a 5-mile corridor that includes bridge, transit, active transportation, and highway improvements to address safety and mobility in the I-5 corridor between Portland, Oregon, and Vancouver, Washington (Figure 1).

I-5 is the main, and only continuous, north-south interstate highway on the west coast, linking the United States, Canada, and Mexico. In the Vancouver-Portland metropolitan region, I-5 and I-205 are the only two roadway crossings of the Columbia River and the major north-south highways that provide interstate connectivity and mobility. While the I-205 crossing provides important connectivity for the region, I-5 directly connects the central cities of Vancouver and Portland.

The 5-mile section of I-5 between State Route (SR) 500/39th Street in Vancouver and Columbia Boulevard in Portland heavily influences the traffic conditions of I-5 crossing over the Columbia River. This section includes seven interchanges that connect three state highways and several major arterial roadways. These interchanges serve a variety of land uses and provide access to downtown Vancouver, two international marine ports, industrial centers, residential neighborhoods, retail centers, and recreational areas.

Highway users and transit service within the IBR Program study area are currently constrained by outdated, substandard highway design features, traffic congestion that increases travel times, and the frequency of crashes that reduce reliability for vehicles and buses traveling between Vancouver and Portland. Additionally, to access light-rail transit (LRT), users traveling to Portland from Hayden Island or Vancouver have to transfer from buses, or walk, bike or drive to nearby park and rides/transit centers at Expo or Delta Park.

Who is leading the IBR Program?

The Federal Highway Administration (FHWA) and Federal Transit Administration (FTA) are the federal lead agencies. Both agencies must comply with the National Environmental Policy Act (NEPA), including the publication of this Draft SEIS, as well as a Final SEIS, before they approve or provide funding to construct the improvements. Following the Final SEIS, FTA and FHWA will sign a Record of Decision (ROD) that will identify the preferred modified design of the selected alternative. The ROD for the Program will supplement the existing ROD for the CRC project that was signed in 2011 (CRC 2011a). The ROD will describe the measures needed to mitigate unavoidable environmental effects, as well as a monitoring and enforcement program to ensure that the mitigation measures are carried out effectively. By signing the ROD, FTA and FHWA are affirming that federal regulations have been met, thereby allowing the Program to proceed with property acquisitions and the final design of the selected alternative.

Figure 1. IBR Program Area Map

State transportation agencies and local governments in the Vancouver–Portland region have joined to develop a strategy for addressing highway, freight, transit, bicycle, and pedestrian needs, and to understand the importance of marine navigation on the Columbia River and North Portland Harbor and protected airspace for Pearson Field and Portland International Airport. The nonfederal joint lead agencies include the Oregon Department of Transportation (ODOT); Washington State Department of Transportation (WSDOT); local transit agencies Tri-County Metropolitan Transportation District (TriMet) and Clark County Public Transportation Benefit Area (C-TRAN); and regional metropolitan planning organizations Oregon Metro (Metro) and the Southwest Washington Regional Transportation Council (RTC). These nonfederal joint lead agencies, together with the Cities of Vancouver and Portland and Ports of Vancouver and Portland, comprise the state and local partner agencies that make-up an Executive Steering Group leading the Program. WSDOT also serves as the lead agency for the Washington State Environmental Policy Act review process.

WSDOT and ODOT are leading the preliminary highway design and Program management according to their respective Federal-State Stewardship & Oversight agreements with FHWA. TriMet and C-TRAN are leading the preliminary transit design and would operate the transit elements of the Program. Metro and RTC maintain the regional and metropolitan transportation plans that would include the Modified LPA for the IBR Program. The Program improvements are within the city limits of both Portland and Vancouver[1] and would connect to the local street networks in both cities. Therefore, the Cities of Portland and Vancouver have special expertise on city facilities and operations as well as local permitting authority over some elements of the Program. The Ports of Portland and Vancouver provide special expertise on regional and local freight movement, in particular, along Marine Drive, Mill Plain Boulevard, and Fourth Plain Boulevard.

Other state and federal agencies, tribes, and community partners are also participating in technical, regulatory, or advisory roles and government-to-government consultation.

The Program has worked with many other local, state, and federal agencies and tribes as well as many private and public community partners during the planning and development of this Program. Details on agency coordination and public involvement can be found in Appendices A and B.

How does the IBR Program build on prior studies and the CRC project?

Regional leaders identified the need to address the I-5 corridor, including the Interstate Bridge, through previous bistate, long-range planning studies. Transportation deficiencies in the IBR Program corridor have been evaluated for more than two decades. Prior studies identified a variety of transportation mobility and safety problems (for additional details on this work, see the CRC Final Environmental Impact Statement (EIS) [CRC 2011b]). For additional details on prior studies and their findings, as well as the development of the Purpose and Need statement, see Chapter 1 of the *Interstate 5 Columbia River Crossing Project Final Environmental Impact Statement and Final Section 4(f) Evaluation* (CRC 2011b).

The CRC project was active between 2005 and 2014. The Purpose and Need statement for the CRC project was developed by the CRC Task Force[2] and the joint lead agencies.[3] During the screening process for the CRC project, over 70 transportation components were screened to identify those that could meet the Purpose and Need. The components that passed the screening were packaged into a range of alternatives and were evaluated in the CRC Draft EIS, with an LPA identified and evaluated in the 2011 Final EIS and selected in the 2011 ROD. Subsequently, the selected alternative was modified by two signed re-evaluations (one in 2012 that raised the maximum vertical navigation clearance of the bridge from 95 feet to 116 feet and a second in 2013 that evaluated a phased construction approach). The CRC Selected Alternative identified in the 2011 ROD, as revised by the 2012 and 2013 re-evaluations, is referred to as the "CRC LPA." While the CRC project successfully completed the NEPA environmental review process when FHWA and FTA issued the ROD in 2011 it did not secure adequate state funding to advance to construction and was discontinued in 2014.

Recognizing that regional transportation issues and necessary improvements to the Interstate Bridge remained unaddressed, on November 18, 2019, Oregon Governor Kate Brown and Washington Governor Jay Inslee signed the Oregon-Washington Memorandum of Intent on Replacing the I-5 Bridge over the Columbia River to express interest in restarting the project. Also in 2019, a bistate legislative committee requested that ODOT and WSDOT restart the CRC project, now called the IBR Program.

---

[1] Improvements at the Ruby Junction Maintenance Facility would be located in the City of Gresham.

[2] The CRC Task Force was a 39-member group formed in 2005 comprising leaders that represented a broad cross section of Washington and Oregon communities. Public agencies, businesses, civic organizations, maritime industries, neighborhoods, and freight, commuter, and environmental groups were represented on the task force. The group met 23 times over the course of the project development phase to advise the CRC project team and provide guidance and recommendations at key decision points. The task force concluded its work in summer 2008 after making its recommendation on the locally preferred alternative.

[3] FHWA, FTA, ODOT, WSDOT, Metro, RTC, TriMet, and C-TRAN.

As part of the NEPA process, in early 2021 the IBR Program began working with regional and local partner agencies and the public to review the Purpose and Need that was adopted for the CRC project. The IBR Program brought the Purpose and Need statement to partner agencies and the Program's three advisory groups to discuss the transportation needs identified for the CRC project. These transportation needs were also brought to the public for comment during an online open house, virtual community briefings, and an online survey. In mid-2021, the Program announced that these efforts validated that the six transportation needs identified in the CRC Purpose and Need statement still exist today, and that the values identified in the Vision and Values document remain community values. **Thus, the Purpose and Need statement for the IBR Program remains the same as documented in the 2011 Final EIS and 2011 ROD for the CRC project.**

Using the CRC LPA as its the baseline, or starting point, the IBR Program restarted and began evaluating whether past design assumptions still addressed today's changed conditions, including physical environment, community priorities, and regulations, or whether updates would be needed. In 2021, the IBR Program prepared a NEPA re-evaluation to assess the extent of changes in conditions and determine whether the previously approved Final EIS and ROD are still valid for a federal action or need to be updated with current conditions and changes in design. FHWA and FTA determined a Supplemental EIS (SEIS) should be prepared to identify and disclose new adverse impacts and mitigation associated with changes in conditions that occurred since 2013 (IBR 2021).

What problems does the IBR Program seek to fix?

As noted above, the Purpose and Need statement for the IBR Program, provided below, remains the same as documented in the 2011 Final EIS and 2011 ROD for the CRC project.

The text of the Purpose and Need has not been edited from its original wording, except for references to the name of the Program. More recent data and supplemental information are provided in sidebars and footnotes.[4]

In 2005, 280,000 vehicle trips crossed the Columbia River daily (northbound and southbound) in the Portland-Vancouver metropolitan region, of which 134,000 used the Interstate Bridge. By 2019, the total number of vehicle trips that crossed the Columbia River had increased to 313,000 per day, of which 143,400 used the Interstate Bridge.

Vehicle trips include those made in single-occupancy vehicles, high-occupancy vehicles, trucks, and transit vehicles (buses).

The **purpose** of the proposed action is to improve I-5 corridor mobility by addressing present and future travel demand and mobility needs in the Program area. The Program area extends from approximately Columbia Boulevard in the south to SR 500 in the north. Relative to the No-Build Alternative, the proposed action of the IBR Program is intended to achieve the following objectives: (a) improve travel safety and traffic operations on the I-5 river crossing and associated interchanges; (b) improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the Program area; (c) improve highway freight mobility and address interstate travel and commerce needs in the Program area; and (d) improve the I-5 river crossing's structural integrity (seismic stability).

The specific **needs** to be addressed by the proposed action of the IBR Program are addressed in the following subsections.

[4] Transportation data provided in the sidebars are from the IBR Transportation Technical Report. Due to the influence of the COVID-19 pandemic on travel patterns between 2020 and 2023, the IBR Program is following industry standards and using 2019 as the baseline year for the existing conditions section of this SEIS. The exception to using 2019 data is outputs from the Metro/RTC regional travel demand model which are from 2015. Metro and RTC had not yet updated their base-year model from 2015 to 2020 when this analysis was completed.

Growing travel demand and congestion

The duration of congestion on the Interstate Bridge roughly doubled from 2005 to 2019. In 2019, the I-5 corridor experienced heavy congestion and delay in both directions lasting up to almost 12 hours daily (compared with 4 to 6 hours daily in 2005).

Daily traffic demand over the I-5 Interstate Bridge is projected to increase by more than 25% by 2045.

Existing travel demand exceeds capacity in the Interstate Bridge and associated interchanges. This corridor experiences heavy congestion and delay lasting 4 to 6 hours daily[5] during the morning and afternoon peak travel periods and when traffic crashes, vehicle breakdowns, or bridge lifts occur. Due to excess travel demand and congestion in the I-5 corridor, many trips take the longer, alternative I-205 route across the Columbia River. Spillover traffic from I-5 onto parallel arterials such as Martin Luther King Jr. Boulevard and Interstate Avenue increases local congestion. In 2005, the two crossings[6] carried 280,000 vehicle trips across the Columbia River daily. Daily traffic demand over the Interstate Bridge is projected to increase by more than 35% during the next 20 years, with stop-and-go conditions increasing to approximately 15 hours daily if no improvements are made.

Impaired freight movement

I-5 is part of the National Truck Network, and the most important freight highway on the West Coast, linking international, national, and regional markets in Canada, Mexico, and the Pacific Rim with destinations throughout the western United States. In the center of the Program area, I-5 crosses over the Columbia River's deep-water shipping and barging channels and two river-level, transcontinental rail lines. The Interstate Bridge provides direct and important highway connections to the Port of Vancouver and Port of Portland facilities located on the Columbia River, as well as the majority of the area's freight consolidation facilities and distribution terminals. Freight volumes moved by truck to and from the area are projected to more than double over the next 25 years. Vehicle-hours of delay on truck routes in the Portland-Vancouver area are projected to increase by more than 90% over the next 20 years. Growing demand and congestion will result in increasing delay, costs, and uncertainty for all businesses that rely on this corridor for freight movement.

In 2019, more than 14,000 freight trips carrying over $132 million in commodities traveled across the I-5 Interstate Bridge each weekday. Freight volumes moved by truck, to and from the area, are projected to increase by 50 to 75% by year 2045.

Deficiencies such as narrow lanes and shoulders, as well as short merging, diverging, and weaving distances, reduce the efficiency and safety of freight truck movement.

[5] The hours of congestion refers to the total number of hours that the corridor experiences congestion. During the CRC project, congestion was defined as occurring when travel speeds were below 35 mph. ODOT and WSDOT are in the process of refining the definition of congestion with congestion occurring when speeds are below 45 miles per hour and severe congestion when speeds are below 35 miles per hour. Therefore, the IBR Program has defined congestion as speeds below 45 miles per hour.

[6] The two crossings are the I-5 Interstate Bridge and the I-205 Glenn Jackson bridge.

Limited public transportation operation, connectivity, and reliability

Due to limited public transportation options, a number of transportation markets are not well served. The key transit markets include trips between Portland Central City and the city of Vancouver and Clark County, trips between north/northeast Portland and the city of Vancouver and Clark County, and trips connecting the city of Vancouver and Clark County with the regional transit system in Oregon. Current congestion in the corridor adversely impacts public transportation service reliability and travel speed. Southbound bus travel times across the bridge are currently up to three times longer during parts of the AM peak compared to off-peak. Travel times for public transit using general purpose lanes on I-5 in the Program area are expected to increase substantially by 2030.

In 2005, southbound bus travel times across the bridges were up to three times longer during parts of the AM peak (i.e., morning high traffic period) than during off-peak times. As of 2019, bus travel times were four times longer during the AM peak.

If the bridges are not replaced, travel times for public transit using general-purpose lanes on southbound I-5 during the AM peak are expected to increase by 2045 because of increased congestion.

Safety and vulnerability to incidents

The Interstate Bridge and its approach sections experience crash rates more than two times higher than statewide averages for comparable facilities. Incident evaluations generally attribute these crashes to traffic congestion and weaving movements associated with closely spaced interchanges and short merge distances. Without breakdown lanes or shoulders, even minor traffic accidents or stalls cause severe delay or more serious accidents (Figure 2).

In 2005, the Interstate Bridge and its approach sections experienced crash rates more than two times higher than statewide averages for comparable facilities. As of 2019, crash rates were three times higher than statewide averages for comparable facilities. Crashes in the IBR Program area could increase by almost 30% by 2045 if no improvements are made.

There were seven fatal crashes in the Program area between 2015 and 2019.

Figure 2. Crash Blocking the Interstate Bridge

Substandard bicycle and pedestrian facilities

The bicycle/pedestrian lanes on the Interstate Bridge are about 3.5 to 4 feet wide, narrower than the 10-foot standard, and are located extremely close to traffic lanes, thus impacting safety for pedestrians and bicyclists (Figure 3). Direct pedestrian and bicycle connectivity are poor in the Program area.

Figure 3. Bicycle and Pedestrian Path on the Interstate Bridge

Compliance with the Americans with Disabilities Act (ADA) varies for the existing shared-use paths. The paths comply with the maximum gradient (4.7%) and there are no objects that overhang or protrude into the paths. However, the paths do not comply with guidelines for curb ramps (both in number and design), width, passing spaces, cross slope, or railing height (FHWA 2001; U.S. Access Board 2013). The paths are also near traffic lanes; this increases bicyclist and pedestrian exposure to vehicular traffic, noise, and emissions.

Seismic vulnerability

The existing Interstate Bridge is located in a seismically active zone. It does not meet current seismic standards and is vulnerable to failure in an earthquake.

All new federally funded highway bridges are required to be designed to the current edition of the American Association of State Highway and Transportation Officials Guide Specifications for Load-and-Resistance Factor Design (LRFD) Seismic Bridge Design (AASHTO 2022). In addition, State Departments of Transportation (DOTs) typically adopt local practices to address potential regional geologic hazards (e.g., the Cascadia Subduction Zone). State DOTs may also prescribe elevated levels of seismic performance based on the importance of the structure as it relates to public safety, national defense, and economic investment, as is the case for the Interstate Bridge.

The existing bridges were designed before modern seismic design codes were established. The foundations are likely to displace during a strong earthquake, resulting in the collapse of the bridge spans into the Columbia River. In addition, the movable span lift towers will be overstressed due to the inertia of the concrete counterweights and will collapse onto the bridge, causing the adjacent spans to fail. This collapse potential is due to the fact that hundreds of timber bridge support piles sit within loose sand that can liquefy during an earthquake.

How is the community engaged?

ODOT and WSDOT convened the 12-member Executive Steering Group to provide regional leadership recommendations on key program issues of importance to the community. Members of the Executive Steering Group include representatives from the 10 bistate partner agencies with a direct delivery or operational role in the integrated, multimodal transportation system around the Interstate Bridge, as well as a community representative from each state who serves on the Community Advisory Group.

The IBR Program has been engaging with partner agencies, tribal governments, local communities and organizations, and the public since late 2020 and has been conducting formal, targeted community engagement since February 2021. Targeted engagement has included user-specific outreach to representatives from the following groups: residents; commuters; transit users; business and freight industry; neighborhood associations and community groups; minorities and limited English speakers; tribal governments; elected officials; and the maritime industry. The IBR Program considers all comments received across these engagement efforts and incorporates recommendations as appropriate. In effect, this engagement has helped shape the communications strategy and implementation, the environmental review process, and the design options that are part of the Modified LPA. More information about the IBR Program's public involvement efforts can be found in Appendix B.

Program staff record and consider all comments received at events and by phone, email, or mail. Summaries or copies of these comments were provided to advisory leadership groups, such as the Executive Steering Group, for their reference in making recommendations. In the fall of 2021, the IBR Program shared design options with the public and sought feedback. The Community Engagement Report summarizes input received from more than 9,600 survey responses and 1,700 survey comments, community briefings, listening sessions, advisory groups, community working groups, and public comments (IBR Program 2021). While the Program cannot report consensus on preferences for specific design options, community feedback confirms a preference for design options that improve travel times, relieve congestion, improve safety, and mitigate negative impacts to people and the environment. Additional comment themes from the community engagement include:

- Number of auxiliary lanes
- Where on- and off-ramps are located
- Equitable implementation of tolling
- Integration of high-capacity transit
- Improved bicycle and pedestrian facilities
- LRT expansion into Vancouver
- Bridge replacement alternatives
- Funding details, including federal and state funding commitments
- Traffic flow disruptions during bridge construction
- Environmental impact mitigation
- Increased freight traffic capacity
- Future Maritime Transportation System navigation capability
- Equity considerations
- Workforce opportunities
- Considerations for services for those impacted by construction

What is the Modified LPA?

The CRC LPA was updated in close coordination with federal, tribal, regional, and local partners to establish the Modified LPA, which was endorsed by WSDOT, ODOT, and all eight local partner agencies in summer 2022. The Modified LPA includes a variety of transportation improvements throughout the 5-mile corridor. Chapter 2, Description of Alternatives, contains a detailed IBR Program description. The basic components of the CRC LPA as revised by the Modified LPA include:

- A new pair of Columbia River bridges—one for northbound and one for southbound travel—built west of the existing bridge. The new bridges would each include three through lanes, safety shoulders, and one auxiliary lane (a ramp-to-ramp connection on the highway that improves interchange safety by providing drivers with more space and time to merge, diverge, and weave) in each direction. When all highway, transit, and active transportation would be moved to the new Columbia River bridges, the existing Interstate Bridge (both spans) would be removed.
  - Three bridge configurations are under consideration: (1) double-deck truss bridges with fixed spans, (2) single-level bridges with fixed spans, and (3) single-level bridges with movable spans over the primary navigation channel. The fixed-span configurations would provide up to 116 feet of vertical navigation clearance, and the movable-span configuration would provide 178 feet of vertical navigation clearance in the open position. The primary navigation channel would be relocated approximately 500 feet south (measured by channel centerline) of its existing location near the Vancouver shoreline.
  - A two auxiliary lane design option (two ramp-to-ramp lanes connecting interchanges) across the Columbia River is also being evaluated. The second auxiliary lane in each direction of I-5 would be added from approximately Interstate Avenue/Victory Boulevard to SR 500/39th Street.
- A 1.9-mile light-rail transit (LRT) extension of the current Metropolitan Area Express (MAX) Yellow Line from the Expo Center MAX Station in North Portland, where it currently ends, to a terminus near Evergreen Boulevard in Vancouver. Improvements would include new stations at Hayden Island, downtown Vancouver (Waterfront Station), and near Evergreen Boulevard (Evergreen Station), as well as revisions to the existing Expo Center MAX Station. Park and rides to serve LRT riders in Vancouver could be included near the Waterfront Station and Evergreen Station. The Tri-County Metropolitan Transportation District of Oregon (TriMet), which operates the MAX system, would also operate the Yellow Line extension.
  - Potential site options for park and rides include three sites near the Waterfront Station and two near the Evergreen Station (up to one park and ride could be built for each station location in Vancouver).
- Associated LRT improvements such as traction power substations, overhead catenary system, signal and communications support facilities, an overnight light-rail vehicle (LRV) facility at the Expo Center, 19 new LRVs, and an expanded maintenance facility at TriMet's Ruby Junction.
- Integration of local bus transit service, including bus rapid transit (BRT) and express bus routes, in addition to the proposed new LRT service.
- Wider shoulders on I-5 from Interstate Avenue/Victory Boulevard to SR 500/39th Street to accommodate express bus-on-shoulder service in each direction.
- Associated bus transit service improvements would include three additional bus bays for eight new electric double-decker buses at the Clark County Public Transit Benefit Area Authority (C-TRAN) operations and maintenance facility (see Section 2.2.7, Transit Operating Characteristics, for more information about this service).

- Improvements to seven I-5 interchanges and I-5 mainline improvements between Interstate Avenue/ Victory Boulevard in Portland and SR 500/39th Street in Vancouver. Some adjacent local streets would be reconfigured to complement the new interchange designs, and improve local east-west connections.
  - An option that shifts the I-5 mainline up to 40 feet westward in downtown Vancouver between the SR 14 interchange and Mill Plain Boulevard interchange is being evaluated.
  - An option that eliminates the existing C Street ramps in downtown Vancouver is being evaluated.
- Six new adjacent bridges across North Portland Harbor: one on the east side of the existing I-5 North Portland Harbor bridge and five on the west side or overlapping with the existing bridge (which would be removed). The bridges would carry (from west to east) LRT tracks, southbound I-5 off-ramp to Marine Drive, southbound I-5 mainline, northbound I-5 mainline, northbound I-5 on-ramp from Marine Drive, and an arterial bridge for local traffic with a shared-use path for pedestrians and bicyclists.
- A variety of improvements for people who walk, bike, and roll throughout the study area, including a system of shared-use paths, bicycle lanes, sidewalks, enhanced wayfinding, and facility improvements to comply with the Americans with Disabilities Act. These are referred to in this document as *active transportation* improvements.
- Variable-rate tolling for motorists using the river crossing as a demand-management and financing tool.

The transportation improvements proposed for the Modified LPA and design options are shown in Figure 4. Additional details (including differences between the IBR Modified LPA and the CRC LPA) are available in Chapter 2.

Figure 4. Modified LPA Components

How would the Modified LPA be constructed?

The construction of bridges over the Columbia River sets the sequencing for other Program components. Accordingly, construction of the Columbia River bridges and the immediately adjacent highway connections and improvement elements would be timed early to aid the construction of other components. Demolition of the existing Interstate Bridge would take place after the new Columbia River bridges were opened to traffic.

Construction activities would require at least one large off-site location to stage equipment and materials. In addition, a large casting yard for fabricating elements of the bridges would likely be needed. Potential off-site locations have been evaluated and are described in detail in Chapter 2.

Electronic tolling infrastructure would be constructed and operational on the existing Interstate Bridge by the start of construction on the new Columbia River bridges. The toll rates and policies for tolling (including pre-completion tolling) would be determined after a more robust analysis and public process by the Oregon Transportation Commission and Washington State Transportation Commission.

Table 1 provides the estimated construction durations and additional information of Modified LPA components. The estimated durations are shown as ranges to reflect the potential for Program funding to be phased over time. In addition to funding, contractor schedules, regulatory restrictions on in-water work, river navigation considerations, permits and approvals, weather, materials, and equipment could all influence construction duration and overlap of certain components. Certain work below the ordinary high water mark of the Columbia River and North Portland Harbor would be restricted to minimize impacts to species listed under the Endangered Species Act and their designated critical habitat.

Throughout construction, active transportation facilities and three lanes in each direction on I-5 (accommodating personal vehicles, freight, and buses) would remain open during peak hours, except for short intermittent restrictions and/or closures. Advanced coordination and public notice would be given for restrictions, intermittent closures, and detours for highway, local roadway, transit, and active transportation users (refer to Section 3.1, Transportation, for additional information). At least one navigation channel would remain open throughout construction. Advanced coordination and notice would be given for restrictions or intermittent closures to navigation channels as required (refer to Section 3.2, Navigation, for additional information).

Table 1. Construction Activities and Estimated Duration

Component	Estimated Duration	Notes
Columbia River bridges	4 to 7 years	• Construction would likely begin with the main river bridges. • General sequence would include initial preparation and installation of foundation piles, shaft caps, pier columns, superstructure, and deck.
North Portland Harbor bridges	4 to 10 years	• Construction duration for North Portland Harbor bridges is estimated to be similar to the duration for Hayden Island Interchange construction. The existing North Portland Harbor bridge would be demolished in phases to accommodate traffic during construction of the new bridges.

Component	Estimated Duration	Notes
Hayden Island interchange	4 to 10 years	• Interchange construction duration would not necessarily entail continuous active construction. Hayden Island work could be broken into several contracts, which could spread work over a longer duration.
Marine Drive interchange	4 to 6 years	• Construction would need to be coordinated with construction of the North Portland Harbor bridges.
SR 14 interchange	4 to 6 years	• Interchange would be partially constructed before any traffic could be transferred to the new Columbia River bridges.
Demolition of the existing Interstate Bridge	1.5 to 2 years	• Demolition of the existing Interstate Bridge could begin only after traffic is rerouted to the new Columbia River bridges.
Three interchanges north of SR 14	3 to 4 years for all three	• Construction of these interchanges could be independent from each other and from construction of the Program components to the south. • More aggressive and costly staging could shorten this timeframe.
Light-rail	4 to 6 years	• The light-rail crossing would be built with the Columbia River bridges. Light-rail construction includes all the infrastructure associated with LRT (e.g., overhead catenary system, tracks, stations, park and rides).
Total construction timeline	9 to 15 years	• Funding, as well as contractor schedules, regulatory restrictions on in-water work and river navigation considerations, permits and approvals, weather, materials, and equipment, could all influence construction duration.

What are the effects of the Modified LPA and how do they compare to the No-Build Alternative?

This section highlights how the Modified LPA compares to the No-Build Alternative in terms of transportation performance and community and environmental effects. Table 2 and Table 3 summarize the key performance and impact differences.[7] Mitigation measures proposed for the effects are identified in Table 4. Chapter 3, Existing Conditions and Environmental Consequences, provides more detail on performance, impacts, and mitigation.

[7] All projections and forecasts in Tables 2 and 3 are for the design year of 2045 unless otherwise stated. The description of effects under the Modified LPA design options are in comparison to the Modified LPA with double-deck fixed-span Configuration, one auxiliary Lane, C Street ramps, and centered I-5.

Table 2. Summary of Transportation Effects or the No-Build Alternative and Modified LPA and Design Options[a]

1 Transportation Area	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Shifted West	6 Modified LPA with Single-Level Fixed-Span Configuration,[b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5[c]	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Hours of congestion/day at Interstate Bridge	SB: 16 hours. NB: 14 hours.	SB: 4.75 hours (70% reduction). NB: 9 hours (36% reduction).	SB: 4.5 hours (72% reduction). NB: 6 hours (57% reduction).	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Southbound weekday peak 2-hour average travel times from I-205 to I-405 in North Portland	AM: 58 minutes. PM: 29 minutes.	AM: 54 minutes (7% reduction). PM: 14 minutes (52% reduction). Total travel time by transit between downtown Vancouver and Pioneer Square [d, h, i]	Express Bus AM SB: 48 minutes Express Bus PM NB: 67 minutes LRT: Service not available.	Express Bus, AM SB: 59 minutes. Express Bus, PM NB: 45 minutes. LRT: 47 minutes (both AM SB and PM NB).	Express Bus, AM SB: 59 minutes. Express Bus, PM NB: 33 minutes. LRT: No change in effects.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Freight mobility and access	No improvement.	Improved access, mobility, and safety with wider lanes and shoulders on the bridge and improved design at critical port access points at Mill Plain and Marine Drive.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Traffic safety	Crashes forecast to increase 28% for I-5 mainline, ramps, and ramp terminal intersections compared to existing conditions.	Crashes forecast to decrease 13% for I-5 mainline, ramps, and ramp terminal intersections compared to No-Build Alternative.	Crashes forecast to decrease 4% for I-5 mainline, ramps, and ramp terminal intersections compared to Modified LPA.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	The movable span configuration would perform worse (experience more crashes) than the fixed-span configurations but better (experience fewer crashes) than the No-Build Alternative.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Arterial and local street intersections operating below standards (AM/PM peaks)	9 intersections.	8 intersections.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	14 intersections.	Same as effects listed in Column 3.

1 Transportation Area	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Shifted West	6 Modified LPA with Single-Level Fixed-Span Configuration,[b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5[c]	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Transit safety and security	No improvement.	Light-rail stations provide a higher level of visibility and lighting than on-street bus stops. Stations would have additional safety measures incorporated into design.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Effect on river navigation	• No improvement. • Provides 263 feet of horizontal clearance and 178 feet of vertical clearance. • Continue risk to navigation from potential earthquake events, including the potential for the bridge failing and blocking or obstructing the navigation channels.	• Reduces the need for and severity of the S-curve maneuver and reduces number of piers. • Increases horizontal clearance to 400 feet and reduces vertical clearance to 116 feet. • Shifts the Upper Vancouver Turning Basin to the west by approximately 300-350 feet. • Navigation Safety: Constructs the new bridges west of the existing Interstate Bridge, reducing the available distance for vessels to align with the openings of the Columbia River bridges and the BNSF Railway Bridge. However, ship pilots and tug masters conducting ship simulations described the Modified LPA as improving navigation safety by providing more space to maneuver due to fewer bridge piers in the water and greater distance between the piers. Provides greater horizontal navigation and reduces the number of direction changes to transit the Interstate Bridge and position for passage through the BNSF bridge.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, except: • 178 feet vertical navigation clearance in the open position. • Higher maximum vertical navigation clearance in the closed position compared to No-Build. • Improved navigation due to wider navigation channel openings. • Movable-span operations, and thus river navigation operations, may need increased restrictions on timing of bridge openings. • Would increase need for additional construction time, materials, and equipment.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

1 Transportation Area	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Shifted West	6 Modified LPA with Single-Level Fixed-Span Configuration,[b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5[c]	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
		• Improved navigation for most users due to wider navigation channel openings; some current users would not be able to pass under the bridges due to height unless accommodations are made. • Introduces a permanent and complete obstruction to navigation upstream of the new Columbia River bridges for vessels or cargo loads with vertical clearance requirements greater than 116 feet. • Improved navigation through increased seismic resiliency in event of potential earthquake by reduction in the risk of bridge failure or collapse and blocking or obstructing the navigation channels.						
Effect on aviation safety	No improvement.	Less intrusion into Pearson Field protected airspace as compared to the No-Build Alternative. Reduced potential for bird nesting and roosting.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Less intrusion into Pearson Field protected airspace.	More intrusion into Pearson Field protected airspace than effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

a All projections and forecasts are for the design year of 2045 unless otherwise stated. The description of effects under the Modified LPA design options (Columns 4 through 9) are in comparison to the modified LPA with double-deck fixed-span Configuration, one auxiliary lane, C Street ramps, and Centered I-5, as described under Column 3.
b The effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.
c The SR 14 interchange without C Street ramps design option would require express bus transit to be rerouted to access downtown Vancouver via Mill Plain Boulevard. This would add more travel time for express bus transit trips in and out of downtown Vancouver on express bus because of added distance and congestion on the mainline.
d Total transit travel times include 10 minutes of walk access (1/4 mile walk on either end of the trip at 3 mph average walk speed) in addition to initial and transfer (if applicable) wait time. Wait times are based on half the headway.
e Route 60 does not stop at Hayden Island southbound, so a trip from Vancouver to Hayden Island travels south to Delta Park and then back north to stop on Hayden Island.
f Route includes 60 Vancouver – Delta Park with transfer to Yellow Line LRT.
g Travel time is on Yellow Line LRT.
h Express Bus includes Route 101 from downtown Vancouver – Rose Quarter or Pioneer Square.
i Express Bus includes two stops between downtown Vancouver and Pioneer Square. LRT includes 16 stops between downtown Vancouver and Pioneer Square.
I- = Interstate; LRT = light-rail transit; LPA = Locally Preferred Alternative; NB = northbound; SB = southbound; SR = State Route

Table 3. Summary of Community and Environmental Effects for the No-Build Alternative and the Modified LPA [a]

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Acquisitions and displacements	None.	Approximately 47 acres of property acquired and displacement of: • 43 residential units. [c] • 36 businesses. [d] • 1 public use sites.	Similar to Column 3, with an additional 0.1 acres of property acquired.	Additional 0.9 acre of property acquired, and an additional 33 residential units and 3 businesses displaced.	Additional 0.2 acres of property acquired.	Same as effects listed in Column 6.	Same as effects listed in Column 3.	**Waterfront locations:** • Site 1: no acquisition or displacement. • Site 2: 0.1 acres acquired, no displacement. • Site 3: 1.5 acres acquired, 1 business displaced. **Evergreen locations:** • Site 1: 3.16 acres acquired, no displacement. • Site 2: no acquisition or displacement.
Land use and economics	• Existing land uses would remain vulnerable to high levels of congestion, unsafe conditions, and potential earthquake-induced failure. • No high-capacity transit, which is inconsistent with the stated policies and goals of regional transportation plans. • Congestion would impair freight movement and reduce area productivity, which could indirectly impact the implementation of land use plans and goals for economic development. • Loss in job growth could lead to decreased housing	• Converts approximately 47 acres of land to transportation use; currently primarily zoned industrial or commercial, with some land zoned residential. • High-capacity transit is consistent with state, regional, and local plans and policies. • Higher toll rates during peak periods would support regional and local policies for congestion and are not expected to change land use patterns. • Property tax revenues would be reduced compared to the No-Build Alternative. • Business displacements have the potential to impact 616 employees; affected businesses would be provided relocation assistance. • Bridge height would exclude up to eight existing users/vessels that require more than 116 feet of vertical clearance from passage	Similar to effects listed in Column 3, except: • Slightly more acquisition of property at the Fort Vancouver National Historic Site. • Improved traffic operations (shorter duration and length of congestion, reduced travel times, and improved mobility options) compared to design options with a single auxiliary lane would result in improved mobility and access for freight and employment.	Similar to effects listed in Column 3, except: • Larger areas of properties would be permanently acquired. • Additional 1 acre of permanent acquisition. • Additional three business displacements. • Potential to impact 142 additional employees.	Similar to effects listed in Column 3, except: • Lower maximum bridge height and reduced highway grade would benefit freight vehicle speed compared to double-deck configuration, with corresponding economic benefits.	Similar to effects listed in Column 3, except: • Bridge openings could interrupt vehicle and truck highway travel, transit service, and active transportation across the new Columbia River bridges. • No existing or future maritime vessels or cargo freight would be excluded from passage. • Lower bridge height compared to fixed-span configurations would allow fewer existing marine users/vessels to pass without a bridge opening. Movable-span operations, and thus river navigation operations, may have increased restrictions on bridge openings, which could impact marine commerce by restricting the	Similar to effects listed in Column 3, except: • Removal of the C Street ramps would result in traffic delay and increased travel times near the Mill Plain Boulevard interchange and in downtown Vancouver, which would have an economic impact on local businesses.	Same as effects listed in Column 3, plus: **Waterfront locations:** • Site 1: no acquisition or displacement. • Site 2: 0.1 acres acquired, no displacement. • Site 3: 1.5 acres acquired, 1 business displaced, 53 additional employees. **Evergreen locations:** • Site 1: 3.16 acres acquired, no displacement. • Site 2: no acquisition or displacement.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
	prices, increased commercial vacancies, and reduced demand for downtown revitalization.	underneath the new Columbia River bridges.				times of day for large vessel movements.		
Neighborhoods	• No change to existing neighborhoods, community facilities, or social resources. Future development might not be fully consistent with goals that assume improved mobility and expanded transit access. Neighborhoods would not benefit from reduced congestion, improved mobility, and access to employment.	• Would not adversely affect community cohesion in neighborhoods, except for Hayden Island. Could increase cohesion in neighborhoods near the Community Connector. • Would affect the Hayden Island neighborhood's community cohesion, including displacement of floating homes and changes to views. Fourteen businesses would be displaced. However, neighborhood cohesion would be improved by a more continuous street system, improved pedestrian and bicycle facilities, and transit that increases connections for residents. • Construction-related impacts such as traffic diversion noise, temporary reductions in air quality, and sidewalk disruptions.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but with potential residential displacements in Esther Short neighborhood.	Similar to effects listed in Column 3, except: • May help to maintain or improve neighborhood cohesion by providing additional transit station location options on Hayden Island, which would provide more opportunities for connection to residences and development.	Similar to the effects listed in Column 6, except: • Bridge openings would cause backups during non-peak commuting hours that would reduce reliability for vehicles, active transportation, similar to the No-Build Alternative, which may negatively affect neighborhood cohesion.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Equity	• Equity priority communities would not benefit from increased mobility and accessibility. • Would avoid short- and long-term displacement of residents and businesses. • Would avoid construction-related impacts such as traffic diversion, noise, temporary reductions in air quality, and cost burdens of tolling.	• Increased access to high-capacity transit, increased availability of active transportation, and highway and driving travel time reductions. The degree of benefits would vary by equity priority community. • Increase in job access for all demographic groups due to faster travel times. • Potential displacement of encampments of houseless populations, residential displacements, and additional transportation cost from tolling. • Construction-related impacts such as traffic diversion, noise, temporary reductions in air quality, and cost burdens of tolling. • Tolling would place a burden on low-income travelers.	Similar to effects listed in Column 3, but: • Would reduce delay and congestion on the Columbia River bridges to a greater extent, which would improve travel times for motorists, express bus riders, and emergency vehicles; slightly greater increase in jobs access for all demographic groups.	Similar to effects listed in Column 3, except: • More residential displacements.	Similar to effects listed in Column 3, except: • Active transportation users would experience shorter distance to cross the bridge. • Users may feel safer due to the extra security from visibility from passing vehicles.	Similar to effects listed in Column 6, except: • There may be travel delays for transit and active transportation users due to openings of the movable span.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Environmental justice	• No displacement of residents, businesses, community resources, or jobs. • Travel times would increase by approximately 50% compared to existing times. Would not bring high-capacity transit to Hayden Island or downtown Vancouver. • Environmental conditions under the No-Build Alternative would affect EJ populations the same as the general population. Therefore, no disproportionately high and adverse effects have been identified.	• Increased access to high-capacity transit and active transportation, and reductions in vehicle travel time. Impacts to EJ populations would be the same as to the general public. • Increase in job access due to faster travel times. Because faster times would result from tolling, tolling would result in disproportionately high and adverse effects on EJ populations. • Residential and business displacements. Displacements in high-priority and meaningfully greater EJ areas such as the Esther Short neighborhood in Vancouver and the Rockwood neighborhood in Gresham would result in disproportionately high and adverse effects on EJ populations.	Same as effects listed in Column 3.	• Similar to effects listed in Column 3, but would increase residential and business displacements. • Additional displacement of the Normandy Apartments in the Esther Short neighborhood as a result of the I-5 westward shift would result in disproportionately high and adverse effects on EJ populations.	Similar to effects listed in Column 3, except: • Shared-use path users would have more exposure to noise. • Users would experience shorter distance to walk across the bridge. • Users may feel safer due to the extra security from visibility from passing vehicles. • Noise and visual impacts to EJ populations would be the same as to the general population.	Similar to effects listed in Column 3, except: • There may be travel delays for transit and active transportation users due to openings of the movable span. • Delays to transit and active transportation users as a result of bridge openings could also contribute to adverse effects on EJ populations.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
		• Increased traffic and noise impacts from construction. • Improved air quality. • Some adverse impacts to community cohesion.						
Public services and utilities	• Increased congestion on I-5 would increase delays in emergency response.	• Emergency service response time would be reduced with improved traffic conditions. • Utilities would be relocated or protected in place during construction and restored to full service following construction.	Similar to effects listed in Column 3, but further reduced congestion and multimodal operations would lead to improved response times.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but response times to transit and shared-use path incidents could improve because emergency vehicles would have better access to transit and active transportation facilities.	Delays and disruptions to emergency response due to bridge openings would continue, but with less frequency than the No-Build Alternative.	Same as effects listed in Column 3.	Utilities at the park-and-ride locations at W 4th Street and W 3rd Street could require relocation or replacement.
Total acres of park and recreation resources acquired (approximate)	0 acres.	1.3 acres	1.3 acres (+1,500 square feet compared to area of acquisitions stated in Column 3)	1.3 acres (-200 square feet compared to area of acquisitions stated in Column 3)	1.3 acres (+760 square feet compared to area of acquisitions stated in Column 3)	1.3 acres (+760 square feet compared to area of acquisitions stated in Column 3)	Same as effects listed in Column 3.	N/A
Linear feet of trails to be reconstructed and/or permanently realigned (approximate)	0 feet.	5,800 feet.	6,000 feet	5,800 feet	6,000 feet	6,000 feet	5,700 feet	N/A
Anticipated transit access to park and recreation resources in the study area	No change.	Would improve access to some large regional parks.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Visual quality (changes to visual resources)	Constructed elements within the Area of Visual Effect (AVE) would not change. Project environment coherence would be negatively affected by increased traffic and congestion. Compatibility with the natural and cultural environments would stay the same.	New visual elements could alter the existing visual character and quality in the AVE (e.g., new bridges across the Columbia River). Landscape units where the effect to visual quality are beneficial or neutral would have a natural, cultural, and project environment that is compatible with existing visual conditions. Adverse effects to visual quality would result from blocking views of the natural environment and changes in visual experience from elevated bridge structures, such as to viewers in the floating homes at the North Portland Harbor bridges.	Additional width would contribute to a slightly increased visual mass for viewers in close proximity or beneath the structures in the Columbia River landscape unit.	Would include an improvement in the perceived visual quality by shifting project elements slightly farther from sensitive viewers at Kanaka Village and other views from Fort Vancouver National Historic Site in the Greater Central Park landscape unit.	May become a beneficial feature from nearby views in the Columbia River landscape unit depending on the chosen architectural design.	In the closed position, the lower height of the bridge decks would be similar, or less visible, than the existing Interstate bridge. Some components of a movable span could protrude higher into the skyline and be visible from the Vancouver, Fort Vancouver, and Hayden Island areas. In an open position, which would be intermittent and limited, the increased visibility of the bridge deck may obstruct additional views and skylines, and likely intensify visual impacts, especially for sensitive recreational viewers. The overall bridge deck would be higher and more visible than the existing bridge deck.	Would eliminate project environment elements associated with the C Street Ramps that would be visible for sensitive recreational viewers in the Greater Central Park landscape unit.	Potential site specific changes in the cultural visual environment in the Vancouver Downtown landscape unit.
Number of NRHP-listed or NRHP-eligible historic built environment resources affected	0	12	12	12	12	12	12	12
Number of archaeological sites affected	0	12	12	12	12	12	12	12
VMT in MSAT study area	3,537,900 VMT in 2045 (66% increase compared to existing conditions).	3,455,400 VMT in 2045 (62% increase compared to existing conditions).	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Changes in air pollutant emissions	Future regional emissions would be substantially lower than existing emissions for all MSAT, CO, NO_X, and $PM_{2.5}$. Future regional emissions of SO_2, VOC would be up to 25% higher than existing conditions due to increased VMT.	Similar to No-Build Alternative (slightly lower emissions due to reduced VMT).	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but may slightly reduce operational emissions due to the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.	Similar to effects listed in Column 6, except for a minor increase in air quality pollutants due to vehicles idling during bridge openings. There would be fewer bridge openings than with the No-Build Alternative.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Changes in MSATs emissions (2045)	• 1,3-Butadiene: 100% reduction • Acetaldehyde: 82% reduction • Acrolein: 89% reduction • Benzene: 69% reduction • Diesel Particulate Matter: 86% reduction • Ethylbenzene: 29% reduction • Formaldehyde: 86% reduction • Naphthalene: 93% reduction • Polycyclic Organic Matter: 93% reduction	• 1,3-Butadiene: 100% reduction • Acetaldehyde: 85% reduction • Acrolein: 90% reduction • Benzene: 70% reduction • Diesel Particulate Matter: 88% reduction • Ethylbenzene: 29% reduction • Formaldehyde: 88% reduction • Naphthalene: 94% reduction • Polycyclic Organic Matter: 96% reduction	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but may slightly reduce operational emissions due to the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.	Similar to effects listed in Column 6, except for a minor increase in air pollutants due to vehicles idling during bridge openings. There would be fewer bridge openings than with the No-Build Alternative.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Changes in regional criteria pollutant emissions	• Carbon Monoxide: 61% reduction • Nitrogen Dioxide: 75% reduction • Sulfur Dioxide: 16% increase • Volatile Organic Compounds: 26% increase • Total PM_{10}: 46% increase • Total $PM_{2.5}$: 39% reduction	• Carbon Monoxide: 63% reduction • Nitrogen Dioxide: 79% reduction • Sulfur Dioxide: 9% increase • Volatile Organic Compounds: 25% increase • Total PM_{10}: 21% increase • Total $PM_{2.5}$: 48% reduction	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but may slightly reduce operational emissions due to the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.	Similar to effects listed in Column 6, except for a minor increase in air quality pollutants due to vehicles idling during bridge openings. There would be fewer bridge openings than with the No-Build Alternative.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

Number of receptors that exceed highway noise thresholds [e]	215	198	Similar to effects listed in Column 3, except: • Highway noise impacts, before and after mitigation, would be slightly different because traffic lanes would be slightly closer to noise-sensitive land uses. • No change to peak-hour traffic volumes, posted speed limit, or vehicle mix.	Similar to effects listed in Column 3, except for a barely perceptible increase in traffic noise west of I-5 near the southbound mainline and ramps.	Similar to effects listed in Column 3, except this option would result in a slight increase in highway noise impacts east and west of the bridge due to the wider bridge span (99 feet wider) and lower roadway deck (29 feet lower).	Similar to effects listed in Column 6.	Similar to effects listed in Column 3, except with minor changes to noise impacts at a level near or below perceptible range.	Same as effects listed in Column 3.
Number of receptors with moderate transit noise impact levels [e]	0	12 [f]	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Number of receptors with severe transit noise impact levels [e]	0	0	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Number of receptors with transit vibration impacts [e]	No vibration impacts without extension of light-rail.	12 residences and 1 theater	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Total Regional Transportation Energy Consumption (mmBtu/day)	• 271,933 in 2045 without electric vehicles • 190,771 in 2045 with electric vehicles	• 271,187 in 2045 without electric vehicles (-0.27% compared to No-Build Alternative) • 190,302 in 2045 with electric vehicles (-0.25% compared to No-Build Alternative)	Similar to effects listed in Column 3. Modeling results estimate a non-statistically significant difference of less than 0.1%.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but would slightly reduce operational emissions due to the reduced profile grade of the new Columbia River bridges.	Similar to effects listed in Column 6, except it would increase energy consumption due to the electricity required to open the bridge and as a result of idling by queued vehicles on the freeway during bridge openings.	Similar to effects listed in Column 3, but would create additional congestion on local streets, which would decrease vehicle efficiency, resulting in increased energy consumption.	Same as effects listed in Column 3.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
EMF	No change.	Similar to effects listed in Column 2. EMF emissions would increase slightly at certain locations but would remain well below exposure guidelines.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Water Quality and Stormwater Management	No change. Stormwater within the area would remain untreated until addressed according to state prioritization and available funding.	• Beneficial effect on receiving water quality (due to best management practices [BMPs] to remove pollutants). • Could cause changes in peak flows and stormwater runoff volumes.	• Beneficial effect on receiving water quality (due to BMPs to remove pollutants) with slight increase to pollutant loads. • Could cause changes in peak flows and stormwater runoff volumes.	Same as effects listed in Column 3.	• Beneficial effect on receiving water quality (due to BMPs to remove pollutants). • Could cause changes in peak flows and stormwater runoff volumes.	Potential for additional and accidental minor spills of materials and pollutants used for maintenance and operation of the movable-span configuration.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Contributing Impervious Area	178 acres total: • 0 acres treated • 21 acres infiltrated • 157 acres untreated	207 acres total: • 190 acres treated • 17 acres infiltrated • 0 acres untreated	211 acres total: • 194 acres treated. • 17 acres infiltrated. • 0 acres untreated.	Same as effects listed in Column 3.	210 acres total: • 193 acres treated. • 17 acres infiltrated. • 0 acres untreated.	214 acres total: • 197 acres treated. • 17 acres infiltrated. • 0 acres untreated. Ecosystem - aquatic resources	• Continued impacts from untreated stormwater from approximately 156.4 acres of existing CIA. • Potential for injury and habitat degradation in the case of a bridge failure.	• Benthic habitat impact: 0.13 acres net restoration. • Additional Overwater Shading (Water Surface Level): 1.04 acres. • Additional Overwater Shading (Elevated Deck Level): 8.22 acres. • Beneficial effect of stormwater treatment for all post-project CIA, including approximately 156.4 acres of existing impervious area that is currently untreated.	• Similar to effects listed in Column 3, except would result in a greater amount of elevated overwater shading. • Overwater Shading (Elevated Deck): +13.02 acres.	Same as effects listed in Column 3.	• Benthic habitat impact: 0.03 acres net reduction. • Additional Overwater Shading (Water Surface Level): 1.41 acres. • Additional Overwater Shading (Elevated Deck Level): 10.78 acres.	• Benthic habitat impact: 0.07 acres net reduction. • Additional Overwater Shading (Water Surface Level): 1.58 acres to 2.16 acres. • Additional Overwater Shading (Elevated Deck Level): 10.78 acres.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Ecosystems - permanent loss of sensitive terrestrial habitat in Oregon (acres)	• Potential for injury and habitat degradation in the case of a bridge failure.	• “High” wildlife/riparian value: 1.12 • “Medium” wildlife/riparian value: 6.20 • Wetlands: 0.58 • Wetland Buffers: 7.39	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, except would slightly reduce impervious surface.	Same as effects listed in Column 3.
Ecosystems - permanent loss of sensitive terrestrial habitat in Washington (acres)	Potential for injury and habitat degradation in the case of a bridge failure	• Riparian buffers: 0.79 • Biodiversity Areas: 0.15 • Oak Woodlands: <0.01 • Wetlands: 0 • Wetland Buffers: 0.06	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Geology/Groundwater	No change (seismic deficiencies remain, would not affect geologic resources, would sustain existing impacts to degradation of the groundwater quality).	• Improved public safety, minimizing damage to infrastructure, and limiting economic disruption due to seismic improvements. • Slight potential for increased use of materials that could spur expansion and/or opening of surface mines. • Benefits to groundwater as a result of stormwater management and treatment.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.	Similar to effects listed in Column 3.	Same as effects listed in Column 3.	Same as effects listed in Column 3.

1 Community and Environmental Effect	2 No-Build Alternative	3 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	4 Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	5 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Mainline Westward Shift	6 Modified LPA with Single-Level Fixed-Span Configuration, [b] One Auxiliary Lane, C Street Ramps, Centered I-5	7 Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	8 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5	9 Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options
Hazardous materials	• No potential for adverse effects from acquisition of contaminated sites. • No beneficial effects from the cleanup of contaminated sites. • Untreated stormwater would continue to enter surface waterbodies and groundwater. • No improvement in existing spill risks from traffic congestion and collisions.	• Moderate potential for increased liability for property owners (ODOT and WSDOT) from the acquisition of contaminated sites. • Beneficial effects on human health and safety and surface and groundwater quality from cleanup and remediation of contaminated areas on acquired sites and limiting the possible off-site migration of contamination. • If residual contamination remains on acquired sites after cleanup, moderate potential for adverse effects on human health and safety if encountered during construction or with the possible off-site migration of contamination. • Beneficial effects from updates in stormwater conveyance and treatment. • Reduction in spill risk due to reduced traffic congestion and collisions.	Same as effects listed in Column 3, except would require the acquisition of a slightly larger area of property with a potential source of contamination.	Same as effects listed in Column 3.	• Requires the acquisition of a slightly larger area of property with a potential source of contamination. • Requires an increased area of in-water work due to larger bridge foundations, which could result in a comparatively greater potential risk of mobilizing hazardous materials in river sediments.	Same as effects listed in Column 3, except would require the acquisition of a slightly larger area of property with a potential source of contamination.	Same as effects listed in Column 3.	Same as effects listed in Column 3.
Climate Change	• Substantially lower energy consumption and greenhouse gas (GHG) emissions in 2045 due to increased electric vehicles in fleet and decarbonized electricity sources.	• Lower energy consumption and GHG emissions in 2045 similar to No-Build Alternative. • Increased mode share of low and no emissions modes (transit, active transportation). • Improvements in climate resilience with materials and design.	Similar to effects listed in Column 3, but would slightly reduce emissions due to improved congestion.	Same as effects listed in Column 3.	Similar to effects listed in Column 3, but would slightly reduce operational emissions due to the reduced profile grade of the new Columbia River bridges.	Similar to effects listed in Column 3, but would increase energy consumption due to the longer construction duration, additional materials required for the larger bridge foundations, and electricity required to raise and lower the bridge and as a result of idling during bridge closures.	Similar to effects listed in Column 3, but additional congestion and idling would decrease vehicle efficiency, resulting in increased GHG emissions.	Same as effects listed in Column 3.

Notes:
a All projections and forecasts are for the design year of 2045 unless otherwise stated. The description of effects under the Modified LPA design options (Columns 4 through 9) are in comparisons to the Modified LPA with double-deck fixed-span configuration, one auxiliary Lane, C Street ramps, and centered I-5, as described in Column 3.
b The effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.
c Does not include the displacement of houseless individuals.
d Does not include the displacement of a billboard and cellular phone tower.
e Information represents noise impacts without mitigation.
f Does not include noise impacts at a hotel within range.
Key: AVE = Area of Visual Effect; EMF = electric and magnetic fields; GHG = greenhouse gas; I- = Interstate; lb = pounds; LPA = Locally Preferred Alternative; mmBtu = one million British thermal units; MSAT = mobile source air toxics; N/A = not applicable; NRHP = National Register of Historic Places; ODOT = Oregon Department of Transportation; PM10 = particulate matter less than or equal to 10 microns in diameter; VMT = vehicle miles traveled; WSDOT = Washington Department of Transportation

What mitigation or compensation is proposed for unavoidable adverse impacts?

This section summarizes the mitigation measures proposed for the community and environmental effects that would occur as a result of the Modified LPA. Mitigation and compensation would be adjusted as needed for differences in effects associated with the design options. As possible mitigations are identified and considered, the IBR Program will determine whether additional environmental analysis is necessary. The IBR Program would comply with all environmental laws and obtain necessary permits that outline protections for local air quality, water quality, fish and wildlife, and community livability (e.g., noise levels, light and glare, dust, etc.) during construction. Table 4 highlights the mitigation or compensation measures proposed for the effects described in Table 3. Chapter 3, Existing Conditions and Environmental Consequences, provides more detail on proposed mitigation or compensation measures.

Table 4. Summary of Mitigation or Compensation for Community and Environmental Effects

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
Transportation	**Long-Term Effects** ***Program-Specific Mitigation*** *I-5 Operations* Potential mitigation to meet ODOT's and/or WSDOT's performance standards on I-5 are summarized below. *Modified LPA* • Providing an additional auxiliary lane northbound and southbound within the IBR Program limits, and/or the program and partners could implement more intensive demand reduction and system management strategies beyond what the IBR Program already includes (variable-rate tolling, improved transit and active transportation systems, and enhanced transportation demand management (TDM) and transportation system management (TSM) systems). *Modified LPA and Design Options* • ODOT will continue to work with partners to study the downstream bottleneck at the I-5/I-405 split in North Portland. This downstream bottleneck is a separate project that ODOT is looking into understanding causes and potential solutions. • The southbound C-D roadway would be impacted by congestion spilling back from I-5 during the AM peak period, but even during the PM peak period when no downstream congestion is present, the CD roadway would not meet WSDOT's mobility standards. Potential mitigation measures could include braiding the Mill Plain on-ramp and SR 14 off-ramp and possibly providing a slip lane to continue providing access for trips traveling from the Mill Plain interchange to SR 14. *Bridge Openings* Measures to minimize disruptions to I-5 operations, transit service, and active transportation associated with bridge openings and gate closures under the Modified LPA with a single-level movable-span configuration could include: • Establish new bridge opening and gate closure timing limitations, which could include scheduled days and/or times that avoid peak periods for passenger vehicles and trucks, in coordination with the USCG. • Incorporate bridge opening and gate closure limitations into transit service schedules.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Disseminate information concerning bridge openings and gate closures to the public, businesses, travel organizations, freight industry, and mariners. *Arterials and Local Streets* • *Modified LPA without C Street ramps:* Six intersections in the Modified LPA design option without C Street ramps may require mitigation improvements and are summarized below. The impacts are caused by the additional traffic volumes accessing the Mill Plain Boulevard/15th Street east-west couplet due to the elimination of I-5 access via the C Street ramps. – Mill Plain Boulevard and Franklin Street – 15th Street and Washington Street – 15th Street and Main Street – Mill Plain Boulevard and Columbia Street – Mill Plain Boulevard and Broadway Street – Mill Plain Boulevard and I-5 northbound on-/off-ramps • Mitigation of this congestion could include retaining the C Street ramps. As part of final design, additional traffic analysis would be conducted to confirm the SEIS analysis and refine mitigation measures as needed. Final mitigation would be determined and agreed upon by the IBR Program and the affected agency. *Transit Reliability* In the course of considering mitigation, an updated on-time performance analysis in the Rose Quarter may be completed. Final mitigation measures will be determined and agreed upon with the appropriate agency partners as needed. The IBR Program could contribute a proportionate share toward identified mitigation to improve on-time performance at the Rose Quarter. **Temporary Effects** ***Regulatory Mitigation*** • Construction activities would comply with ODOT and WSDOT requirements for maintenance of traffic. More specific measures related to maintenance of traffic are discussed in the Program-Specific Mitigation section below. The Transportation Technical Report identifies additional potential mitigation measures and best practices such as for signage, traffic plans and control, access, communications, and safety. ***Program-Specific Mitigation*** *Study-Area Travel* • Develop Work Zone Transportation Management Plan (TMP) and a maintenance of traffic plans to address affected facilities and their mode of transportation. *Freight Mobility and Access* • Mitigation for freight and mobility would be an element of the Work Zone TMP identified above. In addition, the IBR Program would coordinate with all facility owners to notify them of facility or access closures. Construction information would be provided to affected local jurisdictions. Similar information would be provided to WSDOT and ODOT for use in the states' freight notification systems. The IBR Program would provide information in formats required by WSDOT and ODOT. • To minimize impacts to freight rail operations, the Program would coordinate with the railroad owners and rail operators and would obtain all applicable required permits. Construction would be limited to the times approved and coordinated with freight rail operators.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Bridge Openings • During IBR construction, the IBR Program would coordinate with the U.S. Coast Guard, the ports, and other jurisdictions to minimize bridge openings and gate closures to minimize the impact to vehicles, active transportation, and transit. The work zone TMP would include coordination and communication with agencies, mariners, and the public for bridge openings and gate closures. *Arterials and Local Streets* • All minimization measures associated with constructing the Modified LPA would comply with local regulations governing construction traffic control and construction truck routing. The IBR Program would finalize detailed work zone TMPs in close coordination with local jurisdictions during the final design and permitting phases of the Program. *Transit Operations* • Transit service and facility modifications would be coordinated with TriMet and C-TRAN to minimize temporary impacts and disruptions to bus and light-rail facilities and service during construction. Detailed work zone TMPs and coordination/communication plans would be developed. This would include support for public information and communication throughout the construction period, including for periods where alternative routes, facilities, or services would be needed to maintain service. *Active Transportation* • The work zone TMP would include specific measures to maintain access to active transportation facilities and users. The Transportation Technical Report has additional detail on potential measures for construction areas, signage, lighting, communications, safety and maintenance. *Safety* • The IBR Program would implement the latest safety technology during construction (e.g., lane striping, Advanced Traffic Management System, Variable Message Signs, crash barriers, speed warning, etc.). *Transportation Demand Management and Transportation System Management* • The IBR Program would work with partner agencies on adapting and implementing TDM and TSM treatments during construction. Potential strategies could include: – Expanded transit service. – Vanpool/carpool program. – Telecommuting options. – Compressed work week/flexible work schedules. – Active transportation improvements and enhancements. *Tolling and Diversion* • The IBR Program would work with partner agencies to develop a detailed program and schedule for pre-completion tolling and any diversion impacts during construction. • Diversion impacts during construction will be evaluated and potential mitigation will be discussed with partner agencies to offset any impacts.
Aviation	**Long-Term Effects** ***Regulatory Requirements*** • Standards and regulatory measures have been evaluated and screened. These measures have been incorporated during the development of the Modified LPA to the extent possible and will continue to be refined as the design progresses.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• During final design, the IBR Program would comply with the FAA's findings in response to the Program's Form 7460-1. The FAA would issue a finding of "hazard to aviation" or "no hazard to aviation" upon completion of the aeronautical review. In addition, the FAA would have requirements for marking obstacles; this would likely include marking according to FAA AC 70/7460-1M "Obstruction Marking and Lighting" using equipment specified in AC 150/5345-43J "Specification for Obstruction Lighting Equipment." *Program-Specific Mitigation* • Provide obstruction marking and lighting to make the river crossing structures visible to aircraft. Design roadway or accent lighting on the bridges and surrounding interchanges to limit light or glare that could affect aviation at Pearson Field or Portland International Airport. • Place wire mesh or other deterrents over the top of temporary stormwater detention ponds to conceal open water when they are full to prevent birds from landing on open water. • Incorporate designs of proposed structures and features of the Program that minimize locations for birds to roost or nest. **Temporary Effects** *Regulatory Requirements* • To protect and minimize temporary effects on aviation during construction, standard and regulatory mitigation measures such as BMPs would be implemented. Construction BMPs applicable to the Modified LPA are discussed in Section 3.14, Water Quality and Hydrology. • Standard and regulatory mitigation measures for aviation include: – In the area of demolition of the Interstate Bridge and construction activities for the Columbia River bridges and the SR 14 interchange, FAA would review and approve the location and height of tall construction equipment proposed by the contractor. Equipment would be marked following the FAA's Obstruction Marking and Lighting Standards described in Advisory Circular 70/460-1M. – Apply dust control measures, such as watering exposed soil and using gravel surfacing on temporary construction roads, to mitigate potential reduction and visibility to aviation from construction activities in the SR 14 area. Section 3.10.6, Air Quality lists dust control requirements in both Oregon and Washington. Manage construction materials and activities to minimize glare and smoke. *Program-Specific Mitigation* • Construction specifications for contractors working near Pearson Field would include a condition that any electronic devices used for communication or other purposes cannot interfere with equipment required for air navigation and communication. • Place wire mesh or other deterrents over the top of temporary stormwater ponds to prevent birds from landing on open water. • Provide public involvement throughout construction to provide information to pilots and the public.
Navigation	**Long-Term Effects** *Regulatory Requirements* • Standards and regulatory measures have been evaluated and screened. These measures have been incorporated during the development of the Modified LPA to the extent possible and will continue to be refined as the design progresses. *Avoidance Measures*

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• The Modified LPA with a fixed-span configuration would have long-term effects to marine-based operations currently operating on the Columbia River, including five vessels and three upstream fabricators when shipping large cargo requiring vertical navigation clearance over 116 feet. Under the double-deck and single-level fixed-span configurations, these vessels and cargo shipments would be unable to transit beneath the new Columbia River bridges in either some conditions when river levels approach or exceed ordinary high water levels or be permanently precluded from transiting the bridge. The IBR Program would continue to coordinate with the affected vessel owners and river users to reach mutually acceptable decisions and agreements to avoid impacts through adjustments to vessels or business operations prior to publication of the Final SEIS. *Program-Specific Mitigation* • Provide obstruction marking and lighting to make the river crossing structures visible to river traffic. Design roadway or accent lighting on the bridges and surrounding interchanges to limit light or glare that could affect river navigation. • Update navigation charts and other navigation publications to reflect changes to VNC and HNC for future river users. **Temporary Effects** *Regulatory Requirements* • Develop construction phasing and staging plans to help ensure that construction activities would be planned to maintain a minimum channel for navigation. The Construction Staging Plan would be reviewed and approved by the USCG Captain of the Port prior to construction. Coordination and approval by the USCG Captain of the Port would occur for changes to the three navigation channels at each of the different times bridge pier sets would be constructed. Closures or restrictions on river traffic would be communicated in advance, enabling river users to accommodate their schedules, tug and barge configurations, requirements for assist tugs, shipping marine freight by other modes (e.g., truck, rail), use of different vessels with lower vertical clearance, and other options during construction activities that disrupt navigation and enable USACE to fulfill its navigation missions. • Provide Local Notice to Mariners throughout construction to provide information to tug operators, pilots, and the public. *Program-Specific Mitigation* • Make available an assist tug(s) to support safe navigation when vertical or horizontal clearances are reduced and assistance is needed to safely navigate the restricted channel. • Conduct outreach to inform the navigation community, recreational boaters, and other river users of waterway restrictions and other construction activities that may restrict or otherwise change local navigation conditions. • Provide information via local maritime publications, social media, local media, and other similar platforms. • Provide signage and notices at boat ramps, water access points, marinas, and other locations frequented by river users to inform them of the construction activities and where additional information can be found on the Program. • Notify individual vessel owners where information indicates they could be specifically impacted during construction. • Require all construction barges to have active AIS signals and construction channel lines be updated on the published navigation charts. • Modify the USACE Dredge *Yaquina* to have a lowerable mast or other feature to enable passage of the Interstate Bridge during construction.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
Property Acquisitions and Displacements	**Long-Term Effects** *Regulatory Requirements* • Purchase property at fair market value and provide relocation assistance per the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970 (Uniform Act). *Program-Specific Mitigation* No Program-specific mitigation measures are proposed for long-term effects related to property acquisitions and displacements. **Temporary Effects** *Regulatory Requirements* There are no specific regulatory requirements for mitigation of temporary property impacts. *Program-Specific Mitigation* As project design progresses, the IBR Program would develop approaches to managing temporary construction easements as part of the overall project right-of-way plan. The plan would identify measures that would be taken by contractors to avoid, minimize, and mitigate impacts to property temporarily used for construction. Program-specific measures that may be included in the plan to minimize and mitigate for temporary effects related to property acquisition and displacements include: • Mitigation for construction easements could include payment to property owners in exchange for the use of their property during construction. For example, one method for compensation would be to pay the equivalent of a rental based on the property valuation. Site impacts from temporary construction uses would be restored or compensated according to fair market or contributory value. • Mitigation may be needed in areas where construction of the Modified LPA could block or impede access to residences or businesses. Continued access to properties during construction would be maintained to the extent possible. Specific provisions may include signage to let the public know that businesses are open and conducting construction during non-peak business hours.
Land Use and Economic Activity	**Long-Term Effects** *Regulatory Requirements* • Purchase property at fair market value and provide relocation assistance per the Uniform Act. *Program-Specific Mitigation* • The Land Use Technical Report identifies several measures which, although they are not specifically land use mitigation, support the Modified LPA's compatibility with existing land uses: – The use of interchange area management plans to guide development within the vicinity of interchanges. – Mitigation for effects to historic resources, including demolition of the existing Interstate Bridge. – Avoidance of potential land use conflicts by planning and design efforts to support integration of park-and-ride facilities with current and planned land uses in downtown Vancouver.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Temporary Effects *Regulatory Requirements* • Construction BMPs would be used to avoid or minimize indirect construction effects on land use and economics, such as dust, noise, and aesthetic impacts. These measures are discussed in Section 3.10, Air Quality; Section 3.11, Noise and Vibration; and Section 3.9, Visual Quality. *Program-Specific Mitigation* *Land Use* • Monitor noise levels on a regular basis during construction near noise-sensitive receptors located closest to construction activities to reduce disturbance to nearby land uses and confirm compliance with noise thresholds set by local jurisdictions as well as the conditions of any noise variances obtained. • Schedule and manage work activities to minimize community disruption to the greatest extent feasible. • Implement mitigation measures for temporary impacts on residents as discussed in Section 3.3, Property Acquisitions and Displacements. • Carefully plan construction of the Modified LPA to phase work in such a way that reduces or avoids complete closure of affected roadways and access points to nearby businesses. Necessary detours would be routed to reduce travel times and signed to reduce confusion. Construction would be planned to keep business access points open as much as possible and would be well signed. A construction communication plan could be developed to inform travelers about detours and road closures and would direct them to businesses. *Economics* • Reduce impacts to local businesses by implementing a phased construction schedule that avoids complete closures of roads and access points to local businesses. A construction communication plan could be developed to inform travelers about detours and road closures and would direct them to businesses. • Design construction schedules to minimize temporary impacts to BNSF Railway lines and service frequency. • Provide outreach to businesses affected by construction and use assistance programs to help mitigate potential negative construction-related effects. • Coordinate with the Ports of Portland and Vancouver and associated businesses to identify ways to minimize delays for commercial freight vehicles during construction. • To keep freight moving during construction, the IBR Program would conduct outreach to businesses in areas with high volumes of freight traffic to determine access and site circulation needs and maintain access as needed.
Neighborhoods and Equity	**Long-Term Effects** *Regulatory Requirements* • Comply with the Uniform Relocation Act. When displacement cannot be avoided, federal and state regulations require property to be purchased at fair market value and all displaced residents to be provided with replacement housing and relocation assistance. Federal regulations, such as the Uniform Relocation Act, and state statutes determine the standards and procedures for providing such replacement housing, based on the characteristics of individual households. Relocation benefit packages usually include replacement housing for owners and renters, moving costs, and assistance in locating replacement housing.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Relocation benefits for businesses can include moving costs, site search expenses, and business reestablishment expenses. ***Program-Specific Mitigation*** *Neighborhoods* • Work with residents and community members to understand impacts and avoid, minimize, or mitigate overall neutral effect on visual quality in study area neighborhoods. • Strategies to minimize impacts to neighborhood cohesion could include providing additional community gathering spaces such as pedestrian and bicycle facilities. *Equity* • Work with residents and community members to understand impacts and avoid, minimize, or mitigate those impacts. • Develop a package of community benefits, which may be captured in a variety of documents, including contract specifications, environmental documents, a potential workforce agreement and either a community benefits plan or report. Community benefits are likely to include a variety of investments and strategies to ensure workforce and contracting equity, enhance the local community, and offset burdens associated with construction and operation. **Temporary Effects** ***Regulatory Requirements*** • Construction BMPs would reduce impacts to neighborhoods and equity priority communities. These measures are used to address construction effects such as temporary easements, noise, dust, emissions from construction vehicles, and visual clutter. BMPs applicable to the potential impacts described above in Section 3.5.5 are discussed in Section 3.3, Acquisitions and Displacements; Section 3.09, Visual Quality; Section 3.10, Air Quality; and Section 3.11, Noise and Vibration. ***Program-Specific Mitigation*** • Where feasible, implement nighttime construction schedules and shield nighttime lighting. • Hold community meetings before construction starts to inform residents of the construction timeline, relevant staging plans, ramp and road closures, and detour plans. • Use temporary signage, including variable message signs, to inform drivers of traffic delays because of construction and/or heavy equipment entering or leaving the highway. • Provide signs for local business assistance alerting customers of continued operation and a hotline for construction information. • Conduct regional outreach activities to provide information on construction impacts and detours that include communications to businesses, agencies, and community-based organizations within the greater Portland and Vancouver area. Traffic advisories and updates would be made available to the public to help make travel choices. • Place communication and signage for temporary routes for pedestrians and biking well in advance of the detour areas. Wayfinding signage would be accessible, consistent, thorough, and maintained. • Coordinate with affected property owners to minimize potential impacts to structures and access points during construction. • Coordinate with local jurisdictions and other organizations offering services to people experiencing unsheltered houselessness in areas directly affected by construction activities. Services would be provided in advance of construction and could include harm reduction, access to health services, and emergency shelter or alternate housing options.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Restore removed landscaping on properties following construction or as otherwise agreed within the property rights process. • Pay property owners in exchange for the use of their property during construction.
Public Services and Utilities	**Long-Term Effects** *Regulatory Requirements* • Oregon Administrative Rules Database Chapter 660, Division 11: Public Facilities Planning. Governing bodies are directed to avoid, minimize, and mitigate impacts to public services if possible. • Growth Management Act (GMA) Revised Code of Washington 36.70A.030(33) defines public services. GMA directs local governments to avoid, minimize, and mitigate impacts to public services. • For utilities, the IBR Program would develop or modify existing agreements with affected utility owners to specify the locations of utilities within the right of way, access, and maintenance requirements, etc. *Program-Specific Mitigation* • Implement feasible mitigation strategies for increased travel times along emergency services routes as described in Section 3.1, Transportation, of this Draft SEIS. **Temporary Effects** *Regulatory Requirements* • Incorporate measures to maintain traffic flow and access during construction and to avoid and minimize temporary utility service disruptions into contract specifications. • Comply with current federal Dig Once laws (23 Code of Federal Regulations [CFR] 645.307) and associated state regulations and guidelines, which require advanced coordination with the broadband/fiber industry to invite these providers to participate in highway improvement projects. *Program-Specific Mitigation* • Protect utilities in place where feasible and cost effective. • Work with utility providers to relocate utilities when protection in place is not feasible, with the goal of relocating facilities only once to reduce service disruptions. • Work with service providers and the public to minimize temporary effects to the extent practicable. Advance communication with the impacted public services would be conducted to inform dispatchers and responders about planned road closures and detours. A preconstruction communication plan would be developed with affected emergency response groups and other public service agencies detailing how detour and road closure information would be provided to the services. • Evaluate the need for backup on-call emergency services to transport patients during bridge construction to mitigate highway delays. • Conduct public outreach campaigns before construction to ensure that detours and traffic rerouting plans during construction are available to public service providers and the communities they service. Provide detour signs on routes typically used and signed to access public service locations. • Coordinate closely with utility owners during project design to identify temporary facility needs and minimize temporary construction disruptions.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
Parks and Recreation	**Long-Term Effects** *Regulatory Requirements* • If tree removal is unavoidable, replace trees on site and in kind at appropriate replacement ratios in compliance with applicable requirements of Portland and Vancouver city code. • Evaluate the feasibility and reasonableness of noise mitigation in accordance with WSDOT or ODOT criteria to shield park visitors and trail users from increased noise levels. *Program-Specific Mitigation* • If the acquired park land includes play equipment or other amenities, replace those features either in the same park or at one nearby. • Coordinate specific tree removal permitting processes and tree replanting requirements (location and type) for each park with the appropriate jurisdictions. • Screen portions of the transportation improvements from view with trees, vegetation, or built screens. • Explore retaining wall façade treatments to improve the visual quality, where feasible. **Temporary Effects** *Regulatory Requirements* • In compliance with the Cities of Vancouver and Portland's tree conservation requirements and codes, protect trees on park property that would be close to construction activities from adverse impacts as directed by the agency managing the park land (the cities of Vancouver, Portland, and Gresham, National Park Service (NPS), and the Vancouver Public School District). • Employ BMPs, including those outlined in WSDOT and ODOT construction manuals, to minimize increased levels of noise, vibration, glare from construction lights, emissions from construction vehicles, or dust from demolition of existing structures. • Comply with local ordinance requirements to provide additional protection for park users. *Program- Specific Mitigation* • Restore landscaping to its original condition and select plants that are resilient or adaptive to future climate conditions for new landscaping once construction is complete. • Protect trees on park property that would be close to construction activities but not removed, as agreed to with the appropriate jurisdiction. Restore landscaping to its original condition once construction is complete. • Restore landscaping to as close as possible to its original condition once construction is complete. • Establish detour routes based on work zone TMP. • Schedule construction-related closures at public parks and recreation facilities to minimize effects on large events, as feasible. • Provide notice to users of the recreational trails of the temporary limits on recreation in the Columbia River. • Notify recreational anglers of temporary access restrictions to fishing areas and consider other coordination efforts, including working with WDFW/ODFW to share closure information and distribute this information at locations that serve the fishing community.
Cultural Resources	Identification of the mitigation for adverse effects to historic properties assessed under NEPA will be completed through the National Historic Protection Act Section 106 process. FHWA and FTA, in coordination with WSDOT and ODOT, and in consultation with Oregon State Historic

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Preservation Office, Washington Department of Archaeology and Historic Preservation, consulting tribes, and other consulting parties, have chosen to complete the Section 106 process and resolve adverse effects on historic properties through the development of a Programmatic Agreement (PA) pursuant to 36 CFR 800.14(b). A Draft PA, with redactions for sensitive information as deemed appropriate by FHWA and FTA in consultation with consulting tribes and other consulting parties, is currently undergoing consultation and will be made available to the public prior to publication of the Final SEIS, as required by 36 CFR 800.14(b)(2)(ii). The Final PA will be executed prior to the issuance of the ROD and will be included as an appendix to the ROD.
Visual Quality	**Long-Term Effects** ***Regulatory Requirements*** • Meet the design standards of the Cities of Vancouver and Portland, TriMet, and C-TRAN for visual quality, including street furniture and transit stations. • Restore impacted roadsides in interchange and corridor areas in accordance with applicable vegetation and tree mitigation requirements. ***Program-Specific Mitigation*** *Mitigation Common to All Landscape Units, as feasible* • For local streets and transit stations, restore damaged landscapes, replant street trees, and provide enhanced landscapes to integrate the facilities into the community. • Shield station and facility lighting. • Minimize structural bulk, such as for ramps and columns. • Design architectural features to blend with the surrounding community. • Design gateways in coordination with applicable local plans including designs for landscaping, wall treatments, and other Program improvements. *Mitigation for Transit Stops and Stations, as feasible* • Design transit structural and architectural elements to be context-sensitive, and system-related signage and transit patron cues to be consistent with other transit system elements within respective systems. • Design the signal pole color, location, and style in accordance with the lighting district standards of the jurisdiction where the poles would be located (Portland or Vancouver). • Integrate transit facilities into the design of the community connector. *Place-Specific Mitigation, as feasible* • Transit Stations and Park and Rides – Conduct public design charrettes during the final design phases to refine the plans for each station area and park and ride. • Columbia River Landscape Unit – North Portland Harbor Crossings ▪ Preserve views of Mount Hood, to the extent practicable, for all users. – Hayden Island ▪ Integrate transit stations with the ground level, such as with landscaping. ▪ Evaluate surrounding views from the transit platform. ▪ Consult with the federally recognized tribes in the design process and provide opportunities to include cultural features such as, public art, historic education, plazas, or indigenous canoe watercraft landing and taking off locations. – Hayden Island Bridgehead

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	▪ Separate structures to admit daylight, if feasible. Maintain the separation between bridge structures across the island to ensure daylight and viable landscape at ground level, if feasible. ▪ Explore the incorporation of preserved bridgehead character into final design. ▪ Consult with the federally recognized tribes in the design process and provide opportunities to include public art, historic education, plazas, water access, or other cultural features. ▪ Explore public art opportunities on Hayden Island to announce arrival in Oregon, including pylons, piers, and other structures. – Columbia River Spans ▪ Design the active transportation on the Columbia River bridges for as low-stress an environment as possible ▪ Use art and landscaping to build anticipation of the river crossing in those approaching the main span, as feasible. ▪ Include lighting that would give expression to the architecture after dark, as feasible. – North Bank ▪ Incorporate a destination public open space under the bridge area as feasible. ▪ Consult with the federally recognized tribes in the design process and provide opportunities to include cultural features such as public art, historic education, plazas, or water access. ▪ Encourage creating or enhancing spaces, events, or initiatives that activate open spaces and urban environments along the Main Street extension to the river. Enhancements may include public art, street furniture, bike and pedestrian facilities, popup markets and public events, or other measures. ▪ Activate open spaces and screen structures with landscaping. ▪ Use architecture or public art to mark entry and departure from each bridge. • Vancouver Downtown Landscape Unit – Transit Structure “Landing” in Vancouver ▪ Provide landscaping, public art, or other façade treatments for the walls of the light-rail landing structure, as feasible. ▪ Coordinate and design transit structures and facilities in conjunction with the Community Connector. – Park-and-Ride Facilities ▪ Incorporate design guidelines and consider input from downtown interested parties and the general public. ▪ Buffer the park and ride from adjacent uses, mainly with landscaping but potentially with public art, fencing, or other elements, as feasible. ▪ Comply with City of Vancouver Design Standards and have them reviewed by the Vancouver Design Review Committee. ▪ To the extent feasible, eliminate potential glare from the park-and-ride structure components. ▪ Incorporate public art reflective of the unique context at each park-and-ride facility. – McLoughlin Boulevard Crossing ▪ Coordinate lighting under structures with city and I-5 lighting. ▪ Keep the spaces beneath freeway structures clear of unauthorized uses to the extent possible. • Greater Central Park Landscape Unit

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	– SR 14 Interchange ▪ Maintain existing vegetation wherever possible, particularly between the Kanaka Village and SR 14 ramps. Landscape plans should include plantings as visual screens. Replacement trees should be as large caliper trees as practical to replace screening value as quickly as possible. ▪ Provide visual and physical connections between under-bridge structures. Connect the Vancouver Land Bridge and Old Apple Tree Park with downtown Vancouver by combining improved sight lines, improved access, and integrated landscape design. ▪ Use Vancouver Land Bridge landscaping in new landscaped areas as feasible. ▪ Activate open spaces and screen structures with landscaping. Use landscape to organize the diversity and extent of open spaces associated with the interchanges and to screen the railroad berm. • Burnt Bridge Creek Landscape Unit – Ensure compatibility of overpass approaches with neighborhoods with input from the neighborhood facing each end of the bridges, as feasible. – Identify a local design theme for overpasses. **Temporary Effects** *Regulatory Requirements* • There are no regulatory requirements for temporary effects to visual quality, specifically. The Program would meet federal, state, and local design standards for light and glare. *Program-Specific Mitigation* • Follow standard construction specifications regarding the reduction of light and glare. • Shield construction site lighting to reduce spillover light onto nearby residences and businesses, as feasible. • Minimize visual obtrusiveness by locating construction equipment and stockpiling materials in less visually sensitive areas, when feasible, and in areas not visible from the road or to residents and businesses. • Provide, as feasible, public areas to observe the construction and demolition processes, using them as an opportunity for public education.
Air Quality	**Long-Term Effects** *Regulatory Requirements* • There are no regulatory requirements that would be directly implemented by the IBR Program. *Program-Specific Mitigation* • No mitigation proposed as long-term air quality impacts are not expected. **Temporary Effects** *Regulatory Requirements - Oregon* • Comply with Division 208 of Oregon Administrative Rule (OAR) 340. • Comply with ODOT Standard Specifications Section 290. • Comply with the Clean Diesel Construction Standard (OAR-731-005-0800). • Comply with Oregon House Bill 2007, known as the “Clean Diesel Bill."

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Comply with City of Portland Clean Air Construction Program that to reduce diesel emissions by implementing a standard set of idle reduction and diesel equipment requirements on job sites. *Regulatory Requirements - Washington* • Comply with WSDOT Standard Specifications for Road, Bridge, and Municipal Construction, Section 1.07.5(4). • Comply with fugitive dust control BMPs set forth in the Associated General Contractors of Washington Education Foundation and Fugitive Dust Task Force Pamphlet, "Guide to Handling Fugitive Dust From Construction Projects." *Program-Specific Mitigation* • Through contract specifications, encourage all contractors to minimize impacts to surrounding communities such as using newer low-emitting construction equipment and electric equipment, and avoiding haul routes through residential areas.
Noise and Vibration	**Long-Term Effects** *Highway Traffic Noise Mitigation* Mitigation related to highway traffic noise include mitigation (abatement) measures that meet ODOT's and WSDOT's feasibility and reasonableness criteria may be recommended for inclusion in the Modified LPA. Feasibility primarily deals with engineering considerations such as whether substantial noise level reductions can be achieved or whether there would be a negative effect on property access resulting from the placement of noise walls for example. Reasonableness includes three factors: (1) if abatement is cost-effective; (2) if abatement can achieve the design goal; (3) and if the abatement is desired by benefiting receptors. The complete list of potential traffic noise abatement measures can be found in Section 7 of the Noise and Vibration Technical Report. Under ODOT and WSDOT policies, the following noise abatement measures must be considered: • Traffic management measures (for example, traffic control devices and signing for prohibition of certain vehicle types, time-use restrictions for certain vehicle types, modified speed limits, and exclusive land designations). • Highway design measures (for example, alteration of horizontal/vertical alignments). • Acquisition of property rights (either in fee or lesser interest) for construction of noise barriers. • Acquisition of real property or interests therein (predominantly unimproved property) to serve as a buffer zone to preempt development that would be adversely impacted by traffic noise. • Sound insulation of all Activity Category D land uses, including public use or nonprofit institutional structures. • Construction of sound barriers (including landscaping for aesthetic purposes), whether within or outside the highway right of way. Interstate construction funds may not participate in landscaping. Noise mitigation was evaluated at all locations where traffic noise impacts were predicted. Noise walls were evaluated to mitigate noise impacts at 16 locations in Washington and 3 in Oregon. Of those evaluated, 11 noise walls were determined to be feasible and reasonable by ODOT and WSDOT criteria (10 in Washington, 1 in Oregon). *Light-Rail Noise Mitigation in Downtown Vancouver*

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Install tall safety barriers or sound barriers along the elevated structure to mitigate the noise impacts at site LRT-1, which represents the Normandy Apartments located at E 7th Street and E C Street in downtown Vancouver. A 3- to 4-foot acoustical absorbent wall or 6-foot reflective wall would reduce noise levels at this location by 7 to 10 dBA. • Equip all light-rail track curves with a radius of less than 300 feet with wayside lubricators. After construction of the alignment, during the initial testing, if additional curves are identified with wheel squeal, install wayside track lubricators, as necessary. Light-rail noise mitigation was determined not to be needed in Portland. *Light-Rail Vibration Mitigation in Vancouver* • Use resilient rail fasteners to mitigate for vibration impacts located along direct fixation track way. Resilient rail fasteners typically reduce vibration levels by 5 vibration in decibels (VdB), which would not reduce all the predicted vibration levels to below the FTA 72 VdB criteria for residential land uses. Receivers LRV-1 and LRV-2, with predicted levels of 77 VdB and 81 VdB, respectively, would be the only locations where there is still a potential for vibration impact following mitigation. • Perform additional testing to ensure that the vibration levels at LRV-1 and LRV-2 would be below the 72 VdB criteria (Section 3.11, Figure 3.11-9). No vibration impacts are predicted in the Portland segment; therefore, no mitigation is needed. **Temporary Effects** Construction noise and vibration BMPs applicable to the Modified LPA with any design option are discussed below. ***Construction Noise*** *Regulatory Requirements* • Comply with ODOT construction noise abatement measures (§ 00290.32 Noise Control) at the time of construction. • If a specific noise impact complaint occurs during the construction of the Modified LPA, implement noise mitigation measures outlined in Section 3.11.6 as directed by the engineer. Although WSDOT does not have noise control provisions, WSDOT would voluntarily comply with § 00290.32 for work completed in Washington. *Program-Specific Mitigation* In addition to § 00290.32, ODOT and WSDOT would also implement additional noise abatement methods, including: • Limit activities that produce the highest noise levels (such as hauling, loading spoils, jack hammering, and using other demolition equipment) to 7:00 a.m. to 7:00 p.m. Maximum noise levels associated with pile driving could reach 105 dBA at distances of 50 feet. Mitigation of the noise associated with pile driving would, when possible, include drilled shafts or auguring rather than driving piles (however, using an auger is not likely to be feasible or practical for all locations) or limiting the times the activity could take place. Other less effective methods of reducing noise from pile driving include coating the piles, using pile pads, or using piston mufflers. If pile driving exceeds the limits set forth in Table 3.11-4 in Section 3.11, Noise and Vibration, a noise variance would be requested from the local jurisdiction. • Keep a construction log for each of the construction staging areas. The log would contain general construction information such as the time an activity took place, type of equipment used, and other information that might help with potential noise effects. • Establish a complaint hotline to investigate noise complaints and compare them to the construction logs. A construction monitoring and complaint program would help to ensure

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	that all equipment meets state, local, and any manufacturer's specifications for noise emissions. Equipment not meeting the standards would be removed from service until proper repairs were made and the equipment retested for compliance. This procedure would apply to all haul trucks, loaders, excavators, and other equipment that would be used extensively at the construction sites and that would contribute to potential noise effects. • Use equipment complying with pertinent equipment noise standards of the EPA. *Construction Vibration* *Regulatory Requirements* • Monitor all activities that might produce vibration levels at or above 0.5 inches per second if structures are near the construction activity, in compliance with WSDOT and ODOT requirements. This would include pile driving, vibratory sheet installation, soil compacting, and other construction activities with the potential to cause high levels of vibration. • For historic built properties within 500 feet of construction, monitor construction activities where construction-related vibration would exceed 0.2 inches per second for transient vibrations and 0.1 inches per second for continuous vibrations. Additional vibration mitigation measures intended to protect marine life are described in Section 3.16, Ecosystems. Additional mitigation measures related to built historic resources are described in Section 3.8. *Program-Specific Mitigation* No specific mitigation measures are proposed for vibration levels during construction.
Energy	**Long-Term Effects** *Regulatory Requirements* State-level legislation and policy in Oregon and Washington support reducing emissions from transportation to minimize contributions to climate change; However, there are no specific requirements for mitigation actions in federal, state, or local regulations. The Program supports state, regional, and local goals to reduce greenhouse gas emissions. To help facilitate a shift from single-occupancy vehicles, the Program would improve multimodal transportation options including: • Extended light-rail. • Expanded active transportation facilities. • Demand management (e.g., variable-rate tolling). • Operation and maintenance efficiencies. *Program-Specific Mitigation* • Use energy-efficient electrical systems for transit stations and other electrical needs to decrease energy consumption. **Temporary Effects** *Regulatory Requirements* • In Oregon, comply with ODOT Standard Specifications Section 290. • In Washington, company with WSDOT Standard Specifications Division 1-07. *Program-Specific Mitigation* • All work in Washington and Oregon will follow the WSDOT Environmental Manual, Chapter 425: Air Quality, Energy, and Greenhouse Gases, including: – Minimize delays to traffic during peak travel times. – Minimize unnecessary idling of on-site diesel construction equipment.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	– Educate vehicle operators to shut off equipment when not in active use to reduce emissions from idling. – Prepare a traffic control plan with detours and strategic construction timing (e.g., night work) to move traffic through the area and reduce backups and delays to the traveling public to the extent practicable. • Continue to consider advances in energy-reducing and/or energy-saving materials and methods.
Water Quality and Hydrology	**Long-Term Effects** *Regulatory Requirements* • As design progresses, conduct a detailed hydraulic analysis of the affected floodplains. If a rise in the base flood elevation is predicted, assess mitigation through floodplain excavation (cut/fill balance) activities within the footprint of the Modified LPA and determine whether additional land may be required to accomplish the required mitigation. Conduct a Location Hydraulic Study to document the impacts, mitigation measures, evaluation of alternatives, and findings in accordance with the provisions of 23 CFR 650A. • Work with the City of Portland to ensure flood storage compensation does not jeopardize threatened and endangered species and their habitat (revised Floodplain Development Code Chapter 24.50 Flood Hazard Areas). • Comply with ODOT and WSDOT stormwater management requirements and the Cities of Portland and Vancouver regulations for the portions of the Modified LPA along City-managed roads during construction and for the long-term treatment of stormwater runoff prior to discharge into receiving waters. • Select and design water quality BMPs to ensure compliance with all federal, state, and local regulatory requirements, construction and municipal stormwater permit requirements issued through CWA section 401, to reduce suspended solids, particulates, and dissolved metals; to reflect the latest climate models; and to treat newly identified pollutants like 6PPD-quinone. • Construct flow control facilities to infiltrate or reduce the flow rates of all study area runoff, pursuant to local regulatory requirements. Mitigation for increased runoff to the Columbia Slough or the Columbia River would not be required because these water bodies are exempt from stormwater quantity management. However, the effects of increased runoff would be reduced using stormwater infiltration. This would allow groundwater recharge to continue and minimize the increase in runoff volumes and peak discharges. *Program-Specific Mitigation* *Hydrology* • Offset potential rise in the base flood elevation through floodplain excavation (cut/fill balance) activities as determined through a Location Hydraulic Study. • In the Burnt Bridge Creek watershed, construct infiltration facilities to provide complete infiltration of all Program-related runoff, such as providing underground injection control requirements, to the extent practicable, for the wellhead protection zone present in the watershed to manage stormwater volumes. As design progresses, select site-specific BMP facilities. • Prepare stormwater monitoring plan(s) to evaluate the long-term performance and effectiveness of the updated stormwater conveyance and treatment systems. Based on the findings, complete modifications or enhancements to the system(s) to meet discharge performance criteria.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Compensate for additional fill in floodplains to achieve a no net loss of floodplain as a result of removal of materials within the City of Portland Floodplain Hazard Areas. *Water Quality* Where applicable in the project area, the following proposed water quality treatment facilities would be used to treat stormwater runoff and mitigate the increase in contributing impervious surfaces. Definitions of these treatment facility types are presented in Section 7.2.2 of the Water Quality and Hydrology Technical Report. • Treat stormwater runoff through bioretention ponds/planters, biofiltration swales, bioslopes (Oregon), and/or media filter drains (Washington) that provide water quality treatment via infiltration through a phosphorus-free, compost-amended soil medium and/or vegetation. Vegetation also provides uptake of some water. • Water quality treatment facilities that have demonstrated effectiveness for advanced treatment would be designed according to each jurisdiction's specifications such as according to Ecology's Technology Assessment Protocol program (Washington), the 2020 Stormwater Management Manual (Portland), and Vancouver's Surface Water Management Program. **Temporary Effects** *Regulatory Requirements* • Regulatory requirements for temporary effects of stormwater runoff during construction would include compliance with ODOT, WSDOT, Portland, and Vancouver's regulations including the preparation of a spill prevention, control, countermeasure (SPCC) plan and pollution control plan (PCP), and temporary erosion and sediment control. In addition, all federal, state, and local permits related to water quality and hydrology would be obtained. See Section 8 in the Water Quality and Hydrology Technical Report for a complete list of required federal, state, and local permits. *Spill Prevention/Pollution Control Measures* • Require the contractor to prepare an SPCC plan and PCP prior to beginning construction. These plans would be provided to the National Oceanic and Atmospheric Administration Marine Fisheries Service (NOAA Fisheries) for review and approval. The SPCC plan and PCP would identify the appropriate spill containment materials, as well as the means and methods of implementation, response, and reporting, in the event of a spill. All elements of the SPCC plan and PCP would be available at the project site at all times. For additional details, consult ODOT Standard Specification 00290.00 to 00290.90 and WSDOT Standard Specification 1-07.15. *Site Erosion/Sediment Control Measures* • Require the contractor to prepare and implement a temporary erosion and sediment control plan (TESCP) to minimize impacts associated with clearing, vegetation removal, grading, filling, compaction, or excavation. The BMPs identified in the TESCP would be used to control sediments in areas impacted by vegetation removal or ground-disturbing activities. Additional temporary control measures may be required beyond those described in the TESCP if it appears pollution or erosion may result from weather, nature of the materials or progress on the construction. For additional details, consult ODOT Standard Specifications 00280.00 to 00280.90 and WSDOT Temporary Erosion and Sediment Control Manual M3109.02. • Stabilize all exposed soils as directed in measures prescribed in the TESCP. Hydro-seed all bare soil areas following grading activities and revegetate all temporarily disturbed areas with native vegetation indigenous to the location. For additional details, consult ODOT

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Standard Specifications 01030.00 to 01030.90 and WSDOT Temporary Erosion and Sediment Control Manual M3109.02. • Where site conditions support vegetative growth, plant native vegetation indigenous to the location in areas temporarily disturbed by construction activities. Trees would be planted when consistent with highway safety standards. Riparian vegetation would be replanted with species native to geographic region. Planted vegetation would be maintained and monitored to meet regulatory permit requirements. For additional details, consult ODOT Standard Specifications 01040.00 to 01040.90 and WSDOT Temporary Erosion and Sediment Control Manual M3109.02. ***Program-Specific Mitigation*** *Hydrology* • Minimize changes to groundwater hydrology by limiting groundwater pumping to areas where it cannot be avoided. *Water Quality* • Study, test, and remediate sites with existing soil or groundwater contamination near construction areas before any construction. See Section 3.18, Hazardous Materials for specific mitigation actions. • Conduct in-water work during approved periods for the Columbia River, as approved by Washington Department of Fish & Wildlife (WDFW), Oregon Department of Fish & Wildlife (ODFW), NOAA Fisheries, and U.S. Fish and Wildlife Service (USFWS). See Section 3.16, Ecosystems for specific mitigation measures. • Stage construction equipment used for in-water work activities above the ordinary high water mark (OHWM). Only the operational portion of construction equipment would enter the active stream channel (below the OHWM). • If in-water dredging is required outside of a cofferdam, use a clamshell bucket within the established in water work windows. Dredging, handling, and disposal of dredged materials shall be conducted consistent with the requirements and conditions of the regulatory permits issued for the Modified LPA. • If required, monitor turbidity and provide a "rest" period to allow turbidity, if any, to dissipate between in-water work activities.
Wetlands	**Long-Term Effects** ***Regulatory Requirements*** • Develop the Modified LPA consistent with the applicable federal, state, and local agency regulatory mitigation related to filling or removing material in wetlands and other waters of the U.S. and state. • Prepare a compensatory mitigation plan that satisfies applicable federal, state, and local regulatory requirements, and that demonstrates no net loss of function and values of wetland resources. ***Program-Specific Mitigation*** • Continue to evaluate mitigation to offset losses of wetland and waters functions and values, including wetland buffers, as the Modified LPA design progresses. • In cooperation with federal, state, and local agencies, tribes, and conservation groups, identify agency-approved compensatory mitigation banks and potential permittee responsible mitigation sites in both Oregon and Washington to fulfill the compensatory requirements for permanent, temporary, and indirect impacts.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• For unavoidable impacts to Vanport wetlands, increased mitigation ratios would be required because it is an existing wetland mitigation site. **Temporary Effects** *Regulatory Requirements* • Implement appropriate high visibility/exclusionary fencing around avoided wetlands and other waters prior to the start of construction. • Implement appropriate sediment and erosion control procedures during construction activities. • Replace vegetation temporarily cleared for construction activity in accordance with local regulatory guidance. • Avoid working outside of the in-water work window without first seeking an exception. • Offset unavoidable temporary impacts that cannot be minimized through BMPs through the purchase of credits from a mitigation bank or permittee responsible mitigation, similar to the mitigation used for certain long-term effects. *Program-Specific Mitigation* • Avoid and minimize short-term impacts to wetland resources in final design to the extent practicable. • Restore temporarily disturbed wetland and wetland buffer habitats consistent with applicable regulatory requirements.
Ecosystems	**Long-Term Effects** *Regulatory Requirements* • Provide stormwater quality and quantity treatment that meets or exceeds applicable regulatory requirements for all post-project contributing impervious areas. *Program-Specific Mitigation* • Avoid and minimize long-term impacts to ecosystem resources in final design to the extent practicable. • Provide compensatory mitigation for unavoidable impacts to ecosystem resources, consistent with applicable federal, state, and local regulatory requirements. • Prepare a compensatory mitigation plan that satisfies applicable federal, state, and local regulatory requirements, and that demonstrates no net loss of function of ecosystem resources. • Provide an alternate nesting structure, either on the new Columbia River bridges or within the vicinity, to offset removal of an existing peregrine falcon nest from demolition of the existing Interstate Bridge. **Temporary Effects** *Regulatory Requirements* *General Measures and Conditions* • Perform all work according to the requirements and conditions of the regulatory permits that are issued for the Modified LPA. • Require contractor to prepare a Water Quality Protection and Monitoring Plan (WQPMP) to satisfy the monitoring and reporting requirements of the 401 Water Quality Certifications that are ultimately issued for the project. The WQPMP would be provided to NOAA Fisheries for review and approval prior to implementation. The WQPMP would identify the timing and methodology for water-quality sampling during construction of the Modified LPA, as well as

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	methods of implementation and reporting. If, in the future, a standard water-quality monitoring plan is adopted by ODOT and/or WSDOT, this plan, with the agreement of NOAA Fisheries, may replace the contractor plan. • In compliance with ODOT and WSDOT policy and construction administration practice in Oregon and Washington, have one or more department of transportation inspectors on site during construction. The role of the inspector(s) would be to monitor compliance with contract and permit requirements. • If in-water dredging is required outside of a cofferdam, use a clamshell bucket. Dredging and handling and disposal of dredged materials shall be conducted consistent with the requirements and conditions of the regulatory permits issued for the Modified LPA. • Prohibit work barges from grounding out. • Dispose of excess or waste materials in an appropriate manner consistent with applicable local, state, and federal regulations; do not dispose of or abandon waste materials waterward of the OHWM or allow them to enter waters of the state. • All pumps must employ a fish screen that meets the following specifications: – An automated cleaning device with a minimum effective surface area of 2.5 square feet per cubic foot per second and a nominal maximum approach velocity of 0.4 feet per second, or no automated cleaning device, a minimum effective surface area of 1 square foot per cubic foot per second and a nominal maximum approach rate of 0.2 feet per second; and – A round or square screen mesh that is no larger than 0.094 inches (2.38 millimeters [mm]) in the narrow dimension, or any other shape that is no larger than 0.069 inches (1.75 mm) in the narrow dimension; and – Each fish screen must be installed, operated, and maintained according to NOAA Fisheries fish screen criteria. *Spill Prevention/Pollution Control Measures* • Require contractor to prepare an SPCC plan and PCP prior to beginning construction. These plans would be provided to NOAA Fisheries for review and approval. The SPCC plan and PCP would identify the appropriate spill containment materials; as well as the means and methods of implementation, response, and reporting. All elements of the SPCC plan and PCP would be available at the project site at all times. For additional detail, consult ODOT Standard Specification 00290.00 to 00290.90. • Require contractor to designate at least one employee as the erosion and spill control (ESC) lead. The ESC lead would be responsible for the implementation of the SPCC plan and PCP. • Maintain applicable spill response equipment and material designated in the SPCC plan and PCP at the job site. • With the exception of barges and stationary large equipment (cranes, oscillators) operating from barges or work platforms, fuel and maintain equipment at least 150 feet from the OHWM of any waterbody using secondary containment to minimize potential for spills or leaks entering the waterway. • Clean and inspect all equipment to be used for construction activities prior to arriving at the project site, to ensure no potentially hazardous materials are exposed, no leaks are present, free of noxious weeds, and the equipment is functioning properly. Daily inspection and cleanup procedures would be identified. • Should a leak be detected on heavy equipment used for the project, immediately remove the equipment from the area, and do not use again until adequately repaired. Where off-site repair is not practicable, the SPCC plan and PCP would document measures to be implemented to prevent and/or contain accidental spills in the work/repair area to ensure no

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	contaminants escape containment to surface waters and cause a violation of applicable water-quality standards. • Operate construction equipment from on top of floating barges, from the decks of temporary work bridges and platforms, the decks of the existing or replacement bridges, or from portions of the streambank above the OHWM. Barges and support vessels would be operated in the water. • Provide suitable containment measures for all equipment (including barges, work decks, stationary power equipment, and storage facilities) in the SPCC plan and PCP to prevent and/or contain accidental spills to ensure that no contaminants escape containment to surface waters and cause a violation of applicable water-quality standards. • Design and install temporary work bridges and platforms, cofferdams, and drilled shaft isolation casings consistent with the ODOT Hydraulics Manual, which establishes criteria to avoid these structures being overtopped during high water events. • Process water generated on site from construction, demolition or washing activities would be contained and treated to meet applicable water-quality standards before entering or re-entering surface waters. • Do not conduct paving, chip sealing, or stripe painting activities during periods of rain or wet weather. • In the SPCC plan and PCP, establish a concrete truck chute cleanout area to properly contain wet concrete as part of ODOT Standard Specification 00290.30(a). *Site Erosion/Sediment Control Measures* • Require contractor prepare and implement a TESCP to minimize impacts associated with clearing, vegetation removal, grading, filling, compaction, or excavation. The BMPs identified in the TESCP would be used to control sediments from all vegetation removal or ground-disturbing activities. Additional temporary control measures may be required beyond those described in the TESCP if it appears pollution or erosion may result from weather, nature of the materials or progress on the work. For additional detail, consult ODOT Standard Specifications 00280.00 to 00280.90. • As part of the TESCP, delineate clearing limits with orange barrier fencing wherever clearing is proposed in or adjacent to a stream/wetland or its buffer and install perimeter protection/silt fence as needed to protect surface waters and other critical areas. Location would be specified in the field, based upon site conditions and the TESCP. For additional silt fence detail, consult ODOT Standard Specification 00280.16(c). • Require contractor to designate at least one employee as the ESC lead. The ESC lead would be responsible for the implementation of the SPCC plan and PCP and would also be responsible for ensuring compliance with all local, state, and federal erosion and sediment control requirements. • All TESCP measures would be inspected and maintained as required by applicable permit requirements. Contractor would also conduct maintenance and repair of TESCP measures as described in ODOT Standard Specifications 00280.60 to 00280.70. • For landward construction and demolition, locate project staging and material storage areas a minimum of 150 feet from surface waters, in currently developed areas such as parking lots or managed fields, unless determined by an ODOT/WSDOT biologist that the topographic features or other site characteristics allow for site use closer to the edge of surface waters. • Complete excavation activities under dry or dewatered conditions where practicable. All surface water flowing toward the excavation would be diverted through utilization of cofferdams and/or berms. Cofferdams and berms must be constructed of sandbags, clean rock, steel sheeting, or other non-erodible material.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Limit bank shaping to the extent as shown on the approved grading plans. Minor adjustments made in the field would occur only after engineer's review and approval. • Install biodegradable erosion control blankets on areas of ground-disturbing activities on steep slopes (1V:3H or steeper) that are susceptible to erosion and within 150 feet of surface waters. Areas of ground-disturbing activities that do not fit the above criteria would implement erosion control measures as identified in the approved TESCP. For additional erosion control blanket detail, consult ODOT Standard Specification 00280.14I. • Cover erodible materials (material capable of being displaced and transported by rain, wind or surface water runoff) temporarily stored or stockpiled for use in project activities to prevent sediments from being washed from the storage area to surface waters. Temporary storage or stockpiles must follow measures as described in ODOT Standard Specification 00280.42. • Stabilize all exposed soils as directed in measures prescribed in the TESCP. Hydro-seed all bare soil areas following grading activities and revegetate all temporarily disturbed areas with native vegetation indigenous to the location. For additional details, consult ODOT Standard Specifications 01030.00 to 01030.90. • Where site conditions support vegetative growth, plant native vegetation indigenous to the location in areas temporarily disturbed by construction activities. Revegetation of construction easements and other areas would occur after the project is completed. Trees would be planted when consistent with highway safety standards. Riparian vegetation would be replanted with species native to geographic region. Planted vegetation would be maintained and monitored to meet regulatory permit requirements. For additional detail, consult ODOT Standard Specifications 01040.00 to 01040.90. *Pile Installation and Removal BMPs* • Use a vibratory hammer to drive steel piles to the maximum extent practicable, to minimize noise levels. • Conduct impact pile driving below the OHWM between September 15 and April 15. Vibratory pile installation and removal (as well as certain other in-water construction activities) may occur on a year-round basis, provided they are conducted in compliance with all regulatory approvals. • No more than two impact pile drivers would be operated simultaneously within the same waterbody channel. • Employ a bubble curtain or other similarly effective noise attenuation device during all impact pile driving conducted in water depths greater than 2 feet (0.67 meters). • Develop and implement a hydroacoustic monitoring plan, based on the template developed by the Fisheries Hydroacoustic Working Group, in coordination with FHWA and FTA to confirm the effectiveness of the noise attenuation devices and that predicted noise levels adequately capture the area of the potential onset of injury. • Prepare a marine mammal monitoring plan, and establish injury protection zones for marine mammals. • Install cones or other anti-perching devices on open-ended pipe piles to discourage perching by piscivorous birds. • Remove temporary piles with a vibratory hammer, or by direct pulling, and prohibit intentionally breaking by twisting or bending. • If a temporary pile cannot be removed, cut or press the pile 3 feet below the mudline. At locations where hazardous materials are present or adjacent to utilities, temporary piles may be cut off at the mud line with underwater torches, if such activity would not conflict with navigation elements. *Work Area Isolation and Fish Salvage BMPs*

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Develop a temporary water management plan, consistent with the requirements of ODOT Special Provision Section 00245.03, and provide to NOAA Fisheries for review and approval prior to any work area isolation of fish salvage activities. • Install cofferdams and isolation casings in a manner that minimizes fish entrapment. Sheet piles would be installed from upstream to downstream, lowered slowly until contact with the substrate. • Screen drilled shaft isolation casings at the bottom, to minimize potential for fish entrapment during installation. Screen shall have maximum openings of approximately 3/32 inch (2.38 mm) measured on a diagonal (NOAA Fisheries 2022). • Conduct fish salvage according to the best practices established in the biological opinion for ODOT's Federal Aid Highway Programmatic consultation. • Have a qualified fishery biologist conduct and supervise fish capture and release activity to minimize risk of injury to fish. • Prepare a fish salvage report and submit to NOAA Fisheries, USFWS, ODFW, and WDFW following project completion. • Make a reasonable effort to capture Endangered Species Act-listed fish known or likely to be present in an in-water isolated work area using methods that minimize the risk of injury. Attempts to seine and/or net fish would precede the use of electrofishing equipment. • If electrofishing must be used, conduct consistent with NOAA Fisheries "Guidelines for Electrofishing Waters Containing Salmonids Listed under the Endangered Species Act" (NOAA Fisheries 2000), or most recent version. *Work Area Lighting BMPs* • Conduct construction activities consistent with local, state and federal permit restrictions for allowable work hours. If work occurs at night, temporary lighting may be required to provide better visibility for driver and worker safety. If temporary lighting is required, contractor would use directional lighting with shielded luminaries to control glare and direct light onto work area, not surface waters. ***Program-Specific Mitigation*** • Avoid and minimize short-term impacts to ecosystem resources in final design to the extent practicable. • Restore temporarily disturbed terrestrial habitats consistent with applicable regulatory requirements. • Provide compensatory mitigation for unavoidable impacts to ecosystem resources, consistent with applicable federal, state, and local regulatory requirements. • Conduct activities with the potential to impact nesting migratory birds, such as nest removal, consistent with the provisions of the Migratory Bird Treaty Act, which requires nests of migratory birds to be removed only at times when nests are inactive.
Geology and Groundwater	**Long-Term Effects** ***Regulatory Requirements*** • Design structures to comply with federal, state, and city building seismic codes and standards and apply advancements in earthquake science and construction materials and updates in the conceptual model. • Design systems to minimize contamination of groundwater resources in compliance with Vancouver Municipal Code Chapter 14.26 Water and Sewers – Water Resources Protection and Portland City Code Title 21.35, Well Head Protection, and any applicable Washington and Oregon regulations.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Program-Specific Mitigation • Design structures to consider stormwater infiltration or other changed conditions near shallow footings, retaining walls, and other structures that could increase the potential for soil liquefication during a future seismic event. • Design the Modified LPA to accommodate a range of future conditions resulting from climate change to provide resilience for geologic concerns, such as increased erosion and scour, as feasible. • Conduct site-specific assessments of existing geologic hazards such as, but not limited to, faults, ancient landslides, steep cut slopes, non-seismic settlements, and soil liquefaction during design of the Modified LPA, as feasible. Site-specific assessments should include the use of geotechnical drilling, test pitting, material testing, geophysical techniques, subsurface displacement monitoring (inclinometers) and monitoring well installation, as feasible. Assessment would include recommended options for avoiding or mitigating geologic hazards. • Consider the use of light weight fills or geoform in areas adjacent to existing flood control levees and structures to minimize the potential for settlements. • Assess soil stabilization techniques to minimize the potential for soil liquefaction and non-seismic settlements during design of the Modified LPA. Stabilization techniques may include, but are not limited to, the use of soil mixing, compaction grouting, jet grouting, and stone columns. • Locate stormwater treatment facilities, to the extent possible, away from City of Vancouver well head protection zones for WS-1 and WS-3, and the Cascade Expansion groundwater protection area in Gresham for the Ruby Junction location. **Temporary Effects** *Regulatory Requirements* • Prepare and implement erosion control and stormwater pollution prevention plans and grading plans during construction. Plans would adhere to ODOT and WSDOT guidelines. • Prepare and implement stormwater discharge permits for construction. • Conduct inspection and observation monitoring of all Modified LPA elements during construction and long-term operations to ensure that appropriate construction and maintenance measures are being taken. *Program-Specific Mitigation* • Evaluate local geologic resources for future material needs. • Recycle or reuse aggregate, quarry rock, asphalt, and concrete materials to the extent practical.
Hazardous Materials	**Long-Term Effects** *Regulatory Requirements* In accordance with FTA and FHWA standard procedures, the IBR Program has prepared Phase I ESAs to identify existing environmental issues on properties to be acquired. The results and recommendations of the Phase I ESAs have been incorporated into this Draft SEIS. • Prepare Phase II ESAs for properties where identified recognized environmental conditions (RECs) indicate that a subsurface investigation is necessary to confirm the nature and extent of contamination and define the specific measures and applicable regulatory agency approvals needed to address the contamination. Incorporate the Phase II results into the

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Final SEIS and ROD to provide decision-makers with a more detailed understanding of cleanup obligations and costs. • Develop detailed hazardous management plans during the final design and as part of the property acquisition process. Obtain necessary regulatory approvals to address areas where cleanup and remediation are needed. The remediation or cleanup of hazardous material sites affected by the Modified LPA would be required prior to construction. • In accordance with Safety Standards for Construction Work: Lead (Washington Administrative Code [WAC] 296-155) and General Occupational Health Standards: Asbestos (WAC 296-62 Part I-1), conduct hazardous building material surveys on structures proposed for demolition, prior to demolition, to identify any asbestos-containing materials, lead-based paint, and other hazardous materials. Based on the survey results, conduct necessary abatement prior to demolition. Dispose lead-based paint, asbestos-containing materials, and other hazardous materials at facilities permitted to receive these materials in accordance with federal, state, and local agency regulations. • Prepare a Program-wide construction health and safety plan, as required by federal Occupational Safety and Health Act regulations and state regulations, to minimize the potential for exposure of construction workers to hazardous materials and the risk to human health and the environment. • Prepare a site-specific contaminated media management plan to ensure proper characterization, management, storage, disposal, and reporting of contaminated materials encountered during construction activities. The plan would outline the roles and responsibilities of personnel; health and safety requirements; methods and procedures for characterizing, managing, storing, and disposing of waste; and reporting requirements. *Program-Specific Mitigation* • No Program-specific mitigation measures are proposed for long-term effects related to hazardous materials. **Temporary Effects** *Regulatory Requirements* • Construction BMPs applicable to the Modified LPA are discussed in Section 3.14, Water Quality and Hydrology and adherence to program SPCC Plan. Other required measures to reduce the risk of spills, leaks, or other releases during construction activities include: – Conduct fueling, maintenance, and cleaning in areas that are contained by berms or other containment. – Minimize the production or generation of hazardous materials, both upland and during demolition and replacement of over water spans. – Label and store hazardous waste according to federal regulations. – Locate hazardous waste (including contaminated spoils) storage away from storm drains or surface water. – Recycle materials such as used motor oil and water-based paint as appropriate. – Handle potential spills of hazardous materials in conformance with applicable regulatory requirements and adhere to the Program spill prevention, control, and countermeasure plan. *Program-Specific Mitigation* No Program-specific mitigation measures are proposed for temporary effects related to hazardous materials.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
Climate Change	**Regulatory Requirements** State-level legislation and policy in Oregon and Washington support reducing emissions from transportation to minimize contributions to climate change. There are no specific requirements for mitigation actions in federal, state, or local regulations. **Program-Specific Mitigation** As noted above, there are no specific requirements for mitigation actions in federal, state, or local regulations. However, the Program supports state, regional, and local goals to reduce greenhouse gas emissions. The Program is improving and adding multimodal transportation options (to facilitate mode shift), including the extension of light-rail, and the expansion of active transportation facilities; implementing demand management (e.g., variable-rate tolling); and implementing operation and maintenance efficiencies (e.g., using renewable energy for bridge operation needs, using zero-emission transit vehicles). *Long-Term Effects* The IBR Program would reduce GHG emissions in support of local, regional, and state goals. This section outlines concepts to further reduce or minimize GHG emissions associated with the construction or operations and maintenance of the Modified LPA. In developing these concepts, the IBR Program collaborated with ODOT, WSDOT, and the eight local agency partners. The IBR Program team will continue to consider and incorporate mitigation and minimization measures during the development of the EIS and through final design and construction. • User Emissions and User Experience: Design and Implementation Considerations – To increase resiliency, the design will consider future conditions, including more frequent and severe winter storms, lower low water conditions in the dry season, and an increase in the number and intensity of hot days during summer months. – In consideration of the effects of changing future climate conditions on users of the transportation system, the design considers the provision of shade and other treatments, with a focus on active transportation and transit users. • Operations and Maintenance – Minimizing energy use (e.g., LED lights) and using green energy sources. – Providing energy storage on the bridges for operations if power is interrupted. – Maximizing the renewable electricity supply for operations (lights, signs, transit, toll collection) toward 100% as soon as practical. – Exploring potential for wind generation, solar panels for energy needs, or piezoelectric energy harvesters to generate energy from traffic vibration. – Using an all-electric or hydrogen maintenance fleet (anticipated by 2045). – Establishing guidelines for replacement equipment, alternative fuel use, and materials standards. *Construction Effects* Strategies to reduce the energy consumed by the construction of the Modified LPA would include a range of options. Oregon and Washington have standard specifications that would reduce GHG emissions during construction, including: • ODOT Standard Specifications Section 290, which has requirements for environmental protection, and include air pollution control measures. These control measures include vehicle and equipment idling limitations, which would also reduce energy usage and GHG emissions. • Many of WSDOT's standards specifications to minimize air quality impacts would also reduce energy use and GHG emissions, including:

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	– Minimizing delays to traffic during peak travel times. – Minimizing unnecessary idling of on-site diesel construction equipment. – Educating vehicle operators to shut off equipment when not in active use to reduce emissions from idling. – Preparing a traffic control plan with detours and strategic construction timing (such as night work) to continue moving traffic through the area and reduce backups and delays to the traveling public, to the extent possible. As construction packages and plans are developed, the IBR Program will evaluate the potential to further reduce GHGs associated with construction. This could be implemented through construction bid document specifications or performance requirements, and could include: • Construction materials. – Design specifications for materials to reduce embodied emissions; use Environmental Product Declarations to evaluate various material choices and options. – Minimize lengthy supply chains for materials by using local sources where possible while still maintaining acceptable quality levels for materials. – Use cleaner production methods for cement and concrete (e.g., consider different mixes, fuel specifications for kiln and manufacture), and if found viable, incorporate into material specifications. – Maximize inclusion of recycled material to reduce virgin material production and inclusion. This would include recycling existing concrete and asphalt pavements within Program limits to be used as aggregate base, subbase, backfill materials, etc. – Consider prioritizing suppliers that document accountability to their sustainable practices, such as by participating and reporting to the EPA ENERGY STAR Challenge for Industry. • Fuel and energy use. – Specify emissions targets for contractors and encourage use of renewable fuels and electric equipment. – Specify improved diesel emissions standards for construction and vehicles. – Use renewable diesel, renewable propane, or other lower-carbon fuels in construction equipment and transport of materials. – Select specified electrical equipment (e.g., lighting) to maximize for energy efficiency, as long as the equipment meets safety and other project needs and requirements. – Seek to prioritize the use of battery-powered equipment and limit the use of diesel equipment operating under less stringent emissions standards than EPA's Tier 4.[8] • Waste reduction. – Minimize construction waste. – Consider adopting or establishing a zero-waste demolition plan, including a recycling plan, to maximize the recycling or reuse of old bridge components. • Traffic management during construction.[9] • Support and encourage alternative modes during construction, such as transit subsidies or elimination of fares during construction period. • Other approaches as suggested by interested parties, agencies, and the public.

[8] EPA has adopted a comprehensive national program to reduce emissions from nonroad (construction equipment) diesel engines by integrating engine and fuel controls as a system to gain the greatest emission reductions. To meet these Tier 4 emission standards, engine manufacturers will produce new engines with advanced emission control technologies.

[9] Measures for minimizing the effects of construction-related traffic congestion (and thus emissions) are described in the Transportation Technical Report.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
Environmental Justice	**Long-Term Effects** *Regulatory Requirements* The applicable regulatory requirements are listed below: • Title 42 USC Section 4601, the Uniform Relocation Assistance and Real Property Policies Act (1970) • Title 23 CFR Part 772, Procedures for Abatement of Highway Traffic Noise and Construction Noise • ORS 467.010, Chapter 340, Division 35, Noise Control Regulations *Acquisitions and Displacements* • Compliance with Title 42 USC Section 4601, the Uniform Relocation Assistance and Real Property Policies Act (see Section 3.3, Property Acquisitions and Displacements). For low-income populations or populations with special circumstances, a relocation program could include housing assistance. *Noise* • Compliance with ODOT and WSDOT standard specifications for noise abatement that apply to highway construction activities, including noise and vibration monitoring (see Section 3.11, Noise and Vibration). Monitoring would include: – Establish a complaint hotline to investigate noise complaints during construction. A construction monitoring and complaint program would help ensure that all equipment meets state, local, and manufacturer specifications for noise emissions. Equipment not meeting the standards would be removed from service until proper repairs were made and the equipment retested for compliance. This procedure would apply to all haul trucks, loaders, excavators, and other equipment that would be used extensively at the construction sites and that would contribute to potential noise effects. – Conduct vibration monitoring of all activities that might produce vibration levels at or above 0.5 inches per second where structures are near the construction activity. This would include pile driving, vibratory sheet installation, soil compaction, and other construction activities with the potential to cause high levels of vibration. There is no effective method to completely eliminate vibration effects from construction; however, by restricting and monitoring vibration-producing activities, vibration effects from construction can be kept to a minimum. *Tolling* – No regulations are currently in place to offset the impacts of IBR Program tolls on low-income populations, although such regulations may be implemented in the future in support of a low-income tolling program or equitable tolling policy that would reduce or offset the economic burden of tolling on low-income and minority populations. Toll rates and policies implemented on the existing Interstate Bridge (pre-completion tolling) and the new Columbia River bridges under the Modified LPA (long-term tolling) would be jointly set by the Oregon Transportation Commission and the Washington State Transportation Commission. The commissions would consider possible exemptions and discounts, which may include a low-income discount program. Both commissions would work together to determine how to apply such exemptions and discounts to the IBR Program.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	Program-Specific Mitigation *Transportation Impacts* • Monitor and adjust ramp meter rates manage travel times, delay, and other operational performance measures consistent with ODOT and WSDOT highway procedures. • Coordinate with local jurisdictions to adjust local street networks that could include the following actions: – Prohibit on-street parking during peak periods to improve vehicle flow and reduce travel delays associated with slowdowns to accommodate vehicles entering and exiting on-street parking spaces. – Add turn pockets at needed locations (e.g., a southbound right-turn lane at 15th and Columbia Streets in Vancouver) to improve vehicle flow and reduce travel delays associated with bottlenecking at intersections. – Alter traffic signal timing (e.g., for the Mill Plain Boulevard interchange signal) to maximize operational flow and reduce travel delays. *Business Displacements and Loss of Service Industry Jobs* • Provide mitigation for the loss of service industry jobs under a potential future workforce agreement and/or Project Labor Agreement. This agreement would be further defined as project design and planning progress, and would cover such topics as: – Adopting goals for involvement of minority, women-owned, emerging, and disadvantaged businesses in Program construction contracting. – Developing workforce practices to provide experience and business opportunities for disadvantaged workers and companies, such as requiring contractors to have apprentices perform a percentage of construction labor. – Providing job training and establishing preferences in contracting for local services. – Implementing a monitoring and evaluation program to track these measures through final project design, construction, and operation to help ensure that the benefits of promoting participation from minority-owned businesses are realized. *Tolling* Program-specific measures to minimize disproportionately high and adverse effects on EJ populations related to tolling are proposed as part of this EIS. As described in Section 3.20, Environmental Justice, tolling the existing Interstate Bridge and the new Columbia River bridges would result in higher transportation costs as a proportion of household spending for some EJ populations. Some of the project benefits—such as increased investments in the regional transit, walking, and bicycling network—may not be accessible or practical for EJ populations with fixed schedules and employment, school, and/or childcare commitments. Although the method of payment for a potential tolling program has not been determined, a transponder model has the potential to present a burden to low-income and minority populations due to the up-front cost and technical requirements of purchasing and setting up a transponder. Program-specific mitigation measures to address disproportionately high and adverse effects on EJ populations resulting from tolling may include: • A Low-Income and/or Equitable Tolling Program: If the OTC and WSTC choose to implement a low-income toll program on the existing Interstate Bridge (pre-completion tolling) and the new Columbia River bridges under the Modified LPA (long-term tolling), it would play a critical role in mitigating disproportionately high and adverse effects of tolling on EJ populations. Additional mitigation may be needed if I-205 is tolled in the future or if a regional tolling system is implemented. Both transportation commissions are actively studying low-income tolling programs, including how such a program could be implemented in each state. Key work done to date includes:

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	– The Oregon Tolling Program I-205 and I-5 Toll Project's Equity Framework (2023). The OTC has advanced key elements of a low-income toll program – the first of its kind in the nation – that will serve low-income travelers who cannot change their travel schedules or who travel frequently on interstate facilities. The program will balance impacts to other travelers while still achieving overall program goals to reduce traffic congestion and raise revenue for transportation improvements. Key commitments include at least a 50% discount on tolls for customers in Oregon or Washington whose household income is up to 200% of the federal poverty level and exemptions for federally recognized tribes and tribal government vehicles. – WSDOT Low-Income Toll Program Study for I-405 & SR 167 Express Toll Lanes (2021). WSDOT has developed a range of program options and evaluation metrics to assess toll discount program options to benefit equity populations. Options include percentage-based and fixed-rate discounts per trip, time-based toll credits, free toll trips, and lowering the maximum toll rate. Although this study was for the I-405 and SR 167 Express Toll Lanes in Washington and would not directly apply to the IBR Program, the study and its findings may influence future discussions and coordination between the OTC and WSTC regarding the future of a regional toll program. • Equitable Access to Technology and Information: ODOT, WSDOT, and regional partners will provide program-specific information, such as how to obtain transponders and/or how to receive transportation assistance, particularly for low-income drivers. – Locate venues for acquiring transponders near lower-income neighborhoods. The IBR Program would partner with public agencies and public service providers to identify locations that are convenient for low- or lower-income neighborhoods and that are accessible by multiple modes of travel. – Enable populations without credit cards or checking accounts to obtain transponders by paying with cash or electronic bank transfer cards. – Share information with and through other public service providers, particularly those that provide direct service to EJ populations. – Share information about existing rideshare opportunities such as local carpool and vanpool providers or work with partners to develop new programs. • Early, Inclusive, and Equitable Public Engagement: Public engagement and outreach is proposed as a critical step to ensure that transportation users can make informed travel choices when crossing the Columbia River. Public engagement should conduct specific outreach to potentially impacted EJ populations, connect these populations to assistance resources such as a future low-income and/or equitable tolling program and other travel options, and provide transparent information about the costs and impacts to their trips resulting from a future IBR tolling program. **Temporary Effects** *Acquisitions and Displacements* • Meet with property owners who would be affected by temporary acquisitions to discuss details of the acquisition, such as the duration of the acquisition and the operating schedule for construction activities. • Proposed mitigation measures are described in Section 3.3, Property Acquisitions and Displacements. *Transportation* • Proposed mitigation measures are described in Section 3.1, Transportation; Section 3.4, Land Use and Economic Activity; Section 3.5, Neighborhoods and Equity; and Section 3.6, Public Services and Utilities.

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• Maintain safe and accessible pathways, especially near public housing, senior housing, and public services. • Coordinate with TriMet to maintain paratransit service for qualifying mobility-impaired Hayden Island residents. *Noise* • Proposed mitigation measures are described in Section 3.11, Noise and Vibration. *Air Quality* • Proposed mitigation measures are described in 3.10, Air Quality.
Section 6(f) and FLP Resources	**Long-Term Effects** ***Regulatory Requirements*** This Draft SEIS identifies potentially affected Section 6(f)- and Federal Lands to Parks (FLP)-protected parkland resources, potential avoidance alternatives, and agency process requirements, early steps in a much longer process required to convert Section 6(f)- and FLP-protected properties to nonpark uses. The IBR Program has begun this process by initiating consultation with the Oregon Parks and Recreation Department (OPRD) and the City of Portland to discuss potential 6(f) impacts at East Delta Park and NPS, the City of Vancouver, and the City of Portland to discuss potential FLP impacts at Marshall Park, Old Apple Tree Park, and East Delta Park. Looking forward, the conversion process will generally include replacement property proposal and consultation. This process will consider public comment on potential conversion of Land and Water Conservation Fund (LWCF) and FLP lands identified in the Draft SEIS. The IBR Program will continue to look for ways to first avoid and then minimize effects on LWCF and FLP resources. If all practical alternatives to conversion of LWCF and FLP resources have been ruled out, the IBR Program will coordinate with the local agencies with jurisdiction over the LWCF and FLP resources, as well as a broader coordination process with the OPRD, NPS, and the GSA. ***Avoidance*** Alternatives to avoid 6(f) properties including reducing the right-of-way width of I-5 or realigning the Modified LPA farther west were developed. The Program then determined whether other impacts could result from the avoidance alternatives and whether these alternatives would meet the Program's overall Purpose and Need and specific objectives. ***Program-Specific Mitigation*** Program-specific mitigation measures for long-term effects related to LWCF resources will be developed in coordination with mitigation proposed for parks and recreation (see Section 3.7), and will be based on further consultations with the local, state, and national parks agencies throughout and beyond the NEPA process. **Temporary Effects** • Mitigation measures for temporary effects related to LWCF resources will be developed in coordination with mitigation proposed for parks and recreation (see Section 3.7), and will be based on further consultations with the local, state, and national parks agencies throughout and beyond the NEPA process.
Section 4(f) Resources	**Long-Term and Temporary Effects** ***Regulatory Requirements***

Resource Affected	Proposed Mitigation or Compensation for the Modified LPA
	• 23 CFR 774.17 directs agencies to include all reasonable measures to minimize harm or mitigate for adverse impacts and effects to Section 4(f) resources. These measures have been incorporated during the development of the Modified LPA to the extent possible and will continue to be refined as the design progresses. ***Program-Specific Mitigation*** • No program-specific mitigation measures are proposed for long-term or temporary effects related to Section 4(f) resources beyond those proposed under Parks and Recreation.

How will the IBR Program address climate in design and construction?

Climate considerations guide planning for all areas of work on the IBR Program, including design, construction, operation, and maintenance. The effort falls into three broad categories of actions: reducing GHG emissions, managing risks, and building for resiliency. Approaches to these efforts are outlined below.

- Reduce GHG impacts by implementing Program components.
  - Improve transportation options (to facilitate mode shift).
  - Implement demand management (e.g., variable-rate tolling).
  - Optimize construction approaches.
  - Implement operation and maintenance efficiencies (e.g., auxiliary lanes, ramp meters).
- Evaluate risks to determine the consequences of climate hazards in the following categories: social (people, community), environmental (contamination, destruction), and economic (cost of repair, financial losses).
- Optimize the resiliency of the infrastructure by addressing vulnerability from natural hazards.

Local partners can support further GHG reductions by implementing complementary services and policies, such as:

- Providing higher frequency mass transit and deeper investments.
- Approving land uses and building permits in patterns that reduce single occupant vehicle trips.
- Providing mobility hub options.

Questions the IBR Program would continue to address in ongoing design include:

- How would future climate affect our natural systems and infrastructure?
- How would historically vulnerable people be affected by climate change?
- How can the IBR Program lessen the climate impacts for equity priority communities?
- How can we design resilient infrastructure?

How will the IBR Program address equity through process and outcomes?

In tandem with the IBR Equity Advisory Group, the Program adopted an equity framework to guide the processes and desired outcomes in terms of furthering equity. At the core of the framework is a Program-specific equity definition and six equity objectives, which together form the basis for the analysis presented in the Draft SEIS and other Program efforts.

Definition of equity

The IBR Program defines equity in terms of both process and outcomes. Together, process equity and outcome equity contribute to addressing the harmful impacts of and removing longstanding injustices experienced by historically underserved communities.

***Process Equity** means that the Program centers and prioritizes access, influence, and decision-making power for equity priority communities throughout the Program in establishing objectives, design, implementation, and evaluation of success.*

***Outcome Equity** is the result of successful Process Equity and is demonstrated by tangible transportation, community, and economic benefits for equity priority communities.*

Equity priority communities are those who experience and/or have experienced discrimination and exclusion based on identity or status, such as:

- Black, Indigenous, and People of Color
- Tribal governments
- People with disabilities
- Communities with limited English proficiency
- Persons with lower incomes
- Houseless individuals and families
- Immigrants and refugees
- Young people
- Older adults

Equity objectives

The IBR Program has established six equity objectives:

1. **Mobility and accessibility**: Improve mobility, accessibility, and connectivity, especially for lower-income travelers, people with disabilities, and historically underserved communities who experience transportation barriers.
2. **Physical design**: Integrate equity, area history, and culture into the physical design elements of the Program including bridge aesthetics, artwork, amenities, and impacts to adjacent land uses.
3. **Community benefits**: Find opportunities for and implement local community improvements in addition to required mitigations.
4. **Workforce equity and economic opportunity**: Ensure that economic opportunities generated by the Program benefit minority- and women-owned firms; Black, Indigenous, and People of Color (BIPOC) workers; workers with disabilities; and young people.
5. **Decision-making processes**: Prioritize access, influence, and decision-making power for Equity Priority Communities throughout the Program in establishing objectives, design, implementation, and evaluation of success.

6. **Avoid further harm**: Actively seek out options with a harm-reduction priority rather than simply mitigate disproportionate impacts on historically impacted and underserved communities and populations.

What are the next steps and how will a decision be made?

The community has an opportunity to review this Draft SEIS and provide feedback during the public review and comment period. The design of the Modified LPA may be further refined based on public input and findings. Following the public comment period, and in collaboration with the joint leads, cooperating and participating agencies, and tribes, the IBR Program will determine which design options are consistent with the Vision and Values (see Chapter 1) and should be advanced to the Final SEIS and formally recommended by the Program. The design of the Modified LPA would be developed to a level of detail to allow the IBR Program to apply for permits and update cost estimates.

The IBR Program will continue to work and foster relationships with agencies, tribes, and the public through completion of the Program.

How can the public learn more about and be involved in the IBR Program?

The Program website (www.interstatebridge.org) provides more information, including background and the process that has led to the development of this Draft SEIS. The website also has information on upcoming public events, Program milestones, and how to view the Draft SEIS.

You are invited to submit your comments on the Draft SEIS between through November 18, 2024. Comments received during this time will be reviewed and considered, and responses will be published in the Final SEIS. Comments **about the Draft SEIS** can be submitted by several methods:

- **Written comments** on the Draft SEIS can be submitted through the online comment form www.interstatebridge.org/DraftSEIS**,** by email to DraftSEIS@interstatebridge.org**,** or by regular mail to the address below. Written comments should not include any hyperlinks to outside materials or information. Any materials or information the commenter wishes to have considered should be included within the comment.

  IBR Program Draft SEIS
  c/o Chris Regan
  500 Broadway Street, Suite 200
  Vancouver, WA 98660

- **Phone:** Leave a voice message on the IBR Program's comment line at (866) IBR-SEIS (866-427-7347) (toll-free). Voice messages need to explicitly say "**Draft Supplemental EIS**" or "**Draft SEIS**" for them to be identified and addressed as comments on the Draft SEIS.

- **Attend a public hearing:** Public hearings will be held in Portland and Vancouver and virtually at the dates and locations listed below.

  Tuesday, October 15, 2024
  Clark College, Gaiser Hall 150
  1933 Fort Vancouver Way

3.22.2 Existing Conditions 3.22-2
3.22.3 Long-Term Effects 3.22-4

3.22.4 Temporary Effects 3.22-8
3.22.5 Indirect Effects 3.22-9
3.22.6 Potential Avoidance, Minimization, and Mitigation Measures 3.22-9
3.23 Cumulative Effects 3.23-1
3.23.1 Changes or New Information Since 2013 ..... 3.23-1
3.23.2 Past, Present, and Reasonably Foreseeable Future Actions 3.23-2
3.23.3 Cumulative Effects 3.23-6
3.23.4 Temporary Cumulative Effects 3.23-45
3.23.5 Irreversible and Irretrievable Commitments of Resources 3.23-47
4. DRAFT SECTION 4(F) EVALUATION 4-1
4.1 Introduction 4-1
4.1.1 Permanent Incorporation 4-2
4.1.2 *De Minimis* Impact 4-2
4.1.3 Temporary Occupancy 4-3
4.1.4 Constructive Use 4-3
4.1.5 Summary of 2011 Final Section 4(f) Findings 4-4
4.1.6 IBR Draft Section 4(f) Evaluation 4-7
4.2 IBR Section 4(f) Properties 4-7
4.2.1 Section 4(f) Park and Recreation Properties in the IBR Program Study Area 4-7
4.2.2 Section 4(f) Historic Sites in the IBR Program Study Area 4-19
4.3 Evaluation of Use of Section 4(f) Properties 4-28
4.3.1 Section Organization 4-28
4.3.2 Summary of Use of Park, Recreational Areas, Waterfowl Refuges by the IBR Program Modified LPA with All Design Options 4-28
4.3.3 Use of Section 4(f) Park and Recreation Properties (Oregon) 4-32
4.3.4 Use of Section 4(f) Park and Recreation Properties (Washington) 4-36
4.3.5 Summary of Use of Historic Sites by the IBR Program Modified LPA with All Design Options 4-63
4.3.6 Use of Section 4(f) Historic Sites (Oregon) 4-68
4.3.7 Use of the Interstate Bridge 4-83
4.3.8 Use of Section 4(f) Historic Sites (Washington) 4-85
4.4 Avoidance Alternatives 4-116
4.5 Measures to Minimize Harm 4-120
4.5.1 Minimizing Harm to Resources in Oregon 4-122
4.5.2 Minimizing Harm to the Northbound Interstate Bridge 4-125

4.5.3 Minimizing Harm to Resources in Washington....4-125
4.6 Least Overall Harm Analysis.... 4-130
4.6.1 Ability to Mitigate Adverse Impacts to Each Section 4(f) Property, Including Any Measures That Result in Benefits....4-132
4.6.2 The Relative Severity of the Remaining Harm after Mitigation to the Protected Activities, Attributes, or Features That Qualify Each Section 4(f) Property for Protection.4-133
4.6.3 Relative Significance of Each Section 4(f) Property....4-135
4.6.4 Views of Officials with Jurisdiction over Each Section 4(f) Property....4-135
4.6.5 Degree to Which Each Alternative Meets the Purpose and Need for the Program....4-136
4.6.6 After Reasonable Mitigation, the Magnitude of Any Adverse Impacts to Resources Not Protected by Section 4(f)....4-138
4.6.7 Substantial Differences in Costs Among the Alternatives....4-141
4.6.8 Conclusion of Least Overall Harm Analysis....4-141
4.7 Coordination.... 4-146
4.8 Preliminary Section 4(f) Findings.... 4-147

LIST OF TABLES

ABBREVIATIONS AND ACRONYMS

Abbreviation/Acronym	Definition
AASHTO	American Association of State Highway and Transportation Officials
AC	alternating current
ACM	asbestos-containing material
ADA	Americans with Disabilities Act
APE	Area of Potential Effect
AVE	Area of Visual Effect
AWDT	Average weekday daily traffic
BIPOC	Black Indigenous, and People of Color
BLTS	Bike Level of Traffic Stress
BMP	best management practice
BRT	bus rapid transit
CD	collector-distributor
CEQ	Council on Environmental Quality
CESCL	certified erosion and sediment control lead
CFR	Code of Federal Regulations
CIA	contributing impervious area
CMMP	contaminated media management plan
CRC	Columbia River Crossing
CRD	Columbia River Datum
CSZ	Cascadia Subduction Zone
C-TRAN	Clark County Public Transit Benefit Area Authority
CWA	Clean Water Act
DAHP	Washington Department of Archaeology and Historic Preservation

Abbreviation/Acronym	Definition
dB	decibels
dBA	A-weighted decibel
DC	direct current
DDE 4,4’	dichlorodiphenyldichloroethylene
DDT	dichlorodiphenyltrichloroethane
DEQ	Oregon Department of Environmental Quality
DOI	U.S. Department of the Interior
DOT	Department of Transportation
Ecology	Washington State Department of Ecology
EIS	Environmental Impact Statement
EJ	environmental justice
EMF	electromagnetic field
EPA	U.S. Environmental Protection Agency
ESA	Endangered Species Act
ESC	erosion and spill control
ESCP	erosion and sediment control plan
ESHB	Engrossed Substitute House Bill
EV	Electric vehicle
FAA	Federal Aviation Administration
FEMA	Federal Emergency Management Agency
FHWA	Federal Highway Administration
FLP	Federal Lands to Parks
FOE	Finding of Effect
FR	Federal Register
FRA	Federal Railroad Administration

Abbreviation/Acronym	Definition
FTA	Federal Transit Administration
FY	fiscal year
G	gauss
GHG	greenhouse gas
GIS	geographical information system
GSA	General Services Administration
HBC	Hudson's Bay Company
HBE	historic built environment
HNC	horizontal navigation clearance
HPRCSIT	historic properties of religious and cultural significance to Indian tribes
Hz	hertz
I-205	Interstate 205
I-5	Interstate 5
IBR	Interstate Bridge Replacement
ICNIRP	International Commission on Non-Ionizing Radiation Protection
in/sec	inches per second
kV/m	kilovolts per meter
KVP	key viewpoint
Landing	Vancouver Landing at Terminal 1
LCR FNC	Lower Columbia River Federal Navigation Channel
LCR NAV Historic District	Lower Columbia River Federal Navigation Historic District
LCRWT	Lower Columbia River Water Trail
LOS	Level of service
LPA	Locally Preferred Alternative
LRFD	load-and-resistance factor design

Abbreviation/Acronym	Definition
LRT	light-rail transit
LRV	light-rail vehicle
LU	landscape unit
LUST	leaking underground storage tank
LWCF	Land and Water Conservation Fund
MAX	Metropolitan Area Express
MBTA	Migratory Bird Treaty Act
Metro	Oregon Metro
mG	milligauss
mm	millimeters
MOA	memorandum of agreement
MOU	memorandum of understanding
MOVES	MOtor Vehicle Emissions Simulator
mph	miles per hour
MSA	Metropolitan Statistical Area
MSAT	mobile source air toxics
MT	metric tons
NAAQS	National Ambient Air Quality Standards
NAC	noise abatement criteria
NAICS	North American Industry Classification System
NCO	non-commissioned officer
NEPA	National Environmental Policy Act
NHPA	National Historic Preservation Act
NHS	National Historic Site

Abbreviation/Acronym	Definition
NOAA Fisheries	National Oceanic and Atmospheric Administration National Marine Fisheries Service
NPDES	National Pollutant Discharge Elimination System
NPS	National Park Service
NRHP	National Register of Historic Places
NRI	Natural Resource Inventory
OAR	Oregon Administrative Rules
OCS	Obstacle Clearance Surface
ODFW	Oregon Department of Fish and Wildlife
ODOT	Oregon Department of Transportation
OHWM	ordinary high water mark
OPRD	Oregon Parks and Recreation Department
ORS	Oregon Revised Statute
OTC	Oregon Transportation Commission
PA	programmatic agreement
PAH	polycyclic aromatic hydrocarbon
PCB	polychlorinated biphenyl
PCC	Portland City Code
PCP	pollution control plan
PDX	Portland International Airport
PM	particulate matter
PMSA	Primary Metropolitan Statistical Area
PP&R	Portland Parks and Recreation
PRM	permittee responsible mitigation
RCO	Recreation and Conservation Office

Abbreviation/Acronym	Definition
RCP	Representative Concentration Pathway
RCW	Revised Code of Washington
RM	river mile
RMPP	Regional Mobility Pricing Project
ROD	Record of Decision
RTC	Southwest Washington Regional Transportation Council
RTP	Regional Transportation Plan
SAFETEA-LU	Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users
Section 4(f)	Section 4(f) of the U.S. Department of Transportation Act
Section 6(f)	Section 6(f) of the federal Land and Water Conservation Fund Act
SEIS	Supplemental Environmental Impact Statement
SHPO	State Historic Preservation Office
SIP	State Implementation Plan
SMSA	Standard Metropolitan Statistical Area
SOI	species of interest
SPCC	spill prevention control and countermeasure

WSDOT	Washington State Department of Transportation
WSP	Washington State Patrol

Abbreviation/Acronym	Definition
WSTC	Washington State Transportation Commission
ZEV	Zero Emission Vehicle

1. PURPOSE AND NEED

This chapter describes the primary purpose for the Interstate Bridge Replacement Program.

1.1 Importance of the I-5 Corridor and the Interstate Bridge

As the only continuous north-south interstate route on the West Coast of the United States connecting the Canadian and Mexican borders, Interstate 5 (I-5) is vital to the local, regional, state, and national economies. At the Columbia River, I-5 provides a critical economic connection to two major ports, deepwater shipping, upriver barging, two transcontinental rail lines, and much of the region's industrial land. Truck-hauled freight movement over the I-5 Columbia River crossing is critical for industrial centers, for employment, and for the regional and national economies.

Chapter Contents

1.1 Importance of the I-5 Corridor and the Interstate Bridge

1.2 Confirming the I-5 Columbia River Crossing Project's Purpose and Need

1.3 Purpose and Need for the IBR Program

1.4 Compliance with NEPA Regulations

1.5 Vision and Values

1.6 Next Steps

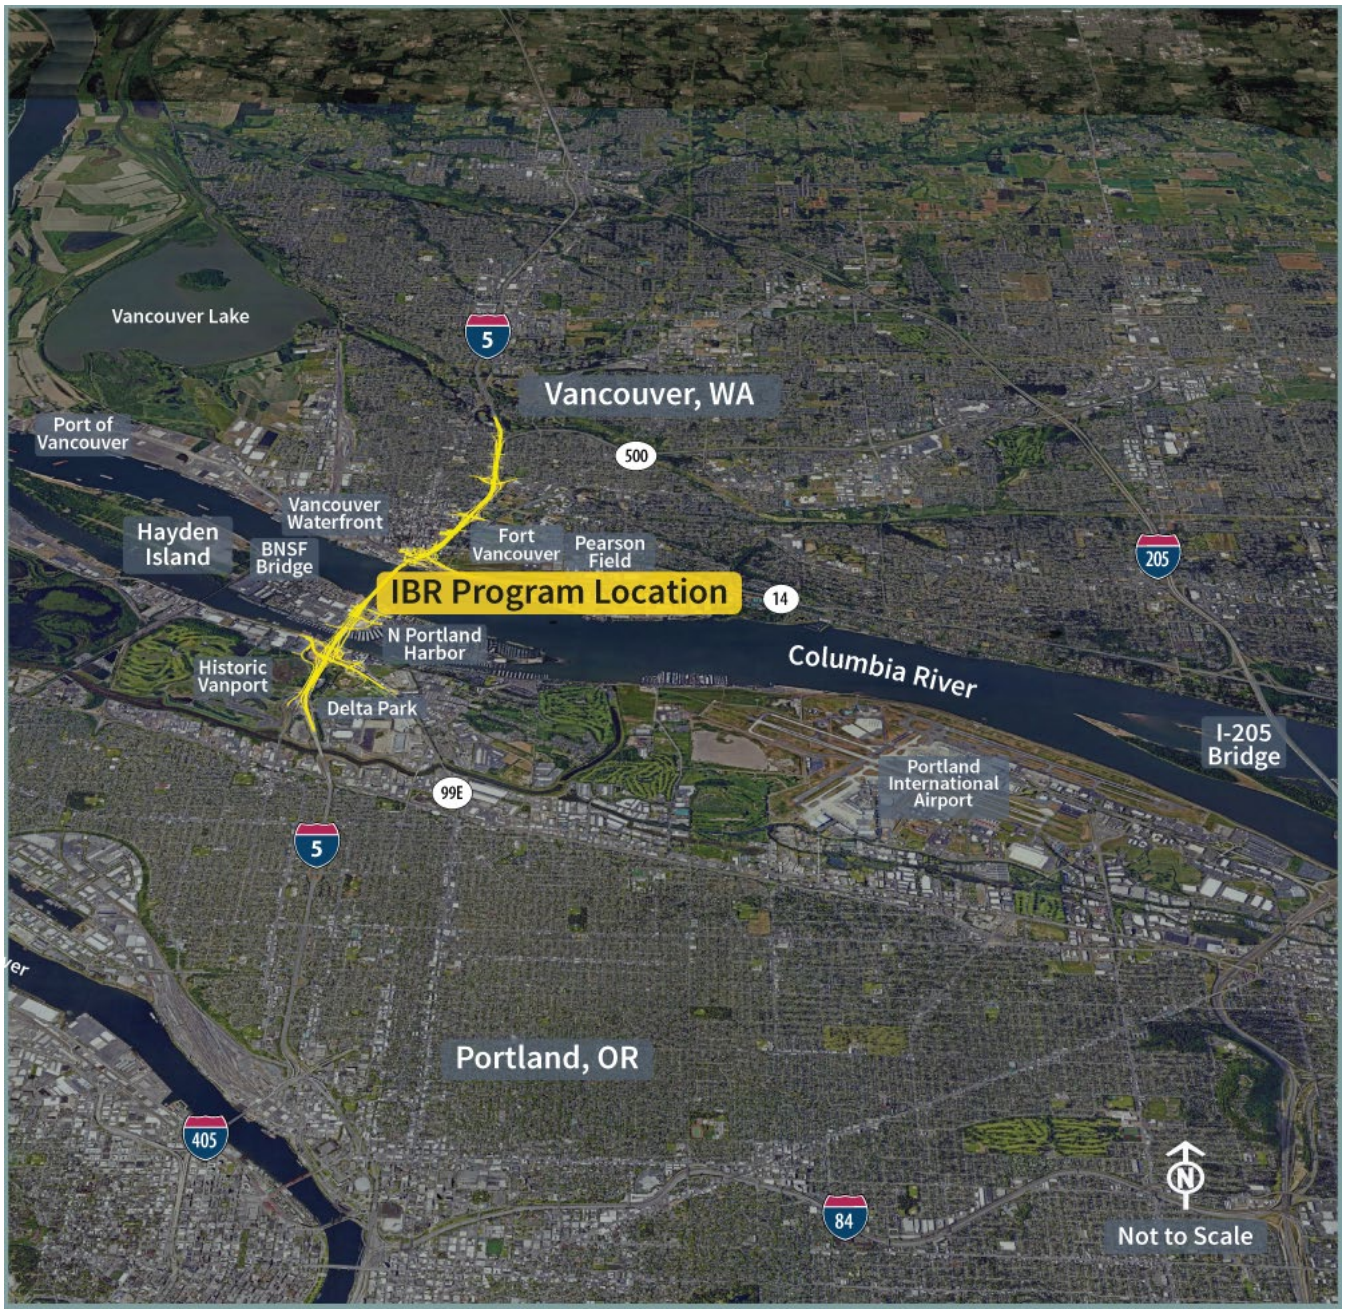
The Interstate Bridge provides the primary transportation link between Vancouver, Washington, and Portland, Oregon, and it is the only direct connection between the downtown areas of these cities. Residents of Vancouver and Portland drive, ride buses, bicycle, and walk across the Interstate Bridge for work, recreation, shopping, and entertainment. In 2019,[1] 143,400 trips were taken over the bridge each weekday by car, transit, bicycle, and walking. The Interstate 205 (I-205) Glenn Jackson Bridge, about 6 miles east, is the only other crossing over the Columbia River within the Portland-Vancouver metropolitan area. I-205 provides important connectivity for the region—particularly eastside suburban areas—but provides a less direct link between the downtown hubs in Portland and Vancouver.

1.2 Confirming the I-5 Columbia River Crossing Project's Purpose and Need

The Interstate Bridge Replacement (IBR) Program is a renewal of the previously suspended Columbia River Crossing (CRC) project, which completed the National Environmental Policy Act (NEPA) process with a signed Record of Decision (ROD) in 2011 and two re-evaluations in 2012 and 2013. Numerous studies conducted for the CRC project and past planning studies in this section of I-5 (see Figure 1-1), identified a variety of transportation mobility and safety problems. For additional details on these studies and their findings, please see Section 1.2 of the *Interstate 5 Columbia River Crossing Project Final Environmental Impact Statement and Final Section 4(f) Evaluation* (CRC 2011a).

[1] 2019 is used as the baseline year for most of the existing conditions data because it provides a more accurate baseline than more recent years, which were influenced by restrictions related to the COVID-19 pandemic.

Figure 1-1. Program Vicinity



The Purpose and Need statement for the CRC project was developed by the CRC Task Force[2] and the joint lead agencies.[3] Please see Chapter 1 of the CRC project Final Environmental Impact Statement (EIS) to learn more about how the Purpose and Need was developed and about agency and public input (CRC 2011a). As part of the NEPA process, the IBR Program began working with regional and local partner agencies and the public in

[2] The CRC Task Force was a 39-member group formed in 2005 that was composed of leaders representing a broad cross section of Washington and Oregon communities. Public agencies, businesses, civic organizations, neighborhoods, and freight, commuter, and environmental groups were represented on the task force. The group met 23 times over the course of the CRC project development phase to advise the project team and provide guidance and recommendations at key decision points. The task force concluded its work in summer 2008 after making its recommendation on the Locally Preferred Alternative.

[3] The joint lead agencies for the CRC project were the Federal Highway Administration (FHWA), Federal Transit Administration (FTA), Oregon Department of Transportation (ODOT), Washington State Department of Transportation (WSDOT), Oregon Metro (Metro), Southwest Washington Regional Transportation Council (RTC), Tri-County Metropolitan Transportation District (TriMet), and Clark County Public Transportation Benefit Area (C-TRAN).

early 2021 to review the Purpose and Need that was adopted for the CRC project. The IBR Program brought the Purpose and Need, as well as the Vision and Values (identified in Section 1.5), to partner agencies[4] and the Program's three advisory groups[5] to discuss the transportation needs identified for the CRC project. These transportation needs were also brought to the public for comment during an online open house, virtual community briefings, and an online survey.

In mid-2021, the IBR Program announced that these efforts confirmed that the six transportation needs identified in the CRC Purpose and Need statement still exist today, and that the values identified in the Vision and Values document remain community values. This was documented in a third NEPA re-evaluation (IBR 2021b) that was prepared in 2021 to evaluate the effect of changes in conditions and regulations since 2013, as well as potential design changes. **Thus, the Purpose and Need statement for the IBR Program, provided below, remains the same as documented in the 2011 Final EIS and 2011 ROD for the CRC project.** Please see the 2021 Community Engagement Summary Report (IBR 2021a) and the NEPA re-evaluation (IBR 2021b) for additional details on how community partner outreach and public engagement helped confirm the Purpose and Need statement.

1.3 Purpose and Need for the IBR Program

One of the first and most important steps of any major project is to define why the project has been initiated and what problem(s) it seeks to address. The Purpose and Need statement provides this definition for projects complying with NEPA and serves as the basis for defining how project alternatives will be developed and evaluated. A reasonable alternative must address the needs specified in the Purpose and Need statement for the alternative to be considered in an EIS; thus, the Purpose and Need is an influential statement that guides future development of the project.

The Purpose and Need statement for the IBR Program, developed by the lead agencies, project sponsors, and CRC Task Force, can be found in Sections 1.3.1 and 1.3.2. The text of the Purpose and Need has not been edited from its original wording, with the exception of references to the name of the Program. More recent data and supplemental information are provided in sidebars and footnotes. [6]

1.3.1 Program Purpose

The purpose of the proposed action is to improve I-5 corridor mobility by addressing present and future travel demand and mobility needs in the Program area. The Program area extends from approximately Columbia Boulevard in the south to State Route (SR) 500 in the north (Figure 1-1). Relative to the No-Build Alternative, the proposed action is intended to achieve the following objectives: (a) improve travel safety and traffic operations on the I-5 river crossing and associated interchanges; (b) improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the Program area; (c) improve highway freight mobility and address interstate travel and commerce needs in the Program area; and (d) improve the I-5 river crossing's structural integrity (seismic stability).

[4] C-TRAN, TriMet, Metro, RTC, the Cities of Portland and Vancouver, and the Ports of Portland and Vancouver.

[5] The Executive Steering Group, Community Advisory Group, and Equity Advisory Group. The advisory groups are detailed in Chapter 6 of this Draft Supplemental EIS (SEIS).

[6] Transportation data provided in the sidebars are from the IBR Program Transportation Technical Report. Due to the influence of the COVID-19 pandemic on travel patterns between 2020 and 2023, the IBR Program is following industry standards and using 2019 as the baseline year for the existing conditions section of this SEIS. The exception to using 2019 data is outputs from the Metro/RTC regional travel demand model which are from 2015. Metro and RTC had not yet updated their base-year model from 2015 to 2020 when this analysis was completed.

1.3.2 Program Needs

The specific needs to be addressed by the proposed action include:

- **Growing travel demand and congestion:** Existing travel demand exceeds capacity on the Interstate Bridge and associated interchanges. This corridor experiences heavy congestion and delay lasting 4 to 6 hours daily[7] during the morning and afternoon peak travel periods and when traffic crashes, vehicle breakdowns, or bridge lifts occur. Due to excess travel demand and congestion in the I-5 corridor, many trips take the longer, alternative I-205 route across the river. Spillover traffic from I-5 onto parallel arterials such as Martin Luther King Jr. Boulevard and Interstate Avenue increases local congestion. In 2005, the two crossings[8] carried 280,000 vehicle trips across the Columbia River daily. Daily traffic demand over the Interstate Bridge is projected to increase by more than 35% during the next 20 years, with stop-and-go conditions increasing to approximately 15 hours daily if no improvements are made.
- **Impaired freight movement:** I-5 is part of the National Truck Network, and the most important freight highway on the West Coast, linking international, national, and regional markets in Canada, Mexico, and the Pacific Rim with destinations throughout the western United States. In the center of the Program area, I-5 intersects with the Columbia River's deep water shipping and barging channels, as well as two river-level, transcontinental rail lines. The Interstate Bridge provides direct and important highway connections to the Port of Vancouver and Port of Portland facilities located on the Columbia River, as well as the majority of the area's freight consolidation facilities and distribution terminals. Freight volumes moved by truck to and from the area are projected to more than double over the next 25 years. Vehicle-hours of delay on truck routes in the Portland-Vancouver area are projected to increase by more than 90% over the next 20 years. Growing demand and congestion will result in increasing delay, costs, and uncertainty for all businesses that rely on this corridor for freight movement.

In 2005, 280,000 vehicle trips crossed the Columbia River daily (northbound and southbound) in the Portland-Vancouver metropolitan region, of which 134,000 used the Interstate Bridge. By 2019, the total number of vehicle trips that crossed the Columbia River had increased to 313,000 per day, of which 143,400 used the Interstate Bridge.

Vehicle trips include those made in single-occupancy vehicles, high-occupancy vehicles, trucks, and transit vehicles (buses).

The duration of congestion on the Interstate Bridge roughly doubled from 2005 to 2019. In 2019, the I-5 corridor experienced heavy congestion and delay in both directions lasting up to almost 12 hours daily (compared with 4 to 6 hours daily in 2005).

Daily traffic demand over the I-5 Interstate Bridge is projected to increase by more than 25% by 2045.

In 2019, more than 14,000 freight trips carrying over $132 million in commodities traveled across the I-5 Interstate Bridge each weekday. Freight volumes moved by truck to and from the area are projected to increase by 50% to 75% by 2045.

Deficiencies such as narrow lanes and shoulders, as well as short merging, diverging, and weaving distances, reduce the efficiency and safety of freight truck movement.

[7] The hours of congestion refers to the total number of hours that the corridor experiences congestion. During the CRC project, congestion was defined as occurring when travel speeds were below 35 mph. ODOT and WSDOT are in the process of refining the definition of congestion with congestion occurring when speeds are below 45 miles per hour and severe congestion when speeds are below 35 miles per hour. Therefore, the IBR Program has defined congestion as speeds below 45 miles per hour.

[8] The two crossings are the I-5 Interstate Bridge and the I-205 Glenn Jackson Bridge.

- **Limited public transportation operation, connectivity, and reliability:** Due to limited public transportation options, a number of transportation markets are not well served. The key transit markets include trips between Portland Central City and the city of Vancouver and Clark County, trips between north/northeast Portland and the city of Vancouver and Clark County, and trips connecting the city of Vancouver and Clark County with the regional transit system in Oregon. Current congestion in the corridor adversely impacts public transportation service reliability and travel speed. Southbound bus travel times across the bridge are currently up to three times longer during parts of the AM peak compared to off-peak. Travel times for public transit using general purpose lanes on I-5 in the Program area are expected to increase substantially by 2030.
- **Safety and vulnerability to incidents:** The Interstate Bridge and its approach sections experience crash rates more than two times higher than statewide averages for comparable facilities. Incident evaluations generally attribute these crashes to traffic congestion and weaving movements associated with closely spaced interchanges and short merge distances. Without breakdown lanes or shoulders, even minor traffic accidents or stalls cause severe delay or more serious accidents (Figure 1-2).

In 2005, southbound bus travel times across the Interstate Bridge were up to three times longer during parts of the AM peak (i.e., morning high traffic period) than during off-peak times. As of 2019, bus travel times were four times longer during the AM peak.

If the Interstate Bridge is not replaced, travel times for public transit using general-purpose lanes on southbound I-5 during the AM peak are expected to increase by 2045 as a result of increased congestion.

In 2005, the Interstate Bridge and its approach sections experienced crash rates more than two times higher than statewide averages for comparable facilities. As of 2019, crash rates were three times higher than average. Crashes in the IBR Program area could increase by almost 30% by 2045 if no improvements are made.

There were seven fatal crashes in the Program area between 2015 and 2019.

Figure 1-2. Crash Blocking the Interstate Bridge

- **Substandard bicycle and pedestrian facilities:** The bicycle/pedestrian lanes on the Interstate Bridge are about 3.5 to 4 feet wide, narrower than the 10-foot standard, and are located extremely close to traffic lanes, thus impacting safety for pedestrians and bicyclists (Figure 1-3). Direct pedestrian and bicycle connectivity are poor in the Program area.

Figure 1-3. Bicycle and Pedestrian Path on the Interstate Bridge

Compliance with the Americans with Disabilities Act (ADA) varies for the existing shared-use paths. The paths comply with the maximum gradient (4.7%), and there are no objects that overhang or protrude into the path. However, the paths do not comply with guidelines for curb ramps (both in number and design), width, passing spaces, cross slope, or railing height (FHWA 2001; U.S. Access Board 2013). The paths are also near traffic lanes; this increases bicyclist and pedestrian exposure to vehicular traffic, noise, and emissions.

- **Seismic vulnerability:** The existing Interstate Bridge is located in a seismically active zone. It does not meet current seismic standards and is vulnerable to failure in an earthquake.

The existing Interstate Bridge was designed before modern seismic design codes were established. The foundations are likely to displace during a strong earthquake, resulting in the collapse of the bridge spans into the Columbia River. In addition, the movable span lift towers would be overstressed due to the inertia of the concrete counterweights and would collapse onto the bridge, causing the adjacent spans to fail. This collapse potential is due to the fact that hundreds of timber bridge support piles sit within loose sand that can liquefy during an earthquake.

All new federally funded highway bridges are required to be designed to the current edition of the AASHTO Guide Specifications for Load-and-Resistance Factor Design (LRFD) Seismic Bridge Design (AASHTO 2022). In addition, State Departments of Transportation (DOTs) typically adopt local practices to address potential geologic hazards in the region (e.g., the Cascadia Subduction Zone). State DOTs may also prescribe elevated levels of seismic performance based on the importance of the structure as it relates to public safety, national defense, and economic investment, as is the case for the Interstate Bridge.

1.4 Compliance with NEPA Regulations

The Federal Highway Administration (FHWA) and the Federal Transit Administration (FTA) are the joint federal lead agencies for the IBR Program and are responsible for preparing the environmental documentation and overseeing the NEPA process. Additional NEPA joint lead agencies include the Oregon and Washington State Departments of Transportation (ODOT and WSDOT), Southwest Washington Regional Transportation Council (RTC), Oregon Metro (Metro), Clark County Public Transportation Benefit Area (C-TRAN), and Tri-County Metropolitan Transportation District (TriMet).

The notice to prepare a Supplemental EIS (SEIS) was published in the Federal Register on April 5, 2023 to advise other federal, state, and local agencies; tribes; and the public that an SEIS was being prepared for the IBR Program. Per the requirements of 23 Code of Regulations (CFR) 771.130(a), FHWA and FTA prepared a NEPA re-evaluation in 2021 that considered changes to existing conditions, including regulations, community priorities, and the physical environment (IBR 2021b). The CRC Locally Preferred Alternative (LPA), as selected in the 2011 ROD and revised in the 2012 and 2013 re-evaluations, included replacing the existing Interstate Bridge with two stacked, fixed-span bridges over the Columbia River; the new bridges would include dedicated space for light-rail transit and a shared-use path, among other improvements.

This Draft SEIS evaluates the Modified LPA, which was created through a collaborative process with partner agencies, tribes, and the public to identify an updated solution that reflects the current and future conditions of the region. The Modified LPA is described in Chapter 2.The development of the Modified LPA is detailed in Section 2.5.1, which summarizes the differences between the CRC LPA and the Modified LPA; this is further detailed in Appendix D.

FHWA and FTA are required to develop an agency coordination plan to outline how the IBR Program will work with the public; tribes; and local, state, and federal agencies with an interest in the Program (23 CFR 771.123). The IBR Program Agency Coordination Plan was first drafted in 2021 and has undergone periodic review and revisions since that time. Appendices A and B of this Draft SEIS document how the Program has coordinated with agencies, tribes, and the public to date.

> Development of the Modified LPA is described in Section 2.5. This section summarizes the changes that have occurred since 2013 that led to modifications in the design and highlights the differences between CRC project components and IBR Program components.

During the CRC project, interested federal, state, and local agencies and tribal governments served as cooperating and participating agencies and tribes as defined in Section 6002 of the Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) during the NEPA process. These designations allow federal, state, and local agencies and tribes to have a formal role in the environmental review process.

In October 2022, FHWA and FTA sent invitations to agencies and tribal governments with an interest in the Program area to reinvite them to be cooperating agencies, participating agencies, or participating tribes for the IBR Program.

Cooperating agencies are federal agencies invited to participate in the development of an EIS and may use this document to fulfill the NEPA review requirements for their permit or approval decision. In addition to federal agencies, a state or local agency or a Native American tribe may, by agreement with the lead agencies, also become a cooperating agency or tribe. The following agencies are serving as cooperating agencies for the IBR Program:

- National Oceanic and Atmospheric Administration National Marine Fisheries Service
- National Park Service

- U.S. Army Corps of Engineers
- U.S. Coast Guard
- U.S. Environmental Protection Agency
- Washington State Department of Archaeology and Historic Preservation

Participating agencies and tribes are federal, state, and local agencies and tribal governments that have an interest in the Program under review. Each participating agency or tribe has the opportunity to participate in Program meetings, open houses, and workshops, in addition to reviewing and providing comments on certain NEPA milestones and activities. Participating agencies and tribes are invited to:

- Participate in the NEPA process starting at the earliest possible time. Participation includes providing comments and responses on NEPA documents, reviewing studies or methodologies on only the areas within the special expertise or jurisdiction of the agency or tribe, and advising on the level of detail for the analysis of impacts.
- Identify, as early as practicable, environmental issues of concern regarding the IBR Program.
- Provide meaningful and timely input on unresolved issues.
- Comment on the proposed NEPA schedule.

Designation as a participating agency or tribe does not imply Program support and, if applicable, does not provide an agency or tribe with increased oversight or approval authority beyond its statutory limits. The following agencies are designated as participating agencies for the Program:

- Federal Aviation Administration
- U.S. Fish and Wildlife Service
- U.S. General Services Administration
- Oregon Department of Environmental Quality
- Oregon Department of Fish and Wildlife
- Oregon Department of Land Conservation and Development
- Oregon Department of State Lands
- Oregon State Historic Preservation Office
- Washington State Department of Ecology
- Washington State Department of Fish and Wildlife
- Washington State Department of Natural Resources
- City of Portland
- City of Vancouver
- Port of Portland
- Port of Vancouver USA
- Urban Flood Safety and Water Quality District

The following are federally recognized tribes identified as participating tribes for the Program:

- Confederated Tribes and Bands of the Yakama Nation

- Confederated Tribes of Siletz Indians of Oregon
- Confederated Tribes of the Colville Reservation
- Confederated Tribes of the Grand Ronde Community of Oregon
- Confederated Tribes of the Umatilla Indian Reservation
- Confederated Tribes of the Warm Springs Reservation of Oregon
- Cowlitz Indian Tribe
- Nez Perce Tribe
- Nisqually Indian Tribe
- Spokane Tribe of the Spokane Reservation

During the CRC project, the NEPA joint lead agencies worked with a group of state and federal agencies likely to have permitting or approval authority over one or more elements of the project. The group was referred to as the Interstate Collaborative Environmental Process group, or InterCEP. Details on InterCEP and agency coordination during the CRC project can be found in the CRC Final EIS (CRC 2011a). In a continuation of this collaborative effort, the IBR Program is hosting an ongoing series of inter-agency working groups with federal, state, and local agencies and tribes as well as inter-tribal meetings. Each working group focuses on a different environmental topic, such as endangered species, and provides an opportunity for the agencies, tribes, and the IBR Program to collaborate on potential solutions and seek early consensus on permitting requirements. Additional details on the working groups can be found in Appendix A.

Cooperating agencies, participating agencies, participating tribes, and the public have been given multiple opportunities for formal comment on several important elements of this Program. These opportunities are described in Appendix A, Agency and Tribal Coordination, and Appendix B, Public Involvement. For the formal comment opportunities provided during the CRC project, please see Chapter 1 of the CRC Final EIS.

1.5 Vision and Values

During the CRC project, the joint lead agencies, with the help and recommendation of the CRC Task Force, developed a vision for how to address the Purpose and Need and the values they would follow in doing so. As previously noted, the values identified in the CRC Vision and Values statement remain community values. **Thus, the Vision and Values statement for the IBR Program, provided below, remains the same as documented in the 2011 Final EIS and 2011 ROD for the CRC project.**

The text of the Vision and Values statement has not been edited from its original wording, with the exception of references to the name of the Program.

These values, along with the Purpose and Need, were instrumental in defining the evaluation criteria used during the development of the range of alternatives evaluated in the CRC project's EIS (see Sections 2.6 through 2.8 of the CRC Final EIS for information on this process).

As with the Purpose and Need, the IBR Program worked with regional and local partner agencies and the public to review and comment on the Vision and Values. Opportunities for the public to comment included an online open house, virtual community briefings, and an online survey.[9] The outcome of these efforts was the confirmation that the Vision and Values listed below remain community values.

The following is a statement of the IBR Program vision:

[9] Additional details on public engagement opportunities are described in Appendix B, Public Involvement.

> *The Interstate Bridge Replacement (IBR) Program Vision provides the foundation for developing criteria and performance measures that will be used to evaluate the IBR Program alternatives. The IBR Program NEPA process will include consideration of crossing infrastructure; multimodal transportation; connectivity; high-capacity transit; land use; funding; community and business interests; under-represented, low income, and minority communities; commuter and freight mobility; maritime mobility; and the environment.*

Values that have guided this Program's development and framed identification and evaluation of alternatives are noted below.

1.5.1 Community Livability

- Supporting a healthy community.
- Supporting a healthy and vibrant mix of residential, commercial, industrial, recreational, cultural, and historic areas land uses.
- Supporting aesthetic quality that achieves the level of a regional landmark.
- Recognizing the history of the community surrounding the Program area, supporting improved community cohesion, and avoiding neighborhood disruption.
- Preserving parks, historic and cultural resources, and green spaces.

1.5.2 Mobility, Reliability, Accessibility, Congestion Reduction, and Efficiency

- Providing congestion reduction and mobility, reliability, and accessibility for all users, and recognizing the requirements of local, intra-corridor, and interstate movement now and in the future.
- Providing an efficient transportation system through transportation system management , encouraging reduced reliance on single-occupancy vehicles, improving incident management, and providing increased capacity measures.

Reliability refers to consistency or dependability in travel times as measured from day to day and/or across different times of the day.

Mobility refers to the ability to easily move between different locations.

Modal refers to the various methods (or modes) of transportation such as motor vehicle, transit, walking, cycling, rolling, or other means.

1.5.3 Modal Choice

- Providing modal choice for users of the river crossing including highway, transit, high-capacity transit, bicycle, and pedestrian modes.

1.5.4 Safety

- Ensuring safety for vehicles (trucks, cars, emergency, and transit), pedestrians, bicyclists, river users, and air traffic at the crossing.

1.5.5 Regional Economy and Freight Mobility

- Supporting a sound regional economy and job growth.
- Enhancing the I-5 corridor as a global trade gateway by addressing the need to move freight efficiently and reliably through the Program area, and allowing for river navigational needs.

1.5.6 Stewardship of Natural and Human Resources

- Respecting, protecting, and improving natural resources including fish, wildlife habitat, and water quality.
- Supporting improved air quality.
- Minimizing impacts of noise, light, and glare.
- Supporting energy efficiency through design, construction, and use.

1.5.7 Distribution of Impacts and Benefits

- Ensuring the fair distribution of benefits and adverse effects of the Program for the region, communities, and neighborhoods adjacent to the Program area.

1.5.8 Cost-Effectiveness and Financial Resources

- Ensuring cost-effectiveness in design, construction, maintenance, and operation.
- Ensuring a reliable funding plan for the Program.

1.5.9 Bi-State Cooperation

- Fostering regional cooperation and planning.
- Supporting existing growth management plans in both states.
- Supporting balanced job growth.

1.6 Next Steps

The community will have an opportunity to review this Draft SEIS and provide feedback during the public review and comment period. The design of the proposed improvements, including the selection of specific design options, may be further refined based on findings and public input, which will be documented in the Final SEIS and an Amended ROD issued by FHWA and FTA. The design of the Modified LPA will be developed to a level of detail that will allow the IBR Program to apply for permits and update cost estimates. The IBR Program will continue to work and foster relationships with agencies, tribes, and the public through completion of the Program.

2. DESCRIPTION OF ALTERNATIVES

2.1 Introduction

Chapter Contents

2.1 Introduction
2.2 Components of the Modified LPA
2.3 Modified LPA Construction
2.4 No-Build Alternative
2.5 Development of the Modified LPA
2.6 Additional Compliance Underway
2.7 Anticipated Permits and Approvals

The Interstate Bridge Replacement (IBR) Program is a continuation of the previously suspended Columbia River Crossing (CRC) project with the same purpose to replace the aging Interstate 5 (I-5) Bridge across the Columbia River with a modern, seismically resilient multimodal structure. The proposed infrastructure improvements are located along a 5-mile stretch of the I-5 corridor that extends from approximately Victory Boulevard in Portland to State Route (SR) 500 in Vancouver as shown in Figure 2-1.

The alternatives evaluated to address the project's Purpose and Need were presented in the CRC Draft EIS (2008) and Final EIS (2011) and are briefly summarized below. The 2008 CRC Draft EIS evaluated a No-Build Alternative and four build alternatives[1] (see Table 2-1). The reasonable range of alternatives evaluated in the CRC Draft EIS included design components (*i.e.*, river crossing type, transit mode) that had passed a Purpose and Need screening process (CRC 2007, 2008), and had been bundled with additional improvements for freight, active transportation, highway traffic, and transportation system management and transportation demand management. Section 2.5.1 includes details about the initial screening effort for the CRC project's National Environmental Policy Act (NEPA) alternatives analysis that determined the range of alternatives evaluated in the CRC Draft EIS. The CRC Final EIS (2011) identified a Locally Preferred Alternative (LPA), which was based on Alternative 3, and included design options[2] of stacked transit/highway bridges and a high-capacity transit (HCT) northern terminus at Clark College. The CRC project completed its NEPA compliance with the identification of a Selected Alternative in a Record of Decision (ROD) in 2011 (CRC 2011b) and was revised by two NEPA re-evaluations that were completed in 2012 and 2013. The CRC Selected Alternative identified in the 2011 ROD, as revised by the 2012 and 2013 re-evaluations, is referred to as the "CRC LPA."[3] In 2014, the CRC project was suspended.

Table 2-1. CRC Draft EIS Alternatives and Design Options

Design Components	Alternative 1 (No-Build)	Alternative 2	Alternative 3	Alternative 4	Alternative 5
Multimodal River Crossing and Highway	Existing Bridges	Replacement	Replacement	Supplemental	Supplemental

[1] A build alternative includes a set of corridor-wide multimodal improvements defined to address the project's purpose and need.

[2] Design options are refinements to an alternative being considered for a specific project component. The design options for each component represent a range of potential options for the design of the component. Identifying design options allows for the analysis and disclosure of the range of potential impacts for that specific component. After public comments are reviewed following the public comment period, design options may be narrowed to a single solution, which may be a specific option evaluated or a solution that is within the range of impacts disclosed in the Draft SEIS.

[3] FHWA and FTA published a notice to prepare a Supplemental Environmental Impact Statement for the Interstate Bridge Replacement Program in the Federal Register (Volume 88, Number 65) on April 5, 2023. This notice referred to the Selected Alternative from the 2011 CRC Project's ROD, which was also known as the Locally Preferred Alternative (LPA). For purpose of this SEIS, the CRC LPA refers to the CRC Selected Alternative from the 2011 ROD, as revised by the 2012 and 2013 re-evaluations.

Design Components	Alternative 1 (No-Build)	Alternative 2	Alternative 3	Alternative 4	Alternative 5

a HCT Mode also dictates the location of a maintenance base expansion. BRT would entail expanding a bus maintenance facility in eastern Vancouver. LRT would entail expanding the Ruby Junction maintenance base in Gresham.

b Alternative 3 was also evaluated without a toll to quantify the traffic effects of tolling the I-5 crossing.

BRT = bus rapid transit; HCT = high-capacity transit; I-5 = Interstate 5; LRT = light-rail transit; MOS = minimum operable segment; N/A = Not applicable; TDM = transportation demand management; TSM = transportation system management

In 2019, a bi-state legislative committee requested that the Oregon Department of Transportation (ODOT) and the Washington State Department of Transportation (WSDOT) restart the CRC project, renaming it the *IBR Program*. The CRC project was never constructed, and the overall problems—the needs for the project—that the CRC project sought to address still existed and remained unresolved. Some detailed characteristics of those problems had evolved and, in some cases, worsened over time (see Section 1.3, Purpose and Need for the IBR Program). The range of alternatives evaluated in the CRC Final EIS continue to be valid for the project overall as they remain technically and economically feasible solutions that meet the Purpose and Need, which has remained unchanged. The range of alternatives—other than the No-Build Alternative and CRC LPA as modified to address changed conditions (described in Section 2.5)—is not altered or reexamined in this Supplemental EIS (SEIS). Only the No-Build Alternative and CRC LPA are reexamined in the Draft SEIS because the CRC LPA was selected in the ROD and is now being advanced to construction by the IBR Program, and the No-Build Alternative provides baseline conditions and a no action option for decision-makers.

Using the CRC LPA as its the baseline, or starting point, the IBR Program restarted the CRC project and began evaluating whether past design assumptions still addressed today's changed conditions, including physical environment, community priorities, and regulations, or whether updates would be needed (see Section 2.5.2, Updating the CRC LPA). In 2021, the Federal Highway Administration (FHWA) and the Federal Transit Administration (FTA) issued a NEPA re-evaluation that assessed the extent of changes in conditions and determined an SEIS should be prepared to identify and disclose new adverse impacts and mitigation associated with changes in conditions affecting the CRC LPA that occurred since 2013 (IBR 2021a).

Figure 2-1. IBR Program Location Overview

While the main components (e.g., a pair of replacement bridges across the Columbia River, extension of light-rail into Vancouver, improvements to seven interchanges, active transportation improvements, and variable-rate tolling) have not changed since the CRC LPA, some details of these components have been revised due to changed conditions. As a result, modifications to the CRC LPA were pursued and no new alternatives were developed. As part of the updates to the CRC LPA, several of the CRC river crossing types and transit modes were revisited in response to public input. Past Purpose and Need screenings of a high-speed rail transit mode and tunnel or new bridge river crossing types were reassessed (IBR 2021b; IBR 2021c; IBR 2021e). In addition, a variation of the draft supplemental bridge alternative in the CRC project was reassessed to determine whether it would meet the Purpose and Need (IBR 2021d). Each of these reassessments concluded the Purpose and Need would not be met by the respective alternative.

The CRC LPA was updated in close coordination with federal, tribal, state, regional, and local partners to establish the Modified LPA. Section 2.5.1, Selected Alternative in the 2011 Record of Decision and Subsequent Modifications in 2012 to 2013, summarizes the differences between the CRC LPA and the Modified LPA. Section 2.5.2,Updating the CRC LPA, summarizes the changes that have occurred since the 2013 CRC Re-evaluation and evaluation of changes and modifications required to address such changes which was conducted as part of the IBR Program, including revisiting past screening and investigating variations on prior design components. This is further detailed in Appendix D, Design Options Development, Screening, and Evaluation Technical Report. **The updated version of the CRC LPA is referred to as the IBR Modified LPA**.

The Modified LPA was developed through a collaborative process with the local and regional agencies partnering with the IBR Program as well as consultation with tribes.

Section 2.2, Components of the Modified LPA, describes specific components of the IBR Program's Modified LPA. Short summaries of the differences between the CRC LPA and the Modified LPA and what triggered those changes are included throughout this chapter in callout boxes titled, *What's changed with IBR?* If there is no callout box, there are no major changes from the CRC LPA. For additional detail on the changes, refer to Sections 2.5.1 and 2.5.2.

Development of the Modified LPA is described in Section 2.5, Development of the Modified LPA. This section summarizes the changes that have occurred since 2013 that prompted modifications in the design and highlights the differences between the CRC LPA and IBR Program Modified LPA.

Section 2.3, Modified LPA Construction, describes how the Modified LPA would be constructed. Section 2.4, No-Build Alternative, describes the No-Build Alternative, which serves as a baseline for evaluating environmental impacts. Section 2.5, Development of the Modified LPA, describes how design options for the Modified LPA were created and evaluated and the ways in which the Modified LPA differs from the CRC LPA. Section 2.6, Additional Compliance Underway, addresses additional regulatory compliance that is underway for the Modified LPA. Section 2.7, Anticipated Permits and Approvals, includes the federal, state, and local permits, clearances, and approvals that are anticipated to be required to construct the Modified LPA.

2.2 Components of the Modified LPA

The basic components of the Modified LPA include:

- A new pair of Columbia River bridges—one for northbound and one for southbound travel—built west of the existing bridge. The new bridges would each include three through lanes, safety shoulders, and one auxiliary lane (a ramp-to-ramp connection on the highway that improves interchange safety by providing drivers with more space and time to merge, diverge, and weave) in each direction. When all highway, transit, and active transportation would be moved to the new Columbia River bridges, the existing Interstate Bridge (both spans) would be removed.
  - Three bridge configurations are under consideration: (1) double-deck truss bridges with fixed spans, (2) single-level bridges with fixed spans, and (3) single-level bridges with movable spans over the primary navigation channel. The fixed-span configurations would provide up to 116 feet of vertical navigation clearance, and the movable-span configuration would provide 178 feet of vertical navigation clearance in the open position. The primary navigation channel would be relocated approximately 500 feet south (measured by channel centerline) of its existing location near the Vancouver shoreline.
  - A two auxiliary lane design option (two ramp-to-ramp lanes connecting interchanges) across the Columbia River is also being evaluated. The second auxiliary lane in each direction of I-5 would be added from approximately Interstate Avenue/Victory Boulevard to SR 500/39th Street.

- A 1.9-mile light-rail transit (LRT) extension of the current Metropolitan Area Express (MAX) Yellow Line from the Expo Center MAX Station in North Portland, where it currently ends, to a terminus near Evergreen Boulevard in Vancouver. Improvements would include new stations at Hayden Island, downtown Vancouver (Waterfront Station), and near Evergreen Boulevard (Evergreen Station), as well as revisions to the existing Expo Center MAX Station. Park and rides to serve LRT riders in Vancouver could be included near the Waterfront Station and Evergreen Station. The Tri-County Metropolitan Transportation District of Oregon (TriMet), which operates the MAX system, would also operate the Yellow Line extension.
  - Potential site options for park and rides include three sites near the Waterfront Station and two near the Evergreen Station (up to one park and ride could be built for each station location in Vancouver).
- Associated LRT improvements such as traction power substations, overhead catenary system, signal and communications support facilities, an overnight light-rail vehicle (LRV) facility at the Expo Center, 19 new LRVs, and an expanded maintenance facility at TriMet's Ruby Junction.
- Integration of local bus transit service, including bus rapid transit (BRT) and express bus routes, in addition to the proposed new LRT service.
- Wider shoulders on I-5 from Interstate Avenue/Victory Boulevard to SR 500/39th Street to accommodate express bus-on-shoulder service in each direction.
- Associated bus transit service improvements would include three additional bus bays for eight new electric double-decker buses at the Clark County Public Transit Benefit Area Authority (C-TRAN) operations and maintenance facility (see Section 2.2.7, Transit Operating Characteristics, for more information about this service).
- Improvements to seven I-5 interchanges and I-5 mainline improvements between Interstate Avenue/ Victory Boulevard in Portland and SR 500/39th Street in Vancouver. Some adjacent local streets would be reconfigured to complement the new interchange designs, and improve local east-west connections.
  - An option that shifts the I-5 mainline up to 40 feet westward in downtown Vancouver between the SR 14 interchange and Mill Plain Boulevard interchange is being evaluated.
  - An option that eliminates the existing C Street ramps in downtown Vancouver is being evaluated.
- Six new adjacent bridges across North Portland Harbor: one on the east side of the existing I-5 North Portland Harbor bridge and five on the west side or overlapping with the existing bridge (which would be removed). The bridges would carry (from west to east) LRT tracks, southbound I-5 off-ramp to Marine Drive, southbound I-5 mainline, northbound I-5 mainline, northbound I-5 on-ramp from Marine Drive, and an arterial bridge for local traffic with a shared-use path for pedestrians and bicyclists.
- A variety of improvements for people who walk, bike, and roll throughout the study area, including a system of shared-use paths, bicycle lanes, sidewalks, enhanced wayfinding, and facility improvements to comply with the Americans with Disabilities Act. These are referred to in this document as *active transportation* improvements.
- Variable-rate tolling for motorists using the river crossing as a demand-management and financing tool.

The transportation improvements proposed for the Modified LPA and the design options are shown in Figure 2-2. The Modified LPA includes all of the components listed above. If there are differences in environmental effects or benefits between the design options, those are identified in the relative Chapter 3 resources sections.

Figure 2-2. Modified LPA Components

Section 2.2.1, Interstate 5 Mainline, describes the overall configuration of the I-5 mainline through the study area, and Sections 2.2.2, Portland Mainland and Hayden Island (Subarea A), through Section 2.2.5, Upper Vancouver (Subarea D), provide additional detail on four geographic subareas (A through D), which are shown on Figure 2-3. In each subarea, improvements to I-5, its interchanges, and the local roadways are described first, followed by transit and active transportation improvements. Design options are described under separate headings in the subareas in which they would be located.

Table 2-2 shows the different combinations of design options analyzed in this Draft SEIS. However, **any combination of design options is compatible**. In other words, any of the bridge configurations could be combined with one or two auxiliary lanes, with or without the C Street ramps, a centered or westward shift of I-5 in downtown Vancouver, and any of the park-and-ride location options. Figures in each section show both the anticipated limit of ground disturbance, which includes disturbance from temporary construction activities, and the location of permanent infrastructure elements.

Bold text indicates which design option is different in each configuration.

2.2.1 Interstate 5 Mainline

Today, within the 5-mile corridor, I-5 has three 12-foot-wide through lanes in each direction, an approximately 6- to 11-foot-wide inside shoulder, and an approximately 10- to 12-foot-wide outside shoulder with the exception of the Interstate Bridge, which has approximately 2- to 3-foot-wide inside and outside shoulders. There are currently intermittent auxiliary lanes between the Victory Boulevard and Hayden Island interchanges in Oregon and between SR 14 and SR 500 in Washington.

What's changed with IBR?

In response to local agency policies and community priorities, the Modified LPA includes one auxiliary lane in each direction, whereas the CRC LPA had two. However, the Modified LPA does include a second auxiliary lane option from Interstate Avenue/Victory Boulevard to SR 500/39th Street that has the same alignment and lane configuration as the CRC LPA. Otherwise, the proposed configuration of the I-5 highway is similar between CRC and IBR.

The Modified LPA would include three 12-foot through lanes from Interstate Avenue/Victory Boulevard to SR 500/39th Street and a 12-foot auxiliary lane from the Marine Drive interchange to the Mill Plain Boulevard interchange in each direction. Many of the existing auxiliary lanes on I-5 between the SR 14 and Main Street interchanges in Vancouver would remain, although they would be reconfigured. The existing auxiliary lanes between the Victory Boulevard and Hayden Island interchanges would be replaced with changes to on- and off-ramps and interchange reconfigurations. The Modified LPA would also include wider shoulders (12-foot inside shoulders and 10- to 12-foot outside shoulders) to be consistent with ODOT and WSDOT design standards. The wider inside shoulder would be used by express bus service to bypass mainline congestion, known as "bus on shoulder" (refer to Section 2.2.7, Transit Operating Characteristics). The shoulder would be available for express bus service when general-purpose speeds are below 35 miles per hour (mph).

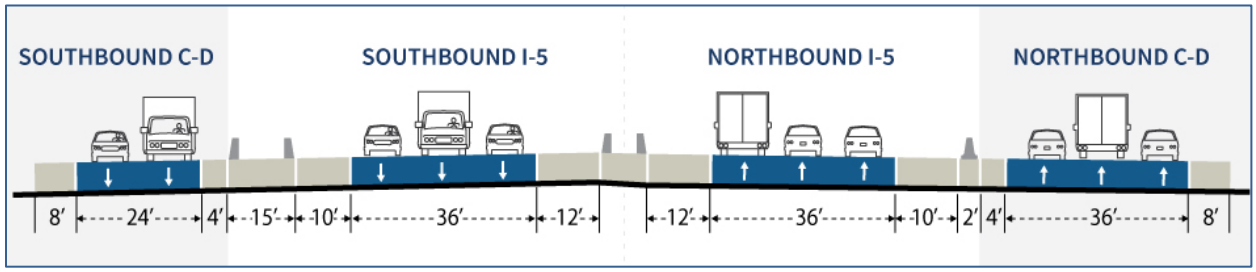
Figure 2-4 shows a cross section of the collector-distributor (C-D)[4] roadways, Figure 2-5 shows the location of the C-D roadways, and Figure 2-6 shows the proposed auxiliary lane layout. The existing Interstate Bridge over the Columbia River does not have an auxiliary lane; the Modified LPA would add one auxiliary lane in each direction across the new Columbia River bridges.

On I-5 northbound, the auxiliary lane that would begin at the on-ramp from Marine Drive would continue across the Columbia River bridge and end at the off-ramp to the C-D roadway, north of SR 14 (see Figure 2-5). The on-ramp from SR 14 westbound would join the off-ramp to the C-D roadway, forming the northbound C-D roadway between SR 14 and Fourth Plain Boulevard. The C-D roadway would provide access from I-5

[4] A collector-distributer roadway parallels and connects the main travel lanes of a highway and frontage roads or entrance ramps.

northbound to the off-ramps at Mill Plain Boulevard and Fourth Plain Boulevard. The C-D roadway would also provide access from SR 14 westbound to the off-ramps at Mill Plain Boulevard and Fourth Plain Boulevard, and to the on-ramp to I-5 northbound.

Figure 2-4. Cross Section of the Collector-Distributor Roadways



On I-5 northbound, the Modified LPA would also add one auxiliary lane beginning at the on-ramp from the C-D roadway and ending at the on-ramp from 39th Street, connecting to an existing auxiliary lane from 39th Street to the off-ramp at Main Street. Another existing auxiliary lane would remain between the on-ramp from Mill Plain Boulevard to the off-ramp to SR 500.

On I-5 southbound, the off-ramp to the C-D roadway would join the on-ramp from Mill Plain Boulevard to form a C-D roadway. The C-D roadway would provide access from I-5 southbound to the off-ramp to SR 14 eastbound and from Mill Plain Boulevard to the off-ramp to SR 14 eastbound and the on-ramp to I-5 southbound.

On I-5 southbound, an auxiliary lane would begin at the on-ramp from the C-D roadway and would continue across the southbound Columbia River bridge and end at the off-ramp to Marine Drive. The combined on-ramp from SR 14 westbound and C Street would merge into this auxiliary lane.

Two Auxiliary Lane Design Option

This design option would add a second 12-foot-wide auxiliary lane in each direction of I-5 with the intent to further optimize travel flow in the corridor. This second auxiliary lane is proposed from the Interstate Avenue/Victory Boulevard interchange to the SR 500/39th Street interchange.

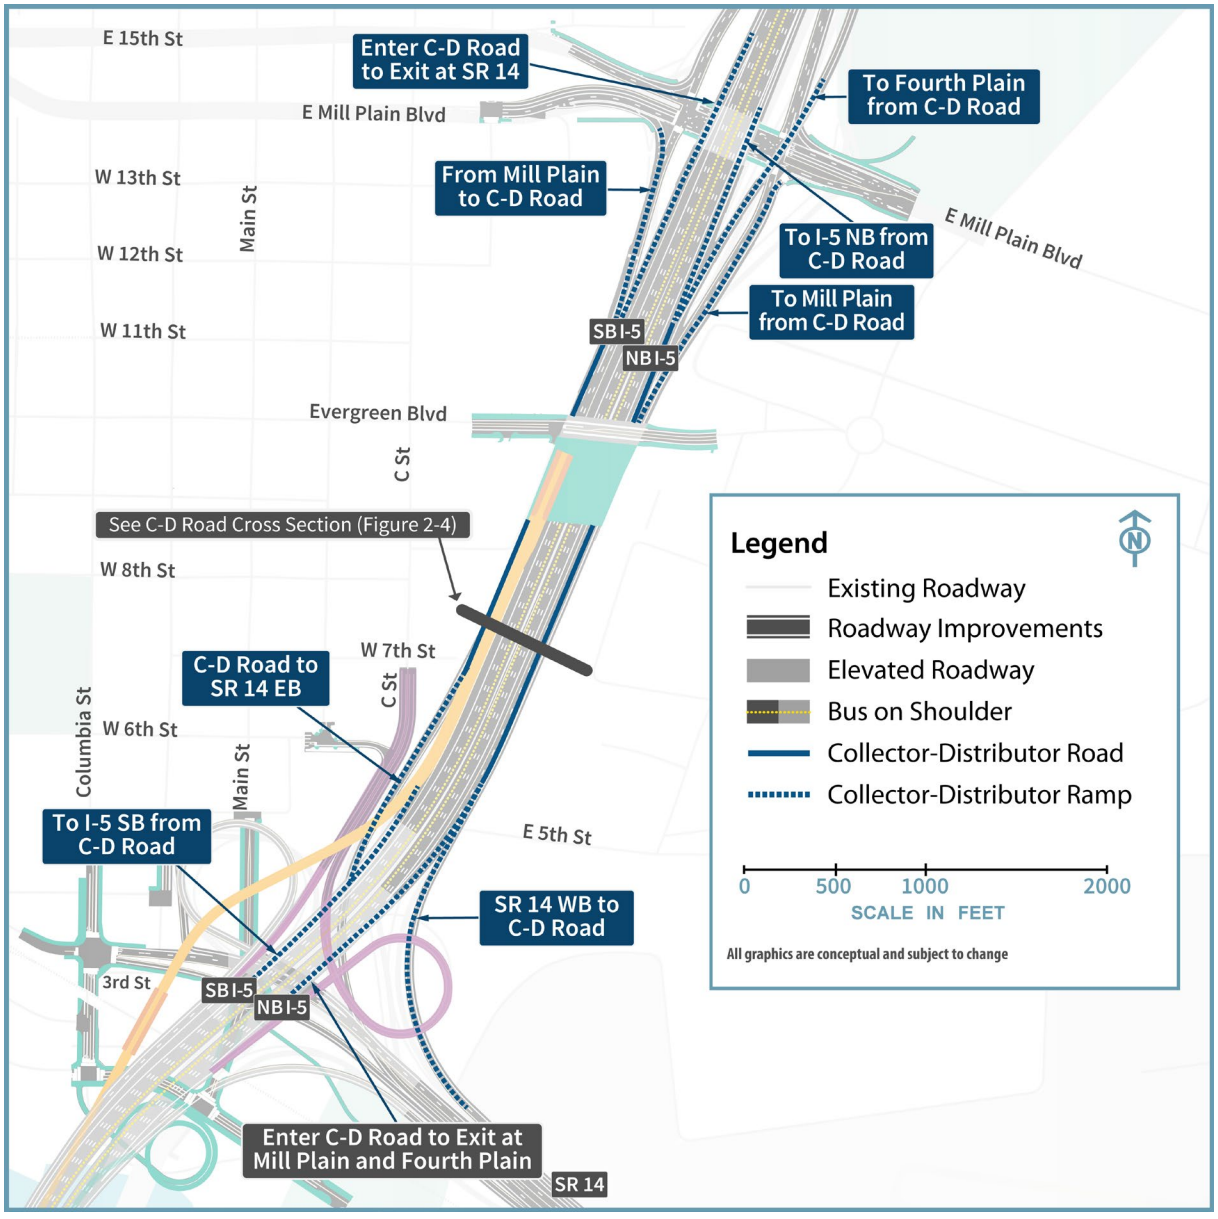
On I-5 northbound, one auxiliary lane would begin at the combined on-ramp from Interstate Avenue and Victory Boulevard, and a second auxiliary lane would begin at the on-ramp from Marine Drive. Both auxiliary lanes would continue across the northbound Columbia River bridge, and the on-ramp from Hayden Island would merge into the second auxiliary lane on the northbound Columbia River bridge. At the off-ramp to the C-D roadway, the second auxiliary lane would end but the first auxiliary lane would continue. A second auxiliary lane would begin again at the on-ramp from Mill Plain Boulevard. The second auxiliary lane would end at the off-ramp to SR 500, and the first auxiliary lane would connect to an existing auxiliary lane at 39th Street to the off-ramp at Main Street.

On I-5 southbound, two auxiliary lanes would begin at the on-ramp from SR 500. Between the on-ramp from Fourth Plain Boulevard and the off-ramp to Mill Plain Boulevard, one auxiliary lane would be added to the existing two auxiliary lanes. The second auxiliary lane would end at the off-ramp to the C-D roadway, but the first auxiliary lane would continue. A second auxiliary lane would begin again at the southbound I-5 on-ramp from the C-D roadway. Both auxiliary lanes would continue across the southbound Columbia River bridge, and the combined on-ramp from SR 14 westbound and C Street would merge into the second auxiliary lane on the southbound Columbia River bridge. The second auxiliary lane would end at the off-ramp to Marine Drive, and the first auxiliary lane would end at the combined off-ramp to Interstate Avenue and Victory Boulevard.

Figure 2-6 shows a comparison of the one auxiliary lane configuration and the two auxiliary lane configuration design options. Figure 2-7 shows a comparison of the footprints (i.e., the limit of permanent improvements) of

the one auxiliary lane and two auxiliary lane configurations on a double-deck fixed-span bridge. For all Modified LPA bridge configurations (described in Section 2.2.3), the footprints of the two auxiliary lane configurations differ only over the Columbia River and in downtown Vancouver. The rest of the corridor would have the same footprint. For all bridge configurations analyzed in this document, the two auxiliary lane option would add 16 feet (8 feet in each direction) in total roadway width compared to the one auxiliary lane option due to the increased shoulder widths for the one auxiliary lane option.[5] The traffic operations analysis incorporating both the one and two auxiliary lane design options applies equally to all bridge configurations in this Draft SEIS.

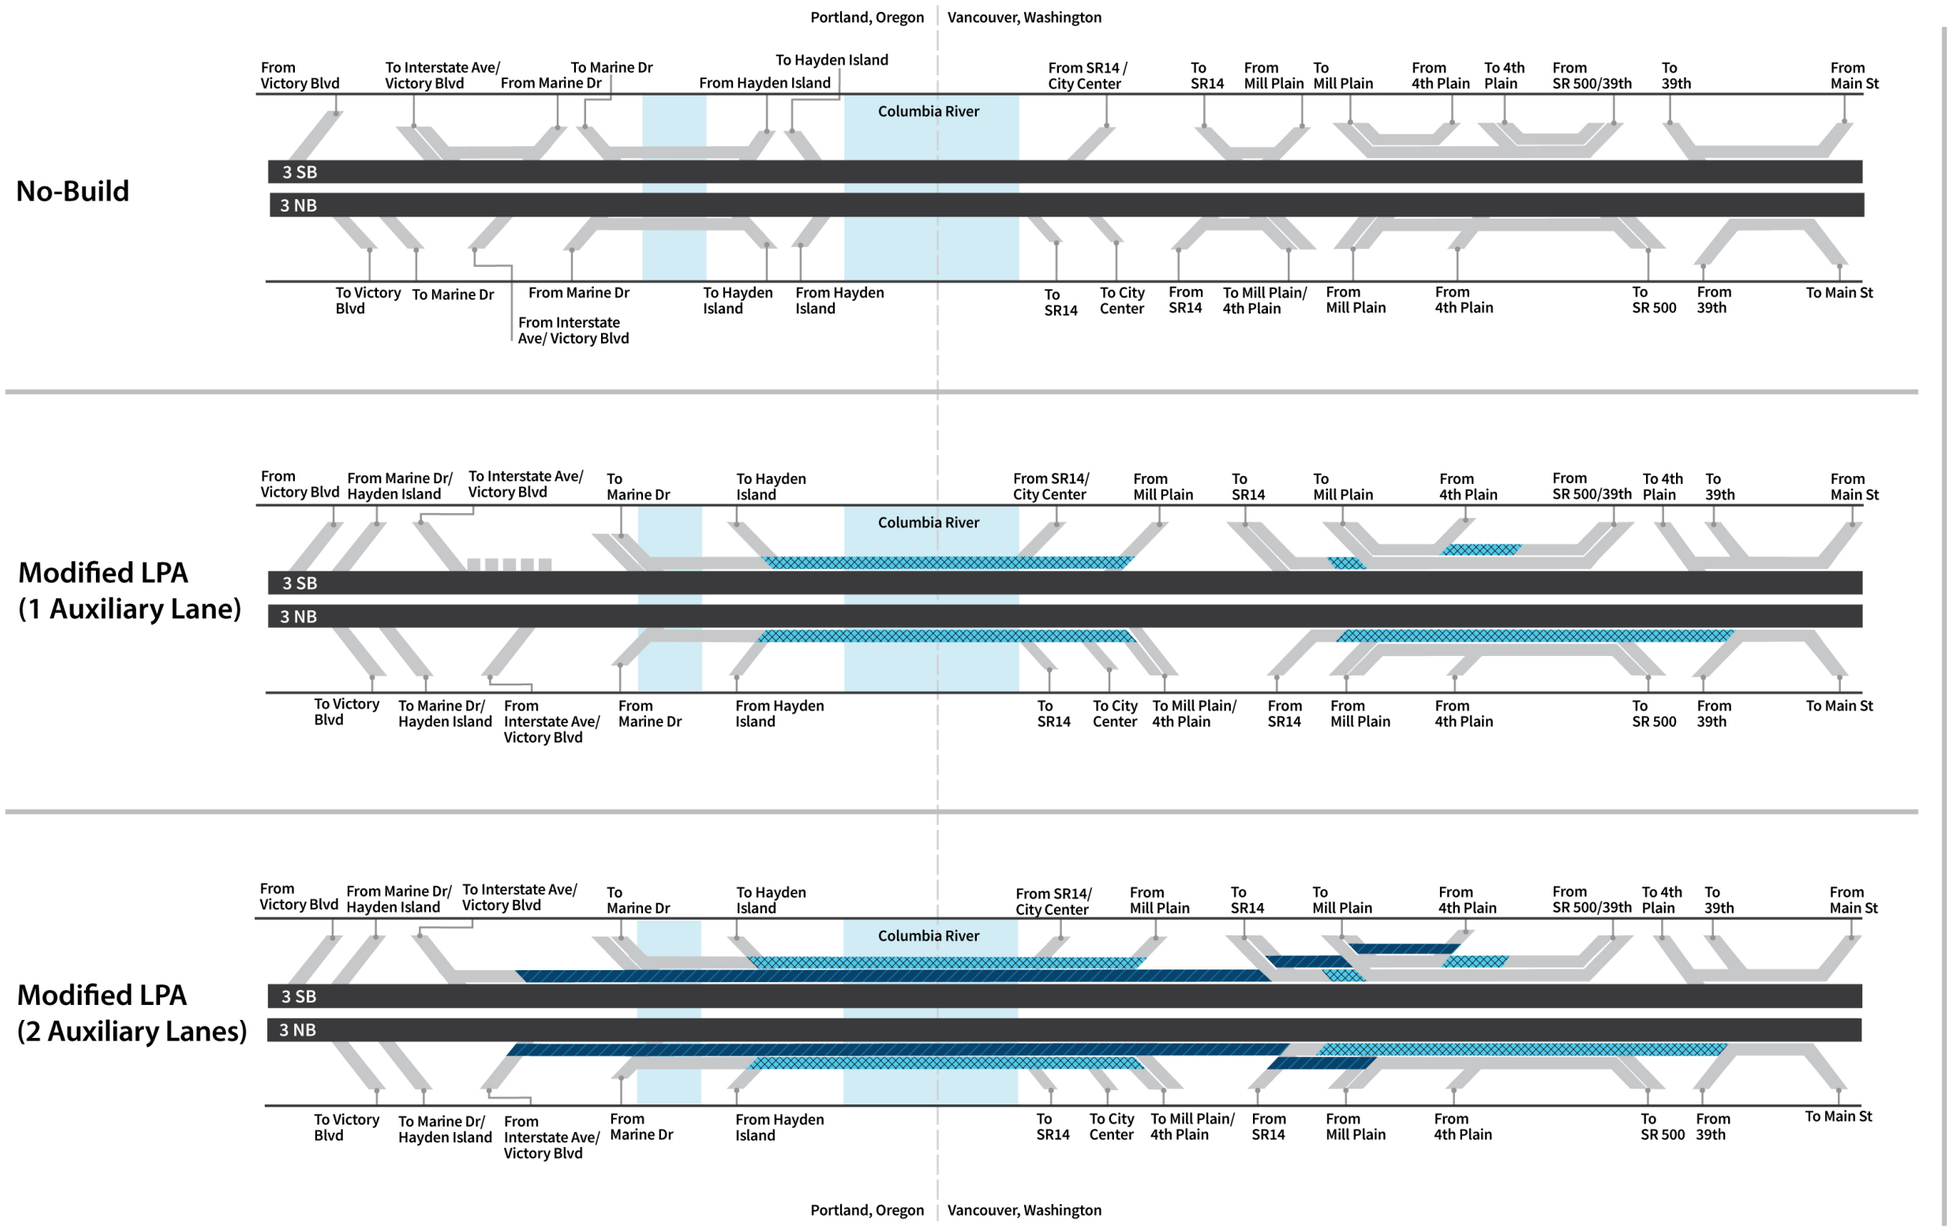
Figure 2-5. Collector-Distributor Roadways



C-D = collector-distributor; EB = eastbound; NB = northbound; SB = southbound; WB = westbound

[5] Under the one auxiliary lane option, the width of each shoulder would be approximately 14 feet to accommodate maintenance of traffic during construction. Under the two auxiliary lane option, maintenance of traffic could be accommodated with 12-foot shoulders because the additional 12-foot auxiliary lane provides adequate roadway width. The total difference in roadway width in each direction between the one auxiliary lane option and the two auxiliary lane option would be 8 feet (12-foot auxiliary lane – 2 feet from the inside shoulder – 2 feet from the outside shoulder = 8 feet).

Figure 2-6. Comparison of Auxiliary Lane Configurations



Each scenario has three through lanes in each direction

- Existing Through Lanes
- Interchange Ramps and Existing Auxiliary Lanes
- Existing Auxiliary Lanes Removed
- One Auxiliary Lane added in Modified LPA
- Second Auxiliary Lane added in Modified LPA

Notes:

Collector Distributor Lanes not shown.

The traffic operations analysis incorporating both the one and two auxiliary lane design option applies equally to all bridge configuration options in this Draft SEIS.

The C Street ramp (NB to City Center) is an option.

Figure is not to scale.

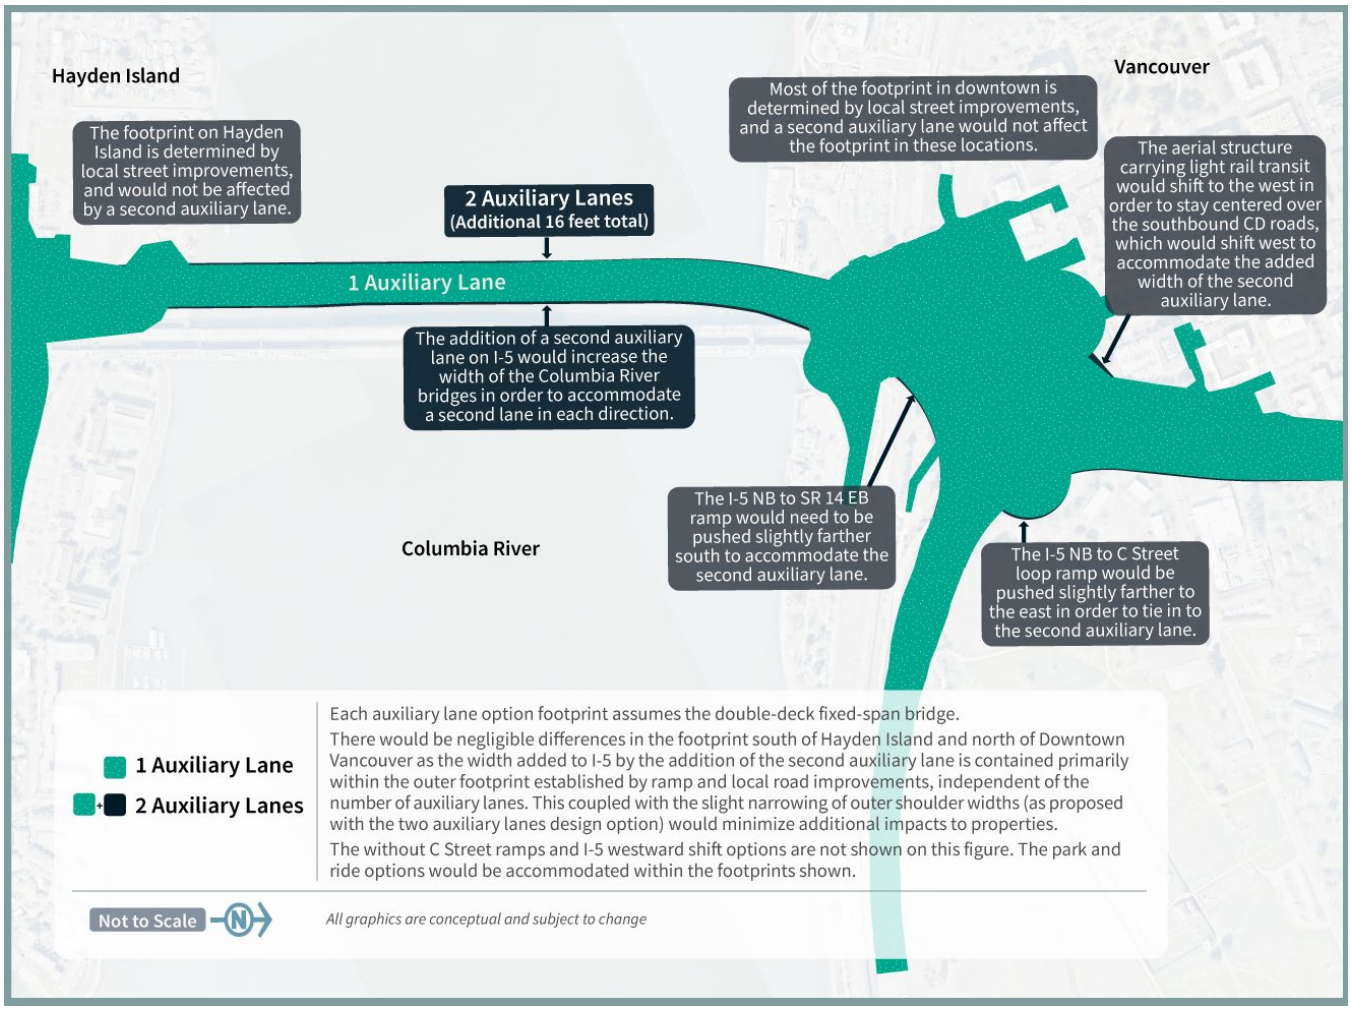
Figure 2-7. Auxiliary Lane Configuration Footprint Differences



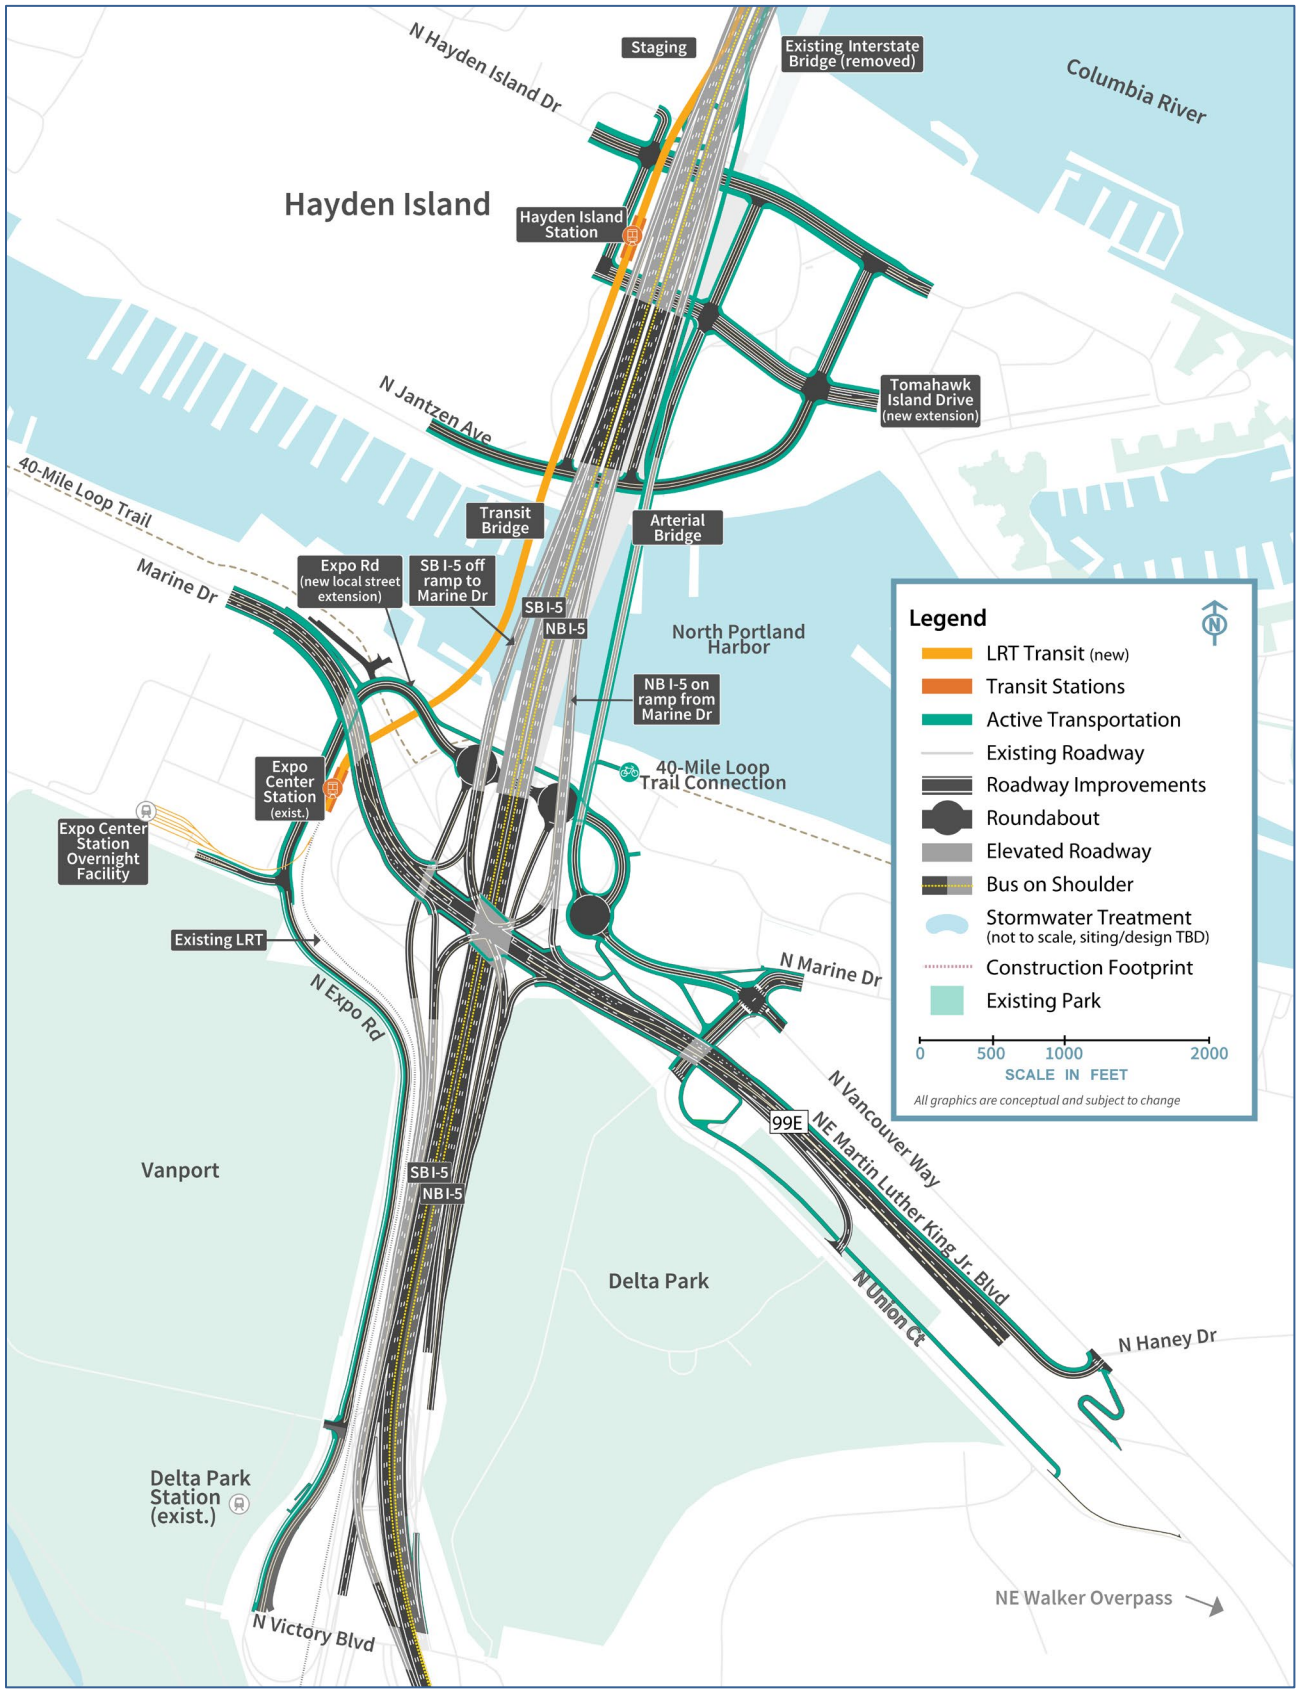
2.2.2 Portland Mainland and Hayden Island (Subarea A)

This section discusses the geographic Subarea A shown in Figure 2-3. See Figure 2-8 for highway and interchange improvements in Subarea A, including the North Portland Harbor bridge. Figure 2-8 illustrates the one auxiliary lane design option; please refer to Figure 2-6 and the accompanying description for how two auxiliary lanes would alter the Modified LPA's proposed design. Refer to Figure 2-3 for an overview of the geographic subareas.

Within Subarea A, the IBR Program has the potential to alter three federally authorized levee systems:

- The Oregon Slough segment of the Peninsula Drainage District Number 1 levee (PEN 1).
- The Oregon Slough segment of the Peninsula Drainage District Number 2 levee (PEN 2).
- The PEN1/PEN2 Cross Levee segment of the PEN 1 levee (Cross Levee).

Figure 2-8. Portland Mainland and Hayden Island (Subarea A)



LRT = light-rail transit; NB = northbound; SB = southbound; TBD = to be determined

The levee systems are shown on Figure 2-9, and intersections with Modified LPA components are described throughout Section 2.2.2, Portland Mainland and Hayden Island (Subarea A), where appropriate. Within Subarea A, the IBR Program study area intersects with PEN 1 to the west of I-5 and with PEN 2 to the east of I-5. PEN 1 and PEN 2 include a main levee along the south side of North Portland Harbor and are part of a combination of levees and floodwalls. PEN 1 and PEN 2 are separated by the Cross Levee that is intended to isolate the two districts if one of them fails. The Cross Levee is located along the I-5 mainline embankment, except in the Marine Drive interchange area where it is located on the west edge of the existing ramp from Marine Drive to southbound I-5.[6]

There are two concurrent efforts underway that are planning improvements to PEN1, PEN2, and the Cross Levee to reduce flood risk:

- The U.S. Army Corps of Engineers (USACE) Portland Metro Levee System (PMLS) project.
- The Flood Safe Columbia River (FSCR) program (also known as "Levee Ready Columbia").

The Urban Flood Safety and Water Quality District (UFSWQD)[7] is working with the USACE through the PMLS project, which includes improvements at PEN 1 and PEN 2 (e.g., raising these levees to elevation 38 feet North American Vertical Datum of 1988 [NAVD 88]).[8] Additionally, as part of the FSCR program, UFSWQD is studying raising a low spot in the Cross Levee on the southwest side of the Marine Drive interchange.

What's changed with IBR?

The Portland Metro Levee System (PMLS) project initiated in 2019 and Flood Safe Columbia River (FSCR) program was established in 2013, after the CRC LPA. There have been no changes to the CRC LPA at the request of the PMLS project or the FSCR program. There will be continued coordination throughout the design phase to ensure acceptable tie-ins to the existing levee system and levee modifications proposed by PMLS.

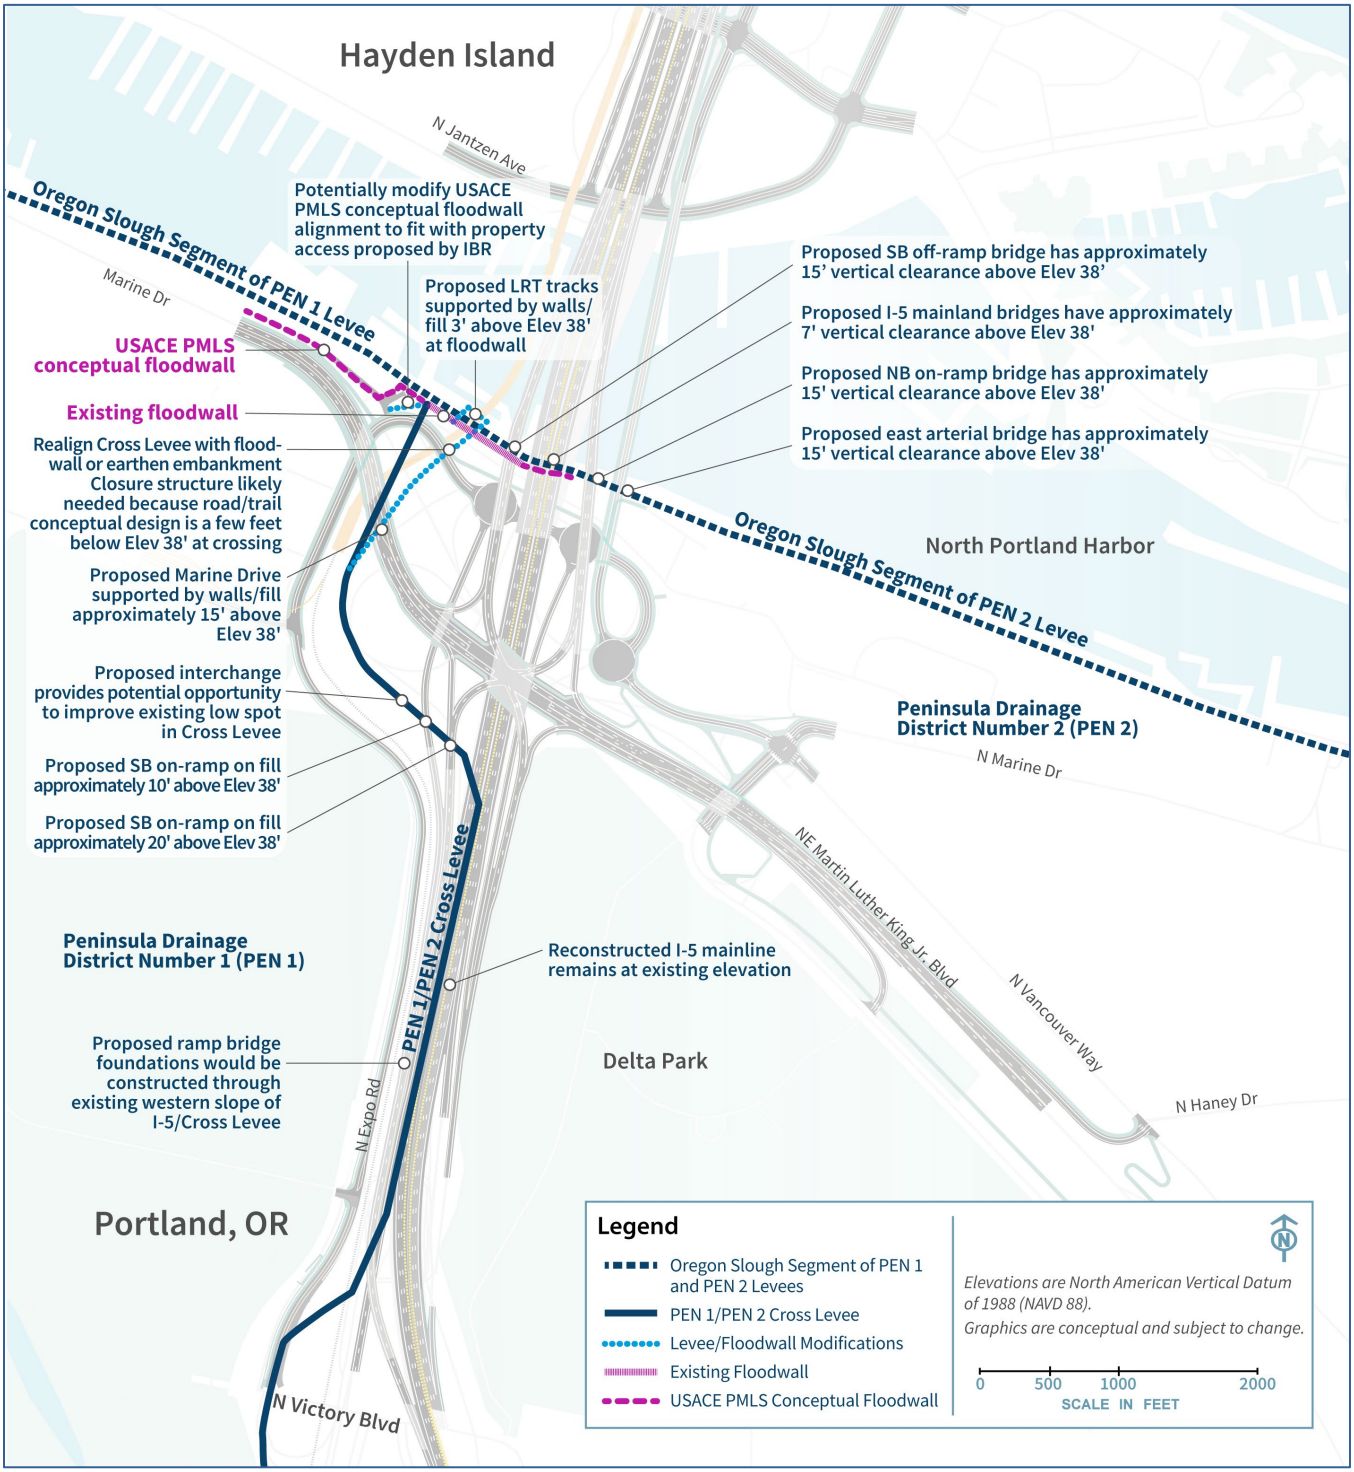
The IBR Program is in close coordination with these concurrent efforts to ensure that the IBR Program's design efforts consider the timing and scope of the PMLS and the FSCR proposed modifications. The intersection of the IBR Program proposed actions to both the existing levee configuration and the anticipated future condition based on the proposed PMLS and FSCR projects are described below, where appropriate.

[6] The portion of the original Denver Avenue levee alignment within the Marine Drive interchange area is no longer considered part of the levee system by UFSWQD.

[7] UFSWQD includes PEN 1 and PEN 2, Urban Flood Safety and Water Quality District No. 1, and the Sandy Drainage Improvement Company.

[8] NAVD 88 is a vertical control datum (reference point) used by federal agencies for surveying.

Figure 2-9. Levee Systems in Subarea A



Highways, Interchanges, and Local Roadways

Victory Boulevard/Interstate Avenue Interchange Area

The southern extent of the Modified LPA would improve two ramps at the Victory Boulevard/Interstate Avenue interchange (see Figure 2-8). The first ramp improvement would be the southbound I-5 off-ramp to Victory Boulevard/ Interstate Avenue; this off-ramp would be braided below (i.e., grade separated or pass below) the Marine Drive to the I-5 southbound on-ramp (see the Marine Drive Interchange Area section below). The other ramp improvement would lengthen the merge distance for northbound traffic entering I-5 from Victory Boulevard and from Interstate Avenue.

The existing I-5 mainline between Victory Boulevard/Interstate Avenue and Marine Drive is part of the Cross Levee (see Figure 2-9). The Modified LPA would require some pavement reconstruction of the mainline in this area; however, the improvements would mostly consist of pavement overlay and the profile and footprint would be similar to existing conditions.

What's changed with IBR?

The Victory Boulevard/Interstate Avenue interchange design is similar to the CRC LPA, except that the IBR Modified LPA on-ramp to northbound I-5 and southbound off-ramp from I-5 would merge and diverge directly from I-5 versus starting or ending the auxiliary lanes. This modification was a result of revising the design to include a one auxiliary lane option in addition to a two auxiliary lane option.

Marine Drive Interchange Area

The next interchange north of the Victory Boulevard/Interstate Avenue interchange is at Marine Drive. All movements within this interchange would be reconfigured to reduce congestion for motorists entering and exiting I-5. The new configuration would be a single-point urban interchange. The new interchange would be centered over I-5 versus on the west side under existing conditions. See Figure 2-8 for the Marine Drive interchange's layout and construction footprint.

The Marine Drive to I-5 southbound on-ramp would be braided over I-5 southbound to the Victory Boulevard/Interstate Avenue off-ramp. Martin Luther King Jr. Boulevard would have a new more direct connection to I-5 northbound.

What's changed with IBR?

Both the Modified LPA and CRC LPA include a single-point interchange at Marine Drive; however, due to changes in agency priorities, the Modified LPA does not include a planned future phase to replace the Marine Drive eastbound to I-5 north ramp with a directional flyover ramp that would bypass the traffic signal at the interchange that was included in the CRC LPA.

The new interchange configuration would change the westbound Marine Drive and westbound Vancouver Way connections to Martin Luther King Jr. Boulevard. An improved connection farther east of the interchange (near Haney Street) would provide access to westbound Martin Luther King Jr. Boulevard for these two streets. For eastbound travelers on Martin Luther King Jr. Boulevard exiting to Union Court, the existing loop connection would be replaced with a new connection farther east (near the access to the East Delta Park Owens Sports Complex).

Expo Road from Victory Boulevard to the Expo Center would be reconstructed with improved active transportation facilities. North of the Expo Center, Expo Road would be extended under Marine Drive and continue under I-5 to the east, connecting with Marine Drive and Vancouver Way through three new connected roundabouts. The westernmost roundabout would connect the new local street extension to I-5 southbound. The middle roundabout would connect the I-5 northbound off-ramp to the local street extension. The easternmost roundabout would connect the new local street extension to an arterial bridge crossing North Portland Harbor to Hayden Island. This roundabout would also connect the local street extension to Marine Dr and Vancouver Way.

To access Hayden Island using the arterial bridge from the east on Martin Luther King Jr. Boulevard, motorists would exit Martin Luther King Jr. Boulevard at the existing off-ramp to Vancouver Way just west of the Walker Street overpass. Then motorists would travel west on Vancouver Way, through the intersection with Marine Drive and straight through the roundabout to the arterial bridge.

From Hayden Island, motorists traveling south to Portland via Martin Luther King Jr. Boulevard would turn onto the arterial bridge southbound and travel straight through the roundabout onto Vancouver Way. At the intersection of Vancouver Way and Marine Drive, motorists would turn right onto Union Court and follow the existing road southeast to the existing on-ramp onto Martin Luther King Jr. Boulevard.

The conceptual floodwall alignment from the proposed USACE PMLS project is located on the north side of Marine Drive, near two industrial properties, with three proposed closure structures[9] for property access. The Modified LPA would realign Marine Drive to the south and provide access to the two industrial properties via the new local road extension from Expo Road. Therefore, the change in access for the two industrial properties could require small modifications to the floodwall alignment (a potential shift of 5 to 10 feet to the south) and closure structure locations.

Marine Drive and the two southbound on-ramps would travel over the Cross Levee approximately 10 to 20 feet above the proposed elevation of the improved levee, and they would be supported by fill and retaining walls near an existing low spot in the Cross Levee.

The I-5 southbound on-ramp from Marine Drive would continue on a new bridge structure. Although the bridge's foundation locations have not been determined yet, they would be constructed through the western slope of the Cross Levee (between the existing I-5 mainline and the existing light-rail).

North Portland Harbor Bridges

To the north of the Marine Drive interchange is the Hayden Island interchange area, which is shown in Figure 2-8. I-5 crosses over the North Portland Harbor when traveling between these two interchanges. The Modified LPA proposes to replace the existing I-5 bridge spanning North Portland Harbor to improve seismic resiliency.

Six new parallel bridges would be built across the waterway under the Modified LPA: one on the east side of the existing I-5 North Portland Harbor bridge and five on the west side or overlapping the location of the existing bridge (which would be removed). From west to east, these bridges would carry:

- The LRT tracks.
- The southbound I-5 off-ramp to Marine Drive.
- The southbound I-5 mainline.
- The northbound I-5 mainline.
- The northbound I-5 on-ramp from Marine Drive.

What's changed with IBR?

The Modified LPA design for crossing North Portland Harbor includes six new bridges spanning the harbor. The CRC LPA would have included five bridges but proposed to reuse the existing highway bridge to accommodate northbound and southbound mainline I-5 traffic while adding four new bridges to carry the LRT tracks, local traffic, and ramps from I-5 to and from the Marine Drive interchange.

The passage of time, the age of the existing bridge, and the structural integrity of the existing bridge were key in the proposal to replace the I-5 mainline bridges rather than retrofit them. The current proposal to replace the North Portland Harbor I-5 highway bridge created an opportunity for the IBR Program to straighten the alignment of the Columbia River bridges, which reduces impacts.

[9] Levee closure structures are put in place at openings along the embankment/floodwall to provide flood protection during high water conditions.

- An arterial bridge between the Portland mainland and Hayden Island for local traffic; this bridge would also include a shared-use path for pedestrians and bicyclists.

Each of the six replacement North Portland Harbor bridges would be supported on foundations constructed of 10-foot-diameter drilled shafts. Concrete columns would rise from the drilled shafts and connect to the superstructures of the bridges. All new structures would have at least as much vertical navigation clearance over North Portland Harbor as the existing North Portland Harbor bridge.

Compared to the existing bridge, the two new I-5 mainline bridges would have a similar vertical clearance of approximately 7 feet above the proposed height of the improved levees (elevation 38 feet NAVD 88). The two ramp bridges and the arterial bridge would have approximately 15 feet of vertical clearance above the proposed height of the levees. The foundation locations for the five roadway bridges have not been determined at this stage of design, but some foundations could be constructed through landward or riverward levee slopes.

Hayden Island Interchange Area

All traffic movements for the Hayden Island interchange would be reconfigured. See Figure 2-8 for a layout and construction footprint of the Hayden Island interchange. A half-diamond interchange would be built on Hayden Island with a northbound I-5 on-ramp from Jantzen Drive and a southbound I-5 off-ramp to Jantzen Drive. This would lengthen the ramps and improve merging/diverging speeds compared to the existing substandard ramps that require acceleration and deceleration in a short distance. The I-5 mainline would be partially elevated and partially located on fill across the island.

There would not be a southbound I-5 on-ramp or northbound I-5 off-ramp on Hayden Island. Connections to Hayden Island for those movements would be via the local access (i.e., arterial) bridge connecting North Portland to Hayden Island (Figure 2-10). Vehicles traveling northbound on I-5 wanting to access Hayden Island would exit with traffic going to the Marine Drive interchange, cross under Martin Luther King Jr. Boulevard to the new roundabout at the Expo Road local street extension, travel east through this roundabout to the easternmost roundabout, and use the arterial bridge to cross North Portland Harbor. Vehicles on Hayden Island looking to enter I-5 southbound would use the arterial bridge to cross North Portland Harbor, cross under I-5 using the new Expo Road local street extension to the westernmost roundabout, cross under Marine Drive, merge with the Marine Drive southbound on-ramp, and merge with I-5 southbound south of Victory Boulevard.

What's changed with IBR?

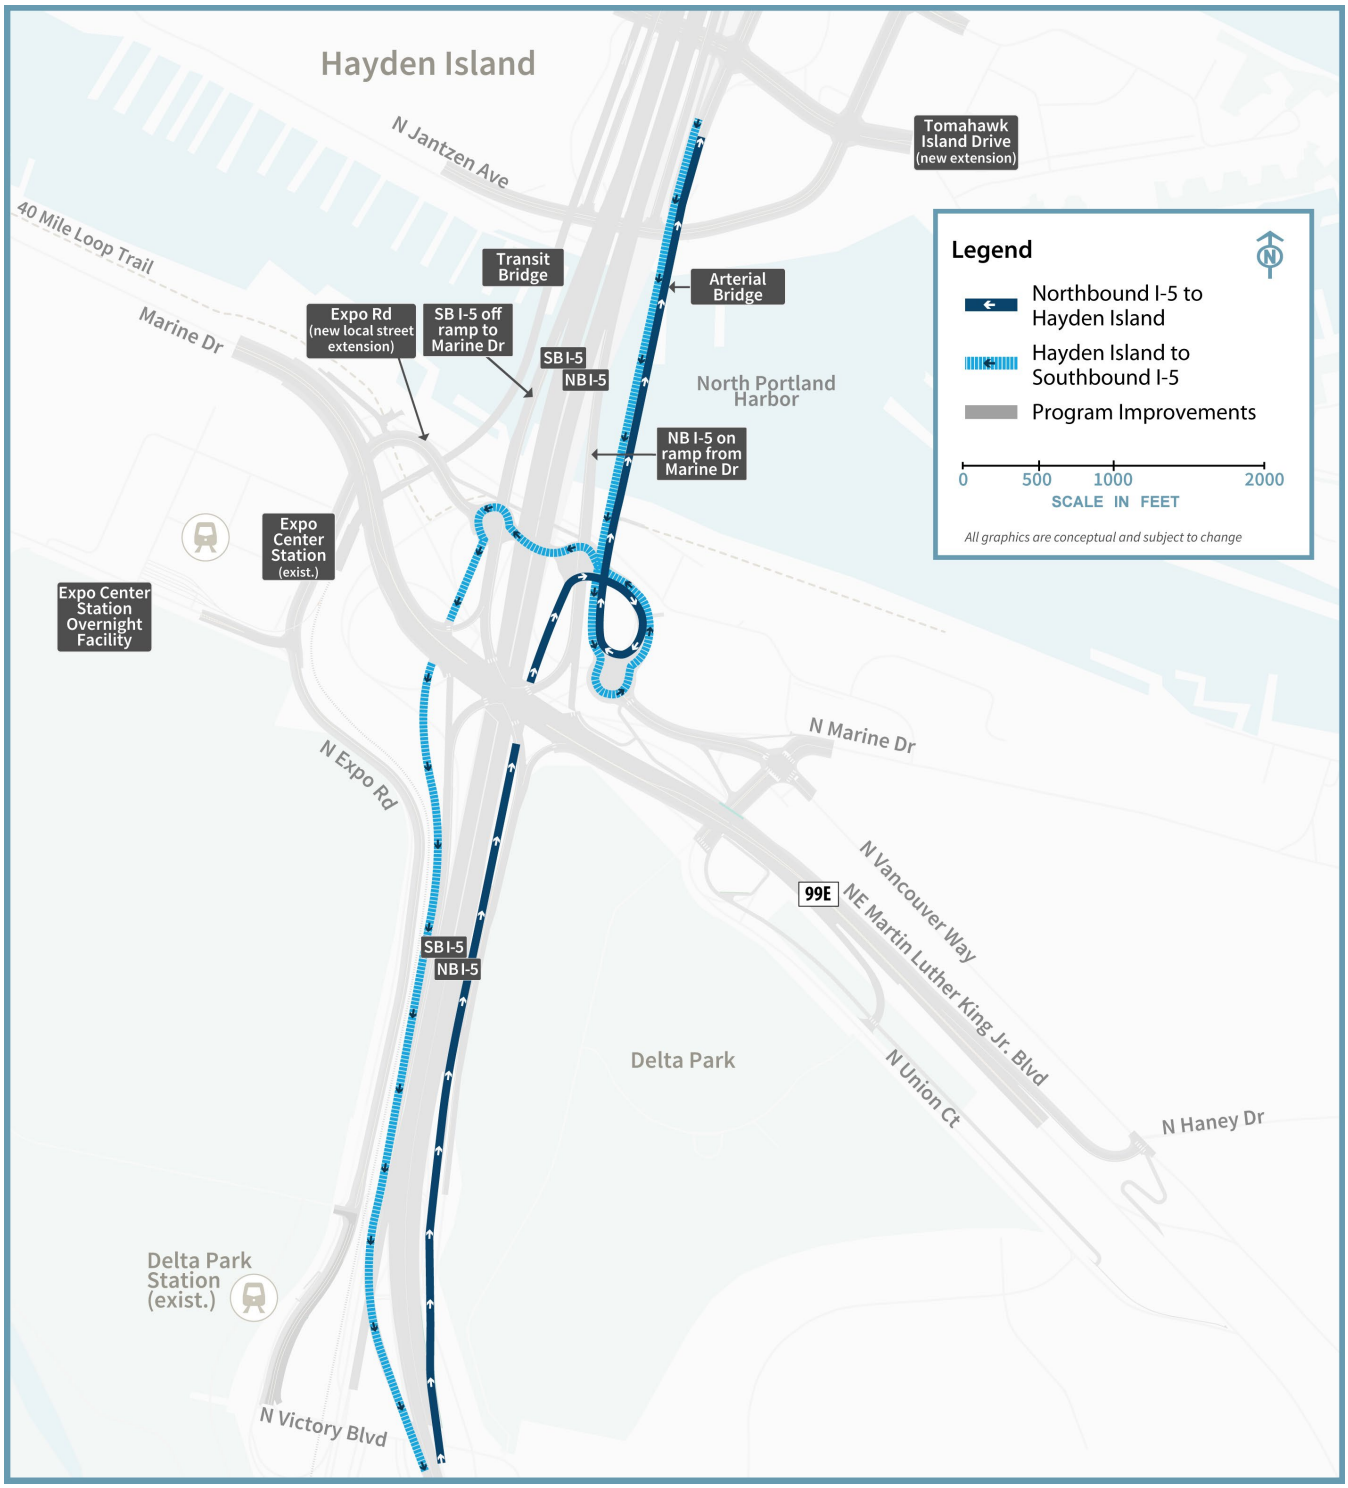
In response to local agency policies and community priorities, the IBR Program identified design modifications that could reduce the footprint (and associated impacts) on Hayden Island. Section 2.5.3, IBR Design Option Development and Screening, describes the screening process used to select design modifications. The Modified LPA includes a half-diamond interchange on Hayden Island, with an off-ramp from southbound I-5 and an on-ramp to northbound I-5 instead of the CRC LPA's proposed full interchange in a split tight-diamond configuration with access to and from both directions of I-5. With the Modified LPA, vehicles traveling between Hayden Island and the Portland mainland would use the new arterial bridge across North Portland Harbor.

Because of the modification to the Hayden Island interchange, local roadways on Hayden Island would also be configured somewhat differently in the Modified LPA than in the CRC LPA.

Improvements to Jantzen Avenue may include additional left-turn and right-turn lanes at the interchange ramp terminals and active transportation facilities. Improvements to Hayden Island Drive would include new connections to the new arterial bridge over North Portland Harbor. The existing I-5 northbound and southbound access points from Hayden Island Drive would also be removed. A new extension of Tomahawk

Island Drive would travel east-west through the middle of Hayden Island and under the I-5 interchange, thus improving connectivity across I-5 on the island.

Figure 2-10. Vehicle Circulation between Hayden Island and the Portland Mainland



NB = northbound; SB = southbound

Transit

A new light-rail alignment for northbound and southbound trains would be constructed within Subarea A (see Figure 2-8) to extend from the existing Expo Center MAX Station over North Portland Harbor to a new station at Hayden Island. An overnight LRV facility would be constructed on the southeast corner of the Expo Center property (see Figure 2-8) to provide storage for trains during hours when MAX is not in service. This facility is described in Section 2.2.6, Transit Support Facilities. The existing Expo Center MAX Station would be modified to remove the westernmost track and platform. Other platform modifications, including track realignment and regrading the station, are anticipated to transition to the extension alignment. This may require reconstruction of the operator break facility, signal/communication buildings, and traction power substations. Immediately north of the Expo Center MAX Station, the alignment would curve east toward I-5, pass beneath Marine Drive, cross the proposed Expo Road local street extension and the 40-Mile Loop Trail at grade, then rise over the existing levee onto a light-rail bridge to cross North Portland Harbor. On Hayden Island, proposed transit components include northbound and southbound LRT tracks over Hayden Island; the tracks would be elevated at approximately the height of the new I-5 mainline. An elevated LRT station would also be built on the island immediately west of I-5. The light-rail alignment would extend north on Hayden Island along the western edge of I-5 before transitioning onto the lower level of the new double-deck western bridge over the Columbia River (see Figure 2-8). For the single-level configurations, the light-rail alignment would extend to the outer edge of the western bridge over the Columbia River.

After crossing the new local road extension from Expo Road, the new light-rail track would cross over the main levee (see Figure 2-9). The light-rail profile is anticipated to be approximately 3 feet above the improved levees at the existing floodwall (and improved floodwall), and the tracks would be constructed on fill supported by retaining walls above the floodwall. North of the floodwall, the light-rail tracks would continue onto the new light-rail bridge over North Portland Harbor (as described above).

The Modified LPA's light-rail extension would be close to or would cross the north end of the Cross Levee. The IBR Program would realign the Cross Levee to the east of the light-rail alignment to avoid the need for a closure structure on the light-rail alignment. This realigned Cross Levee would cross the new local road extension. A closure structure may be required because the current proposed roadway is a few feet lower than the proposed elevation of the improved levee.

Active Transportation

In the Victory Boulevard interchange area (see Figure 2-8), active transportation facilities would be provided along Expo Road between Victory Boulevard and the Expo Center; this would provide a direct connection between the Victory Boulevard and Marine Drive interchange areas, as well as links to the Delta Park and Expo Center MAX Stations.

What's changed with IBR?

The Modified LPA would modify the alignment of the CRC LPA shared-use path to connect to other planned active transportation projects in the area (e.g., the 40-Mile Loop Trail, the two-way cycle track on Fourth Plain).

New shared-use path connections throughout the Marine Drive interchange area would provide access between the Bridgeton neighborhood (on the east side of I-5), Hayden Island, and the Expo Center MAX Station. There would also be connections to the existing portions of the 40-Mile Loop Trail, which runs north of Marine Drive under I-5 through the interchange area. The path would continue along the extension of Expo Road under the interchange to the intersection of Marine Drive and Vancouver Way, where it would connect under Martin Luther King Jr. Boulevard to Delta Park.

East of the Marine Drive interchange, new shared-use paths on Martin Luther King Jr. Boulevard and on the parallel street, Union Court, would connect travelers to Marine Drive and across the arterial bridge to Hayden

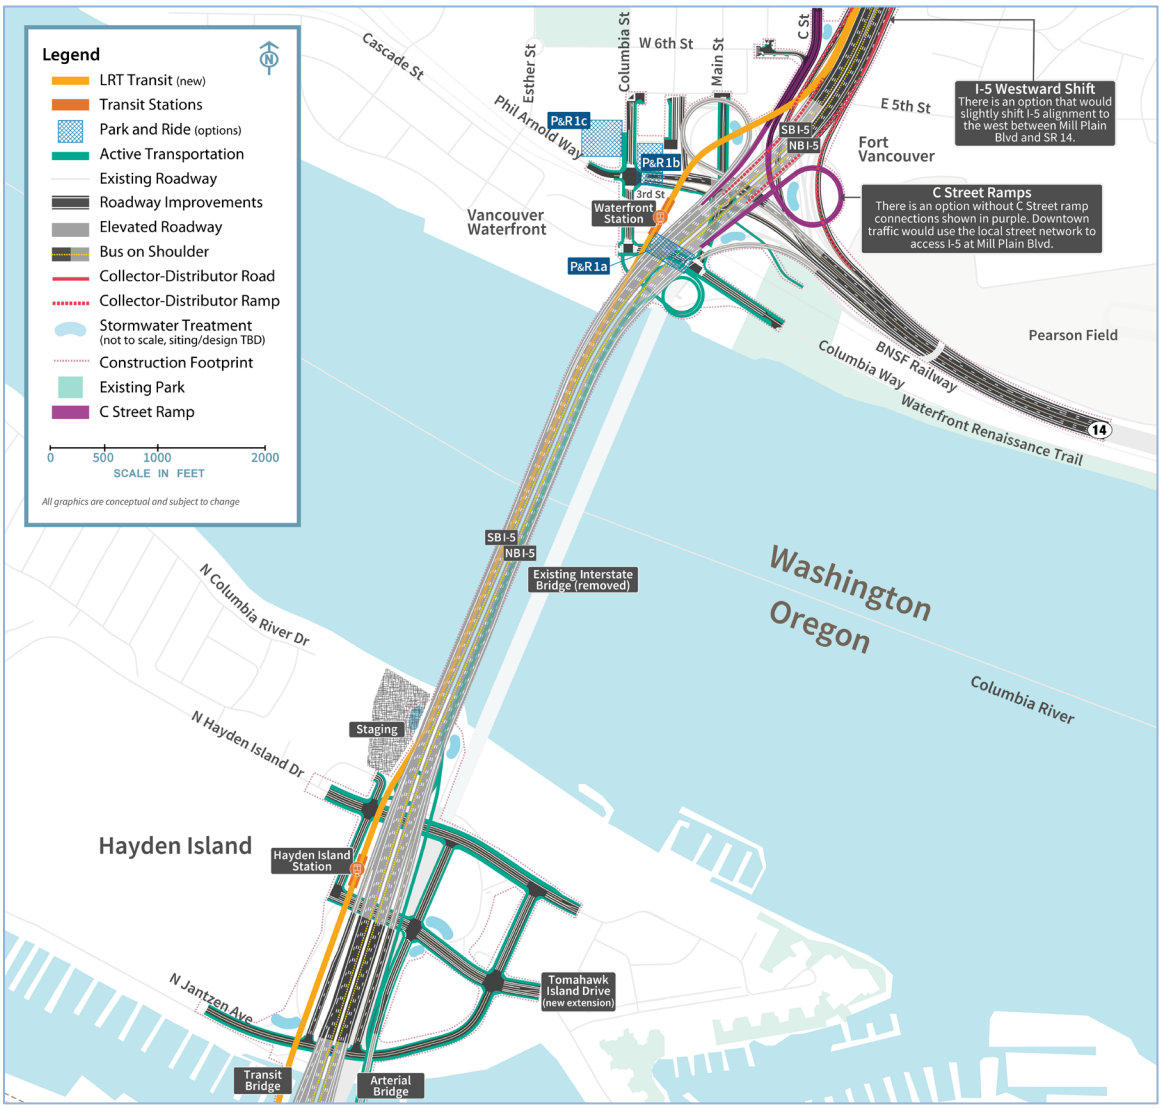
Island. The shared-use facilities on Martin Luther King Jr. Boulevard would provide westbound and eastbound cyclists and pedestrians with off-street crossings of the interchange and would also provide connections to both the Expo Center MAX Station and the 40-Mile Loop Trail to the west.

The new arterial bridge over North Portland Harbor would include a shared-use path for pedestrians and bicyclists (see Figure 2-8). On Hayden Island, pedestrian and bicycle facilities would be provided on Jantzen Avenue, Hayden Island Drive, and Tomahawk Island Drive. The shared-use path on the arterial bridge would continue along the arterial bridge to the south side of Tomahawk Island Drive. A parallel, elevated path from the arterial bridge would continue adjacent to I-5 across Hayden Island and cross above Tomahawk Island Drive and Hayden Island Drive to connect to the lower level of the new double-deck eastern bridge or the outer edge of the new single-level eastern bridge over the Columbia River. A ramp down to the north side of Hayden Island Drive would be provided from the elevated path.

2.2.3 Columbia River Bridges (Subarea B)

This section discusses the geographic Subarea B shown in Figure 2-3. See Figure 2-11 for highway and interchange improvements in Subarea B. Refer to Figure 2-3 for an overview of the geographic subareas.

Figure 2-11. Columbia River Bridges (Subarea B)



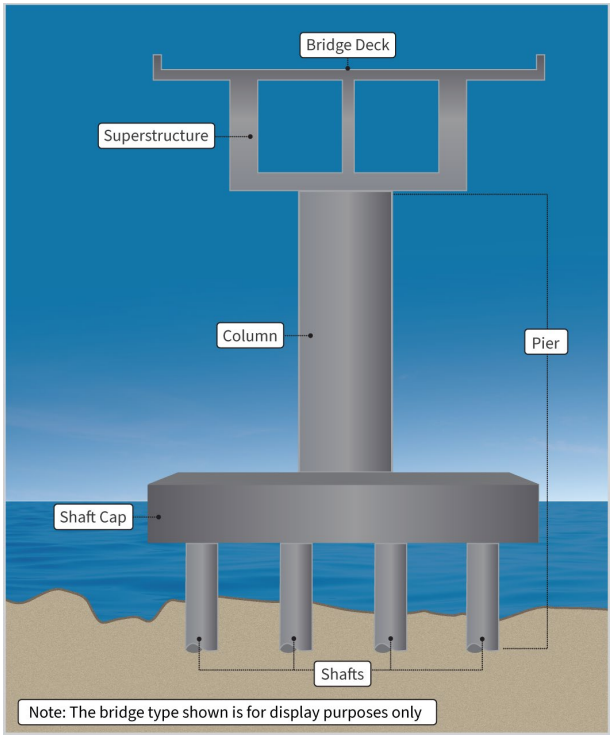
Highways, Interchanges, and Local Roadways

The two existing parallel I-5 bridges that cross the Columbia River would be replaced by two new parallel bridges, located west of the existing bridges (see Figure 2-11). The new eastern bridge would accommodate northbound highway traffic and a shared-use path. The new western bridge would carry southbound traffic and two-way light-rail tracks. Whereas the existing bridges each have three lanes with no shoulders, each of the two new bridges would be wide enough to accommodate three through lanes, one or two auxiliary lanes, and shoulders on both sides of the highway. Lanes and shoulders would be built to full design standards.

As with the existing bridge (Figure 2-13), the new Columbia River bridges would provide three navigation channels: a primary navigation channel and two barge channels (see Figure 2-14). The current location of the primary navigation channel is near the Vancouver shoreline where the existing lift spans are located. Under the Modified LPA, the primary navigation channel would be shifted south approximately 500 feet (measured by channel centerlines), and the existing center barge channel would shift north and become the north barge channel. The new primary navigation channel would be 400 feet wide (this width includes a 300-foot congressionally or USACE-authorized channel plus a 50-foot channel maintenance buffer on each side of the authorized channel) and the two barge channels would also each be 400 feet wide.

The existing Interstate Bridge has nine in-water pier sets,[10] whereas the new Columbia River bridges (any bridge configuration) would be built on six in-water pier sets, plus multiple piers on land (pier locations are shown on Figure 2-14). Each in-water pier set would be supported by a foundation of drilled shafts; each group of shafts would be tied together with a concrete shaft cap. Columns or pier walls would rise from the shaft caps and connect to the superstructures of the bridges (see Figure 2-12).

Figure 2-12. Bridge Foundation Concept



Bridge Configurations

Three bridge configurations are being considered: (1) double-deck fixed-span (with one bridge type), (2) a single-level fixed-span (with three potential bridge types), and (3) a single-level movable-span (with one bridge type). Both the double-deck and single-level fixed-span configurations would provide 116 feet of vertical navigation clearance at their respective highest spans; the same as the CRC LPA. The CRC LPA included a double-deck fixed-span bridge configuration. The single-level fixed-span configuration was developed and is being considered as part of the IBR Program in response to physical and contextual changes (i.e., design and operational considerations) since 2013 that necessitated examination of a refinement in the double-deck bridge configuration (e.g., ingress and egress of transit from the lower level of the double-deck fixed-span configuration on the north end of the southbound bridge).

[10] A pier set consists of the pier supporting the northbound bridge and the pier supporting the southbound bridge at a given location.

Consideration of the single-level movable-span configuration as part the IBR Program was necessitated by the U.S. Coast Guard's (USCG) review of the Program's navigation impacts on the Columbia River and issuance of a Preliminary Navigation Clearance Determination (PNCD) (USCG 2022). The USCG PNCD set the preliminary vertical navigation clearance recommended for the issuance of a bridge permit at 178 feet; this is the current vertical navigation clearance of the Interstate Bridge.

What's changed with IBR?

The CRC LPA included a double-deck fixed-span bridge configuration. The single-level fixed-span configuration was developed for the Modified LPA in response to physical and contextual changes (i.e., design and operational considerations) that necessitated examination of LRT ingress and egress of transit from the lower level of the double-deck fixed-span configuration on the north end of the southbound bridge.

The single-level movable-span configuration was developed to provide up to 178 feet VNC as recommended by the USCG in the Preliminary Navigation Clearance Determination (USCG 2022).

The IBR Program is carrying forward the three bridge configurations to address changed conditions, including changes in the USCG bridge permitting process, in order to ensure a permittable bridge configuration is within the range of options considered in the SEIS. The IBR Program continues to refine the details supporting navigation impacts and is coordinating closely with the USCG to determine how a fixed-span bridge may be permittable. Although the fixed-span configurations do not comply with the current USCG PNCD, they do meet the Purpose and Need and provide potential improvements to traffic (passenger vehicle and freight), transit, and active transportation operations. Additional discussion on pending actions to obtain authorizations from USCG and USACE for the Columbia River bridges' vertical and horizontal clearances and primary navigation channel location, including discussion with river users potentially affected by the fixed-span bridges, are described in Section 2.6, Additional Compliance Underway.

Each of the bridge configurations assumes one auxiliary lane; two auxiliary lanes could be applied to any of the bridge configurations. All typical sections for the one auxiliary lane option would provide 14-foot shoulders to maintain traffic during construction of the Modified LPA and future maintenance.

Figure 2-13. Existing Navigation Clearances of the Interstate Bridge

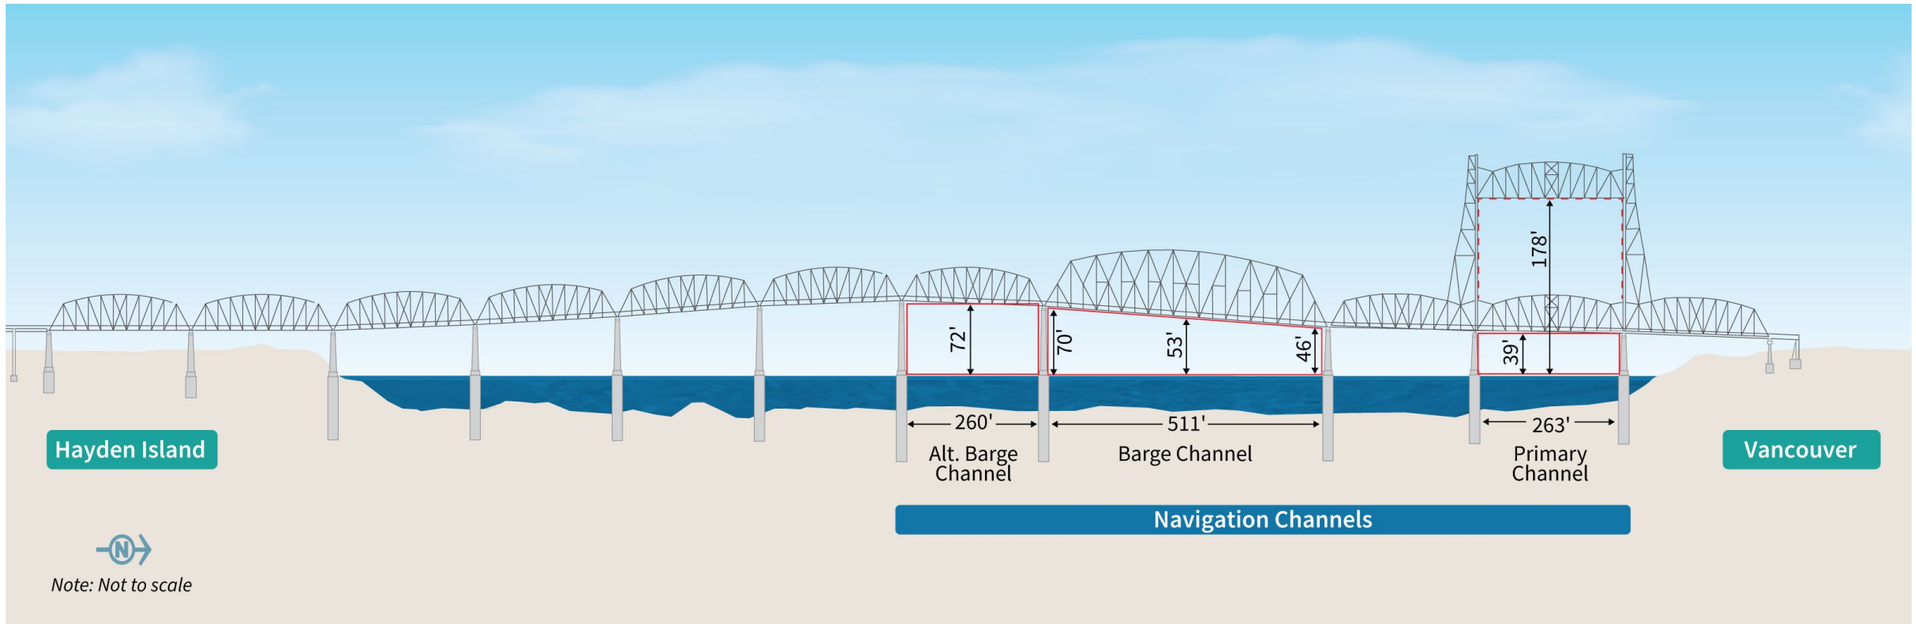


Figure 2-14. Profile and Navigation Clearances of the Proposed Modified LPA Columbia River Bridges with a Double-Deck Fixed-Span Configuration

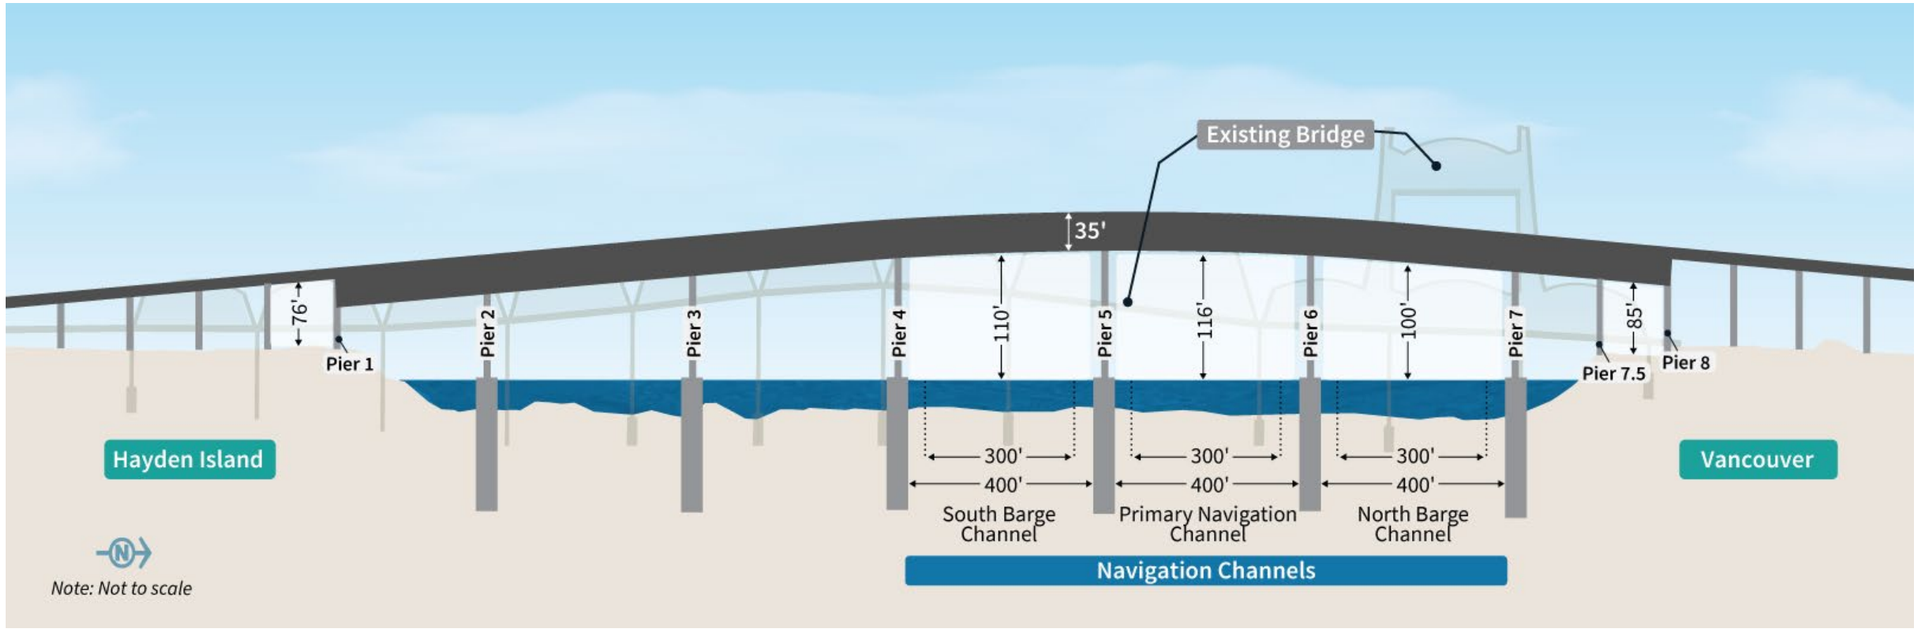


Note: The location and widths of the proposed navigation channels would be same for all bridge configuration and bridge type options. The three navigation channels would each be 400 feet wide (this width includes a 300-foot congressionally or USACE-authorized channel (shown in dotted lines) plus a 50-foot channel maintenance buffer on each side of the authorized channel). The vertical navigation clearance would vary.

Double-Deck Fixed-Span Configuration

The double-deck fixed-span configuration would be two side-by-side, double-deck, fixed-span steel truss bridges. Figure 2-15 is an example of this configuration (this image is subject to change and is shown as a representative concept; it does not depict the final design). The double-deck fixed-span configuration would provide 116 feet of vertical navigation clearance for river traffic using the primary navigation channel and 400 feet of horizontal navigation clearance at the primary navigation channel, as well as barge channels. This bridge height would not impede takeoffs and landings by aircraft using Pearson Field or Portland International Airport.

The eastern bridge would accommodate northbound highway traffic on the upper level and the shared-use path and utilities on the lower level. The western bridge would carry southbound traffic on the upper level and two-way light-rail tracks on the lower level. Each bridge deck would be 79 feet wide, with a total out-to-out width of 173 feet.[11]

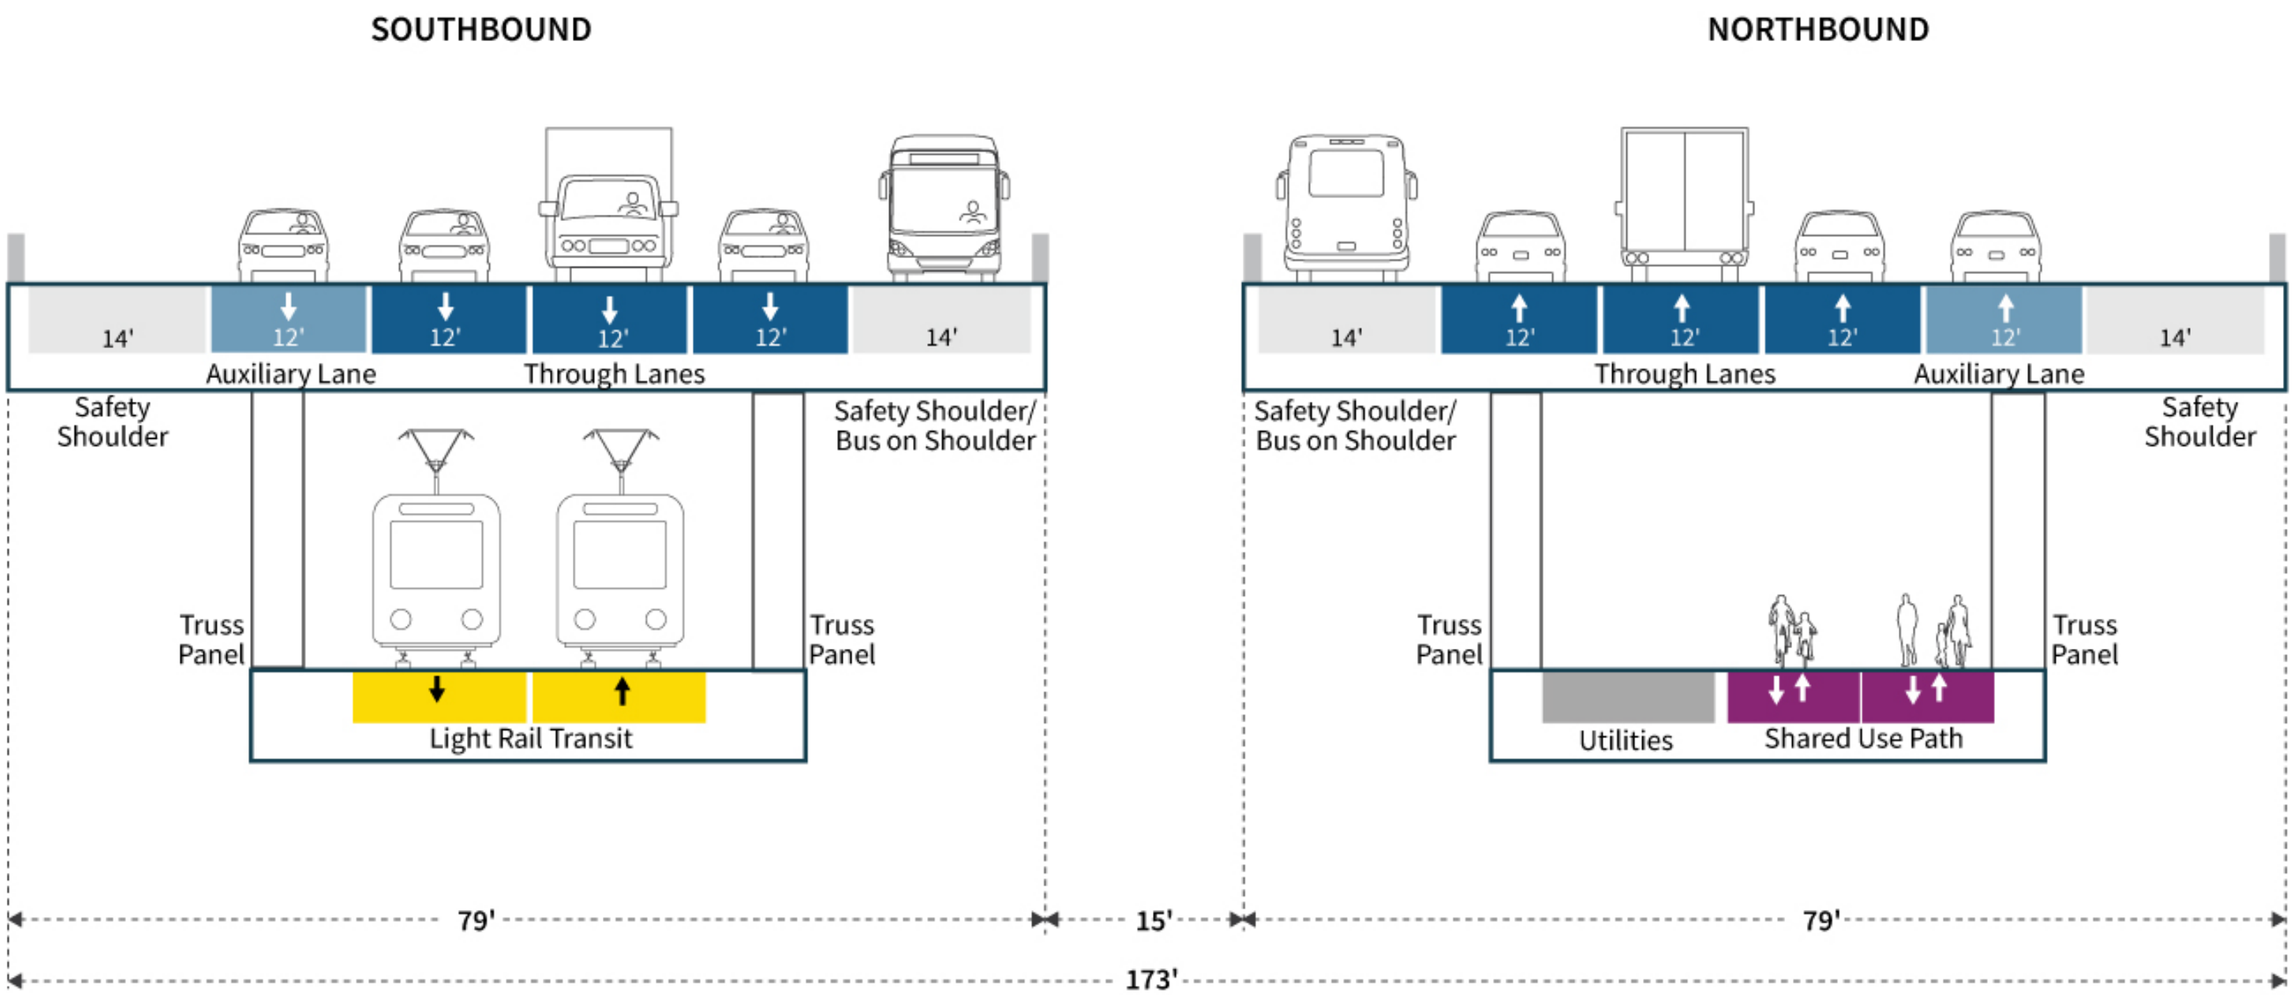
Figure 2-15. Conceptual Drawing of a Double-Deck Fixed-Span Configuration

Note: Visualization is looking southwest from Vancouver.

Figure 2-16 is a cross section of the two parallel double-deck bridges. Like all bridge configurations, the double-deck fixed-span configuration would have six in-water pier sets. Each pier set would require 12 in-water drilled shafts, for a total of 72 in-water drilled shafts. Each individual shaft cap would be approximately 50 feet by 85 feet. This bridge configuration would have a 3.8% maximum grade on the Oregon side of the bridge and a 4% maximum grade on the Washington side.

[11] "Out-to-out width" is the measurement between the outside edges of the bridge across its width at the widest point.

Figure 2-16. Cross Section of the Double-Deck Fixed-Span Configuration



Single-Level Fixed-Span Configuration

The single-level fixed-span configuration would have two side-by-side, single-level, fixed-span steel or concrete bridges. This SEIS considers three single-level fixed-span bridge type options: a girder bridge, an extradosed bridge, and a finback bridge. The description in this section applies to all three bridge types (unless otherwise indicated). Conceptual examples of each of these options are shown on Figure 2-17. These images are subject to change and do not represent final design.

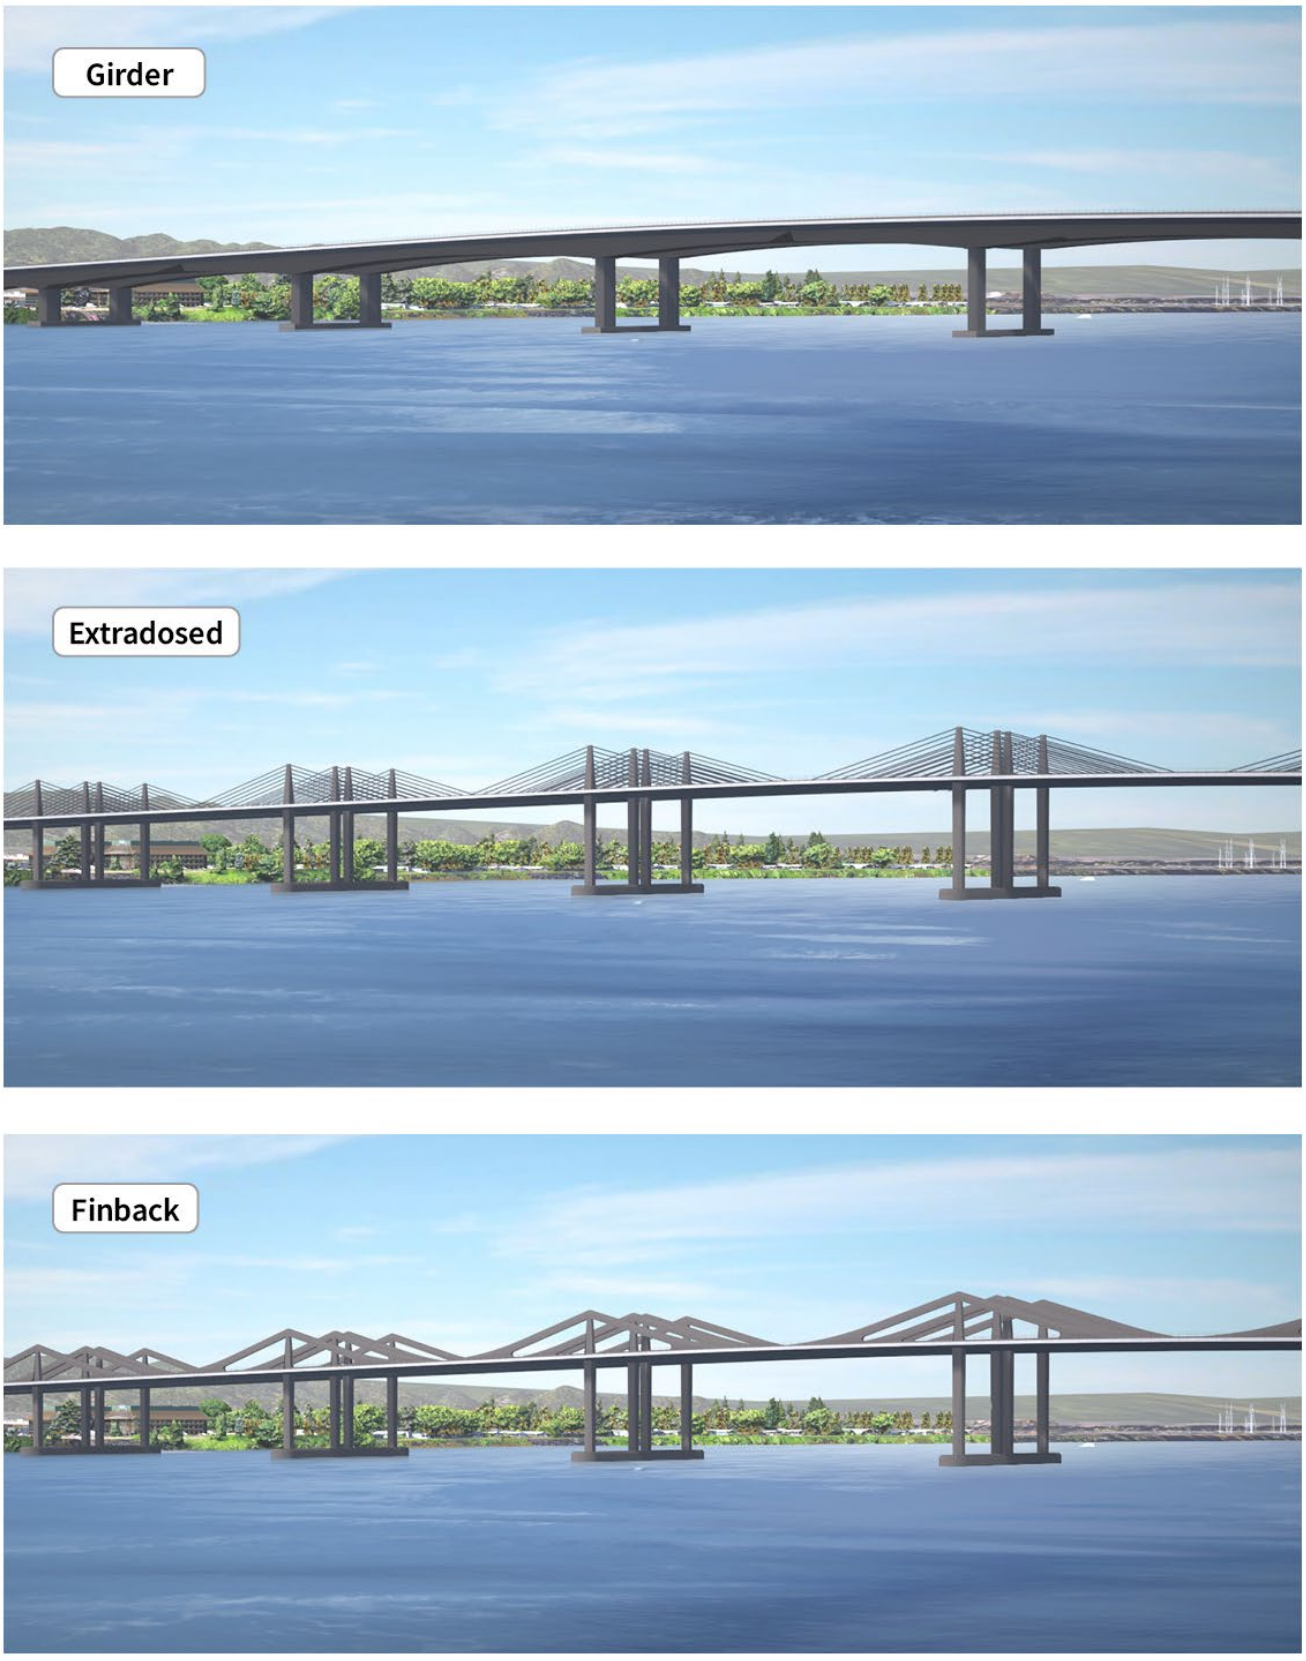
This configuration would provide 116 feet of vertical navigation clearance for river traffic using the primary navigation channel and 400 feet of horizontal navigation clearance at the primary navigation channel, as well as barge channels. This bridge height would not impede takeoffs and landings by aircraft using Pearson Field or Portland International Airport.

The eastern bridge would accommodate northbound highway traffic and the shared-use path; the bridge deck would be 104 feet wide. The western bridge would carry southbound traffic and two-way light-rail tracks; the bridge deck would be 113 feet wide. The I-5 highway, light-rail tracks, and the shared-use path would be on the same level across the two bridges, instead of being divided between two levels with the double-deck configuration. The total out-to-out width of the single-level fixed-span configuration (extradosed or finback options) would be 272 feet at its widest point, approximately 99 feet wider than the double-deck configuration. The total out-to-out width of the single-level fixed-span configuration (girder option) would be 232 feet at its widest point. Figure 2-18 shows a typical cross section of the single-level configuration. This cross section is a representative example of an extradosed or finback bridge as shown by the 10-foot-wide superstructure above the bridge deck; the girder bridge would not have the 10-foot-wide bridge columns shown on Figure 2-18.

There would be six in-water pier sets with 16 in-water drilled shafts on each combined shaft cap, for a total of 96 in-water drilled shafts. The combined shaft caps for each pier set would be 50 feet by 230 feet.

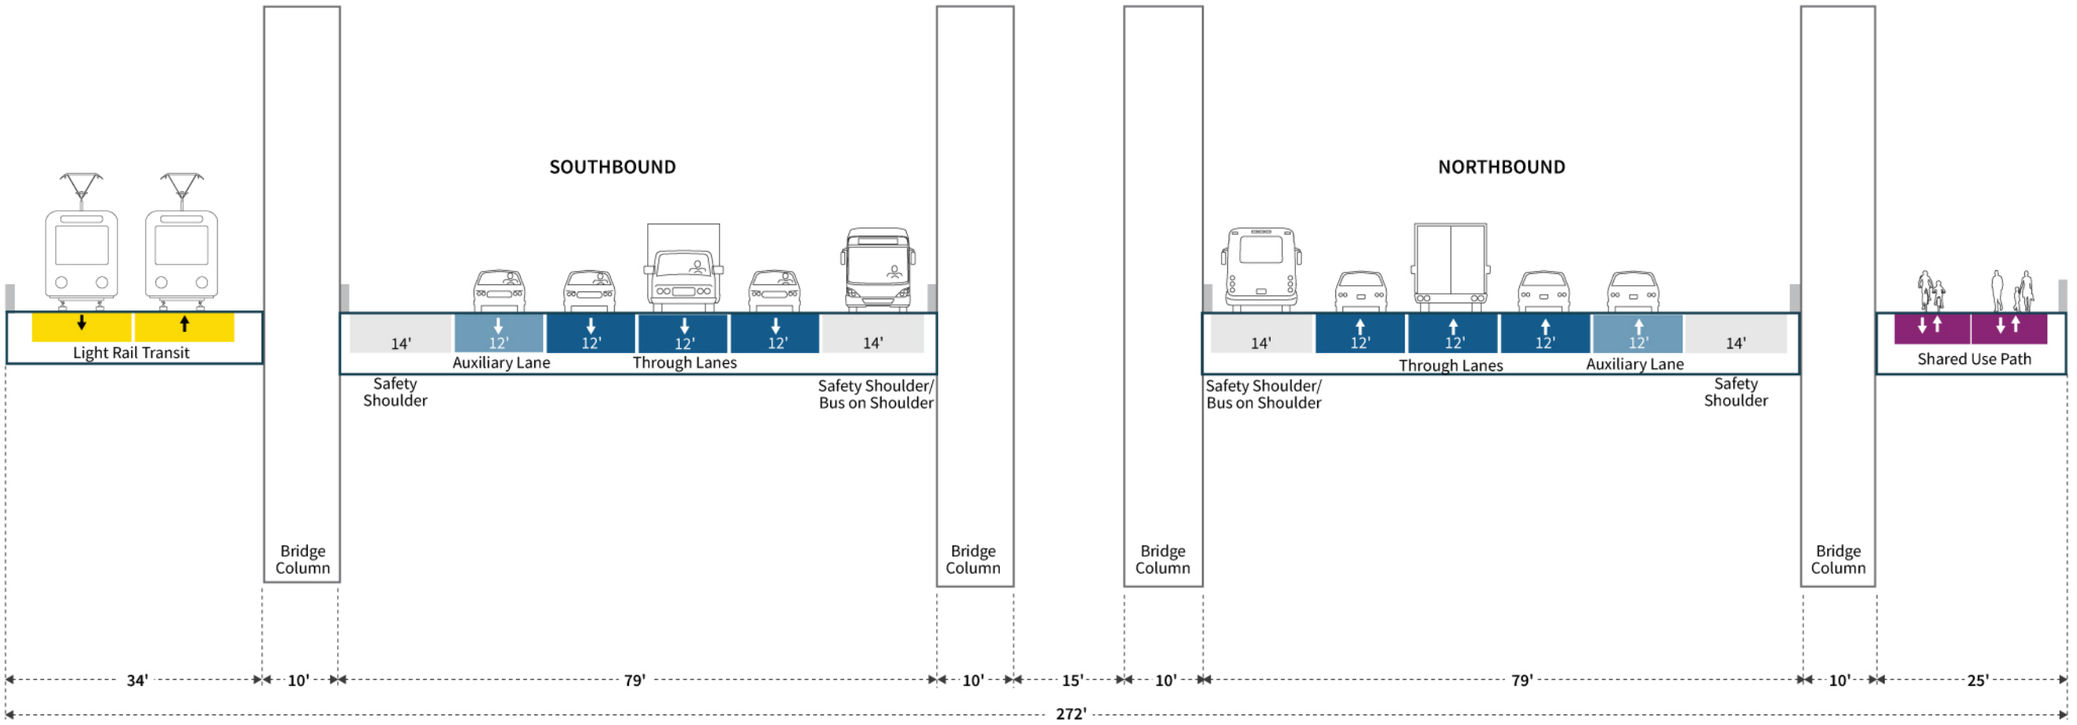
This bridge configuration would have a 3% maximum grade on both the Oregon and Washington sides of the bridge.

Figure 2-17. Conceptual Drawings of Single-Level Fixed-Span Bridge Types



Note: Visualizations are for illustrative purposes only. They do not reflect property impacts or represent final design. Visualization is looking southwest from Vancouver.

Figure 2-18. Cross Section of the Single-Level Fixed-Span Configuration (Extradosed or Finback Bridge Types)



Note: The cross section for a girder type bridge would be the same except that it would not have the four 10-foot bridge columns making the total out-to-out width 232 feet.

Single-Level Movable-Span Configuration

The single-level movable-span configuration would have two side-by-side, single-level steel girder bridges with movable spans between Piers 5 and 6. For the purpose of this Draft SEIS, the IBR Program assessed a vertical lift movable-span configuration with counterweights based on the analysis in the *River Crossing Bridge Clearance Assessment Report – Movable-Span Options,* included as part of Attachment C in Appendix D, Design Options Development, Screening, and Evaluation Technical Report. A conceptual example of a vertical lift-span bridge is shown in Figure 2-19. These images are subject to change and do not represent final design.

A movable span must be located on a straight and flat bridge section (i.e., without curvature and with minimal slope). To comply with these requirements, and for the bridge to maintain the highway, transit, and active transportation connections on Hayden Island and in Vancouver while minimizing property acquisitions and displacements, the movable span is proposed to be located 500 feet south of the existing lift span, between Piers 5 and 6. To accommodate this location of the movable span, the IBR Program is coordinating with USACE to obtain authorization to change the location of the primary navigation channel, which currently aligns with the Interstate Bridge lift spans near the Washington shoreline.

The single-level movable-span configuration would provide 92 feet of vertical navigation clearance over the proposed relocated primary navigation channel when the movable spans are in the closed position, with 99 feet of vertical navigation clearance available over the north barge channel. The 92-foot vertical clearance is based on achieving a straight, movable span and maintaining an acceptable grade for transit operations. In addition, it satisfies the requirement of a minimum of 72 feet of vertical navigation clearance (the existing Interstate Bridge's maximum clearance over the alternate (southernmost) barge channel when the existing lift span is in the closed position).

In the open position, the movable span would provide 178 feet of vertical navigation clearance over the proposed relocated primary navigation channel.

Similar to the fixed-span configurations, the movable span would provide 400 feet of horizontal navigation clearance for the primary navigation channel and for each of the two barge channels.

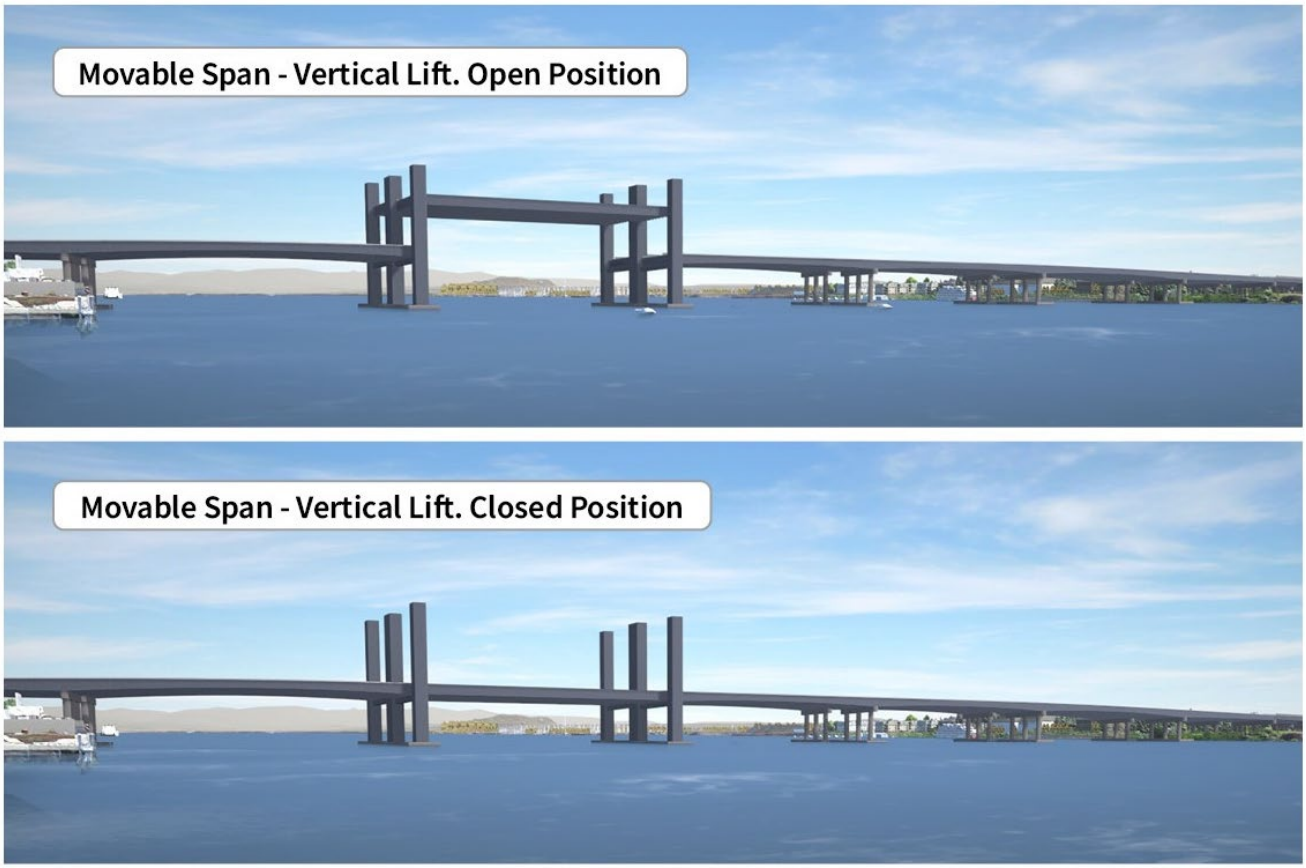
The vertical lift-span towers would be approximately 243 feet high; this is shorter than the existing lift-span towers, which are 247 feet high. This height of the vertical lift-span towers would not impede takeoffs and landings by aircraft using Portland International Airport. At Pearson Field, the Federal Aviation Administration issues obstacle departure procedures to avoid the existing Interstate Bridge lift towers; the single-level movable-span configuration would retain the same procedures.

Similar to the single-level fixed-span configuration, the eastern bridge would accommodate northbound highway traffic and the shared-use path, and the western bridge would carry southbound traffic and two-way light-rail tracks. The I-5 highway, light-rail tracks, and shared-use path would be on the same level across the bridges instead of on two levels as with the double-deck configuration. Cross sections of the single-level movable-span configuration are shown in Figure 2-20; the top cross section depicts the vertical lift spans (Piers 5 and 6), and the bottom cross section depicts the fixed spans (Piers 2, 3, 4, and 7). The movable and fixed cross sections are slightly different because the movable span requires lift towers, which are not required for the other fixed spans of the bridges.

There would be six in-water pier sets and two piers on land per bridge. The vertical lift span would have 22 in-water drilled shafts each for Piers 5 and 6; the shaft caps for these piers would be 50 feet by 312 feet to accommodate the vertical lift spans. Piers 2, 3, 4, and 7 would have 16 in-water drilled shafts each; the shaft caps for these piers would be the same as for the fixed-span options (50 feet by 230 feet). The vertical lift-span configuration would have a total of 108 in-water drilled shafts.

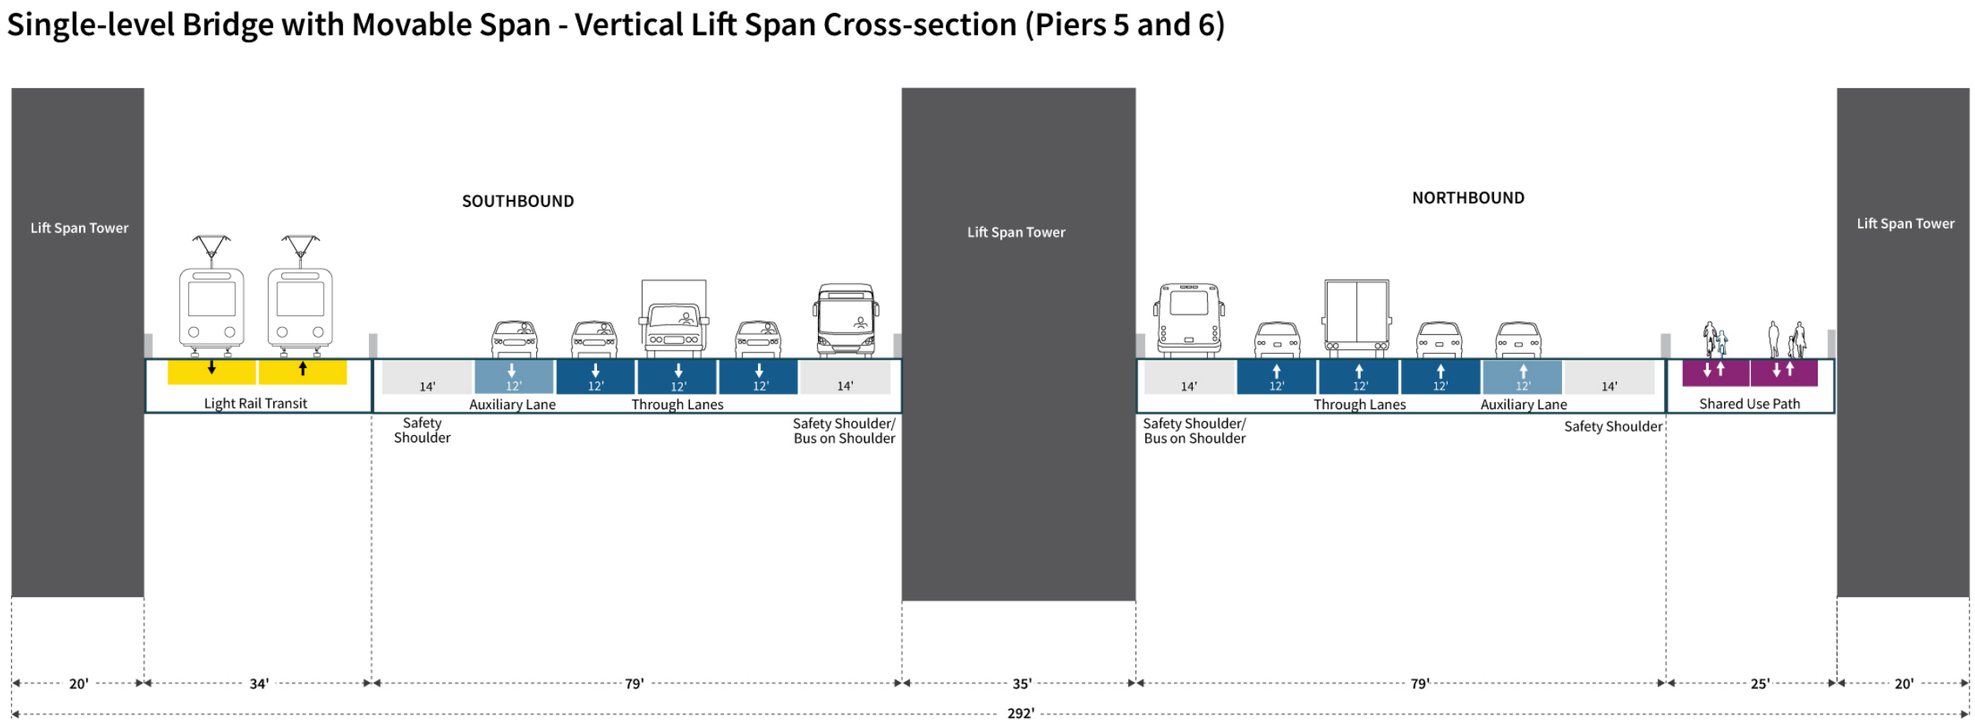
This single-level movable-span configuration would have a 3% maximum grade on the Oregon side of the bridge and a 1.5% maximum grade on the Washington side.

Figure 2-19. Conceptual Drawings of Single-Level Movable-Span Configurations in the Closed and Open Positions

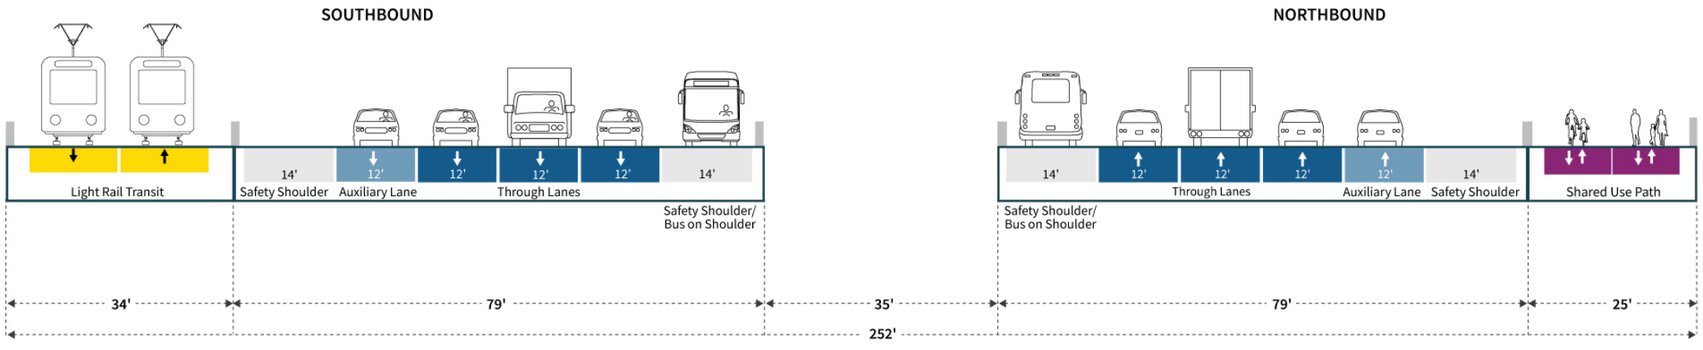


Note: Visualizations are for illustrative purposes only. They do not reflect property impacts or represent final design. Visualization is looking southeast (upstream) from Vancouver.

Figure 2-20. Cross Section of the Single-Level Movable-Span Bridge Type



Single-level Bridge with Movable Span - Fixed Spans Cross-section (Piers 2, 3, 4, and 7)



Summary of Bridge Configurations

This section summarizes and compares each of the bridge configurations. Table 2-3 lists the key considerations for each configuration. Figure 2-21 compares each configuration's footprint. The footprints of each configuration would differ in only three locations: over the Columbia River and at the bridge landings on Hayden Island and Vancouver. The rest of the I-5 corridor would have the same footprint. Over the Columbia River, the footprint of the double-deck fixed-span configuration would be 173 feet wide. Comparatively, the finback or extradosed bridge types of the single-level fixed-span configuration would be 272 feet wide (approximately 99 feet wider), and the single-level fixed-span configuration with a girder bridge type would be 232 feet wide (approximately 59 feet wider). The single-level movable-span configuration would be 252 feet wide (approximately 79 feet wider than the double-deck fixed-span configuration), except at Piers 5 and 6, where larger bridge foundations would require an additional 40 feet of width to support the movable span. The single-level configurations would have a wider footprint at the bridge landings on Hayden Island and Vancouver because transit and active transportation would be located adjacent to the highway, rather than below the highway in the double-deck option.

Figure 2-22 compares the basic profile of each configuration. The lower deck of the double-deck fixed-span and the single-level fixed-span configuration would have similar profiles. The single-level movable-span configuration would have a lower profile than the fixed-span configurations when the span is in the closed position.

Figure 2-21. Bridge Configuration Footprint Comparison

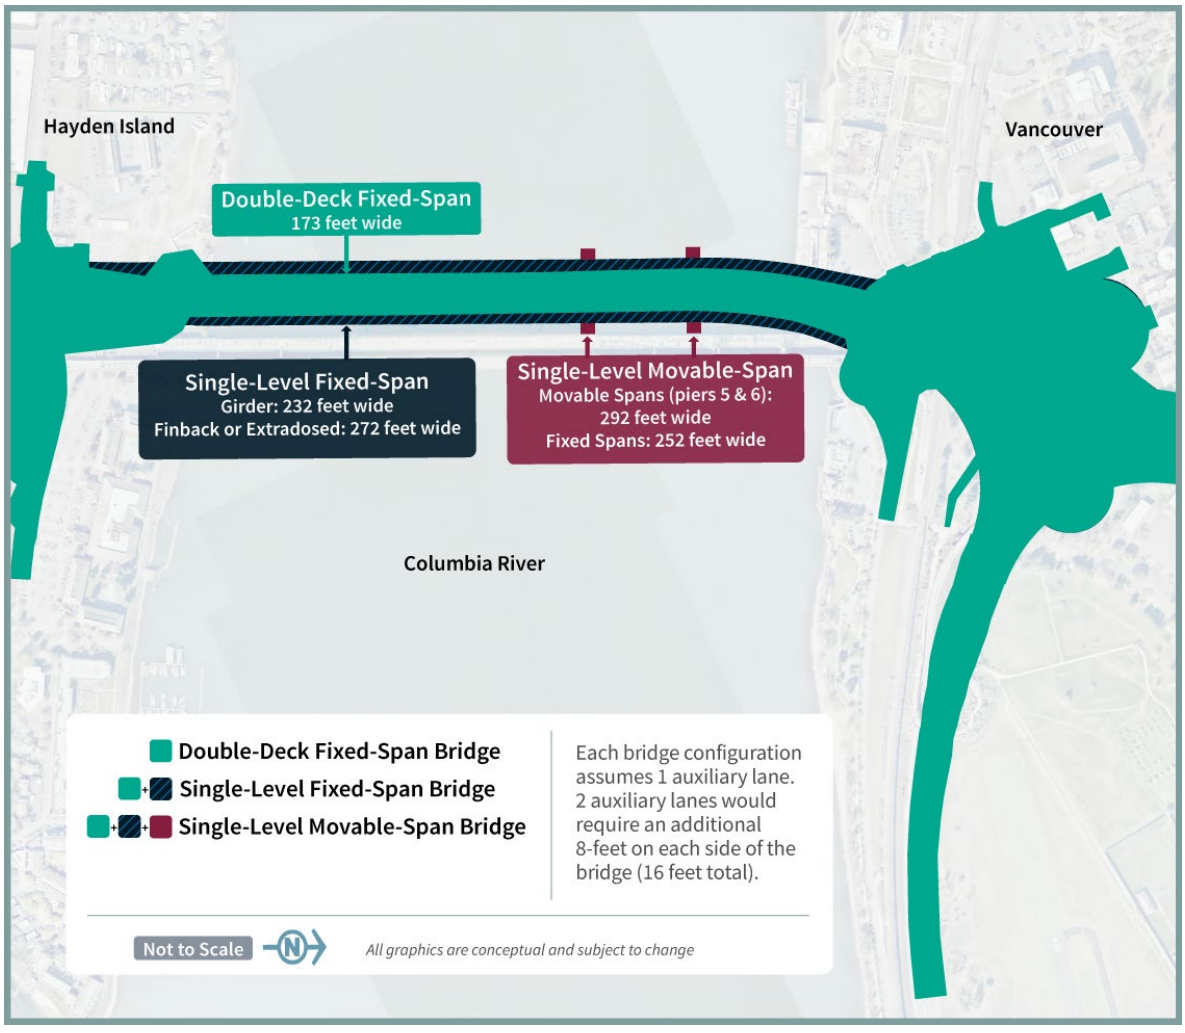


Figure 2-22. Bridge Configuration Profile Comparison

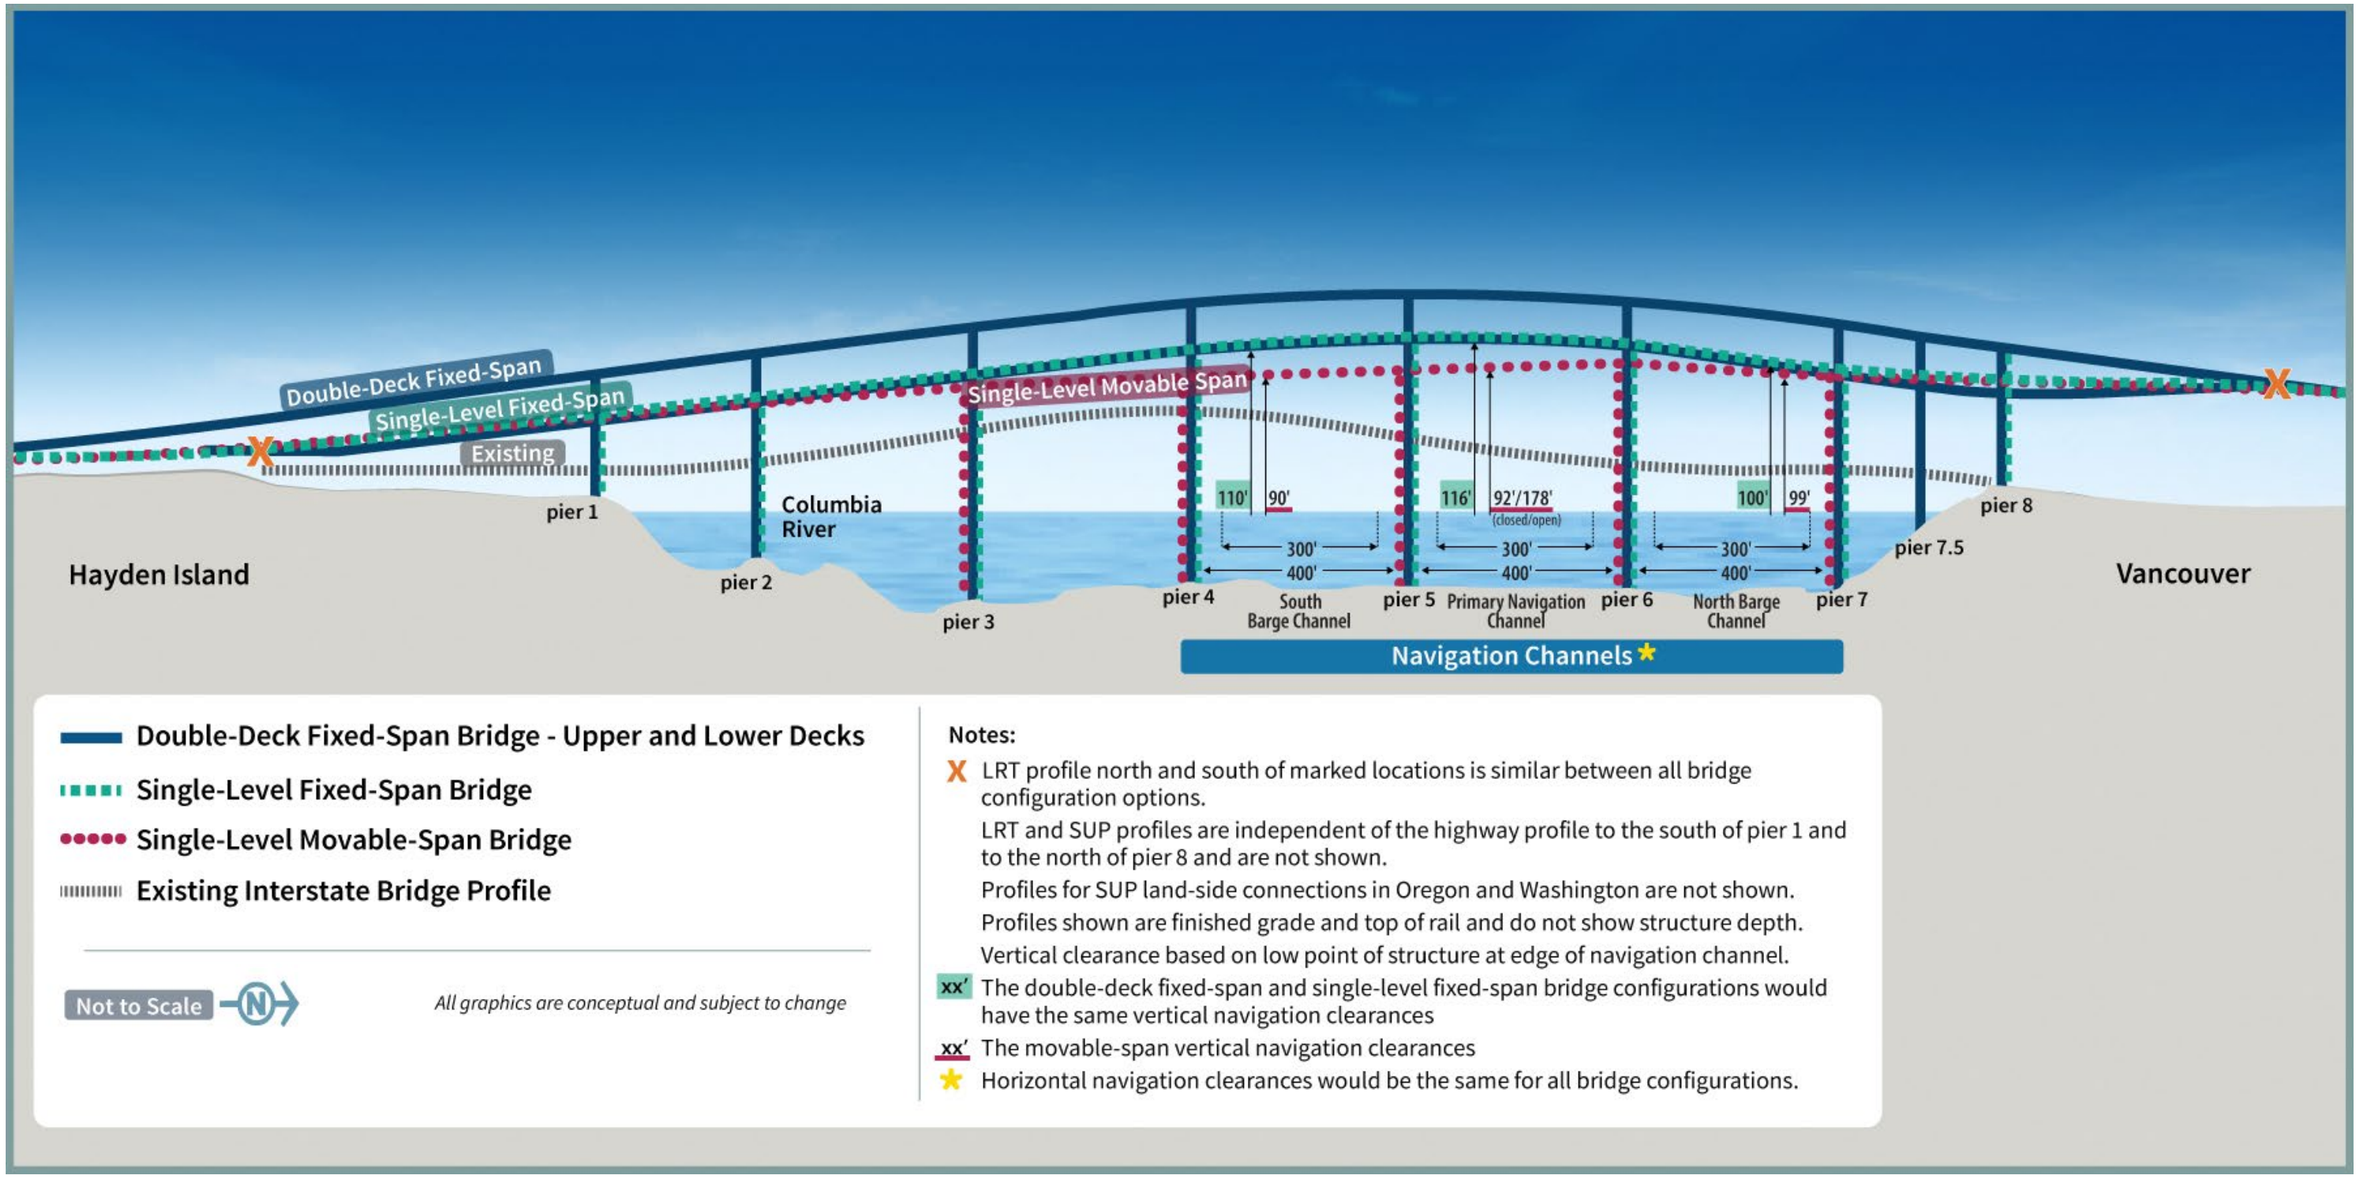


LRT = light-rail transit; SUP = shared-use path

Table 2-3. Summary of Bridge Configurations

	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration	Modified LPA with Single-Level Fixed-Span Configuration [a]	Modified LPA with Single-Level Movable-Span Configuration
Bridge type	Steel through-truss spans.	Double-deck steel truss.	Single-level, concrete or steel girders, extradosed or finback.	Single-level, steel girders with vertical lift span.
Number of bridges	Two	Two	Two	Two
Movable-span type	Vertical lift span with counterweights.	N/A	N/A	Vertical lift span with counterweights.
Movable-span location	Adjacent to Vancouver shoreline.	N/A	N/A	Between Piers 5 and 6 (approximately 500 feet south of the existing lift span).
Lift opening restrictions	Weekday peak AM and PM highway travel periods. [b]	N/A	N/A	Additional restrictions to daytime bridge openings; requires future federal rulemaking process and authorization by USCG (beyond the assumed No-Build Alternative bridge restrictions for peak AM and PM highway travel periods).[b] Typical opening durations are assumed to be 9 to 18 minutes [c] for the purposes of impact analysis but would ultimately depend on various operational considerations related to vessel traffic and river and weather conditions. Additional time would also be required to stop traffic prior to opening and restart traffic after the bridge closes.
Out-to-out width [d]	138 feet total width.	173 feet total width.	Girder: 232 feet total width. Extradosed/Finback: 272 feet total width.	• 292 feet at the movable span. • 252 feet at the fixed spans.

	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration	Modified LPA with Single-Level Fixed-Span Configuration [a]	Modified LPA with Single-Level Movable-Span Configuration
Deck widths	52 feet (SB) 52 feet (NB)	79 feet (SB) 79 feet (NB)	Girder: • 113 feet (SB) • 104 feet (NB) Extradosed/Finback: • 133 feet (SB) • 124 feet (NB)	113 feet SB fixed span. 104 feet NB fixed span.
Vertical navigation clearance	Primary navigation channel: • 39 feet when closed. • 178 feet when open. Barge channel: • 46 feet to 70 feet. Alternate barge channel: • 72 feet (maximum clearance without opening).	Primary navigation channel: • 116 feet maximum. North barge channel: • 100 feet maximum. South barge channel: • 110 feet maximum.	Primary navigation channel: • 116 feet maximum. North barge channel: • 100 feet maximum. South barge channel: • 110 feet maximum.	Primary navigation channel: • Closed position: 92 feet. • Open position: 178 feet. North barge channel: • 99 feet maximum. South barge channel: • 90 feet maximum.
Horizontal navigation clearance	263 feet for primary navigation channel. 511 feet for barge channel. 260 feet for alternate barge channel.	400 feet for all navigation channels (300-foot congressionally or USACE-authorized channel plus a 50-foot channel maintenance buffer on each side).	400 feet for all navigation channels (300-foot congressionally or USACE-authorized channel plus a 50-foot channel maintenance buffer on each side).	400 feet for all navigation channels (300-foot congressionally or USACE-authorized channel plus a 50-foot channel maintenance buffer on each side).
Maximum elevation of bridge component (NAVD 88)[e]	247 feet at top of lift tower.	166 feet.	Girder: 137 feet. Extradosed/Finback: 179 feet at top of pylons.	243 feet at top of lift tower.
Movable span length (from center of pier to center of pier)	278 feet.	N/A	N/A	450 feet.

	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration	Modified LPA with Single-Level Fixed-Span Configuration [a]	Modified LPA with Single-Level Movable-Span Configuration
Number of in-water pier sets	Nine	Six	Six	Six
Number of in-water drilled shafts	N/A	72	96	108
Shaft cap sizes	N/A	50 feet by 85 feet.	50 feet by 230 feet.	Piers 2, 3, 4, and 7: 50 feet by 230 feet. Piers 5 and 6: 50 feet by 312 feet (one combined footing at each location to house tower/equipment for the lift span).
Maximum grade	5%	4% on the Washington side. 3.8% on the Oregon side.	3% on the Washington side. 3% on the Oregon side.	1.5% on the Washington side. 3% on the Oregon side.
Light-rail transit location	N/A	Below highway on SB bridge.	West of highway on SB bridge.	West of highway on SB bridge.
Express bus	Shared roadway lanes.	Inside shoulder of NB and SB (upper) bridges.	Inside shoulder of NB and SB bridges.	Inside shoulder of NB and SB bridges.
Shared-use path location	Sidewalk adjacent to roadway in both directions.	Below highway on NB bridge.	East of highway on NB bridge.	East of highway on NB bridge.

a When different bridge types are not mentioned, data applies to all bridge types under the specified bridge configuration.
b The No-Build Alternative assumes existing conditions that restrict bridge openings during weekday peak periods (Monday through Friday 6:30 a.m. to 9 a.m.; 2:30 p.m. to 6 p.m., excluding federal holidays). This Draft SEIS analysis estimates the potential frequency for bridge openings for vessels requiring more than 99 feet of clearance.
c For the purposes of the transportation analysis in this Draft SEIS (Section 3.1, Transportation), the movable-span opening time is assumed to be an average of 12 minutes.
d "Out-to-out width" is the measurement between the outside edges of the bridge across its width at the widest point.
e NAVD 88 (North American Vertical Datum of 1988) is a vertical control datum (reference point) used by federal agencies for surveying.
NB = northbound; SB = southbound; USCG = U.S. Coast Guard

2.2.4 Downtown Vancouver (Subarea C)

This section discusses the geographic Subarea C shown in Figure 2-3. See Figure 2-23 for all highway and interchange improvements in Subarea C. Refer to Figure 2-3 for an overview of the geographic subareas.

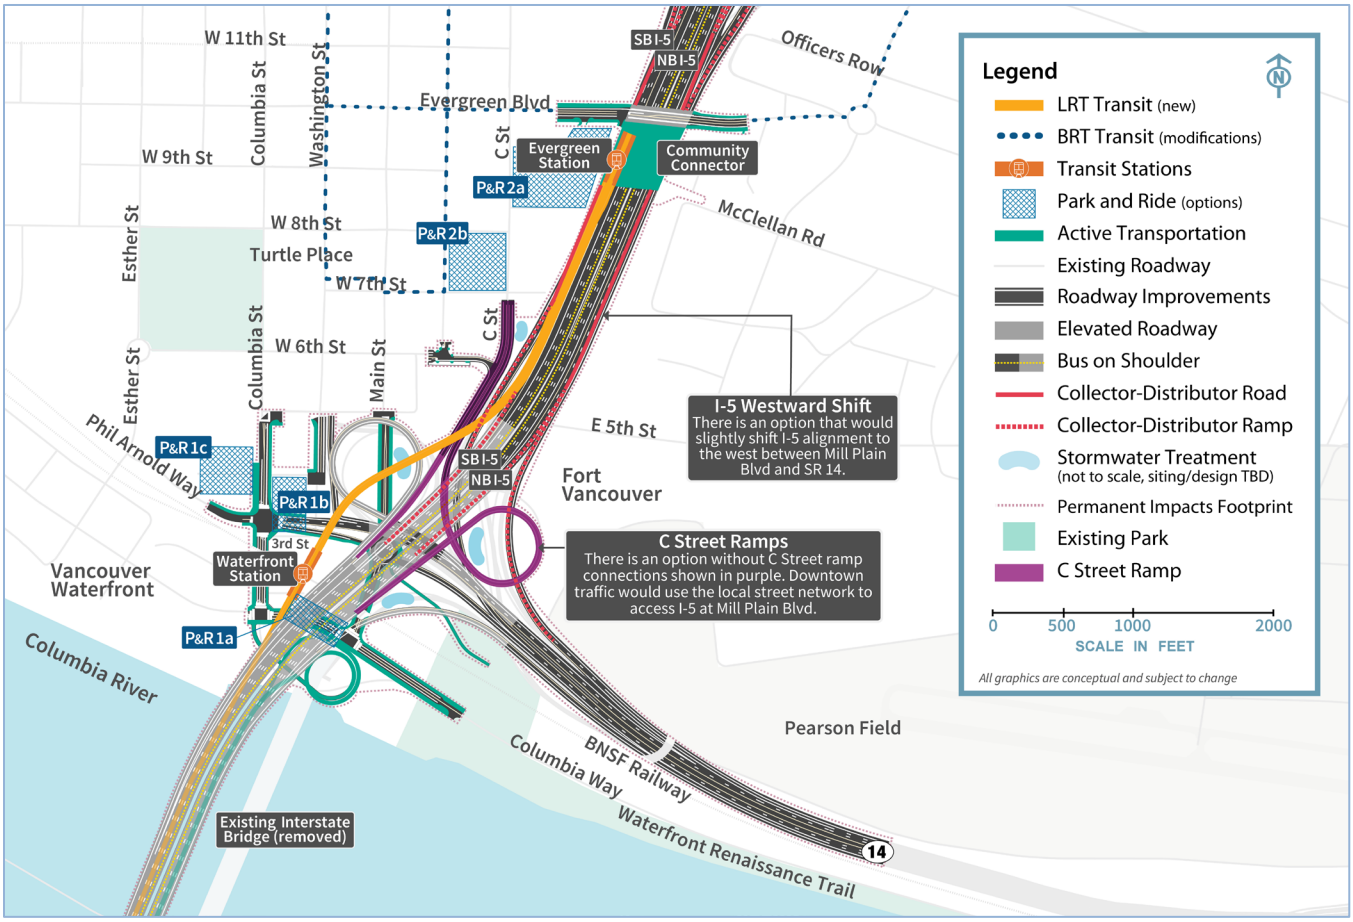
Highways, Interchanges, and Local Roadways

North of the Columbia River bridges in downtown Vancouver, improvements are proposed to the SR 14 interchange (Figure 2-23).

SR 14 Interchange

The new Columbia River bridges would touch down just north of the SR 14 interchange (Figure 2-23). The function of the SR 14 interchange would remain essentially the same as it is now, although the interchange would be elevated. Direct connections between I-5 and SR 14 would be rebuilt. Access to and from downtown Vancouver would be provided as it is today, but the connection points would be relocated. Downtown Vancouver I-5 access to and from the south would be at C Street as it is today, while downtown connections to and from SR 14 would be from Columbia Street at 3rd Street.

Figure 2-23. Downtown Vancouver (Subarea C)



BRT = bus rapid transit; LRT = light-rail transit; NB = northbound; P&R = park and ride; SB = southbound

Main Street would be extended between 5th Street and Columbia Way. Vehicles traveling from downtown Vancouver to access SR 14 eastbound would use the new extension of Main Street to the roundabout underneath I-5. If coming from the west or south (waterfront) in downtown Vancouver, vehicles would use the

Phil Arnold Way/3rd Street extension to the roundabout, then continue to SR 14 eastbound. The existing Columbia Way roadway under I-5 would be realigned to the north of its existing location and would intersect both the new Main Street extension and Columbia Street with T intersections.

In addition, the existing overcrossing of I-5 at Evergreen Boulevard would be reconstructed.

Design Option Without C Street Ramps

Under this design option, downtown Vancouver I-5 access to and from the south would be through the Mill Plain interchange rather than C Street. There would be no eastside loop ramp from I-5 northbound to C Street and no directional ramp on the west side of I-5 from C Street to I-5 southbound. The existing eastside loop ramp would be removed. This design option has been included because of changes in local planning that necessitate consideration of design options that reduce the footprint and associated direct and temporary environmental impacts in Vancouver.

What's changed with IBR?

The CRC project did not evaluate options to eliminate the C Street ramps or shift the I-5 mainline westward. Both options are included in the IBR Program in response to changed local agency planning considerations to reduce or shift the footprint and associated direct and temporary impacts in Vancouver.

Design Option to Shift I-5 Westward

This design option would shift the I-5 mainline and ramps approximately 40 feet to the west between SR 14 and Mill Plain Boulevard. The westward I-5 alignment shift could also be paired with the design option without C Street ramps. The inclusion of this design option is due to changes in local planning, which necessitate consideration of design options that that shifts the footprint and associated direct and temporary environmental impacts in Vancouver.

Transit

Light-Rail Alignment and Stations

Under the Modified LPA, the light-rail tracks would exit the highway bridge and be on their own bridge along the west side of the I-5 mainline after crossing the Columbia River (see Figure 2-23). The light-rail bridge would cross approximately 35 feet over the BNSF Railway tracks. An elevated light-rail station near the Vancouver waterfront (Waterfront Station) would be situated near the overcrossing of the BNSF tracks between Columbia Way and 3rd Street. Access to the elevated station would be primarily by elevator as the station is situated approximately 75 feet above existing ground level. A stairwell(s) would be provided for emergency egress. The number of elevators and stairwells provided would be based on the ultimate platform configuration, station location relative to the BNSF trackway, projected ridership, and fire and life safety requirements. Passenger drop-off facilities would be located at ground level and would be

What's changed with IBR?

In response to changes in community and local agencies' priorities, and to reduce property and streetscape impacts compared to the CRC LPA, the light-rail alignment proposed in the Modified LPA was realigned to run along the west side of I-5 along an elevated structure in Vancouver, with an elevated station at the Vancouver waterfront and an at-grade station near Evergreen Boulevard, adjacent to the Community Connector. In the CRC LPA, the light-rail alignment would have used a stand-alone structure from the Columbia River bridges to transition to/from at-grade tracks along Washington and Broadway Streets, with stations in downtown Vancouver at 9th and 15th Streets. The CRC LPA light-rail alignment would then have extended into upper Vancouver and turned east on 17th Street, terminating at Clark College (east of I-5 on McLoughlin Boulevard).

The Modified LPA was developed in close coordination with C-TRAN, TriMet, and the City of Vancouver and was informed by extensive community input and data. A terminus at Evergreen maximizes transfer opportunities given the direct connections to several local bus routes as well as planned BRT routes.

coordinated with the C-TRAN bus service at this location. The elevated light-rail tracks would continue north, cross over the westbound SR 14 on-ramp and the C Street/6th Street on-ramp to southbound I-5, and then straddle the southbound I-5 C-D roadway. Transit components in the downtown Vancouver area are similar between the two SR 14 interchange area design options discussed above.

North of the Waterfront Station, the light-rail tracks would continue to the Evergreen Station, which would be the terminus of the light-rail extension (see Figure 2-23). The light-rail tracks from downtown Vancouver to the terminus would be entirely on an elevated structure supported by single columns, where feasible, or by columns on either side of the roadway where needed. The light-rail tracks would be a minimum of 27 feet above the I-5 roadway surface. The Evergreen Station would be located at the same elevation as Evergreen Boulevard, on the proposed Community Connector, and it would provide connections to the existing C-TRAN BRT system. Passenger drop-off facilities would be near the station and would be coordinated with the C-TRAN bus service at this location.

Park and Rides

Up to two park and rides could be built in Vancouver along the light-rail alignment: one near the Waterfront Station and one near the Evergreen Station. Additional information regarding the park and rides can be found in Section 3.1, Transportation and the Transportation Technical Report.

Park and rides can expand the catchment area of public transit systems, making transit more accessible to people who live farther away from fixed-route transit service, and attracting new riders who might not have considered using public transit otherwise.

Waterfront Station Park-and-Ride Options

There are three site options for the park and ride near the Waterfront Station (see Figure 2-23). Each would accommodate up to 570 parking spaces.

1. Columbia Way (below I-5). This park-and-ride site would be a multilevel aboveground structure located below the new Columbia River bridges, immediately north of a realigned Columbia Way.
2. Columbia Street/SR 14. This park-and-ride site would be a multilevel aboveground structure located along the east side of Columbia Street. It could span across (or over) the SR 14 westbound off-ramp to provide parking on the north and south sides of the off-ramp.
3. Columbia Street/Phil Arnold Way (Waterfront Gateway Site). This park-and-ride site would be located along the west side of Columbia Street immediately north of Phil Arnold Way. This park and ride would be developed in coordination with the City of Vancouver's Waterfront Gateway program and could be a joint-use parking facility not constructed exclusively for park-and-ride users.

What's changed with IBR?

The park-and-ride location options have changed from the CRC LPA due to the change in LRT alignment and new development in Vancouver. The CRC LPA had three park and rides: Columbia (near the SR 14 interchange), Mill Plain (in uptown Vancouver), and Clark (on McLoughlin Boulevard near Clark College). Under the Modified LPA, the Columbia (Waterfront Station) park-and-ride site was modified because of new development at the CRC LPA site. The other park-and-ride sites were modified because of the change in the LRT terminus to Evergreen Boulevard in Vancouver, instead of Clark College in Vancouver, which was the light-rail terminus under the CRC LPA.

Evergreen Station Park-and-Ride Options

There are two site options for the park and ride near the Evergreen Station (see Figure 2-23).

1. Library Square. This park-and-ride site would be located along the east side of C Street and south of Evergreen Boulevard. It would accommodate up to 700 parking spaces in a multilevel belowground structure according to a future agreement on City-owned property associated with Library Square. Current design concepts suggest the park and ride most likely would be a joint-use parking facility for park-and-ride users and patrons of other uses on the ground or upper levels as negotiated as part of future decisions.
2. Columbia Credit Union. This park-and-ride site is an existing multistory garage that is located below the Columbia Credit Union office tower along the west side of C Street between 7th Street and 8th Street. The existing parking structure currently serves the office tower above it and the Regal City Center across the street. This would be a joint-use parking facility, not for the exclusive use of park-and-ride users, that could serve as additional or overflow parking if the 700 required parking spaces cannot be accommodated elsewhere.

Active Transportation

Within the downtown Vancouver area, the shared-use path on the northbound (or eastern) bridge would exit the bridge at the SR 14 interchange, loop down on the east side of I-5 via a vertical spiral path, and then cross back below I-5 to the west side of I-5 to connect to the Waterfront Renaissance Trail on Columbia Street and into Columbia Way (see Figure 2-23). Access would be provided across state right of way beneath the new bridges to provide a connection between the recreational areas along the City's Columbia River waterfront east of the bridges and existing and future waterfront uses west of the bridges.

Active transportation components in the downtown Vancouver area would be similar without the C Street ramps and with the I-5 westward shift.

At Evergreen Boulevard, a Community Connector is proposed to be built over I-5 just south of Evergreen Boulevard and east of the Evergreen Station (see Figure 2-23). The structure is proposed to include off-street pathways for active transportation modes including pedestrians, bicyclists, and other micro-mobility modes, and public space and amenities to support the active transportation facilities. The primary intent of the Community Connector is to improve connections between downtown Vancouver on the west side of I-5 and the Vancouver National Historic Reserve on the east side.

2.2.5 Upper Vancouver (Subarea D)

This section discusses the geographic Subarea D shown in Figure 2-3. See Figure 2-24 for all highway and interchange improvements in Subarea D. Refer to Figure 2-3 for an overview of the geographic subareas.

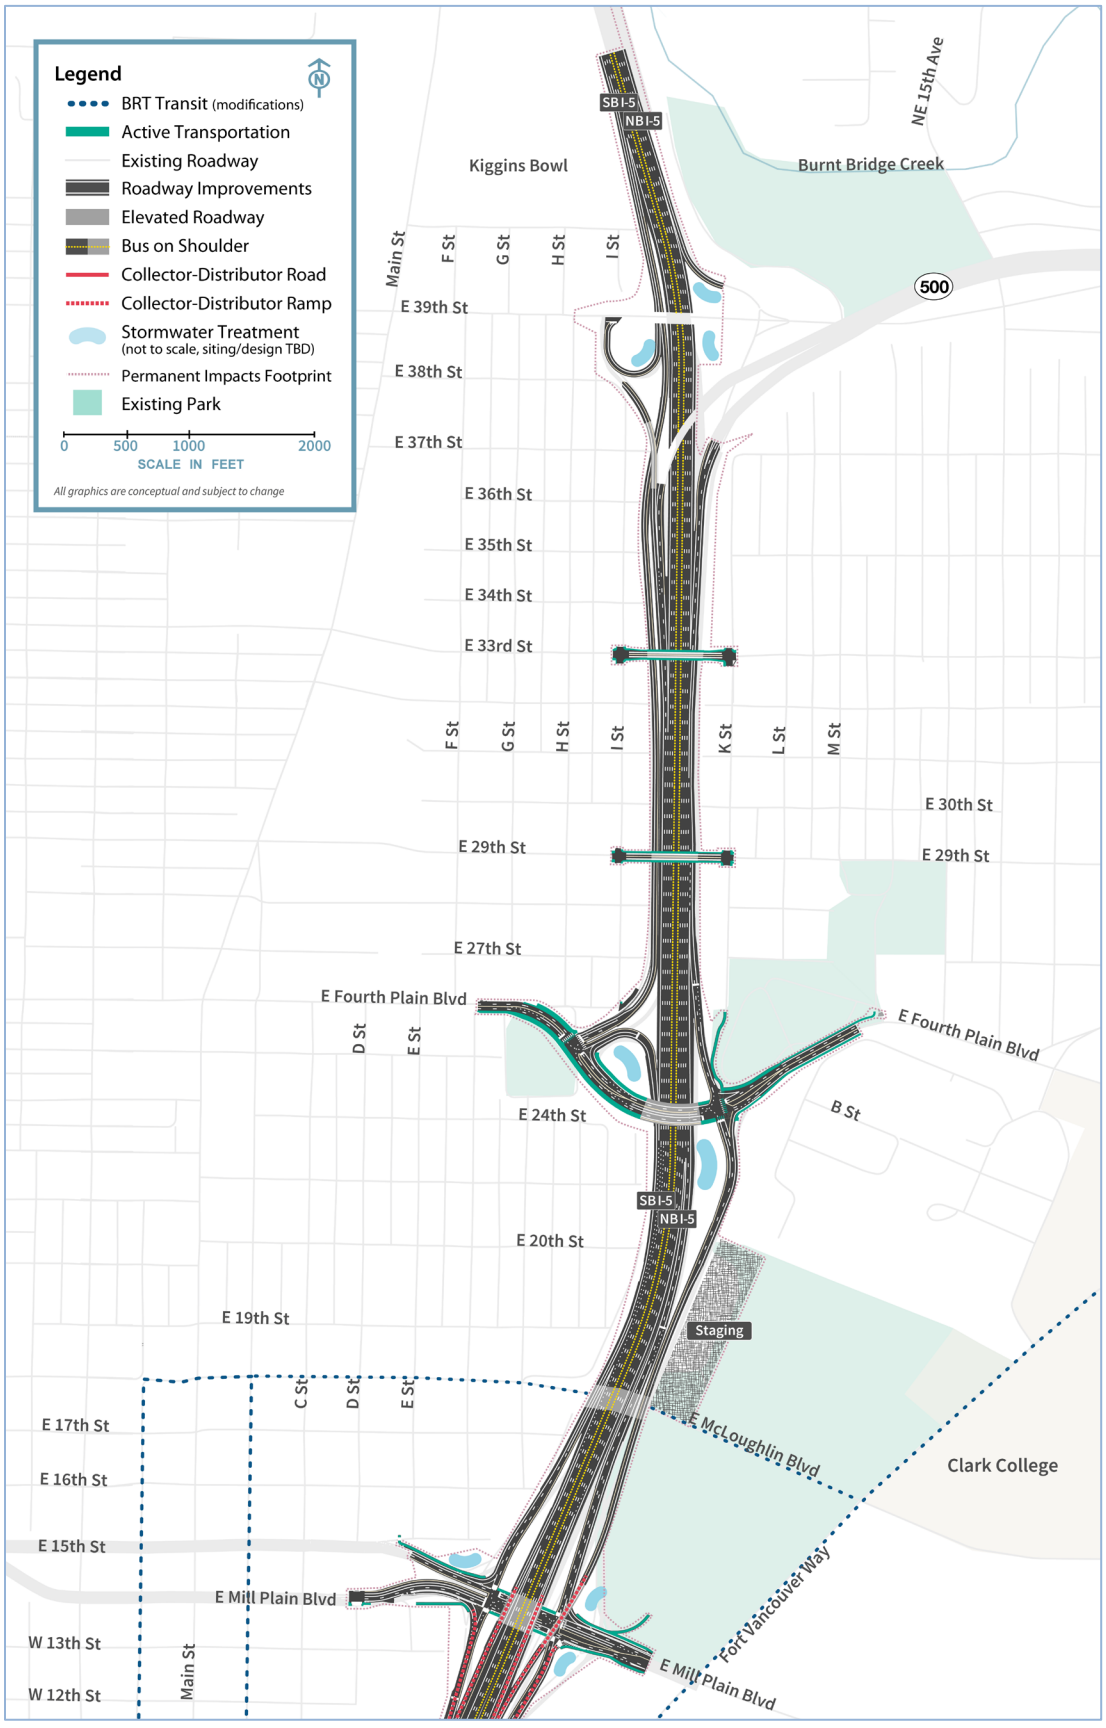
Highways, Interchanges, and Local Roadways

Within the upper Vancouver area, the IBR Program proposes improvements to three interchanges—Mill Plain, Fourth Plain, and SR 500—as described below.

Mill Plain Boulevard Interchange

The Mill Plain Boulevard interchange is north of the SR 14 interchange (see Figure 2-24). This interchange would be reconstructed as a tight-diamond configuration but would otherwise remain similar in function to the existing interchange. The ramp terminal intersections would be sized to accommodate high, wide heavy freight vehicles that travel between the Port of Vancouver and I-5. The off-ramp from I-5 northbound to Mill Plain Boulevard would diverge from the C-D road that would continue north, crossing over Mill Plain Boulevard, to provide access to Fourth Plain Boulevard via a C-D roadway. The off-ramp to Fourth Plain Boulevard would be reconstructed and would cross over Mill Plain Boulevard east of I-5, similar to the way it functions today.

Figure 2-24. Upper Vancouver (Subarea D)



BRT = bus rapid transit; TBD = to be determined

Fourth Plain Boulevard Interchange

At the Fourth Plain Boulevard interchange (Figure 2-24), improvements would include reconstruction of the overpass of I-5 and the ramp terminal intersections. Northbound I-5 traffic exiting to Fourth Plain Boulevard would first exit to the northbound C-D roadway which provides off-ramp access to Fourth Plain Boulevard and Mill Plain Boulevard. The westbound SR 14 to northbound I-5 on-ramp also joins the northbound C-D roadway before continuing north past the Fourth Plain Boulevard and Mill Plain Boulevard off-ramps as an auxiliary lane. The southbound I-5 off-ramp to Fourth Plain Boulevard would be braided below the 39th Street on-ramp to southbound I-5. This change would eliminate the existing nonstandard weave between the SR 500 interchange and the off-ramp to Fourth Plain Boulevard. It would also eliminate the existing westbound SR 500 to Fourth Plain Boulevard off-ramp connection. The existing overcrossing of I-5 at 29th Street would be reconstructed to accommodate a widened I-5, provide adequate vertical clearance over I-5, and provide pedestrian and bicycle facilities.

SR 500 Interchange

The northern terminus of the I-5 improvements would be in the SR 500 interchange area (Figure 2-24). The improvements would primarily be to connect the Modified LPA to existing ramps. The off-ramp from I-5 southbound to 39th Street would be reconstructed to establish the beginning of the braided ramp to Fourth Plain Boulevard and restore the loop ramp to 39th Street. Ramps from existing I-5 northbound to SR 500 eastbound and from 39th Street to I-5 northbound would be partially reconstructed. The existing bridges for 39th Street over I-5 and SR 500 westbound to I-5 southbound would be retained. The 39th Street to I-5 southbound on-ramp would be reconstructed and braided over (i.e., grade separated or pass over) the new I-5 southbound off-ramp to Fourth Plain Boulevard.

The existing overcrossing of I-5 at 33rd Street would also be reconstructed to accommodate a widened I-5, provide adequate vertical clearance over I-5, and provide pedestrian and bicycle facilities.

Transit

There would be no LRT facilities in upper Vancouver. Proposed operational changes to bus service, including I-5 bus-on-shoulder service, are described in Section 2.2.7, Transit Operating Characteristics.

What's changed with IBR?

The Modified LPA design at the SR 500 interchange is similar to the CRC LPA, although the CRC LPA would have contained future phased options to construct new direct connections between I-5 and SR 500, new on- and off-ramps, and a tunnel beneath I-5. In response to changes in local agencies' priorities, the Modified LPA does not include these connections. The CRC 2013 NEPA re-evaluation also considered a phased construction option that would have limited improvements to the existing SR 500 interchange ramps. The Modified LPA would have the same limited improvements to the SR 500 interchange.

Active Transportation

Several active transportation improvements would be made in Subarea D consistent with City of Vancouver plans and policies. At the Fourth Plain Boulevard interchange, there would be improvements to provide better bicycle and pedestrian mobility and accessibility; these include bicycle lanes, neighborhood connections, and a connection to the City of Vancouver's planned two-way cycle track on Fourth Plain Boulevard. The reconstructed overcrossings of I-5 at 29th Street and 33rd Street would provide pedestrian and bicycle facilities on those cross streets. No new active transportation facilities are proposed in the SR 500 interchange area. Active transportation improvements at the Mill Plain Boulevard interchange include buffered bicycle lanes and sidewalks, pavement markings, lighting, and signing.

What's changed with IBR?

The Modified LPA's active transportation improvements in upper Vancouver are similar to those proposed in the CRC LPA. However, the Modified LPA includes a connection to the city of Vancouver's planned two-way cycle track on Fourth Plain Boulevard that was not yet proposed when the CRC Final EIS was completed.

2.2.6 Transit Support Facilities

Ruby Junction Maintenance Facility Expansion

The TriMet Ruby Junction Maintenance Facility in Gresham, Oregon, would be expanded to accommodate the additional LRVs associated with the Modified LPA's LRT service (the Ruby Junction location relative to the study area is shown in Figure 2-25). Improvements would include additional storage for LRVs and maintenance materials and supplies, expanded LRV maintenance bays, expanded parking and employee support areas for additional personnel, and a third track at the northern entrance to Ruby Junction. Figure 2-25 shows the proposed footprint of the expansion.

What's changed with IBR?

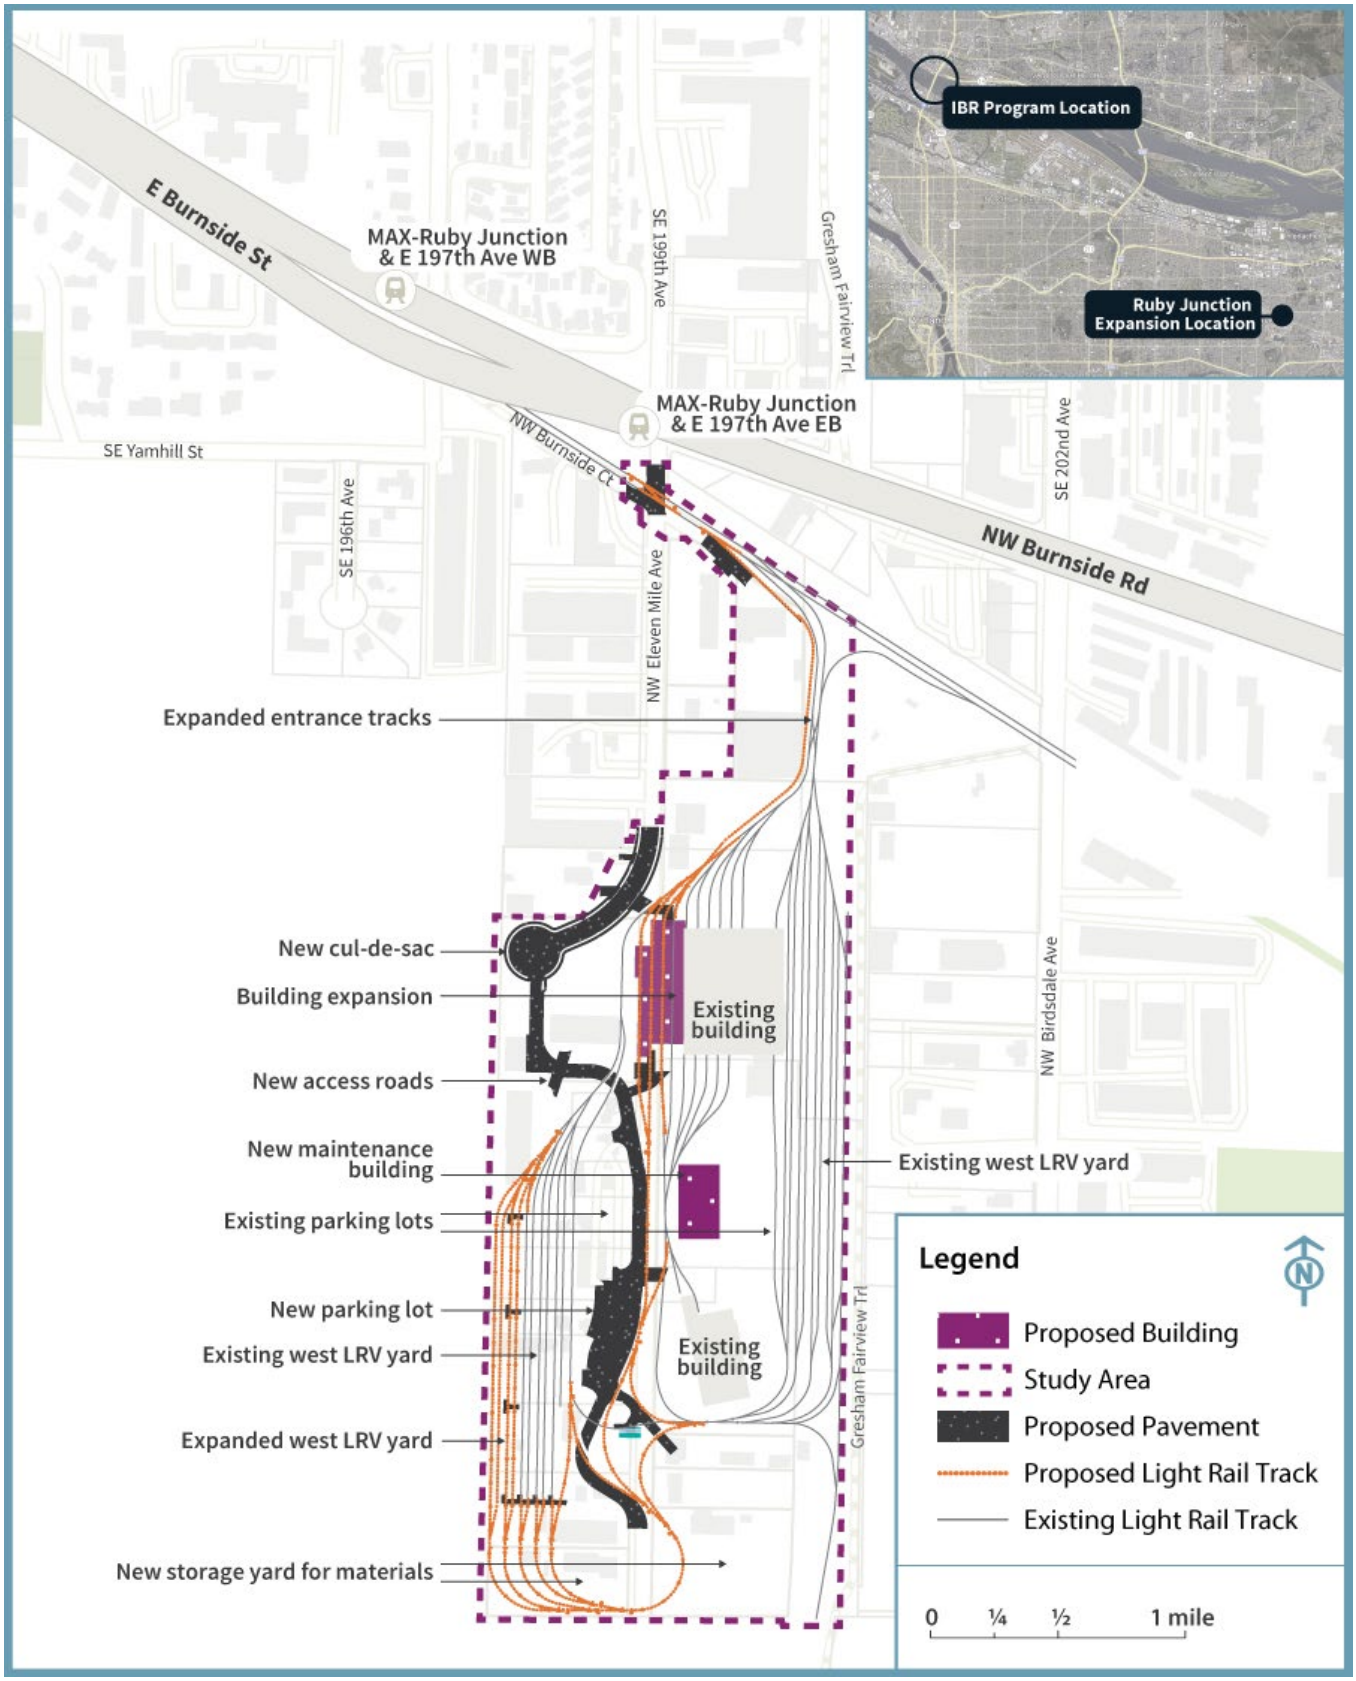
The Modified LPA would expand the TriMet Ruby Junction Maintenance Facility to accommodate additional LRVs. The CRC LPA also would have expanded Ruby Junction; some of that expansion was completed in the years following the CRC ROD. The changes described with the Modified LPA include both new and previously proposed elements that have not already been completed to accommodate planned LRT service associated with the IBR Program.

The existing main building would be expanded west to provide additional maintenance bays. To make space for the building expansion, Eleven Mile Avenue would be vacated and would terminate in a new cul-de-sac west of the main building. New access roads would be constructed to maintain access to TriMet buildings south of the cul-de-sac.

The existing LRV storage yard, west of Eleven Mile Avenue, would be expanded to the west to accommodate additional storage tracks and a runaround track (a track constructed to bypass congestion in the maintenance yard). This expansion would require partial demolition of an existing TriMet building (just north of the LRV storage) and would require relocating the material storage yard to the properties just south of the south building.

All tracks in the west LRV storage yard would also be extended southward to connect to the proposed runaround track. The runaround track would connect to existing tracks near the existing south building. The connections to the runaround track would require partial demolition of an existing TriMet building plus full demolition of one existing building and partial demolition of another existing building on the private property west of the south end of Eleven Mile Avenue. The function of the existing TriMet building would either be transferred to existing modified buildings or to new replacement buildings on site.

Figure 2-25. Ruby Junction Maintenance Facility Study Area



EB = eastbound; LRV = light-rail vehicle; WB = westbound

The existing parking lot west of Eleven Mile Avenue would be expanded toward the south to provide more parking for TriMet personnel.

A third track would be needed at the north entrance to Ruby Junction to accommodate increased train volumes without decreasing service. The additional track would also reduce operational impacts during construction and maintenance outages for the yard. Constructing the third track would require reconstruction of Burnside Court east of Eleven Mile Avenue. An additional crossover would also be needed on the mainline track where it crosses Eleven Mile Avenue; it would require reconstruction of the existing track crossings for vehicles, bicycles, and pedestrians.

Expo Center Overnight LRV Facility

An overnight facility for LRVs would be constructed on the southeast corner of the Expo Center property (as shown on Figure 2-8) to reduce deadheading between Ruby Junction and the northern terminus of the MAX Yellow Line extension. Deadheading occurs when LRVs travel without passengers to make the vehicles ready for service. The facility would provide a yard access track, storage tracks for approximately 10 LRVs, one building for light LRV maintenance, an operator break building, a parking lot for operators, and space for security personnel. This facility would necessitate relocation and reconstruction of the Expo Road entrance to the Expo Center (including the parking lot gates and booths). However, it would not affect existing Expo Center buildings.

What's changed with IBR?

An overnight LRV facility at the Expo Center was not part of the CRC LPA, which assumed additional LRVs would be accommodated through the expansion of Ruby Junction. With Modified LPA changes in Vancouver resulting from community and local agency priorities the IBR Program examined ways to reduce the long-term operations and maintenance costs on the system. This led to the consideration and inclusion of the Expo Center site as an overnight LRV facility.

The overnight facility would connect to the mainline tracks by crossing Expo Road just south of the existing Expo Center MAX Station. The connection tracks would require relocation of one or two existing LRT facilities, including a traction power substation building and potentially the existing communication building, which are both just south of the Expo Center MAX Station. Existing artwork at the station may require relocation.

Additional Bus Bays at the C-TRAN Operations and Maintenance Facility

Three bus bays would be added to the C-TRAN operations and maintenance facility. These new bus bays would provide maintenance capacity for the additional express bus service on I-5 (see Section 2.2.7, Transit Operating Characteristics). Modifications to the facility would accommodate new vehicles as well as maintenance equipment.

2.2.7 Transit Operating Characteristics

LRT Operations

Nineteen new LRVs would be purchased to operate the extension of the MAX Yellow Line. These vehicles would be similar to those currently used for the TriMet MAX system. With the Modified LPA, LRT service in the new and existing portions of the Yellow Line in 2045 would operate with 6.7-minute average headways (defined as gaps between arriving transit vehicles) during the 2-hour morning peak period. Mid-day and evening headways would be 15 minutes, and late-night headways would be 30 minutes. Service would operate between the hours of approximately 5 a.m. (first southbound train leaving Evergreen Station) and 1 a.m. (last northbound train arriving at the station), which is consistent with current service on the Yellow

Line. LRVs would be deadheaded at Evergreen Station before beginning service each day. A third track at this northern terminus would accommodate layovers.

Express Bus Service and Bus on Shoulder

C-TRAN provides bus service that connects to LRT and augments travel between Washington and Oregon with express bus service to key employment centers in Oregon. Beginning in 2022, the main express route providing service in the IBR corridor, Route 105, had two service variations. One pattern provides service between Salmon Creek and downtown Portland with a single intermediate stop at the 99th Street Transit Center, and one provides service between Salmon Creek and downtown Portland with two intermediate stops: 99th Street Transit Center and downtown Vancouver. This route currently provides weekday service with 20-minute peak and 60-minute off-peak headways.

What's changed with IBR?

Coordination with Program partners led to a transit solution that allows LRT and express bus to both operate to maximize opportunity and capacity for cross-river transit demand. The Modified LPA includes additional express bus service on I-5 between Salmon Creek and downtown Portland to provide needed capacity for carrying trips across the Columbia River. The CRC LPA ended that service at an LRT station in downtown Vancouver. The CRC LPA had more park-and-ride spaces; with fewer park-and-ride spaces at LRT stations under the Modified LPA, express bus on I-5 provides needed service for cross-river markets further into Clark County. The additional express bus service in the Modified LPA necessitated the addition of vehicles and maintenance facility capacity.

Once the Modified LPA is constructed, C-TRAN Route 105 would be revised to provide direct service from the Salmon Creek Park and Ride and 99th Street Transit Center to downtown Portland, operating at 5-minute peak headways with no service in the off-peak. The C-TRAN Route 105 intermediate stop service through downtown Vancouver would be replaced with C-TRAN Route 101, which would provide direct service from downtown Vancouver to downtown Portland at 10-minute peak and 30-minute off-peak headways.

Two other existing C-TRAN express bus service routes would remain unchanged after completion of the Modified LPA. C-TRAN Route 190 would continue to provide service from the Andresen Park and Ride in Vancouver to Marquam Hill in Portland. This route would continue to operate on SR 500 and I-5 within the study area. Route headways would be 10 minutes in the peak periods with no off-peak service. C-TRAN Route 164 would continue to provide service from the Fisher's Landing Transit Center to downtown Portland. This route would continue to operate within the study area only in the northbound direction during PM service to use the I-5 northbound high-occupancy vehicle lane in Oregon before exiting to eastbound SR 14 in Washington. Route headways would be 10 minutes in the peak and 30 minutes in the off-peak.

C-TRAN express bus Routes 105 and 190 are currently permitted to use the existing southbound inside shoulder of I-5 from 99th Street to the Interstate Bridge in Vancouver. However, the existing shoulders are too narrow for bus-on-shoulder use in the rest of the I-5 corridor in the study area. The Modified LPA would include inside shoulders on I-5 that would be wide enough (14 feet on the Columbia River bridges and 11.5 to 12 feet elsewhere on I-5) to allow northbound and southbound buses to operate on the shoulder, except where I-5 would have to taper to match existing inside shoulder widths at the north and south ends of the corridor. Figure 2-8, Figure 2-16, Figure 2-23, and Figure 2-24 show the potential bus-on-shoulder use over the Columbia River bridges. Bus on shoulder could operate on any of the Modified LPA bridge configurations and bridge types. Additional approvals (including a continuing control agreement), in coordination with ODOT, may be needed for buses to operate on the shoulder on the Oregon portion of I-5.

After completion of the Modified LPA, two C-TRAN express bus routes operating on I-5 through the study area would be able to use bus-on-shoulder operations to bypass congestion in the general-purpose lanes. C-TRAN Route 105 would operate on the shoulder for the full length of the study area. C-TRAN Route 190 would

operate on the shoulder for the full length of the corridor except for the distance required to merge into and out of the shoulder as the route exits from and to SR 500. These two express bus routes (105 and 190) would have a combined frequency of every 3 minutes during the 2045 AM and PM peak periods. To support the increased frequency of express bus service, eight electric double-decker or articulated buses would be purchased.

If the C Street ramps were removed from the SR 14 interchange, C-TRAN Route 101 could also use bus-on-shoulder operations south of Mill Plain Boulevard; however, if the C Street ramps remained in place, Route 101 could still use bus-on-shoulder operations south of the SR 14 interchange but would need to begin merging over to the C Street exit earlier than if the C Street ramps were removed. Route 101 would operate at 10-minute peak and 30-minute off-peak headways. C-TRAN Route 164 would not be anticipated to use bus-on-shoulder operations because of the need to exit to SR 14 from northbound I-5.

Local Bus Route Changes

The TriMet Line 6 bus route would be changed to terminate at the Expo Center MAX Station, requiring passengers to transfer to the new LRT connection to access Hayden Island. TriMet Line 6 is anticipated to travel from Martin Luther King Jr. Boulevard through the newly configured area providing local connections to Marine Drive. It would continue west to the Expo Center MAX Station. Table 2-4 shows existing service and anticipated future changes to TriMet Line 6.

What's changed with IBR?

The TriMet Line 6 bus route has changed since the CRC LPA. This operational change, as well as changes in local agency priorities, led to the proposal to terminate the route at the Expo Center MAX Station under the Modified LPA.

As part of the Modified LPA, several local C-TRAN bus routes would be changed to better complement the new light-rail extension. Most of these changes would reroute existing bus lines to provide a transfer opportunity near the new Evergreen Station. Table 2-4 shows existing service and anticipated future changes to C-TRAN bus routes. In addition to the changes noted in Table 2-4, other local bus route modifications would move service from Broadway to C Street. The changes shown may be somewhat different if the C Street ramps are removed.

Table 2-4. Proposed TriMet and C-TRAN Bus Route Changes

Bus Route	Existing Route	Changes with Modified LPA
TriMet Line 6	Connects Goose Hollow, Portland City Center, N/NE Portland, Jantzen Beach and Hayden Island. Within the study area, service currently runs between Delta Park MAX Station and Hayden Island via I-5.	Route would be revised to terminate at the Expo Center MAX Station. Route is anticipated to travel from Martin Luther King Jr. Boulevard through the newly configured Marine Drive area, then continue west to connect via facilities on the west side of I-5 with the Expo Center MAX Station.

Bus Route	Existing Route	Changes with Modified LPA
C-TRAN Fourth Plain and Mill Plain bus rapid transit (The Vine)	Runs between downtown Vancouver and the Vancouver Mall Transit Center via Fourth Plain Boulevard, with a second line along Mill Plain Boulevard. In the study area, service currently runs along Washington and Broadway Streets through downtown Vancouver.	Route would be revised to begin/end near the Evergreen Station in downtown Vancouver and provide service along Evergreen Boulevard to Fort Vancouver Way, where it would travel to or from Mill Plain Boulevard or Fourth Plain Boulevard depending on clockwise/counterclockwise operations. The Fourth Plain Boulevard route would continue to serve existing Vine stations beyond Evergreen Boulevard.
C-TRAN #2 Lincoln	Connects the 99th Street Transit Center to downtown Vancouver via Lincoln and Kaufman Avenues. Within the study area, service currently runs along Washington and Broadway Streets between 7th and 15th Streets in downtown Vancouver.	Route would be modified to begin/end near C Street and 9th Street in downtown Vancouver.
C-TRAN #25 St. Johns	Connects the 99th Street Transit Center to downtown Vancouver via St. Johns Boulevard and Fort Vancouver Way. Within the study area, service currently runs along Evergreen Boulevard, Jefferson Street/Kaufman Avenue, 15th Street, and Franklin Street in downtown Vancouver.	Route would be modified to begin/end near C Street and 9th Street in downtown Vancouver.
C-TRAN #30 Burton	Connects the Fisher's Landing Transit Center with downtown Vancouver via 164th/162nd Avenues and 18th, 25th, 28th, and 39th Streets. Within the study area, service currently runs along McLoughlin Boulevard and on Washington and Broadway Streets between 8th and 15th Streets.	Route would be modified to begin/end near C Street and 9th Street in downtown Vancouver.
C-TRAN #60 Delta Park Regional	Connects the Delta Park MAX station in Portland with downtown Vancouver via I-5. Within the study area, service currently runs along I-5, Mill Plain Boulevard, and Broadway Street.	Route would be discontinued.

2.2.8 Tolling

Tolling cars and trucks that would use the new Columbia River bridges is proposed as a method to help fund the bridge construction and future maintenance, as well as to encourage alternative mode choices for trips across the Columbia River. Federal and state laws set the authority to toll the I-5 crossing. The IBR Program plans to toll the I-5 river bridge under the federal tolling authorization program codified in 23 U.S. Code Section 129 (Section 129). Section 129 allows public agencies to impose new tolls on federal-aid interstate highways for the reconstruction or replacement of toll-free bridges or tunnels. In 2023, the Washington State Legislature authorized tolling on the Interstate Bridge, with toll rates and policies to be set by the Washington State Transportation Commission (WSTC). In Oregon, the legislature authorized tolling giving the Oregon Transportation Commission the authority to toll I-5, including the ability to set the toll rates and policies. Subsequently, the Oregon Transportation Commission (OTC) is anticipated to review and approve the I-5 tollway project application that would designate the Interstate Bridge as a "tollway project" in 2024. At the

beginning of 2024, the OTC and the WSTC entered into a bi-state tolling agreement to establish a cooperative process for setting toll rates and policies. This included the formation of the I-5 Bi-State Tolling Subcommittee consisting of two commissioners each from the OTC and WSTC and tasked with developing toll rate and policy recommendations for joint consideration and adoption by each state's commission. Additionally, the two states plan to enter into a separate agreement guiding the sharing and uses of toll revenues, including the order of uses (flow of funds) for bridge construction, debt service, and other required expenditures. WSDOT and ODOT also plan to enter into one or more agreements addressing implementation logistics, toll collection, and operations and maintenance for tolling the bi-state facility.

The Modified LPA includes a proposal to apply variable tolls on vehicles using the Columbia River bridges with the toll collected electronically in both directions. Tolls would vary by time of day with higher rates during peak travel periods and lower rates during off-peak periods. The IBR Program has evaluated multiple toll scenarios generally following two different variable toll schedules for the tolling assessment. For purposes of this NEPA analysis, the lower toll schedule was analyzed with tolls assumed to range between $1.50 and $3.15 (in 2026 dollars as representative of when tolling would begin) for passenger vehicles with a registered toll payment account. Medium and heavy trucks would be charged a higher toll than passenger vehicles and light trucks. Passenger vehicles and light trucks without a registered toll payment account would pay an additional $2.00 per trip to cover the cost of identifying the vehicle owner from the license plate and invoicing the toll by mail.

The analysis assumes that tolling would commence on the existing Interstate Bridge—referred to as pre-completion tolling—starting April 1, 2026. The actual date pre-completion tolling begins would depend on when construction would begin. The traffic and tolling operations on the new Columbia River bridges were assumed to commence by July 1, 2033. The actual date that traffic and tolling operations on the new bridges begin would depend on the actual construction completion date. During the construction period, the two commissions may consider toll-free travel overnight on the existing Interstate Bridge, as was analyzed in the Level 2 Toll Traffic and Revenue Study, for the hours between 11 p.m. and 5 a.m. This toll-free period could help avoid situations where users would be charged during lane or partial bridge closures where construction delays may apply. Once the new I-5 Columbia River bridges open, twenty-four-hour tolling would begin.

Tolls would be collected using an all-electronic toll collection system using transponder tag readers and license plate cameras mounted to structures over the roadway. Toll collection booths would not be required. Instead, motorists could obtain a transponder tag and set up a payment account that would automatically bill the account holder associated with the transponder each time the vehicle crossed the bridge. Customers without transponders, including out-of-area vehicles, would be tolled by a license plate recognition system that would bill the address of the owner registered to that vehicle's license plate. The toll system would be designed to be nationally interoperable. Transponders for tolling systems elsewhere in the country could be used to collect tolls on I-5, and drivers with an account and transponder tag associated with the Interstate Bridge could use them to pay tolls in other states for which reciprocity agreements had been developed. There would be new signage, including gantries, to inform drivers of the bridge toll. These signs would be on local roads, I-5 on-ramps, and on I-5, including locations north and south of the bridges where drivers make route decisions (e.g., I-5/I-205 junction and I-5/I-84 junction).

2.2.9 Transportation System- and Demand-Management Measures

Many well-coordinated transportation demand-management and system-management programs are already in place in the Portland-Vancouver metropolitan region. In most cases, the impetus for the programs comes from state regulations: Oregon's Employee Commute Options rule and Washington's Commute Trip Reduction law (described in the sidebar).

The physical and operational elements of the Modified LPA provide the greatest transportation demand-management opportunities by promoting other modes to fulfill more of the travel needs in the corridor. These include:

- Major new light-rail line in exclusive right of way, as well as express bus routes and bus routes that connect to new light-rail stations.
- I-5 inside shoulders that accommodate express buses.
- Modern bicycle and pedestrian facilities that accommodate more bicyclists and pedestrians and improve connectivity, safety, and travel time.
- Park-and-ride facilities.
- A variable toll on the new Columbia River bridges.

In addition to these fundamental elements of the Modified LPA, facilities and equipment would be implemented that could help existing or expanded transportation system management measures maximize the capacity and efficiency of the system. These include:

- Replacement or expanded variable message signs in the study area. These signs alert drivers to incidents and events, allowing them to seek alternate routes or plan to limit travel during periods of congestion.
- Replacement or expanded traveler information systems with additional traffic monitoring equipment and cameras.
- Expanded incident response capabilities, which help traffic congestion to clear more quickly following accidents, spills, or other incidents.
- Queue jumps or bypass lanes for transit vehicles where multilane approaches are provided at ramp signals for on-ramps. Locations for these features will be determined during the detailed design phase.
- Active traffic management including strategies such as ramp metering, dynamic speed limits, and transit signal priority. These strategies are intended to manage congestion by controlling traffic flow or allowing transit vehicles to enter traffic before single-occupant vehicles.

State Laws to Reduce Commute Trips

Oregon and Washington have both adopted regulations intended to reduce the number of people commuting in single-occupancy vehicles (SOVs). Oregon's Employee Commute Options Program, created under Oregon Administrative Rule 340-242-0010, requires employers with over 100 employees in the greater Portland area to provide commute options that encourage employees to reduce auto trips to the work site. Washington's 1991 Commute Trip Reduction (CTR) Law, updated as the 2006 CTR Efficiency Act (Revised Code of Washington §70.94.521) addresses traffic congestion, air pollution, and petroleum fuel consumption. The law requires counties and cities with the greatest traffic congestion and air pollution to implement plans to reduce SOV demand. An additional provision mandates "major employers" and "employers at major worksites" to implement programs to reduce SOV use.

2.3 Modified LPA Construction

The following information on the construction activities and sequence follows the information prepared for the CRC LPA. Construction durations have been updated for the Modified LPA. Because the main elements of the IBR Modified LPA are similar to those in the CRC LPA (i.e., multimodal river crossings and interchange

improvements), this information provides a reasonable assumption of the construction activities that would be required.

The construction of bridges over the Columbia River sets the sequencing for other Program components. Accordingly, construction of the Columbia River bridges and immediately adjacent highway connections and improvement elements would be timed early to aid the construction of other components. Demolition of the existing Interstate Bridge would take place after the new Columbia River bridges were opened to traffic.

Electronic tolling infrastructure would be constructed and operational on the existing Interstate Bridge by the start of construction on the new Columbia River bridges. The toll rates and policies for tolling (including pre-completion tolling) would be determined after a more robust analysis and public process by the OTC and WSTC (refer to Section 2.2.8, Tolling).

2.3.1 Construction Components and Duration

Table 2-5 provides the estimated construction durations and additional information of Modified LPA components. The estimated durations are shown as ranges to reflect the potential for Program funding to be phased over time. In addition to funding, contractor schedules, regulatory restrictions on in-water work and river navigation considerations, permits and approvals, weather, materials, and equipment could all influence construction duration and overlap of construction of certain components. Certain work below the ordinary high-water mark of the Columbia River and North Portland Harbor would be restricted to minimize impacts to species listed under the Endangered Species Act and their designated critical habitat.

Throughout construction, active transportation facilities and three lanes in each direction on I-5 (accommodating personal vehicles, freight, and buses) would remain open during peak hours, except for short intermittent restrictions and/or closures. Advanced coordination and public notice would be given for restrictions, intermittent closures, and detours for highway, local roadway, transit, and active transportation users (refer to Section 3.1, Transportation, for additional information). At least one navigation channel would remain open throughout construction. Advanced coordination and notice would be given for restrictions or intermittent closures to navigation channels as required (refer to Section 3.2, Navigation, for additional information).

Table 2-5. Construction Activities and Estimated Duration

Component	Estimated Duration	Notes
Columbia River bridges	4 to 7 years	• Construction is likely to begin with the main river bridges. • General sequence would include initial preparation and installation of foundation piles, shaft caps, pier columns, superstructure, and deck.
North Portland Harbor bridges	4 to 10 years	• Construction duration for North Portland Harbor bridges is estimated to be similar to the duration for Hayden Island interchange construction. The existing North Portland Harbor bridge would be demolished in phases to accommodate traffic during construction of the new bridges.
Hayden Island interchange	4 to 10 years	• Interchange construction duration would not necessarily entail continuous active construction. Hayden Island work could be broken into several contracts, which could spread work over a longer duration.

Component	Estimated Duration	Notes
Marine Drive interchange	4 to 6 years	• Construction would need to be coordinated with construction of the North Portland Harbor bridges.
SR 14 interchange	4 to 6 years	• Interchange would be partially constructed before any traffic could be transferred to the new Columbia River bridges.
Demolition of the existing Interstate Bridge	1.5 to 2 years	• Demolition of the existing Interstate Bridge could begin only after traffic is rerouted to the new Columbia River bridges.
Three interchanges north of SR 14	3 to 4 years for all three	• Construction of these interchanges could be independent from each other and from construction of the Program components to the south. • More aggressive and costly staging could shorten this timeframe.
Light-rail	4 to 6 years	• The light-rail crossing would be built with the Columbia River bridges. Light-rail construction includes all of the infrastructure associated with light-rail transit (e.g., overhead catenary system, tracks, stations, park and rides).
Total construction timeline	9 to 15 years	• Funding, as well as contractor schedules, regulatory restrictions on in-water work and river navigation considerations, permits and approvals, weather, materials, and equipment, could all influence construction duration.

2.3.2 Potential Staging Sites and Casting Yards

Equipment and materials would be staged in the study area throughout construction generally within existing or newly purchased right of way, on land vacated by existing transportation facilities (e.g., I-5 on Hayden Island), or on nearby vacant parcels. However, at least one large site would be required for construction offices, to stage the larger equipment such as cranes, and to store materials such as rebar and aggregate. Criteria for suitable sites include large, open areas for heavy machinery and material storage, waterfront access for barges (either a slip or a dock capable of handling heavy equipment and material) to convey material to the construction zone, and roadway or rail access for landside transportation of materials by truck or train.

Two potential major staging sites have been identified (see Figure 2-8 and Figure 2-23). One site is located on Hayden Island on the west side of I-5. A large portion of this parcel would be required for new right of way for the Modified LPA. The second site is in Vancouver between I-5 and Clark College. Other staging sites may be identified during the design process or by the contractor. Following construction of the Modified LPA, the staging sites could be converted for other uses.

In addition to on-land sites, some staging activities for construction of the new Columbia River and North Portland Harbor bridges would take place on the river itself. Temporary work structures, barges, barge-mounted cranes, derricks, and other construction vessels and equipment would be present on the river during most or all of the bridges' construction period. The IBR Program is working with USACE and USCG to obtain necessary clearances for these activities.

A casting or staging yard could also be required for construction of the overwater bridges if a precast concrete segmental bridge design is used. A casting yard would require access to the river for barges, a slip or a dock capable of handling heavy equipment and material, a large area suitable for a concrete batch plant and associated heavy machinery and equipment, and access to a highway or railway for delivery of materials. As

with the staging sites, casting or staging yard sites may be identified as the design progresses or by the contractor and would be evaluated via a NEPA re-evaluation or supplemental NEPA document for potential environmental impacts at that time.

2.4 No-Build Alternative

The No-Build Alternative illustrates how transportation and environmental conditions would likely change by the year 2045 if the Modified LPA is not built. This alternative makes the same assumptions as the Modified LPA regarding population and employment growth through 2045, and it assumes that the same transportation and land use projects in the region would occur as planned.

Regional transportation projects included in the No-Build Alternative are those in the financially constrained 2018 *Regional Transportation Plan* (2018 RTP) adopted in December 2018 by the Metro Council (Metro 2018a) and in March 2019 (RTC 2019) by the Southwest Washington Regional Transportation Council (RTC) Board of Directors is referred to as the 2018 RTP in the Draft SEIS. The 2018 RTP has a planning horizon year of 2040 and includes projects from state and local plans necessary to meet transportation needs over this time period; financially constrained means these projects have identified funding sources. The Transportation Technical Report lists the projects included in the financially constrained 2018 RTP.

The implementation of regional and local land use plans is also assumed as part of the No-Build Alternative. For the IBR Program analysis, population and employment assumptions used in the 2018 RTP were updated to 2045 in a manner consistent with regional comprehensive and land use planning. In addition to accounting for added growth, adjustments were made within Portland to reallocate the households and employment based on the most current update to Portland's comprehensive plan, which was not complete in time for inclusion in the 2018 RTP.

Other projects assumed as part of the No-Build Alternative include major development and infrastructure projects that are in the permitting stage or partway through phased development. These projects are discussed as reasonably foreseeable future actions in the IBR Cumulative Effects Technical Report. They include the Vancouver Waterfront project, Terminal 1 development, the Renaissance Boardwalk, the Waterfront Gateway Project, improvements to the levee system, several restoration and habitat projects, and the Portland Expo Center.

In addition to population and employment growth and the implementation of local and regional plans and projects, the No-Build Alternative assumes that the existing Interstate Bridge would continue to operate as it does today. As the bridge ages, needs for repair and maintenance would potentially increase, and the bridge would continue to be at risk of mechanical failure or damage from a seismic event.

2.5 Development of the Modified LPA

As described earlier in this chapter, the 2011 ROD for the CRC project included a Selected Alternative that was modified through NEPA re-evaluations in 2012 and 2013 (CRC LPA). The CRC project was suspended in 2014. In 2019, a bi-state legislative committee requested that ODOT and WSDOT restart the CRC project, renaming it the IBR Program. This section describes the 2011 Selected Alternative cleared through the CRC NEPA process, changes that have occurred since that NEPA process was completed, and the screening of new design options for the IBR Program.

2.5.1 Selected Alternative in the 2011 Record of Decision and Subsequent Modifications in 2012 to 2013

Substantial technical analysis was completed to support the development of the CRC project. During the initial screening effort for the CRC project's NEPA alternatives analysis, the CRC team conducted a two-step

screening process that narrowed the number of alternatives to be evaluated in the Draft EIS. Step A evaluated 23 river crossing and 14 transit components using a pass/fail test designed to eliminate ideas beyond the scope of the project or ideas that clearly could not address the project's Purpose and Need statement. Results of Step A are detailed in Appendix C of the CRC Draft EIS (2008) and are summarized as follows:

- Fourteen of the 23 river crossing components were eliminated from further consideration. Some of the river crossing components that were eliminated included a high-level replacement bridge, supplemental bridge, replacement tunnel, and new corridor crossings.
- Eight of the 14 transit components were eliminated. Transit components that were eliminated included high-speed rail, ferry service, monorail system, magnetic levitation railway, commuter rail in the BNSF trackage, heavy rail, personal rapid transit, and people mover/automated guideway transit.

During Step B, components were scored on the project's Vision and Values (see Chapter 1 for more information on the Purpose and Need and Vision and Values). Results from Step B concluded that each of the remaining river crossing components had their strengths and weaknesses, but none were removed from consideration based on Step B screening. The remaining options were then shared with external partners and combined into 12 multimodal alternatives. These 12 alternatives received extensive public and agency input and analysis. In November 2006, based on this input and analysis, CRC project staff recommended advancing a range of alternatives to the CRC Draft EIS that included two HCT modes and a replacement mid-level fixed-span bridge (CRC 2007). The CRC staff recommendation stated "a replacement bridge would accommodate all types of travel over the Columbia River, including vehicles, freight, public transit, bicycles, and pedestrians. The bridge would be built high enough to avoid the need for a lift span [under the then-effective Coast Guard requirements]. It also would be designed to avoid impacts to the airspace of Pearson Air Park [sic]" (CRC 2007). The results of the analyses of these build alternatives in the CRC EIS informed project planning, design, and preconstruction activities. FHWA and FTA issued the ROD for the project on December 7, 2011. After the ROD was issued in 2011, the project design was further refined, and two NEPA re-evaluations were completed in 2012 and 2013, which analyzed the bridge height[12] and phased construction, respectively.[13]

2.5.2 Updating the CRC LPA

Table 2-6 lists the components of the CRC LPA, the corresponding modifications in the Modified LPA, and the changed conditions that prompted the modifications; the sections that follow detail the changed conditions that have occurred since 2013 and how those changed conditions resulted in modifications to the CRC LPA. Figure 2-26 shows, generally, which CRC project components have been changed for the Modified LPA.

[12] The Bridge Height NEPA Re-evaluation was signed by FHWA and FTA in December 2012. This re-evaluation considered an increase in the bridge's maximum vertical navigation clearance height from 95 feet to 116 feet; no significant additional impacts were identified. This re-evaluation was prepared in response to a request from the USCG to conduct additional analysis on navigation impacts. The CRC project team prepared an updated survey of river users and vessels and published a Navigation Impact Report in 2012 that provided detailed evaluation of midlevel bridge design refinement options with vertical clearances ranging from 95 to 125 feet above zero Columbia River Datum. Based on this analysis, and to further reduce navigational impacts, the CRC project maintained a fixed-span bridge but refined the bridge design and increased the bridge height to allow a vertical clearance in the primary navigation channel of 116 feet above zero Columbia River Datum.

[13] The Phased Construction NEPA Re-evaluation was signed by FHWA and FTA in September 2013. This re-evaluation considered the effects of phasing the construction of the Selected Alternative; phasing was disclosed as an option in the Final EIS and ROD. The re-evaluation also included design refinements to the full Selected Alternative as described in the ROD to make the first phase operate better. Some of the design refinements included modifying the Hayden Island interchange in the Selected Alternative first phase to reduce the number of new bridges over North Portland Harbor and to reduce cost while still improving interchange performance. The September 2013 re-evaluation found that the impacts associated with the full Selected Alternative and the Selected Alternative first phase were similar and within the range of impacts reported in the Final EIS and ROD.

Table 2-6. Comparison of CRC LPA and Modified LPA

Component	CRC LPA	IBR Program Modified LPA	Changed Conditions
Columbia River bridges (#6 in Figure 2-26)	• Replacement on a curved alignment: – Double-deck fixed-span truss bridge with 116 feet VNC.	• Replacement on a straight alignment: – Double-deck fixed-span truss bridges with 116 feet VNC. – Single-level fixed-span with 116 feet VNC. – Single-level movable-span with 178 feet VNC.	• 2013 Bridge Permit • USCG Bridge Permit Application Guide • Design optimization
I-5 highway (#1, 2, 4, 5, 6, and 7 in Figure 2-26)	• Improvements to seven interchanges (from south to north): Victory Boulevard, Marine Drive, Hayden Island (full interchange), SR 14, Mill Plain Boulevard, Fourth Plain Boulevard, and SR 500 (with new direct connections between SR 500 and I-5, new on- and off-ramps, and a tunnel beneath I-5), as well as related enhancements to the local street network. • Two auxiliary lanes added between Interstate Avenue/Victory Boulevard to SR 500.	• Improvements to seven interchanges (from south to north): Victory Boulevard, Marine Drive, Hayden Island (half-diamond interchange), SR 14, Mill Plain Boulevard, Fourth Plain Boulevard, and SR 500 (without proposed I-5 connections, ramps, or tunnel), as well as related enhancements to the local street network. • One or two auxiliary lanes between Marine Drive and SR 500. The two auxiliary lane option has the same alignment and lane configuration as the CRC LPA from Interstate Avenue/Victory Boulevard to SR 500. • An option that shifts the I-5 mainline up to 40 feet westward in downtown Vancouver between the SR 14 interchange and Mill Plain Boulevard interchange. • An option that eliminates the existing C Street ramps in Vancouver.	• Portland land use • Vancouver land use • Freight movements • Climate change • Portland's transportation hierarchy • Design optimization
North Portland Harbor bridge (#4 in Figure 2-26)	• Improvements to seismically retrofit the existing I-5 mainline bridge over North Portland Harbor; three new bridges over this waterway associated with I-5; and one new multimodal bridge carrying LRT, local traffic, pedestrians, and bicyclists.	• Replace the existing I-5 mainline bridge over North Portland Harbor and construct six new bridges that would carry LRT, southbound I-5 off-ramp, southbound I-5 mainline, northbound I-5 mainline, northbound I-5 on-ramp, and an arterial road for local traffic, pedestrians, and bicyclists.	• Updated AASHTO LRFD Bridge Design Specifications and AASHTO Seismic Guide Specifications • Degraded seismic resiliency

Component	CRC LPA	IBR Program Modified LPA	Changed Conditions
Active Transportation (see Figure 2-26)	• Bicycle and pedestrian improvements throughout the project corridor including a multiuse path connecting to the existing active transportation system and the Community Connector over I-5, just south of Evergreen Boulevard.	• Bicycle and pedestrian improvements throughout the project corridor including a multiuse path connecting to the existing active transportation system and the Community Connector over I-5, just south of Evergreen Boulevard.	• Active transportation connections • Portland's transportation hierarchy • Design optimization
Transit (#3, 6, 7, 8, and 9 in Figure 2-26)	• Extension of LRT from the Expo Center MAX Station in Portland to Clark College in Vancouver via at-grade tracks in Downtown Vancouver and associated transit improvements. • Five transit stations: one on Hayden Island, three in downtown Vancouver, and a terminus station near Clark College. • Three park and rides: Columbia (near the SR 14 interchange), Mill Plain (in uptown Vancouver) and Clark (on McLoughlin Boulevard near Clark College). • Improvements would have been made to retrofit the existing rails and electrical system on the Steel Bridge to allow trains to travel at a higher speed. • Local bus route changes. • Expansion of the Ruby Junction LRT maintenance facility.	• Extension of LRT from the Expo Center MAX Station in Portland to Evergreen Boulevard in Vancouver via elevated tracks adjacent to I-5 and associated transit improvements. • Three transit stations: one on Hayden Island, one in downtown Vancouver (Waterfront Station), and a terminus station near Evergreen Boulevard. • Two park and rides: Waterfront Station (Columbia Way, Columbia Street/SR 14, or Columbia Street/Phil Arnold Way) and Evergreen Station (Library Square or Columbia Credit Union). • Local and express bus route changes, including bus on the I-5 shoulders. • Expansion of the Ruby Junction LRT maintenance facility and an LRT overnight facility near Expo Center. • Wider shoulders on I-5 to accommodate express bus-on-shoulder service in each direction. • Additional bus bays for new electric double-decker buses at the C-TRAN operations and maintenance facility.	• Vancouver land use • Historic resources • Transit system and service • Design optimization

Component	CRC LPA	IBR Program Modified LPA	Changed Conditions
• Transportation demand and system management measures	• Variable-rate tolling for motorists using the river crossing as a demand-management and financing tool. • Other TDM and TSM measures including variable message signage, traveling information systems, ramp metering, signal prioritization, and other traffic management tools.	• Variable-rate tolling for motorists using the river crossing as a demand-management and financing tool. • Other TDM and TSM measures including variable message signage, traveling information systems, ramp metering, signal prioritization, and other traffic management tools.	• No changes.

AASHTO = American Association of State Highway and Transportation Officials; CRC = Columbia River Crossing; C-TRAN = Clark County Public Transit Benefit Area Authority; HCT = high-capacity transit; I-5 = Interstate 5; LPA = Locally Preferred Alternative; LRFD = load and resistance factor design; LRT = light-rail transit; MAX = Metropolitan Area Express; PNCD = Preliminary Navigation Clearance Determination; SR = State Route; USCG = U.S. Coast Guard; VNC = vertical navigation clearance

Figure 2-26. IBR Program Modifications to the CRC LPA Components

IBR Program Modifications

9 Park and Rides

Modifies park-and-ride locations (design options for locations at the Waterfront and Evergreen stations)

8 Light Rail Transit

Modifies alignment through downtown Vancouver to hug I-5 and moves terminus from Clark College to near Evergreen Blvd

7 Downtown Vancouver

Modifies access to/from SR 14

Modifies Waterfront Station location (design option without a C Street ramp and design option with I-5 westward shift)

6 Columbia River Bridges

Modifies the two bridges from a curved alignment to a straight alignment (bridge configurations with a double-deck fixed-span, single-level fixed-span, and single-level movable-span)

5 Hayden Island Interchange

Modifies full interchange to half-diamond interchange

Minor modifications to local road configuration

4 North Portland Harbor I-5 Bridge

Replaces existing North Portland Harbor I-5 bridge (instead of retrofitting) and moves local access bridge to east side of I-5

3 Expo Center Overnight Facility

Adds overnight maintenance facility for TriMet light rail vehicles

2 Marine Drive Interchange

Modifies interchange access

1 Victory Boulevard Interchange

Minor modifications to access

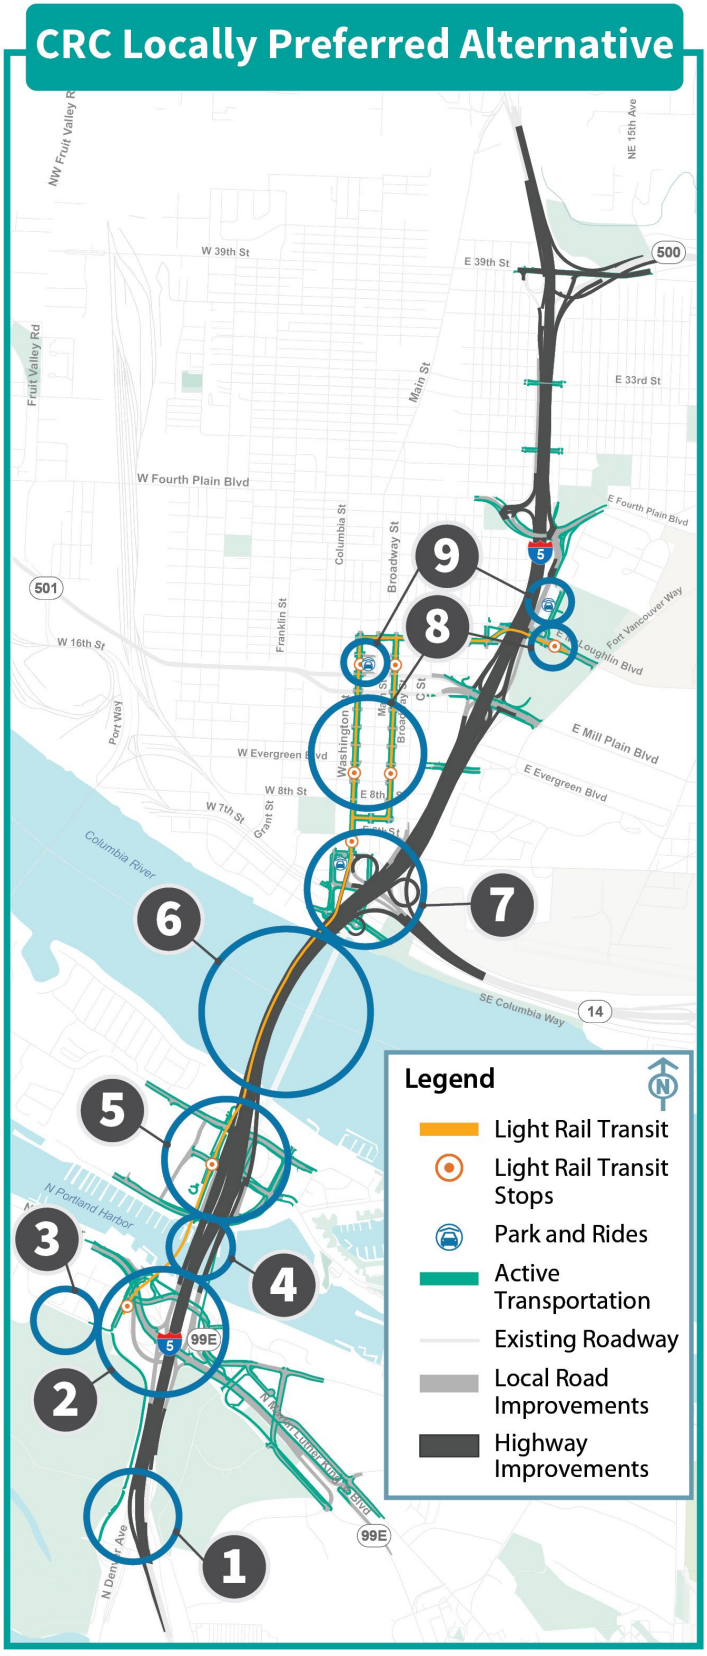
Active Transportation

Modifies alignment of shared-use path and ties in to planned projects (e.g., 40-Mile Loop Trail and two-way cycle track on Fourth Plain)

Auxiliary Lanes

Reduces number of auxiliary lanes from two to one (design option for two auxiliary lanes)

CRC Locally Preferred Alternative



Changes in Conditions since 2013

Since the issuance of the CRC ROD, as revised by the 2012 and 2013 re-evaluations (CRC LPA), existing environmental conditions have changed; these changes range from physical changes in the environment within the Program footprint to regulatory changes to changes in community priorities and interests. Many of these physical and quantifiable changes have caused agencies to adjust their preferences and priorities to better reflect the evolving needs of the communities they represent. A summary of the changes since 2013 include the following:

- **Active transportation connections.** Local agencies have made changes to active transportation planning, including both existing and planned active transportation in Portland and Vancouver. For example, currently planned or existing active transportation that was not in existence at the time of the CRC project include the 40-Mile Loop Trail in Portland and the two-way cycle track on Fourth Plain Boulevard in Vancouver. This changed condition resulted in modifications to the active transportation component of the Modified LPA.
- **2013 Bridge permit.** The USCG Bridge Permit was issued on September 27, 2013. Because the CRC project was suspended in 2014, this permit is no longer valid. The height and span of the replacement bridges need to be reexamined in accordance with the 2016 bridge permit application guidance, with input from USCG to ensure the replacement bridge design would meet reasonable needs of navigation and would obtain required permits. This changed condition resulted in modifications to the Columbia River bridge component of the Modified LPA.
- **Changes in regulations.** Many environmental regulations, procedures, and permit requirements have changed or been updated since the issuance of the CRC LPA. The discipline-specific technical reports prepared for this Draft SEIS include additional detail on specific regulations that have changed since 2013.
- **Climate change.** Since 2011, awareness and acceptance of the implications and impacts of climate change has grown. Many communities, agencies, and businesses are reassessing their behavior and operations to identify how they might be contributing to global warming and resultant climate change, and they are examining how their environment is changing due to climate change. Both Washington and Oregon have established new climate plans, policies, and legislation since 2011. Washington has established statewide greenhouse gas (GHG) reduction targets and is charging state agencies (like WSDOT) to reduce transportation emissions through investments and spending decisions. Oregon has established statewide GHG reduction targets, updated statewide planning rules to reduce emissions, and created an ODOT Climate Action Plan to reduce emissions from the transportation system and improve resilience. Local governments in the study area have also established new climate plans and polices since 2011. Additionally, recent exceptional weather events are driving changes in considerations and assumptions about climatic conditions and related community needs for climate resiliency. See Section 3.19, Climate Change, for additional information. This changed condition resulted in modifications to the I-5 highway component of the Modified LPA.
- **Degraded seismic resiliency.** With no improvements made to the existing North Portland Harbor bridge, its seismic resiliency continues to degrade as time passes. This changed condition resulted in modifications to the North Portland Harbor bridge component of the Modified LPA.
- **Demographics.** The Portland-Vancouver metropolitan area added more than a quarter of a million residents between 2010 and 2020, with the majority being Black, Indigenous, or People of Color (BIPOC) and/or Hispanic/Latino (U.S. Census Bureau 2010; U.S. Census Bureau 2020). This changed condition did not result in design modifications, but was considered in the existing conditions and environmental consequences analysis in Chapter 3.

- **Design optimization.** Engineering decisions related to the CRC LPA were revisited for some components to determine if avoidance and minimization to environmental resources, constructability improvements, or cost-reduction strategies were available. Additionally, because of the intrinsic connectivity of each of the Program elements, a change in design to one component of the CRC LPA often necessitates a design change to a connected component. This resulted in design modifications to the Columbia River bridges, the I-5 highway, active transportation, and transit components of the Modified LPA.
- **Endangered Species Act (ESA).** ESA listings and critical habitat designations have changed since the 2013 consultations with the National Oceanic and Atmospheric Administration (NOAA) National Marine Fisheries Service (NOAA Fisheries) and the U.S. Fish and Wildlife Service (USFWS) (NOAA n.d.; USFWS 2021). These changes require consideration of how to best avoid and minimize impacts to species and their habitat, including the timing of the in-water work and updating run timing for salmon species. The IBR Program inititiated new Section 7 ESA consultations with NOAA Fisheries and USFWS on September 25, 2023 to bring the consultations up to date with current species listings and critical habitat designations and to reflect changes in best available science. USFWS issued a new Letter of Concurrence on December 11, 2023 and NOAA Fisheries will prepare a new biological opinion. This changed condition did not result in design modifications, but was considered in the existing conditions and environmental consequences analysis in Chapter 3.
- **Freight movements.** Freight movements by truck have changed, with less freight anticipated to be moved through the Hayden Island interchange as the Port of Portland is no longer planning to develop West Hayden Island into a port facility. Meanwhile, industrial development, much of which uses trucks delivery has grown in North Portland industrial areas, has added truck volume to the Marine Drive interchange. This changed condition resulted in modifications to the I-5 highway component of the Modified LPA.
- **General Bridge Act of 1946, as amended (USCG Bridge Permit Application Guide).** USCG issued a new bridge permit application guide (COMDTPUB P16591.3D) in July 2016 which requires the preparation and submittal of a navigation impact report to the USCG to analyze the navigational impacts from bridge design alternatives and document current and prospective navigation on a waterway. A navigation impact report is prepared early in project planning and is updated periodically during project development because waterways and waterway usage are dynamic and may change over time. The USCG then issues a PNCD to inform the NEPA alternatives analysis for the environmental documentation (USCG 2016). Also, the USCG Bridge Permit process must now be completed in accordance with the USCG -FHWA-FTA Federal-Railroad Administration Memorandum of Understanding (2014) and the USCG-FHWA Memorandum of Agreement (2014). This changed condition resulted in modifications to the Columbia River bridge component of the Modified LPA.
- **Historic resources.** Additional historic-aged structures potentially eligible for listing on the National Register of Historic Places have aged into consideration since the previous historic period survey. To thoroughly consider resources that may reach historic-age during construction, the historic resources period has been extended 15 years to consider buildings built in or prior to 1982. This changed condition resulted in modifications to the transit component of the Modified LPA.
- **Housing costs.** The cost of housing increased significantly, forcing many households with lower incomes to move to neighborhoods where housing is more affordable but that may be farther from job and activity centers (Metro 2015). The combination of longer distances traveled and limited public transit service in these areas puts an added transportation cost burden on these community members, including many who moved from Portland, Oregon, to Clark County, Washington, but still need to travel to Portland for work, medical appointments, family, or other needs (Metro 2018b). Related to rising housing costs is a growing houseless population throughout the region (Clark County Council for the Homeless 2022; Multnomah County Joint Office of Homeless Services 2022). The number of encampments has increased,

including in the highway right of way and throughout the study area. This changed condition did not result in design modifications, but was considered in the existing conditions and environmental consequences analysis in Chapter 3.

- **Levees.** USACE, in partnership with the UFSWQD, is planning improvements to the existing levees along the south side of North Portland Harbor (the Levee Ready Project). It is anticipated that the new levee design will require the IBR Program to stay above a 38-foot elevation (NAVD 88). Alterations to I-5 will require review by the USACE, UFSWQD, and the City of Portland for compliance with levee requirements associated with the Levee Ready Project. This changed condition did not result in design modifications, but was considered in the existing conditions and environmental consequences analysis in Chapter 3.
- **Portland land use.** Portland has undergone significant changes in land use policy, particularly through the adoption of the 2035 Comprehensive Plan, which emphasizes the integration of nature and green infrastructure and encourages the design and management of streets to serve as multifunctional spaces. Planned land uses on Hayden Island and near Marine Drive have changed, with a shift to less intensive uses (e.g., a marine terminal is no longer planned at the west end of Hayden Island). Portland's 2009 *Hayden Island Plan* (City of Portland 2009) calls for the development of new parks and open spaces for habitat on Hayden Island, including a potential new park west of the existing I-5 and under the replacement bridges. Portland's *2035 Comprehensive Plan* (City of Portland 2020) also anticipates several watershed restoration projects in the Delta Park area. This changed condition resulted in modifications to the I-5 highway component of the Modified LPA.
- **Portland transportation hierarchy.** The City of Portland uses a transportation hierarchy to prioritize modes when making transportation investment and design decisions. Variations of this hierarchy existed during the CRC project, but it was last updated with policy 9.6 in the City of Portland's *2035 Comprehensive Plan* (City of Portland 2020). The prioritization of modes has changed since the CRC project, including the elevation of transit to the third priority, following walking and biking. This changed condition resulted in modifications to the I-5 highway and active transportation components of the Modified LPA.
- **Project footprint.** Community and local agency feedback suggested that the project's footprint on Hayden Island was too large under the CRC LPA. Although this preference was voiced during CRC, the design was not adjusted at that time. Similar feedback was heard during the design option development phase (see Section 2.5.3, IBR Design Option Development and Screening) and was integrated into the Modified LPA. This changed condition resulted in modifications to the I-5 highway component of the Modified LPA.
- **Tolling.** Tolling programs are being studied in Oregon (ODOT n.d.). Tolling on the new Columbia River bridges was included in the CRC analysis and is included in the IBR analysis. This changed condition did not result in design modifications, but was considered in the existing conditions and environmental consequences analysis in Chapter 3.
- **Traffic.** Changes have occurred since 2013 in traffic volumes and activities (RTC n.d.). The IBR Program has updated traffic models to extend the forecast to 2045 (CRC used 2030). This changed condition did not result in design modifications, but was considered in the existing conditions and environmental consequences analysis in Chapter 3.
- **Transit system and service.** Changes in existing transit services and activities include the construction and operation of the C-TRAN Fourth Plain and Mill Plain Vine BRT routes, which began service in 2017 and 2023, respectively, and bus-on-shoulder operations on I-5 north of the Interstate Bridge, which began in 2020. A third BRT line that would extend north from downtown Vancouver along Highway 99 is in the planning stage. A Fourth Plain extension serving Fourth Plain Boulevard and 162nd Avenue is also in the

planning stage. TriMet has also expanded operations and planning for additional BRT service in the region. This changed condition resulted in modifications to the transit component of the Modified LPA.

- **Updated American Association of State Highway and Transportation Officials (AASHTO) Load and Resistance Factor Design (LRFD) Bridge Design Specifications and the AASHTO Seismic Guide Specifications.** The current AASHTO LRFD Bridge Design Specifications and the AASHTO Seismic Guide Specifications have been updated. This changed condition resulted in modifications to the North Portland Harbor bridge component of the Modified LPA.
- **Vancouver land use.** Localized development has occurred in downtown Vancouver and at the Vancouver waterfront that includes construction and buildings developed since issuance of the CRC ROD or building permit applications. This development is consistent with local development plans including the Vancouver City Center Vision, Waterfront Master Plan, and Terminal 1 Concept Development Plan. Design modifications are necessary to minimize property impacts and improve access. This changed condition resulted in modifications to the I-5 highway and transit components of the Modified LPA.

How the Changed Conditions Modified the CRC LPA and Resulted in the IBR Modified LPA

Many of the changed conditions listed above resulted in modifications to certain CRC LPA components and resulted in the Modified LPA. How the changed conditions led to each Modified LPA component is described below.

Columbia River Bridges

The following changed conditions contributed to modifications to the Columbia River bridges component: USCG Bridge Permit Application Guide, the 2013 Bridge Permit, and design optimization. Modifications to the Columbia River bridges include straightening the bridge alignment and adding additional bridge configuration options.

The Modified LPA has a straightened bridge alignment because of the changed conditions that prompted replacement of the North Portland Harbor bridge (described below). Previously, the North Portland Harbor bridge would have been retrofitted in place, which would have required the Columbia River bridges to have a curved alignment in order to connect to the existing North Portland Harbor bridge. Under the Modified LPA, the replacement North Portland Harbor bridges would be located west of the existing location, shifting I-5 slightly west and enabling the Columbia River bridges to have a straight alignment, which would improve constructability.

The Modified LPA has two single-level bridge configuration options. These configurations were included in response to design optimization efforts to make improvements to address ingress and egress of transit, which is located on the lower level of the double-deck fixed-span configuration.

A single-level movable-span configuration was included in response to changes to the USCG Bridge Permit Application Guide and because the 2013 Bridge Permit has expired. After following the updated USCG permit process, the USCG issued a PNCD in June 2022 that required at least 178 feet of vertical navigation clearance (VNC), which is consistent with the existing VNC of the Interstate Bridge. The single-level movable-span configuration would provide 178 feet of VNC.

I-5 Highway

The following changed conditions contributed to modifications to the I-5 highway component: Portland and Vancouver land use, freight movements, climate change, Portland's transportation hierarchy, and design optimization. Modifications to the I-5 highway include changes to interchanges and access, the addition of a one auxiliary lane option, and the addition of options to remove the C Street ramp and shift the I-5 alignment west in downtown Vancouver.

Some interchange improvements and access were modified in response to changed conditions, including changes to Portland and Vancouver land uses and changes to freight movement. For example, the Hayden Island interchange was changed from a full interchange in the CRC LPA to a half-diamond interchange in the Modified LPA due to reductions in planned freight movement on the island and changes in Portland land use.

A one auxiliary lane option was included as part of the Modified LPA to reduce the highway footprint and increase multimodal transportation use in response to community and local agency priorities, including climate change policies and the City of Portland's transportation hierarchy. To optimize the design, further modifications to interchanges were necessitated to accommodate the one auxiliary lane option.

Design optimization efforts also resulted in adding an option to shift the I-5 mainline slightly west in downtown Vancouver to evaluate another approach to minimize impacts to environmental resources on both sides of I-5. Design optimization efforts also resulted in adding an option to eliminate the C Street ramps in Vancouver to reduce the Program footprint.

North Portland Harbor Bridge

Both of the following changed conditions contributed to modifications to the North Portland Harbor component: updated AASHTO LRFD Bridge Design Specifications and AASHTO Seismic Guide Specifications and degraded seismic resiliency. Modifications to the North Portland Harbor bridge include replacing the bridge instead of retrofitting it.

The Modified LPA replaces the North Portland Harbor bridge because the bridge's seismic resiliency has continued to degrade over time, to the point that it would be cost prohibitive to retrofit the existing bridge to address seismic vulnerability. In addition, the current AASHTO LRFD Bridge Design Specifications and the AASHTO Seismic Guide Specifications have been updated and, when applied to the existing bridge, indicate an increased need to replace this seismically deficient structure to improve seismic resiliency in the corridor. Replacement bridges over North Portland Harbor and the Columbia River would be designed to the same seismic and resiliency standards to provide consistent seismic resiliency from the North Portland mainland to Vancouver, a complete river crossing.

Active Transportation

The following changed conditions contributed to modifications to the active transportation component: active transportation connections, Portland's transportation hierarchy, and design optimization. Modifications to the active transportation component include modifications in the design to connect to existing and planned active transportation systems in the Program area. Bicycle and pedestrian improvements would continue to be incorporated throughout the Program area.

Some details of the bicycle and pedestrian improvements were modified due to changes in active transportation connections and a change in the City of Porland's transportation hierarchy. For example, existing and planned active transportation projects in Portland and Vancouver that prompted design modifications to maintain connectivity include the 40-Mile Loop Trail in Portland and the two-way cycle track on Fourth Plain Boulevard in Vancouver.

Additionally, the changed conditions that prompted the replacement of the North Portland Harbor bridge (described above) allowed the IBR Program to optimize the location of the local arterial bridge to the east of I-5 under the Modified LPA (previously west of I-5 in the CRC LPA), which necessitated changes in active transportation connections in the vicinity of the Marine Drive and Hayden Island interchanges. In addition, design optimization efforts resulted in realigning active transportation facilities near modified interchanges.

Changes to transit station locations and the LRT alignment (described below) also led to changes in active transportation connections to these transit facilities.

Transit

The following changed conditions contributed to modifications to the transit components: Vancouver land use, historic resources, the existing and planned regional transit system and service, and design optimization. Modifications to the transit component include modifications to the LRT alignment, terminus, and station locations; bus-on-shoulder and express bus operations; and transit facilities.

Changes to Vancouver land use, including new development and new transit service, have increased development in downtown Vancouver, in and around the Vancouver waterfront, and along the path of the LRT alignment under the CRC LPA. In addition, there was an increase in the number of historic resources (i.e., additional historic-aged structures potentially eligible for listing on the National Register of Historic Places, as described in Section 3.8, Cultural Resources) in downtown Vancouver. These changed conditions necessitated design modifications, including shifting the LRT alignment adjacent to I-5 and elevating the LRT tracks. These modifications help minimize property impacts in Vancouver and improve access to C-TRAN bus routes.

In addition to a change in alignment, the terminus at Clark College in the CRC LPA has been modified to end near Evergreen Boulevard. Since the CRC LPA, C-TRAN has implemented a BRT system that serves the area of the CRC LPA terminus at Clark College. This new service was one of the contributing reasons for a change in LRT terminus under the Modified LPA. In the Modified LPA, a terminus near Evergreen Boulevard maximizes transfer opportunities to C-TRAN transit service as it provides direct connections to several local routes, as well as existing and planned BRT routes.

The change in LRT alignment and terminus (described above), as well as new development in downtown Vancouver (Vancouver Land Use), and transit systems and service enhancements that have been made within the Program footprint as part of C-TRAN's transportation planning, also necessitated changes to the stations and park-and-ride locations and the number of parking spaces that are planned for as part of the Modified LPA.

The CRC LPA assumed that the I-5 express bus service would be reduced between downtown Vancouver and Portland, with the I-5 route from Salmon Creek ending in downtown Vancouver and forcing a transfer to light-rail for the trip across the Columbia River. C-TRAN began express bus-on-shoulder operations in limited sections of its express routes in 2017, after the CRC project was halted. The successful implementation of express bus-on-shoulder on the southbound inside shoulder of I-5 in Vancouver—along with local agency and community priorities to minimize transfers and provide added capacity that is needed to meet cross-river demand—prompted the design modifications to I-5 shoulders through the Program area in the Modified LPA. With these changes, the Modified LPA would allow C-TRAN to continue to provide express bus service operating in shoulders in the southbound direction and add the ability to operate in shoulders in the northbound direction. The shoulder operations would extend through the entire Program area and would allow faster operational speeds than are currently possible (35 mph maximum speeds vs. 25 mph maximum speeds currently). In addition to bus-on-shoulder design modifications, service increases on I-5 express buses were needed because the lower number of proposed park-and-ride locations in Washington under the Modified LPA increased the importance of C-TRAN's connected express bus service across the Columbia River. The need for greater express bus service in turn necessitated the need for additional bus bays at the C-TRAN operations and maintenance facility.

Both TriMet and C-TRAN continually update their service in response to changing system needs. Since the CRC LPA was developed, both agencies have implemented BRT service, and C-TRAN has implemented cross-river regional service and modified how it operates its express services. Both BRT services have been updated in future year networks to reflect how these agencies currently operate and how they anticipate operating in the future, which is different from the assumptions upon which the CRC LPA was based. To accommodate current transit service and operations for both agencies, the designs of both the Waterfront

and Evergreen Stations include integration of C-TRAN BRT, express and local bus service and at the redesigned Expo Station include integration of TriMet local bus service.

An overnight LRV facility at the Expo Center was not part of the CRC LPA, which assumed that LRVs would be accommodated through the expansion of Ruby Junction. With changes to the Modified LPA in Vancouver resulting from community and local agency priorities, as discussed above, the IBR Program examined ways to reduce the long-term operations and maintenance costs on the system. This led to the consideration and inclusion of the Expo Center site as an overnight LRV facility.

Transportation Demand and System Management Measure

There were no changes to the transportation demand and system management measures from the CRC LPA to the Modified LPA.

2.5.3 IBR Design Option Development and Screening

During the early planning phase for the IBR Program, feedback from partner agencies, tribes, organizations, and the public identified changed conditions within the study area that had occurred since the selection of the CRC LPA. In response, the IBR Program identified that several components of the CRC LPA required design modifications. Potential options for each of these components went through a multitiered screening process that included input from Program partners, tribes, and community members. The screening process, including details on why design options were advanced or dropped from further screening, is included in Appendix D, Design Options Development, Screening, and Evaluation Technical Report. The components evaluated were:

- Hayden Island and Marine Drive
- Main Columbia River crossing
- Transit mode, general alignment, and termini
- Auxiliary lanes

The IBR Program held a targeted period of engagement between January and April 2021 to gather feedback from advisory groups and the public on transportation problems and to understand community priorities and values. Feedback from these groups emphasized that *equity* and *climate* considerations are high priorities for the region. The Program developed equity and climate frameworks to define performance measures and ensure that these values are reflected in Program decisions. Equity and climate considerations were included in the screening process to develop the Modified LPA (see Appendix D).

The evaluation of each component is described briefly below. For more detailed information on the process by which design modifications were required to address changed conditions since the 2011 ROD, as revised by the 2012 and 2013 re-evaluations, were developed and screened, see Appendix D, the Design Options Development, Screening, and Evaluation Technical Report.

Hayden Island and Marine Drive

The IBR Program identified the following changes in conditions since 2013 related to Marine Drive and Hayden Island through advisory group input, community feedback, and input from agency partners serving on the Hayden Island/Marine Drive Task Force[14] (refer to Appendix D, Design Options Development, Screening, and Evaluation Technical Report, for additional information). These changed conditions, detailed in Section 2.5.2,

[14] The Hayden Island/Marine Drive Task Force met 18 times between late spring 2021 and early winter 2022. There was an average of 50 participants per meeting, with staff from 10 local partner agencies and technical staff from the IBR Program.

Updating the CRC LPA, necessitated the development of design options for the Marine Drive and Hayden Island interchanges:

- Freight movements
- Levee
- North Portland Harbor bridge
- Portland land use
- Project footprint
- Portland's transportation hierarchy

The primary design considerations for Hayden Island and Marine Drive were the interchange type on Hayden Island and the resulting multimodal connections with Marine Drive and I-5. The IBR Program evaluated multiple concepts, ultimately advancing five full-, partial-, and no-interchange options for Hayden Island into the screening process. All design options included a full interchange at I-5/Marine Drive; an arterial bridge across North Portland Harbor to serve local traffic; a shared-use path for active transportation connecting North Portland, Hayden Island, and the 40-Mile Loop Trail; and the extension of Tomahawk Island Drive under I-5 to provide an additional east-west local street connection on Hayden Island.

The Hayden Island/Marine Drive Task Force identified the following five design options to advance for screening (refer to Appendix D, the Design Options Development, Screening, and Evaluation Technical Report, for a complete description of each design option):

- Design Option 1 – Full Interchange
- Design Option 2 – Partial Interchange 1
- Design Option 3 – Partial Interchange 2
- Design Option 4 – No Interchange
- Design Option 5 – Partial Interchange 3

During screening, the task force collected data for approximately 90 metrics and scored each design option against the others for a given metric. Screening metrics were categorized as climate impacts/adaptation, natural environmental, built environment, active transportation, transit access, vehicles, freight, cost, and seismic. Design Options 1 and 5 performed best out of all design options. They had a similar freight/vehicle traffic performance on Marine Drive, including at ramp terminal intersections, and were both compatible with all transit investments currently under consideration.

Tradeoffs and benefits between Design Options 1 and 5 are listed in Table 2-7 to further differentiate between the two options.

Table 2-7. Tradeoffs and Benefits Between Hayden Island/Marine Drive Design Options 1 and 5

Design Option 1 – Full Interchange	Design Option 5 – Partial Interchange
Larger footprint over North Portland Harbor.	**Smaller** footprint over North Portland Harbor.
More floating home impacts.	**Fewer** floating home impacts.
Larger scale and complexity of I-5 over Hayden Island provides **lower**-quality experience for active	**Smaller** scale and complexity of I-5 over Hayden Island provides **higher**-quality experience for active

Design Option 1 – Full Interchange	Design Option 5 – Partial Interchange
transportation and transit access on east-west streets.	transportation and transit access on east-west streets.
Hayden Island vehicle/freight access to/from Portland **via Hayden Island Drive I-5 ramps.**	Hayden Island vehicle/freight access to/from Portland **via local roads and I-5 ramps that cross under Marine Drive.**
Hayden Island vehicle/freight access to/from Vancouver via Jantzen Drive I-5 ramps.	Hayden Island vehicle/freight access to/from Vancouver via Jantzen Drive I-5 ramps.
Scores **medium-high** from a **climate** perspective.	Scores **high** from a **climate** perspective.
Scores **medium** from an **equity** perspective.	Scores **medium** from an **equity** perspective.

Based on the findings in Table 2-7, Design Option 5 (Partial Interchange) was advanced for further study and refinement and ultimately inclusion in the Modified LPA. Design Option 5 would construct a partial interchange at Hayden Island and a full interchange at Marine Drive; it was selected because it would be designed to minimize impacts while making improvements to freight and workforce traffic and active transportation on Hayden Island and Marine Drive. Refer to Appendix D, the Design Options Development, Screening and Evaluation Technical Report, for additional detail.

Main River Crossing

The IBR Program identified the following changes in conditions since 2013 related to the main river crossing through advisory group input, community feedback, and input from agency partners serving on the River Crossing Task Force[15] (refer to Appendix D, Design Options Development, Screening, and Evaluation Technical Report, for additional information). These changes, detailed in Section 2.5.2, Updating the CRC LPA, necessitated the development of design options for the river crossing. Additionally, design options for the river crossing are necessary to accommodate the potential design changes identified for the Hayden Island and Marine Drive interchanges, described above.

- Active transportation connections
- 2013 Bridge Permit
- Changes in regulations
- ESA
- Transit system and service
- Vancouver land use

The river crossing area covers the main span of the existing Interstate Bridge over the Columbia River. This component extends from where the bridge begins on Hayden Island to where the bridge touches down in Vancouver. The design options considered ways to move all modes across the river, as well as the configuration of these modes in relation to each other (e.g., the location of the shared-use path in relation to vehicle lanes and transit lines). The design options included variations designed for a two-bridge or

[15] The River Crossing task force consisted of technical staff from ODOT, WSDOT, C-TRAN, TriMet, Metro, RTC, City of Portland, City of Vancouver, Port of Portland, Port of Vancouver, and the IBR Program. The task force met 11 times between summer 2021 and winter 2022 with an average of 50 participants per meeting.

one-bridge river crossing option, and they assumed a mid-level fixed-span bridge that provides 116 feet of vertical navigation clearance.[16]

Following agency and public input, the River Crossing Task Force identified three design options to advance for screening (refer to Attachment C.C-1, River Crossing Bridge Clearance Assessment Report – Movable Span Options, in Appendix D, the Design Options Development, Screening, and Evaluation Technical Report, for a complete description of each design option):

- Design Option 1 – Two Straight Bridges (Refined 2013 Design)
- Design Option 2 – One Bridge (Double-Stacked)[17]
- Design Option 3 – One Bridge (Hybrid-Stacked)

During screening, the task force collected data for approximately 90 metrics and scored each design option against the others for a given metric. Screening metrics were categorized as climate impacts/adaptation, natural environment, built environment, active transportation, vehicles/freight, and cost. Design Options 1 and 3 performed the best of the design options during the screening.

Tradeoffs and benefits between Design Options 1 and 3 are listed in Table 2-8 to further differentiate between the two options.

Table 2-8. Tradeoffs and Benefits between River Crossing Design Options 1 and 3

Design Option 1 – Two Straight Bridges	Design Option 3 – One Bridge (Hybrid-Stacked)
Reduces shared-use path users' exposure to noise and elements.	**Increases** shared-use path users' exposure to noise and elements.
Creates **visually uncluttered** structures on Hayden Island and scales them to surroundings.	Results in **complex** bridge approaches on Hayden Island and in Vancouver.
Easier-to-fund river crossing bridge because it would allow phased construction to maintain operational traffic on I-5 across the Columbia River.	**Harder**-to-fund river crossing bridge because it would not allow for phased construction or maintenance on I-5 across the Columbia River.
No undesignated space on upper deck.	**Creates undesignated** space on upper deck.
Fewer right-of-way acquisitions and impacts to Fort Vancouver.	**More** right-of-way acquisitions and impacts to Fort Vancouver because the lower deck would be wider on the eastern side and would require additional right of way to accommodate the shared-use path ramp from the bridge to ground level.
Smaller footprint over land.	**Larger** footprint over land because the lower deck would be wider on the eastern side and would require additional right of way to accommodate the shared-use path ramp from the bridge to ground level.

[16] 116 feet of vertical navigation clearance was assumed during this screening effort because it was the same vertical navigation clearance assumed after the CRC project's 2012 re-evaluation regarding bridge height. Additional analysis regarding the consideration of a tunnel and movable-span bridge is included in Attachment C-1 of the Design Options Development, Screening, and Evaluation Technical Report (Appendix D).

[17] "Double stacked" means that both the northbound and southbound highway would be stacked, and the transit and SUP would be stacked. The upper level of the bridge would have southbound highway traffic adjacent to the shared-use path and the lower level would have northbound highway traffic adjacent to transit.

Design Option 1 – Two Straight Bridges	Design Option 3 – One Bridge (Hybrid-Stacked)
Simpler wayfinding on northbound I-5.	Overhead structure **complicates** wayfinding on northbound I-5 (requires approvals for signage smaller than standards).
Can maintain traffic on existing Interstate Bridge during construction.	**Cannot maintain** traffic on existing Interstate Bridge during construction.
Scores **medium-high** from an **equity** perspective.	Scores **medium** from an **equity** perspective.
Scores **medium-high** from a **climate** perspective.	Scores **medium-high** from a **climate** perspective.
Longer construction period.	**Shorter** construction period.
Emergency vehicles access shared-use path via **shared-use path ramps** on Hayden Island and downtown Vancouver.	Emergency vehicles access shared-use path via **northbound I-5** or **shared-use path ramps** on Hayden Island and downtown Vancouver.
Likely uses **more** construction materials (based on the footprint, not expected tailpipe emissions).	Uses marginally **fewer** construction materials (based on the footprint, not expected tailpipe emissions).
More in-water piers/obstructions: • 12 in-water piers (each pair of piers measures approximately 200 feet combined in direction of river channel).	**Fewer** in-water piers/obstructions: • 6 in-water piers (each pier measures approximately 175 feet in direction of river channel).
Larger footprint over aquatic habitat (approximately 12 acres).	**Smaller** footprint over aquatic habitat (approximately 10 acres).
Lower deck shared-use path **not visible** to vehicular traffic, does not benefit from "eyes on the path" (a safety concern for active transportation users).	**Allows some visibility** between shared-use path and vehicular traffic on lower deck.

Based on the findings in Table 2-8, Design Option 1 (Two Straight Bridges) was advanced for further study and refinement. Design Option 1 would construct two bridges from Hayden Island to Vancouver on a straight alignment. The eastern bridge would accommodate northbound highway traffic on the upper bridge deck, with a bicycle and pedestrian path underneath; the western bridge would carry southbound traffic on the upper bridge deck, with two-way transit below. Design Option 1 was selected because it would have fewer impacts, can maintain traffic during construction, and scored higher from an equity and climate perspective. Design Option 1 is referred to as the double-deck fixed-span configuration in this SEIS. Refer to Appendix D, the Design Options Development, Screening, and Evaluation Technical Report, for additional information.

The CRC project proposed to construct a bridge with a vertical navigation clearance of 116 feet because that design balanced the needs of navigation, airfield operations, and surface transportation, while minimizing additional landside and environmental impacts. In September 2013, the USCG issued a bridge permit for the construction of the replacement bridges over the main span of the Columbia River as proposed by the CRC project. That permit expired when CRC was suspended; other required permits/authorizations were not completed, mitigation was not implemented, and construction had not started within three years, so a new bridge permit would be required for the IBR Program. In November 2021 (revised in May 2022), the IBR Program prepared a navigation impact report as an update to the 2012 CRC Navigation Impact Report to reflect changed conditions and development since the original navigation impact report and to reflect the change in USCG guidance since the CRC project was suspended. The IBR Program's Navigation Impact Report

provides detailed consideration of a fixed-span bridge over the Columbia River with a vertical clearance of 116 feet to 121 feet over 0 feet Columbia River Datum because these heights and associated avoidance and mitigation strategies would be expected to support reasonable navigation.

In June 2022, USCG issued a PNCD that set a requirement for a vertical clearance of 178 feet for the reasonable needs of navigation. In response to the determination, the IBR Program developed a bridge configuration for the Modified LPA that would include a single-level movable-span bridge over the Columbia River that provides 178 feet of vertical navigation clearance. The IBR Program also added a single-level fixed-span configuration in response to physical and contextual changes since 2013 that warranted a refinement in the double-deck configuration based on current design and operational requirements. The IBR Program is carrying forward the three bridge configurations to address changes in the USCG bridge permitting process and to ensure a permittable bridge configuration is evaluated in the Draft SEIS. The IBR Program continues to refine the details supporting navigation impacts and is coordinating closely with the USCG to determine how a fixed-span bridge may be permittable. All three bridge configurations are described in Section 2.2.3, Columbia River Bridges (Subarea B) and are analyzed throughout this Draft SEIS.

Transit – Mode, General Alignment, and Termini

The IBR Program identified the following changes in conditions since 2013 related to transit through advisory group input, community feedback, and input from agency partners serving in the Transit Options Technical Session (refer to Appendix D, Design Options Development, Screening, and Evaluation Technical Report, for additional information). These changes, detailed in Section 2.5.2, Updating the CRC LPA, led to the development of transit options that were analyzed.

- Transit system and service
- Vancouver land use

The IBR Program and the agency partners serving in the Transit Options Technical Session developed 13 representative transit investments (listed in Table 2-9) to better understand how different combinations of mode (BRT and LRT), alignment, station locations, termini (end points), and park-and-ride locations could perform relative to each other. Each of the representative transit investments was modeled through the Metro/RTC regional travel demand model to arrive at forecasts for the year 2045. IBR Program partners and the IBR team developed measures to better understand how the representative transit investments would perform relative to each other.

The IBR Program's screening process confirmed the CRC decision to extend LRT into Vancouver; however, the process also led to refinements of the proposed alignment, station locations, park-and-ride facilities, and termini locations as compared to CRC. The IBR Program advanced the extension of LRT from the Expo Center MAX Station in Portland north to a new station on Hayden Island, continuing across the Columbia River on the new Columbia River bridge, following I-5 to multiple stations in Vancouver with a northern terminus at Evergreen Station. Table 2-9 describes the 13 representative transit investments that were evaluated, and the sections below describe how the Modified LPA transit mode, general alignment, and termini were selected. Also refer to Appendix D, the Design Options Development, Screening, and Evaluation Technical Report, for additional information.

Table 2-9. Representative Transit Investment Descriptions

Representative Transit Investment	General Description
No-Build	The No-Build scenario reflects planned systemwide increases in background transit service by both TriMet and C-TRAN as adopted by both Metro and RTC in their respective regional transportation plans but reflects no replacement of the existing Interstate Bridge, no reconstructed interchanges, no tolls on the Interstate Bridge, and no extension of additional high-capacity transit service north from the existing MAX Yellow Line alignment into Vancouver.
2045 CRC ROD	2013 CRC LPA, assuming fully dedicated LRT tracks extending from the Expo Center MAX Station to a terminus near McLoughlin/I-5 via the Vancouver central business district. Includes five new stations and three park and rides.
Bus on Shoulder	Express bus operates as bus on shoulder in study area (both directions). Regional route operates in the auxiliary lanes between the Vancouver central business district and Hayden Island, Delta Park. No new stations or park and rides.
BRT Turtle Place to Expo Center MAX Station	Dedicated BRT lane between the Expo Center MAX Station and a terminus at Turtle Place in downtown Vancouver. Includes three stations: Expo Center, Hayden Island, and Turtle Place.
BRT I-5 to Kiggins Bowl	Fully dedicated BRT lane between the Expo Center MAX Station and a terminus near McLoughlin Boulevard/I-5. Dedicated lane on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and the Expo Center MAX Station similar to the 2013 LPA. Includes six stations: Kiggins Bowl, 33rd Street, McLoughlin Boulevard, Evergreen Boulevard, Hayden Island, and the Expo Center MAX Station.
BRT in ROD Alignment	Fully dedicated BRT lane between the Expo Center MAX Station and a terminus near McLoughlin Boulevard/I-5 to the Expo Center MAX Station with alignment and station locations similar to CRC project. Includes six stations: I-5/McLoughlin, McLoughlin and Washington Street (southbound)/16th and Broadway (northbound), 12th and Washington (southbound)/13th and Broadway (northbound), Turtle Place, Hayden Island, and the Expo Center MAX Station.
Hybrid	Fully dedicated LRT tracks between the Expo Center MAX Station and a new station at Hayden Island and fully dedicated BRT lane between Hayden Island and Turtle Place. Includes two stations: Hayden Island and Expo Center MAX Station.
LRT One Station in Vancouver	Fully dedicated LRT tracks between the Expo Center MAX Station and a terminus near Turtle Place in downtown Vancouver. Includes two stations: Hayden Island and Turtle Place.
LRT I-5 to McLoughlin	Fully dedicated LRT tracks between the Expo Center MAX Station and a terminus near McLoughlin Boulevard/I-5. Dedicated tracks on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and the Expo Center MAX Station similar to 2013 LPA. Includes three stations: I-5/McLoughlin, Evergreen, and Hayden Island.

Representative Transit Investment	General Description
LRT I-5 to Kiggins Bowl	Fully dedicated LRT tracks from the Expo Center MAX Station to a terminus near I-5/Kiggins Bowl. Dedicated tracks on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and Expo Center MAX Station similar to 2013 LPA. Includes five stations: Kiggins Bowl, 33rd Street, I-5/McLoughlin, Evergreen, and Hayden Island.
LRT Delta Park to McLoughlin	Fully dedicated LRT Extension from Delta Park (joint Hayden Island/Expo Center MAX Station) to a terminus near McLoughlin/I-5 on an I-5-adjacent alignment (Center/West Side of I-5). This option was eliminated from consideration early in the decision process based on partner feedback.
LRT I-5 to McLoughlin with Columbia	Fully dedicated LRT tracks between the Expo Center MAX Station to a terminus near McLoughlin Boulevard/I-5. Dedicated tracks on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and the Expo Center MAX Station similar to 2013 LPA. Includes four stations: I-5/McLoughlin, Evergreen, Waterfront, and Hayden Island.
LRT I-5 to Evergreen with Columbia	Fully dedicated LRT tracks between the Expo Center MAX Station to a terminus near I-5/Evergreen. Dedicated tracks on Vancouver segment assumed to be adjacent to I-5 with a dedicated connection to Hayden Island and the Expo Center MAX Station similar to 2013 LPA. Includes three stations: Evergreen, Waterfront, and Hayden Island.

BRT = bus rapid transit; LRT = light-rail transit; RTC = Southwest Washington Regional Transportation Council

Mode

The IBR Program considered three transit modes to meet transit demand: express bus operating on the shoulder, BRT, and LRT. Bus-on-shoulder capability in the study area was included in all representative transit investments, but it was not considered as a standalone transit option since it would provide substantially less capacity than other transit options to meet demand.

Based on analysis and coordination with partner agencies, the advantages and disadvantages listed in Table 2-10 were identified for BRT and LRT. Based on these findings, and when considering the specific needs of the HCT investment for the IBR Program, LRT was advanced as the preferred transit mode. See Appendix D, the Design Options Development, Screening, and Evaluation Technical Report, for additional information on the transit mode evaluation.

Table 2-10. Summary of Transit Mode Evaluation

Light-Rail Transit	Bus Rapid Transit
• Higher vehicle capacity allows the Program to carry more people across the river. • Compared to existing conditions and BRT, would improve access to jobs and services for many residents, including BIPOC and low-income populations, in part due to the one-seat ride experience that would not involve transfers for more riders. • Allows for preservation of the current and future C-TRAN Vine and express bus system while providing convenient connections to new LRT stations.	• Lower vehicle capacity than LRT and would require a transfer to connect to the regional light-rail system. • Less competitive travel time compared to LRT due to a required transfer at the Expo Center MAX Station.

Light-Rail Transit	Bus Rapid Transit
• Offers a more competitive travel time compared with trips that require a transfer at the Expo Center MAX Station. • Extension of the MAX Yellow Line from the Expo Center MAX Station into Vancouver best integrates existing transit investment in the region in a manner that maintains both C-TRAN's and TriMet's respective approaches to operations of their transit systems. • Based on initial estimates of how investments might perform if submitted to the FTA CIG program, LRT is more competitive for FTA discretionary funding.	• Compared to existing conditions, would improve access to jobs for many residents including BIPOC and low-income populations. • Preserves the current and future C-TRAN Vine and express bus system. • Did not rate as favorably for cost effectiveness, mobility, congestion relief and environmental benefits.

Note: The information in this table is from the design option screening and evaluation conducted in 2021 and 2022 (see Appendix D).
BIPOC = Black, Indigenous, and people of color; BRT = bus rapid transit; CIG = capital investment grant; LRT = light-rail transit

Alignment

Twelve potential transit alignments were evaluated by the Program and partner agencies. These potential alignments fell into two categories: accessing downtown Vancouver or aligning with the existing I-5 corridor. Detailed conceptual design work on the potential alignments (and their impacts) was brought to the advisory groups, community groups, and partner agencies.

When selecting an alignment, a key consideration was the need to integrate new transit investments while considering the existing and planned transit networks of TriMet and C-TRAN. Since 2013, C-TRAN has developed a BRT system, The Vine, with two BRT lines in operation and two in planning. The Vine and C-TRAN express bus service provide frequent and reliable service within Clark County and to downtown Portland, respectively. The extent to which any transit investment could complement The Vine system, including existing and planned service, was evaluated.

The City of Vancouver has worked with C-TRAN to design station environments for The Vine system on Broadway and Washington Streets in the central business district. Design elements of the transit alignment could be coordinated with existing design for The Vine to provide more efficient functionality within the larger transit network and respective operating environments. The downtown Vancouver LRT alignment would impact C-TRAN's BRT alignments in the downtown area. In addition to the existing and planned transit networks, potential alignments could impact existing development in the study area. In comparison to the I-5 alignment, the downtown Vancouver alignment would require additional property and streetscape impacts.

Based on conversations with the community and partners, the I-5 general alignment was advanced for further study.

Terminus

The IBR Program evaluated terminus options for each alignment and mode (described above) based on ridership, impacts, and preservation of and connections to existing systems. These terminus options included Hayden Island in Portland and Waterfront, Turtle Place, Evergreen/I-5, McLoughlin/I-5, and Kiggins Bowl in Vancouver.

The evaluation of Hayden Island as a terminus was a hybrid option that included the extension of LRT north from the Expo Center MAX Station to Hayden Island and the extension of BRT from Turtle Place south to Hayden Island. It was an exploratory option that did not perform as well as others in the evaluation process from a ridership standpoint, and ultimately it was removed from consideration in combination with the decision to select LRT as the mode to extend into Vancouver.

On the Vancouver side, the five terminus options included two that would result in a single station just across the Columbia River (Waterfront and Turtle Place) and three that would extend farther north, including options for one additional station (Evergreen/I-5), two additional stations (McLoughlin/I-5), or four additional stations (Kiggins Bowl). The single station terminus options did not perform as well as others that extended farther into Vancouver from a ridership standpoint, regardless of which mode was considered. Alignments with stations north of Evergreen Boulevard offered more ridership, but with greater impacts to properties and increased costs.

Through analysis and conversations with partners, it was determined that an Evergreen Boulevard terminus would:

- Have fewer potential property impacts compared to other locations.
- Have lower operating and capital costs compared to other locations.
- Avoid impacts to Clark Community College as a result of the station, alignment, and park and ride that were included in options that assumed McLoughlin/I-5 as a terminus.
- Avoid impacts to C-TRAN network and The Vine service.
- Avoid impacts to the City of Vancouver's vision and downtown development.
- Provide increased transfer options to additional C-TRAN routes.
- Connect directly to downtown library, jobs, services, and amenities.
- Support transit-oriented development opportunities at Library Square and on nearby City-owned parcels.
- Maximize transfer opportunities given planned direct connections to several local routes, as well as existing and planned BRT routes.
- Provide convenient access to Evergreen Boulevard, which connects east over I-5 to the Historic Reserve, and west through downtown to Main Street and Esther Short Park via the planned 9th Street pedestrian way.

Based on evaluation during screening along with feedback from partner agencies, the IBR Program and partner agencies recommended advancing the terminus at Evergreen Boulevard for further study and refinement.

Auxiliary Lanes

Auxiliary lanes improve traffic safety and reliability by providing sufficient merge, diverge, and weaving space for vehicles entering and exiting the highway while allowing the through traffic to maintain fuel-efficient driving speeds in the adjacent through lanes. The IBR Program identified the following changes in conditions since 2013 related to auxiliary lanes through advisory group input, community feedback, and input from agency partners (refer to Appendix D, the Design Options Development, Screening, and Evaluation Technical Report, for additional information). These changes, detailed in Section 2.5.2, Updating the CRC LPA, necessitated the development of design options for auxiliary lanes.

- Climate change
- Portland's transportation hierarchy

In addition to maintaining the existing three through lanes in each direction across the bridge, the IBR Program evaluated the addition of one and two auxiliary lanes in each direction. Two options (one auxiliary lane and two auxiliary lanes) were advanced for additional analysis and consideration. The results of the auxiliary lane evaluation are summarized in Table 2-11 and described in more detail in Appendix D, the Design Options Development, Screening and Evaluation Report.

Table 2-11. Summary of Initial Auxiliary Lanes Evaluation Results

General Benefits of Auxiliary Lanes Compared to the No-Build Alternative	Specific Additional Benefits of One Auxiliary Lane Compared to the No-Build Alternative	Specific Additional Benefits of Two Auxiliary Lanes Compared to the No-Build Alternative
• Mode choice benefits (high-capacity transit, bus on shoulder, and active transportation). • Mode shift; the daily transit share is anticipated to increase from 7% to 11%. • Reduced overall congestion. • Off-peak benefits including weekends. • Less diversion to local streets. • Faster congestion recovery from crashes and incidents. • Fewer lane changes required (i.e., lane balance). • Safety improvements realized due to fewer sideswipe crashes and improved visibility. • Lane widths to allow for current vehicle widths, turning, and comfort. • Anticipated greenhouse gas reduction due to less congestion.	• Travel time improvements : – Southbound AM travel time would be reduced by 3 minutes (5% faster) between I-5/I-205 split and I-405. – Northbound PM travel time would be reduced by 11 minutes (30% faster) between Broadway Street and SR 500. • Reduced congestion: – Congestion would be reduced by 37% (southbound) and 36% (northbound) during the 8-hour AM/PM peak period.	• Travel time improvements : – Southbound AM travel time would be reduced by 6 minutes (10% faster) between I-5/I-205 split and I-405. – Northbound PM travel time would be reduced by 25 minutes (70% faster) between Broadway Street and SR 500. • Reduced congestion: – Congestion would be reduced by 48% (southbound) and 75% (northbound) during the 8-hour AM/PM peak period.

Note: The data in this table are from the design option screening and evaluation conducted in 2021 and 2022 (see Appendix D). Updated data are included in Section 3.1, Transportation.

Based on initial feedback from the partner agencies, one auxiliary lane northbound and one auxiliary lane southbound were recommended to be included in the Modified LPA. The Modified LPA includes one auxiliary lane in each direction across the new Columbia River bridges between Marine Drive and Mill Plain Boulevard, which would allow for weave, merge, and diverge movements outside the through lanes. Initial findings indicate that I-5 does not meet all transportation performance standards with this configuration, and close interchange spacing remains an issue. Therefore, a two auxiliary lane design option is also included for analysis in this Draft SEIS. The two auxiliary lane design option consists of two auxiliary lanes in both the northbound and southbound directions across the Columbia River bridges.

The addition of auxiliary lanes (one or two) can help optimize use of the existing three through lanes and allow for more efficient movement through the corridor, as well as facilitate local trips across the Columbia River, thus improving safety, helping to relieve congestion with better traffic flow, and reducing emissions from vehicles idling in congestion. Studying one or two auxiliary lanes in each direction recognizes the desire to balance all of the regional needs and priorities, including safe, efficient, and reliable travel, as well as equity and climate goals. Refer to Appendix D, the Design Options Development, Screening, and Evaluation Report, for additional information.

2.5.4 Adopting Foundational Components of the Modified LPA

The boards, councils, and commissions of each of the eight IBR Program partners—including the regional transit agencies, cities, metropolitan planning organizations, and ports—met between June 22 and July 14, 2022, to consider the IBR Program's recommendation for the Modified LPA and voted to endorse the IBR Program's Modified LPA through a resolution by each agency. In addition to the Modified LPA resolutions, many partners included conditions reflecting their priorities and requests for additional work, considerations, and analysis. The IBR Program acknowledges that the preliminary analysis to support the Modified LPA was conceptual; more design refinement, transportation and transit analysis, financial analysis, and environmental evaluation is needed to better understand the impacts and benefits of the Modified LPA as the Program continues to develop a multimodal corridor solution. Therefore, the IBR Program is committed to further refinements and analysis, as well as sharing the results to gather additional input on the Modified LPA.

Environmental analyses for this Draft SEIS have been conducted to evaluate benefits and impacts to environmental and community resources (e.g., air quality, climate, land use, transportation, etc.) and to identify potential mitigation for adverse impacts. Agencies, tribes, advisory groups, and the public will have additional opportunities to provide input and feedback on the Modified LPA, environmental analyses, and proposed mitigation. The opportunities include a public comment period, public hearings held for the Draft SEIS, and other options to be identified.

2.6 Additional Compliance Underway

There are several environmental compliance processes that are underway at the time the Draft SEIS is published. These processes are listed below; some will be completed prior to publishing the Final SEIS, and others will be completed prior to construction. Changes to the Modified LPA from ongoing environmental compliance would be coordinated across all relevant agencies.

- **ESA, Section 7.** Obtain a biological opinion from NOAA Fisheries and a concurrence letter from USFWS prior to the publication of the Final SEIS.
- **Section 4(f) of the U.S. Department of Transportation Act of 1966.** Finalize all Section 4(f) documentation with correspondence from the officials with jurisdiction and approval by FHWA and FTA.
- **Section 6(f) of the Land and Water Conservation Act and Federal Lands to Parks.** Three parklands within the study area (East Delta Park, Marshall Park, and Old Apple Tree Park) were either created or improved with grants from the Land and Water Conservation Act or through the Federal Lands to Parks (FLP) Program. Both programs require replacement of land converted out of park ownership and use. Potentially impacted Section 6(f) resources and FLP resources are disclosed in this Draft SEIS. Detailed impacts, determination of Section 6(f) and FLP parkland converted to transportation use, and potential mitigation cannot be determined until design is advanced and a park boundary determination is completed.
- **Section 106 of the National Historic Preservation Act.** The IBR Program is updating the Area of Potential Effects, updating historic property inventories, evaluating additional historic properties, assessing potential additional effects on historic properties, and coordinating with consulting parties and tribes. The IBR Program is currently coordinating with FHWA, FTA, and the National Park Service on Section 106 compliance for the Modified LPA, which is considered a new undertaking under Section 106. Given the complexities of the IBR Program and the anticipated mix of construction contract delivery methods, FHWA and FTA are developing a new programmatic agreement (PA) instead of a memorandum of agreement to resolve adverse effects for this undertaking. FHWA and FTA consultation with WSDOT, ODOT, Oregon State Historic Preservation Office, Washington Department of Archaeology and Historic

Preservation, tribes, and other consulting parties on a draft PA is ongoing. The draft PA will be made available to the public prior to publication of the Final SEIS. The executed PA will be attached to the ROD.

- **Tribal consultation.** Continue tribal consultation to identify impacts and mitigation for cultural resources and natural resources.
- **U.S. Army Corps of Engineers Section 408.** Obtain Section 408 authorizations from USACE for alterations to a USACE Civil Works project. Anticipated activities include developing and submitting design packages to address proposed alterations to the federally authorized navigation channel in the Columbia River, levees along North Portland Harbor, and other aids to navigation as well as conducting any additional environmental analysis required to support the design advancement of these alterations. In addition, the Modified LPA proposes to relocate the Columbia River primary navigation channel from its current location along the north shore to the south. The result would be generally swapping the locations of the current primary navigation channel with the barge channel (which would become the north barge channel) and expanding the vertical and horizontal navigation clearances of both channels. Authorizations would be issued by USACE following issuance of the ROD and prior to the beginning of construction.
- **U.S. Army Corps of Engineers Section 404 of the Clean Water Act.** Obtain Section 404 permits from USACE for impacts to designated waters of the United States. Program activities underway to support the permit applications include wetland delineation, coordination with USACE to provide jurisdictional determination, and evaluation of potential impacts to wetlands and other waters from development of the Modified LPA. Permits would be issued by USACE following issuance of the ROD and prior to the beginning of construction.
- **U.S. Coast Guard Bridge Permit, under the Authority of the General Bridge Act of 1946.** Obtain USCG Bridge Permits for construction of bridges across navigable waterways under the jurisdiction of USCG. USCG issued new bridge permit application guidance (COMDTPUB P16591.3D) in July 2016. The IBR Program prepared a new navigation impact report, which resulted in the USCG issuance of PNCDs (2022) for new bridges over the Columbia River and North Portland Harbor. The IBR Program will submit new bridge permit applications for bridges proposed over these waterways in accordance with the 2016 Bridge Permit Application Guidance. In addition, the IBR Program will comply with the 2014 USCG-FHWA-FTA-Federal Railroad Administration Memorandum of Understanding (2014) and the 2014 USCG-FHWA Memorandum of Agreement (2014). The bridge permits would be issued after issuance of the ROD and prior to the start of construction. If the single-level movable-span configuration is advanced, the IBR Program will also coordinate with USCG to alter the current bridge lift opening timing restrictions to optimize openings for vessels while minimizing delays to highway and transit operations via the federal rulemaking process. Consideration of the three bridge configurations involves coordination with the USACE and USCG regarding multiple navigation related items. Table 2-12 summarizes the current and future actions necessary to reach resolution on an acceptable bridge configuration for the IBR Program.

Table 2-12. Navigation Considerations

Navigation Consideration	Decision Authority	Steps to Resolve	Timing
Vertical Navigation Clearance. The PNCD was issued with 178 feet of vertical navigation clearance, and the Modified LPA fixed-span bridge configurations provide 116 feet of vertical navigation clearance.	USCG	IBR Program coordinates with affected river users to resolve vertical navigation clearance requirements and enter into agreements.	Current/ongoing.
		IBR Program prepares updated navigation impact report as new information is available to inform reconsideration of the PNCD.	Upon completion of coordination with river users.
		USCG to evaluate updated navigation impact report and reissue the PNCD. [a]	Prior to Final SEIS.
		IBR Program to prepare and submit application for USCG Bridge Permit.	Ongoing and following updated PNCD.
		USCG to issue Bridge Permit.	Prior to construction.
Primary Navigation Channel Location (Vancouver to The Dalles). The Modified LPA would move the channel south.	USACE	IBR Program to conduct ship/tug simulations and other studies evaluating channel configurations as part of a multiphase review to obtain Section 408 Authorization to modify the federal navigation channels.	Current/ongoing.
		USACE to determine required process (Section 408 Authorization or U.S. Congressional action through the Water Resources Development Act) needed to relocate the channel.	Current/ongoing.
		Obtain Section 408 Authorization to change the channel location.	Prior to construction.
Horizontal Navigation Clearance.	USCG/USACE	If the movable-span configuration is identified as the preferred alternative in the Final SEIS, the IBR Program would coordinate with USACE to optimize the horizontal clearance for navigation, channel maintenance, design feasibility, and cost.	Following identification of the preferred alternative in the Final SEIS.
		If necessary, USCG to reissue PNCD to reflect modified horizontal navigation clearance.	Prior to construction.
		IBR Program to include information reflecting horizontal navigation clearance in USCG Bridge Permit and USACE Section 408 Authorization applications.	Prior to construction.
		USCG to issue bridge permit. USACE to issue Section 408 Authorization.	Prior to construction.

Navigation Consideration	Decision Authority	Steps to Resolve	Timing
Movable-Span Opening Restrictions (timing).	USCG	IBR Program to evaluate the impacts from daytime and nighttime bridge openings to vehicular traffic, transit service, and maritime operations as part of the movable-span opening restriction request (refer also to Section 3.1, Transportation).	Prior to Final SEIS and ROD.
		If the movable-span configuration is identified as the preferred alternative in the Final SEIS, the IBR Program would prepare a request for movable-span operating limitations for USCG consideration.	Following Final SEIS and ROD.
		USCG to evaluate the IBR Program request and determine the need for review or rulemaking including the need to obtain information from the navigation community on movable-span restrictions.	Following submittal of request from the IBR Program.
		USCG to complete rulemaking process including public review.	Prior to completion of the bridge.

a If a movable span is selected as a Modified LPA, an updated navigation impact report and revised PNCD are not anticipated as this option would meet the horizontal and vertical navigation clearances specified in the issued PNCD.

PNCD = preliminary navigation clearance determination; ROD = record of decision; SEIS = supplemental environmental impact statement; USACE = U.S. Army Corps of Engineers; USCG = U.S. Coast Guard

2.7 Anticipated Permits and Approvals

Table 2-13 lists the federal, state, and local permits, clearances, and approvals that are anticipated to be required to construct the Modified LPA.

Table 2-13. Anticipated Permits and Approvals

Permit or Approval	Issuing Agency
7460 permits for permanent and construction obstructions	FAA
23 USC 129(a)(1)(E), Federal Tolling Authority	FHWA
Access revision report approval	FHWA
Design analysis approval	FHWA
Design approval	FHWA
Real estate acquisition review	FHWA
Right-of-way (interstate) approval	FHWA
Right-of-way (railroad) approval	BNSF Railway
Air quality conformity determination	FTA
ESA Section 7 consultation	NOAA Fisheries, USFWS
Magnuson-Stevens Fishery Conservation Management Act	NOAA Protected Resources Division
Marine Mammal Protection Act	NOAA Fisheries
National Historic Preservation Act Section 106	FHWA, FTA, National Park Service (NPS), Oregon State Historic Preservation Office (SHPO), Washington State Department of Archaeology and Historic Preservation (DAHP)

Permit or Approval	Issuing Agency
Archaeological Resources Protection Act permit	NPS
Section 4(f) of the U.S. Department of Transportation Act of 1966 evaluation	FHWA, FTA
Section 6(f) of the Land and Water Conservation Fund Act documentation	FHWA, FTA, NPS
Bridge permit in accordance with the General Bridge Act of 1946	USCG
Section 404 of the CWA permit	USACE
Section 14 of the Rivers and Harbors Appropriation Act of 1899, as amended and codified in 33 USC 408 (Section 408)	USACE
Section 10 of the Rivers and Harbors Appropriation Act of 1899, as amended and codified in 33 USC 401 et seq.	USACE
Sole Source Aquifer Protection Act approval	U.S. Environmental Protection Agency (EPA)
Migratory Bird Treaty Act	USFWS
FLP Program	U.S. General Services Administration (GSA), NPS
Approval of rail crossing, intersection, signals, and right-of-way encroachment permit	ODOT, WSDOT
Voluntary Cleanup Pathway approval	Oregon Department of Environmental Quality (DEQ)
CWA National Pollutant Discharge Elimination System construction stormwater permits	DEQ, Washington State Department of Ecology (Ecology)
CWA Section 401 water quality certifications	DEQ, Ecology
Air quality permits	DEQ, Ecology
Removal-Fill Permit	Oregon Department of State Lands (DSL)
Aquatic land use (aquatic lands lease) authorization	DSL
Oregon Fish Passage Act approval	Oregon Department of Fish and Wildlife (ODFW)
Archaeological Excavation Permit	SHPO, DAHP
Aquatic use authorization	Washington State Department of Natural Resources (DNR)
Hydraulic Project Approval	Washington Department of Fish and Wildlife (WDFW)
City of Portland local permits and approvals (design review/land use review, historic resources review, noise variance, improvements in right of way, building permit – site development, sign permit, trade permits, non-park use permit)	City of Portland
City of Vancouver local permits and approvals (public facilities master plan [hybrid approach], transportation development review, traffic impact analysis, shoreline substantial development permit, critical areas permit, noise permit, waiver of certificate of appropriateness, building permit, trade permits, temporary use permit, access closure, sign permit [temporary])	City of Vancouver

Permit or Approval	Issuing Agency
Right-of-way permit for any encroaching in public right of way or City easements, tree permit, design review	City of Gresham

CWA = Clean Water Act; DAHP = Washington State Department of Archaeology and Historic Preservation; DEQ = Oregon Department of Environmental Quality; DNR = Washington State Department of Natural Resources DSL = Oregon Department of State Lands; Ecology = Washington State Department of Ecology; EPA = U.S. Environmental Protection Agency; ESA = Endangered Species Act; FAA = Federal Aviation Administration; FHWA = Federal Highway Administration; Fisheries = National Marine Fisheries Service; FLP = Federal Lands to Parks; FTA = Federal Transit Administration; GSA = U.S. General Services Administration; NOAA = National Oceanic and Atmospheric Administration; NPS = National Park Service; ODFW = Oregon Department of Fish and Wildlife; ODOT= Oregon Department of Transportation; SHPO = Oregon State Historic Preservation Office; USACE = U.S. Army Corps of Engineers; USFWS = U.S. Fish and Wildlife Service; WDFW = Washington Department of Fish and Wildlife; WSDOT = Washington State Department of Transportation

3. EXISTING CONDITIONS AND ENVIRONMENTAL CONSEQUENCES

Each section in this chapter summarizes key findings for one or more elements of the environment. Following a brief discussion of new information or changes in existing conditions since the NEPA evaluation for the Columbia River Crossing project, each section identifies the benefits and effects of the No-Build Alternative and the Modified LPA, including how benefits or effects would differ across the various design options.

Each section includes a detailed discussion of the long-term benefits and effects (those that will remain after construction of the Modified LPA is completed), the short-term benefits and effects (those that would occur during construction), and the indirect effects (those caused by the Modified LPA and that occur later in time but are still reasonably foreseeable). In addition, each section identifies the potential mitigation measures that can address the identified effects. Mitigation will be finalized in the Final SEIS. Cumulative effects, which are the incremental effects of the Modified LPA when added to those of other past, present, and future actions, are analyzed in Section 3.23. The analysis of the Modified LPA includes all design options described in Chapter 2, Description of Alternatives, and listed in Table 3-1. If there is a difference in effects among design options, those differences are identified and described specifically.

The findings summarized in this chapter are based on detailed technical reports prepared for the Draft SEIS. The technical reports are cited throughout the chapter, as appropriate, and are incorporated by reference into the Draft SEIS. All technical reports are listed in Appendix H and published with the Draft SEIS. All projections and forecasts are for the design year of 2045 unless otherwise stated.

A summary of the components of the Modified LPA analyzed in the Draft SEIS is shown in Table 3-1.

3.9 Visual Quality

3.10 Air Quality

3.11 Noise and Vibration

3.12 Energy

3.13 Electric and Magnetic Fields

3.14 Water Quality and Hydrology

3.15 Wetlands and Other Waters

3.16 Ecosystems

3.17 Geology and Groundwater

3.18 Hazardous Materials

3.19 Climate Change

3.20 Environmental Justice

3.21 Section 6(f) and Federal Lands to Parks

3.22 Aviation

3.23 Cumulative Effects

Table 3-1. Summary of Components of the Modified LPA

Component	Modified LPA
Columbia River Bridges	• Two bridges built west of the existing Interstate Bridge (which would be removed). – Three bridge configuration options: double-deck fixed-span (truss bridge type); single-level fixed-span (girder, extradosed, or finback bridge type); or single-level movable-span (vertical lift bridge type). The effects and benefits analysis of a particular bridge configuration would be the same for each bridge type, unless otherwise specified. • Variable-rate tolling for motorists using the river crossing as a demand-management and financing tool.
I-5	• One auxiliary lane in each direction from Marine Drive to Mill Plain Boulevard or two auxiliary lanes in each direction (one from Marine Drive to Mill Plain Boulevard and one from Interstate Avenue/Victory Boulevard to SR 500/39th Street) • Improvements to seven interchanges between Victory Boulevard in Portland and SR 500 in Vancouver. – An option to eliminate the existing C Street ramps. – An option to shift I-5 to the west in downtown Vancouver near the SR 14 interchange. • Reconfiguration of some local streets to complement the new interchange designs.
LRT	• Extension of the MAX Yellow Line from Expo Center Station in North Portland to a terminus near Evergreen Boulevard in Vancouver.[a] • Modifications to the existing Expo Center Station and new stations at Hayden Island, Vancouver Waterfront, and near Evergreen Boulevard. • Up to two park and rides in Vancouver along the light-rail alignment: one near the Waterfront Station (three site options) and one near the Evergreen Station (two site options). • Associated LRT improvements such as traction power substations, signal and communications support facilities, an overnight light-rail vehicle facility at the Expo Center, and an expanded maintenance facility at Ruby Junction.
Associated Bus Improvements	• Wider inside shoulders on I-5 from Victory Boulevard to SR 500 to accommodate express bus-on-shoulder service. • Improvements to local bus transit service to integrate the proposed new LRT service and local bus routes.
Active Transportation	• A variety of improvements for people who walk, bicycle, and roll, including a shared-use path over the Columbia River and North Portland Harbor, enhanced wayfinding, and facility improvements to comply with the Americans with Disabilities Act.
North Portland Harbor Bridges	• Replacement bridges that would carry LRT, I-5 through traffic, traffic to/from N Marine Drive, and an arterial bridge for local traffic to and from Hayden Island.

Note:
a TriMet, which operates the MAX system, would also operate the Yellow Line extension.
Key: I-5 = Interstate 5; LRT = light-rail transit; MAX = Metropolitan Area Express; N/A = not applicable; SR = State Route; TriMet = Tri-County Metropolitan Transportation District of Oregon

3.1 Transportation

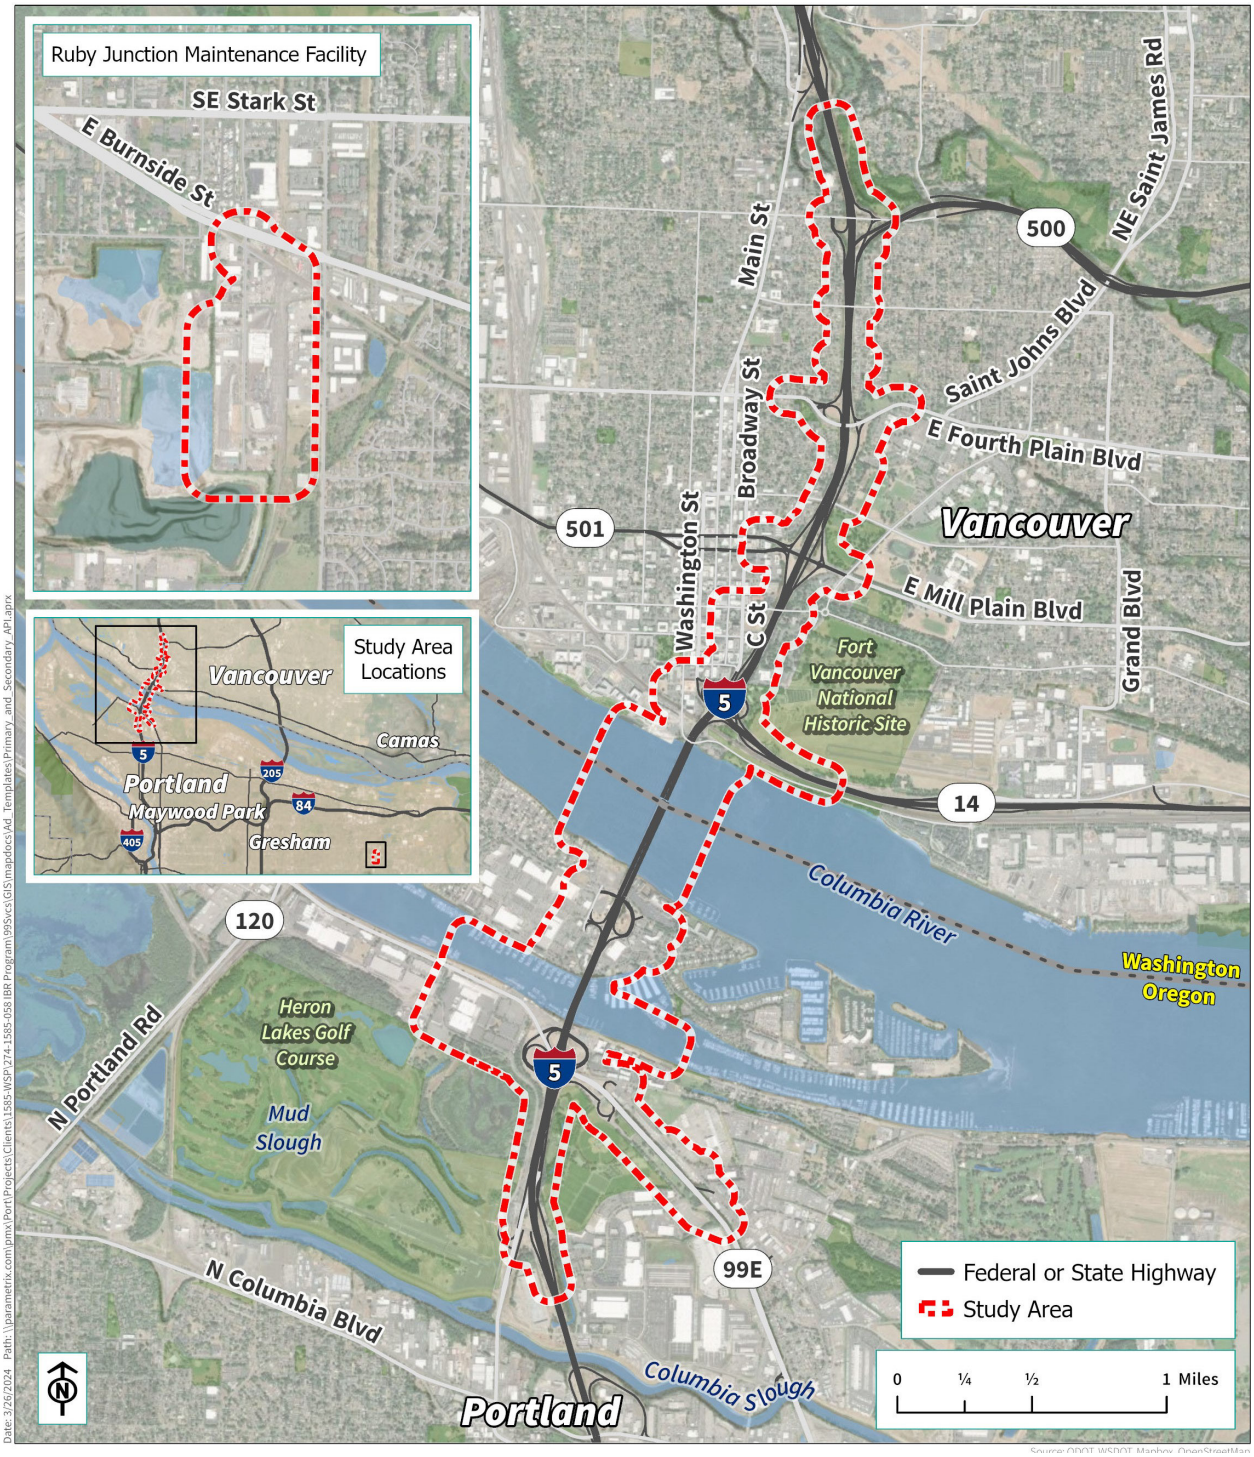
This section describes how the No-Build Alternative and the Modified LPA and options would affect travel patterns and mobility for cars, trucks/freight, transit vehicles, transit riders, pedestrians, and bicyclists. New information developed since 2013 is identified, and anticipated long-term, temporary, and indirect effects of the Modified LPA and options compared to the No-Build Alternative are summarized. Potential measures to avoid, minimize, and/or mitigate impacts, as well as to increase the mobility benefits of the IBR Program, are presented.

The IBR Program study area, shown in Figure 3.1-1, is centered on Interstate 5 and the bridge crossing of the Columbia River between Oregon and Washington. This study area also encompasses other interstate and state highways, transit, local roadways, bicycle and pedestrian facilities, and other facilities that serve the study area and influence travel behavior and conditions.

The information presented in this section is based on the Transportation Technical Report, which provides additional details on the following aspects of transportation:

- Regional transportation, including major freeway and highway facilities, vehicle miles of travel, vehicle hours of travel, vehicle hours of delay, and mode share.
- Freeway operations, including I-5 vehicle and person-trip volumes, bottlenecks, level of service (LOS), volume-to-capacity (V/C) ratios, travel times, and speeds.
- Freight mobility and access.
- Bridge openings and gate closures, including yearly and hourly frequency as well as average event duration.
- Arterial and local streets, including corridor analysis, intersection operations, and impacts to local roadways caused by freeway congestion.
- Transit, including regional and local transit services, corridor and station ridership, and transit operations.
- Sufficiency and quality of active transportation (bicycle and pedestrian facilities) around stations as well as circulation/connections to existing networks.
- Safety.
- Transportation demand management (TDM) and transportation system management (TSM).
- Tolling and diversion.

Figure 3.1-1. IBR Program Study Area



3.1.1 Changes and New Information Since 2013

The Columbia River Crossing (CRC) Final Environmental Impact Statement and Record of Decision were completed in 2011. Since then, due to changes that have occurred in the study area since the previous planning effort and NEPA evaluation, several design modifications have been made as

described in Chapter 2, Section 2.5. These include changes to the design of interchanges and access configurations and in the routing of light-rail transit through downtown Vancouver. Several design options for the Modified LPA are also being evaluated, including three bridge configurations, two auxiliary lane configurations (i.e., either one or two auxiliary lanes in specified portions of the I-5 mainline), potential elimination of the C Street ramps, a westward shift of I-5 near the SR 14 interchange, and options for park-and-ride locations near the light-rail stations in Vancouver. See Chapter 2 for additional details on the proposed modifications from the CRC Selected Alternative to address changed conditions and the design options being considered for the IBR Program.

3.1.2 Existing Conditions

The COVID-19 pandemic that began in 2020 altered travel patterns and trends, traffic volumes, and transit ridership in the region and in the transportation study area for the IBR Program. Traffic volumes and transit ridership dropped below historical levels, and then began to increase as health emergency restrictions gradually eased over the following 3 years. As of March 2023, according to traffic count data from both WSDOT and ODOT (WSDOT 2022a; ODOT 2021), traffic volumes were close to pre-pandemic levels for auto and freight traffic within the study area. Transit has been slower to recover, with 2023 ridership levels approximately 62% of ridership levels in the fall of 2019 for the four-county region, but according to both the Clark County Public Transportation Benefit Area Authority (C-TRAN) and the Tri-County Metropolitan Transportation District of Oregon (TriMet), transit service levels and ridership continue to see increases as more time goes by since the start of the pandemic (C-TRAN n.d.; TriMet n.d.).

Transportation analyses generally incorporate the most recently available data. However, due to the influence of the COVID-19 pandemic on travel patterns between 2020 and 2023 as explained above, the most recently available data is not representative of standard conditions. Therefore, the IBR Program is following industry standards and using 2019 as the baseline year for the existing conditions instead since it most closely resembles standard conditions. Exceptions to this include the following:

- Outputs that rely on the Metro/RTC[1] regional travel demand model that had not yet updated its base year model from 2015 to 2020.
- Safety data which summarize 5 years of data from 2015–2019.
- Bridge lift/gate closure data which summarize 12 years of data (2012–2023) which is consistent with the data summarized for the Navigation Impact Report.

The Metro/RTC regional travel demand model outputs summarize 2015 data based on 2015 land use, population, and employment data. Following standard practices for NEPA evaluation of transportation projects, the analysis methods for the IBR Program apply the Metro/RTC travel demand model to replicate some of the regional existing conditions. These regional data provide the basis for predicting future conditions and travel demand in the year 2045. Additional details on the transportation analysis methods are presented in the Transportation Technical Report and its appendices.

[1] Metro = Oregon Metro; RTC = Southwest Washington Regional Transportation Council

Regional Roadways

Regional roadways within the study area include Interstate 5 (I-5), SR 500, SR 14, and Martin Luther King Jr. Boulevard (Highway 99E), all of which are limited-access corridors. Table 3.1-1 summarizes their characteristics in the study area.

Table 3.1-1. Existing Regional Roadways in Study Area

Regional Roadway	Roadway Classification	Number of Travel Lanes	Speed Limit (mph)	Average Weekday Daily Traffic [a]	Bicycle Facilities [b]	Pedestrian Facilities [b]
I-5	Interstate	4–9	50–60	60,000–146,500	Yes	Yes
SR 500	State Highway (Washington)	4–6	55	35,000–52,000	No	No
SR 14	State Highway (Washington)	4–6	60	58,000–73,000	No	No
MLK Jr. Boulevard (Hwy 99E)	State Highway (Oregon)	4	30–55	16,200–18,400	Yes	No

Source: WSDOT Online Map Center Historic Traffic Counts. ODOT Traffic Volume Tables for State Highways 2019

a A range of average weekday daily traffic volumes is shown, as the volumes differ along freeway segments in the Portland metropolitan region.

b Shared-use paths exist on the Interstate Bridge over the Columbia River.

MLK = Martin Luther King

The study area covers a 5-mile section of I-5 between the Interstate Avenue/Victory Boulevard interchange in Portland and the SR 500/39th Street interchange in Vancouver. It includes seven interchange areas: Interstate Avenue/Victory Boulevard, Marine Drive, Hayden Island, City Center/SR 14, Mill Plain Boulevard, Fourth Plain Boulevard, and SR 500/39th Street.

Most of the traffic (between 77% and 86%) crossing the Interstate Bridge in peak directions during the AM and PM peak periods is entering and/or exiting I-5 at one of these seven interchanges.

Regional Travel Measures

The typical measures of travel performance on a regional level are vehicle miles traveled (VMT), vehicle hours traveled (VHT), and vehicle hours of delay (VHD). These measures are calculated using the Metro/RTC regional travel demand model. As noted above, 2015 is the current base year available from the Metro/RTC regional travel demand model.

Table 3.1-2 shows existing (2015) VMT, VHT, and VHD at two regional scales, both of which extend beyond the study area (see the Transportation Technical Report for figures of these study areas). The first includes the entire region covered by the Metro/RTC regional travel demand model. The second is a smaller traffic subarea within the most densely developed areas of Portland and Vancouver, covering a triangle around I-5 from I-205 to I-84 on the west, I-205 from I-5 to I-84 on the east, and I-84 from I-5 to I-205 on the south.

Table 3.1-2. Regional Travel Measures – Existing 2015 Daily Vehicle Miles Traveled, Vehicle Hours Traveled, and Vehicle Hours of Delay

Area	Vehicle Miles Traveled	Vehicle Hours Traveled	Vehicle Hours of Delay [a]
Portland Metropolitan Region	43,115,600	1,225,400	19,400
Traffic Subarea (I-5, I-205, and I-84)	11,277,600	326,900	10,100

Source: Metro/RTC regional travel demand model

a Delay is measured as time spent in congestion on network links that exceed 0.9 volume/capacity ratio.

Traffic Volume

The analysis of traffic volumes uses several measures to describe existing conditions and allow comparisons to future conditions. These measures (screenlines, I-5 mainline and ramp volumes, and daily person throughput) are described below.

Screenlines

Screenlines are imaginary lines drawn across major roadways (highways and arterials) within the study area to measure the total amount of traffic moving in each direction across multiple facilities. These north/south and east/west screenlines are a snapshot of typical existing AM and PM peak traffic conditions. The Transportation Technical Report includes figures and lists of the screenlines used for this traffic analysis.

I-5 Mainline and Ramp Vehicle Volumes

The IBR team collected data from ODOT and WSDOT for 2019. ODOT and WSDOT maintain permanent traffic counters throughout their freeway and highway systems that collect hourly traffic counts 365 days a year, 24 hours a day. This information was used to estimate average weekday daily traffic volumes in 2019 for the I-5 mainline and ramps in the study area.

Daily Person Throughput

Person throughput measures the number of people that a transportation facility serves within a given time frame. The number of vehicles (passenger cars, freight trucks, and buses) crossing the Interstate Bridge was multiplied by average vehicle occupancy assumptions to calculate total person throughput. Southbound, daily person throughput across the Interstate Bridge is 93,400 people. Northbound, the daily person throughput is 92,400 people. Consistent with historical traffic counts on the Interstate Bridge, the northbound and southbound traffic volumes are slightly different due to external through-trip patterns and different transit routing between the AM and PM peak periods.

I-5 Operations

As noted above, the IBR study area is the approximately 5-mile section of I-5 between the SR 500/39th Street interchange in Vancouver and the Interstate Avenue/Victory Boulevard interchange in Portland. Because traffic volumes and congestion within and outside of the study area influence each other, these interactions were captured by analyzing a longer section of I-5. This section (referred to as the freeway

analysis area) consists of a 17-mile length of I-5 between the I-205 interchange north of Vancouver and the Marquam Bridge in Portland.

Existing conditions for freeway operations for I-5 within the freeway analysis area were evaluated using VISSIM microsimulation models. The models were developed and calibrated for all travel modes to simulate the observed and regularly occurring traffic operations along northbound and southbound I-5 during the 6 to 10 a.m. and 3 to 7 p.m. peak periods. These models incorporate average traffic volumes and simulate the recurring congestion that occurs when vehicle volumes approach the capacity of the facility at a given location or bottleneck. They account for the effects of on- and off-ramps, merging/diverging segments, weaving segments, lane adds and drops, and design constraints such as curves, grades, underpasses, and narrow or nonexistent shoulders. However, the models do not account for non-recurring congestion caused by traffic incidents, work zones or lane closures, bad weather, special events, or bridge closures or openings.

ODOT and WSDOT define congestion as speeds below a certain threshold. ODOT has historically defined congestion as when speeds drop below 75% of the posted speed limit due to constrained conditions (for example, speeds slower than 45 mph in an area with a posted speed 60 mph). ODOT has recently refined its measures of congestion into two levels, with congestion defined as speeds below 45 mph and severe congestion defined as speeds below 35 mph. Therefore, the IBR Program has defined congestion as speeds below 45 mph. Table 3.1-3 shows the critical bottleneck locations under existing conditions and summarizes the hours of congestion at bottlenecks according to this definition.

Table 3.1-3. Weekday AM and PM Peak-Period Bottleneck Locations When Speeds Are below 45 mph – 2019 Existing Conditions

Direction	Location	Time of Day	Duration (hours)	Maximum Extent (miles)
Southbound	Interstate Bridge	6–9 a.m.	3 hours	3 miles
	I-5/I-405 Split in North Portland	6:30 a.m.–1 p.m.	6.5 hours	3 miles
	Rose Quarter	7:15 a.m.–7:45 p.m.	12.5 hours	3 miles
Northbound	Interstate Bridge	11:15 a.m.–8:00 p.m.	8.75 hours	10+ miles

Source: IBR Transportation Technical Report

Southbound Congestion

In the southbound direction, the Interstate Bridge experiences 3 hours of congestion between 6 and 9 a.m. The congestion extends from the Interstate Bridge back to the SR 500/39th Street interchange, and vehicle speeds vary from zero to 10 to 20 mph for much of that time. The congestion is caused by approaching traffic that is above the bridge's limited capacity, limited sight distance, substandard shoulders, short merge and diverge locations north and south of the bridge, heavy on- and off-ramp flows north of the river, and heavy truck volumes.

Southbound travel in the study area is also affected by backups from regional bottlenecks south of the IBR Program study area such as the I-5/I-405 split in North Portland, which results in 6.5 hours of congestion between 6:30 a.m. and 1 p.m. that can extend north and combine with the Interstate

Bridge bottleneck. Another southbound regional bottleneck is near the Rose Quarter, where I-5 is reduced from three to two travel lanes, congestion occurs for 12.5 hours from 7:15 a.m. to 7:45 pm.

Northbound Congestion

In the northbound direction, the Interstate Bridge bottleneck lasts for 8.75 hours between 11:15 a.m. and 8 p.m. The congestion extends south from the Interstate Bridge and influences traffic flows south of the study area, back to I-405 and I-84. The northbound congestion at the Interstate Bridge occurs for similar reasons as the southbound congestion, including limited bridge capacity; limited sight distance; substandard shoulders; short merge and diverge locations north and south of the bridge; heavy merging, diverging, and weaving flows of traffic; and heavy freight flows. As with southbound conditions, northbound speeds through the congested segments of the corridor vary between 0 and 20 mph.

Peak-Period Travel Times

The VISSIM traffic operations model was used to determine AM and PM peak-period travel times along the I-5 corridor, northbound and southbound. Table 3.1-4 shows travel times on I-5 between I-205 in Vancouver and I-405 in North Portland in the AM and PM peak periods for both northbound and southbound travel. Southbound AM peak-period travel times are the most affected by congestion, while southbound PM peak-period travel times are similar to free-flow conditions. Northbound peak-period travel times are free flow during the AM peak period and affected by congestion during the PM peak period.

Table 3.1-4. I-5 Average Weekday AM and PM Peak-Period Travel Times between I-205 and I-405 in North Portland – 2019 Existing Conditions

Direction	Metric [a]	6 AM	7 AM	8 AM	9 AM	3 PM	4 PM	5 PM	6 PM
Southbound	Hourly Average Travel Time	24	38	32	21	13	13	14	13
	Peak 2-hour Average Travel Time	-	35	35	-	-	14	14	-
Northbound	Hourly Average Travel Time	13	13	13	13	36	40	31	19
	Peak 2-hour Average Travel Time	-	13	13	-	-	35	35	-

Source: IBR Transportation Technical Report

a Travel time metric is minutes.

Level of Service and Volume-to-Capacity Ratios

As described in the Transportation Technical Report, WSDOT uses LOS as its standard for highway performance, while ODOT uses volume-to-capacity (V/C) ratios to set mobility standards and performance targets. WSDOT's LOS standard for I-5 in Washington is LOS D. ODOT's performance standard for I-5 in Oregon is a V/C ratio of 1.1 for the highest peak hour and 0.99 for all other hours.

The Transportation Technical Report and its appendices provide more information on how these standards are defined and evaluated.

Table 3.1-5 and Table 3.1-6 list the I-5 study area highway segments with below-standard performance (shown with bold text) for southbound and northbound traffic during peak periods. Results for Washington segments are shown in terms of LOS, and results for Oregon segments are shown in terms of V/C. At the Interstate Bridge freeway segment, both LOS and V/C ratios are reported. The Transportation Technical Report provides additional information, including maps of the segments.

Impacts to Local Roads

During the AM peak period, I-5 mainline congestion affects the ability of vehicles to enter the freeway on southbound on-ramps. This routinely affects the operations of local roads and intersections, including interchanges at Washington Street, SR 14, Mill Plain Boulevard, Fourth Plain Boulevard, and SR 500.

During the PM peak period, congestion on I-5 northbound and backups on northbound on-ramps impact the operations of local roads and intersections at Marine Drive, Martin Luther King Jr. Boulevard, and the Victory Boulevard/Interstate Avenue on-ramps.

Freight Mobility and Access

The I-5 crossing is critical to national and international freight flow. I-5 serves direct international land connections to Mexico and Canada. The Portland-Vancouver region is the fourth largest freight hub for domestic and international trade on the West Coast behind Los Angeles/Long Beach, Seattle/Tacoma, and San Francisco/Oakland. National, West Coast, and regional freight flows depend on the efficient functioning of I-5 within the study area.

I-5 is the primary truck route for local, regional, national, and international movement of goods through the Portland-Vancouver region. Trucks carry 55% of all freight in Clark County and 74% of all freight in the Portland-Vancouver region. Approximately $133 million in commodity value was transported daily across the Interstate Bridge in 2019.

Approximately 14,000 heavy and medium trucks crossed the Interstate Bridge on an average weekday in 2019, accounting for approximately 10% of all bridge traffic. About 70% of the truck trips using the Interstate Bridge either start or end in the Portland-Vancouver metropolitan area. Freight traffic does not peak during typical commute hours (6 to 9 a.m. and 3 to 6 p.m.). Instead, the highest freight volumes occur during the middle of the day as freight truck operators try to avoid the most congested periods.

The busiest interchanges for truck traffic are at Mill Plain Boulevard, City Center/SR 14, and Marine Drive, which all provide access to the Ports of Vancouver and Portland and surrounding industrial areas.

Bridge Openings and Gate Closures

Bridge openings occur when the movable spans are physically raised for the passage of commercial and non-commercial maritime vessels that exceed the available vertical clearance between the water level and the bridge in its closed position. When bridge openings occur, all forms of both northbound and southbound traffic, freight, transit, and active transportation users on the Interstate Bridge are stopped.

The maximum vertical navigation clearance under the Interstate Bridge at any time depends on the water level in the Columbia River (higher river levels result in less clearance) and which of the three navigation channels a ship is using (the primary navigation channel, the barge channel, or the alternate barge channel). The alternate barge channel, which is aligned with the highest point of the bridge, has a vertical clearance of up to 72 feet above the Columbia River. The primary navigation channel, which aligns with the Interstate Bridge lift spans, provides a maximum vertical navigation clearance of 39 feet when the lift spans are in the closed position and 178 feet when the spans are fully raised.

In addition to vertical clearance, vessels passing beneath the bridge must also consider horizontal clearance between the Interstate Bridge piers and the piers of the BNSF Railway Bridge located approximately 0.9 miles downstream. The existing horizontal clearances for the Interstate Bridge are approximately 263 feet for the primary channel, 511 feet for the barge channel, and 260 feet for the alternate barge channel. The alignments of the navigation channels factor into vessel passage of both the Interstate Bridge and the BNSF bridge; due to the proximity of the two, vessel operators typically plan their route based on navigation factors associated with both bridges. Vessels needing less than 33 feet of vertical navigation clearance to pass the BNSF Railway Bridge may take a route other than the primary navigation channel, while vessels needing additional vertical navigation clearance require the BNSF Railway Bridge swing span to be opened and must use the primary navigation channel. More information on clearances and navigation channels can be found in Section 3.2, Navigation.

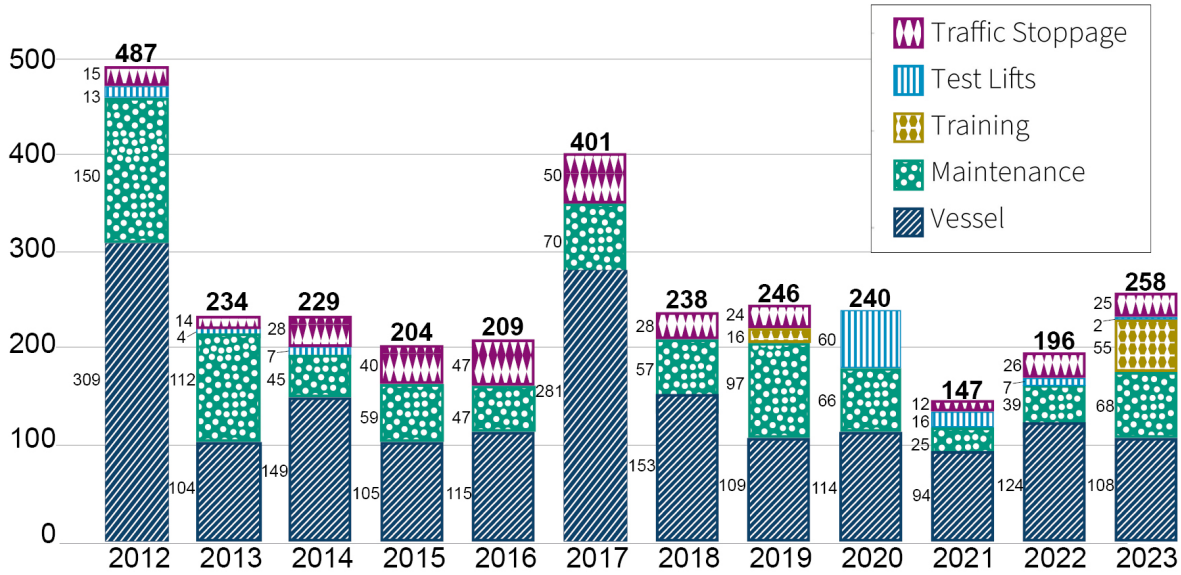
Frequent river traffic (tug and tows, river cruise ships, and recreational craft) typically does not require a bridge opening, as these vessels often opt to pass the bridge using either the alternate barge channel or the barge channel. However, bridge openings are needed for some government vessels, tall ships and sailboats, floating construction equipment, larger ocean-going tugs or vessels, and specialty shipments from area fabricators that require more than 72 feet of vertical navigation clearance. A bridge opening is also needed if a vessel requiring more than 39 feet of clearance must use the primary navigation channel to pass through the Interstate Bridge and the BNSF Railway Bridge for maneuverability and safety considerations. Additional detail on river traffic and existing navigation considerations is provided in Section 3.2, Navigation.

In addition to bridge openings, traffic on the bridge is affected by gate closure events, where traffic is stopped to allow for bridge-related activity without the bridge being raised. These gate closure events occur for several reasons, including bridge maintenance and on-site training of department of transportation personnel. Training and practice openings are performed during the day and overnight periods. Depending on the reason for the event, traffic may be stopped in one or both directions.

For the 12-year period from January 1, 2012, to December 31, 2023, there were 3,089 bridge openings and gate closure events. On average, the bridge was opened/gate closed 257 times per year, with the range over the 12-year period fluctuating between 147 and 487 bridge openings and gate closures per year. Above average high-water levels occurred in 2012 and 2017, resulting in more bridge openings in

those two years. Figure 3.1-2 displays bridge opening and gate closure events for each year, by reason, from 2012 to 2023.

Figure 3.1-2. Interstate Bridge Opening and Gate Closure Events 2012–2023



Source: ODOT, WSDOT

The average bridge opening and gate closure duration during this period was 13.2 minutes. While bridge openings are not allowed during peak periods on Monday to Friday (except in emergency situations), they are allowed before and after the peaks. Depending on the closure time and duration as well as traffic levels, it can take between 5 and 110 minutes for traffic to recover from a bridge opening and gate closure. A closure just before the peak period can last even longer, affecting conditions throughout the peak.

Arterial and Local Street Network and Intersection Operations

In addition to the regional roadways that connect population and employment centers, the study area contains ODOT and WSDOT highways and City of Portland and City of Vancouver arterials and local streets that serve travel to and from the regional network, as well as providing for local access and circulation. Many of these roads and highways include bicycle and pedestrian facilities.

The study area includes 80 intersections: 58 in Vancouver and 22 in Portland. See the Transportation Technical Report for a list and graphic identifying the study intersections. These include intersections originally evaluated in the CRC Final EIS and additional intersections that were identified for analysis in this Draft Supplemental EIS (SEIS) based on data reviews, consultations with partner agency staff, and the potential for intersection operations to be affected by I-5 operations or IBR Program improvements. More information on how study area intersections were identified can be found in the Transportation Technical Report. The study intersections were categorized into four subareas, based on their proximity to interchange areas and because different partner agencies have different

performance standards. The four subareas include three in Vancouver (subareas 1-3) and one in Portland (subarea 4):

1. SR 500/Main Street/39th Street/Fourth Plain Boulevard (17 study intersections).
2. Mill Plain Boulevard (18 study intersections).
3. SR 14/City Center Interchange/Columbia Way (23 study intersections).
4. Hayden Island/Marine Drive/Victory Boulevard/Columbia Boulevard (22 study intersections).

Under existing conditions, four intersections in the study area do not meet the applicable agency performance standards. The three Vancouver area intersections that do not meet agency standards under existing conditions are listed in Table 3.1-7, and the one Portland area intersections that does not meet agency standards is listed in Table 3.1-8. The detailed existing conditions information in the Transportation Technical Report includes information on peak-hour intersection volumes as well as intersection operations.

Table 3.1-7. Vancouver Intersections Not Meeting Agency Standards (2019 Existing Conditions)

Transit

Transit Providers and Systems

Transit service in the region and study area is provided by TriMet and C-TRAN.

To serve its three-county service area in metropolitan Portland, TriMet has a bus fleet of approximately 700 vehicles and operates the 60-mile-long Metropolitan Area Express (MAX) light-rail transit (LRT) system. The MAX system has five lines that operate at frequencies of 15 minutes or less between approximately 5 a.m. and 1 a.m., 7 days a week. This includes the Yellow Line, also known as Interstate MAX, which runs northbound and southbound from downtown Portland (Portland State University) to the Expo Center. South of downtown, the Yellow Line transitions to the Orange Line and continues south to Milwaukie. The TriMet MAX system does not currently provide service across North Portland Harbor to Hayden Island or across the Columbia River into Clark County. TriMet has five operations and maintenance facilities: three for buses and two for rail.

C-TRAN is the transit provider in the Clark County service area, with a fixed-route fleet of approximately 122 buses that serve 28 bus lines and The Vine bus rapid transit (BRT) service. The Vine service began operations in 2017 between downtown Vancouver and the Vancouver Mall Transit Center, primarily along Fourth Plain Boulevard. New Vine BRT service along Mill Plain Boulevard began in October 2023. (Note that, for consistency with existing data reflecting 2019 conditions, this service is not included in BRT summaries for existing conditions in the Draft SEIS, but it is reflected in future year forecasts for both the No-Build Alternative and the Modified LPA.) In addition to local bus and BRT service, C-TRAN operates three regional routes that provide transit service crossing the Columbia River to connect with the TriMet rail system and Portland International Airport, as well as seven express routes that provide connections between regional park-and-ride locations, downtown Vancouver, and the downtown Portland area. C-TRAN has a fleet of 64 demand-responsive vehicles and 40 vanpool vehicles. C-TRAN currently operates one bus operations and maintenance facility.

Several transit centers and park-and-ride facilities are used for travel between Clark County and Portland. These are served by various combinations of local, express, and regional bus routes as well as MAX. Tables detailing each of these facilities and routes that serve them are available in the Transportation Technical Report.

Transit Service in the Study Area

There are 27 bus routes and one MAX light-rail line that serve the study area, including BRT, local, express, and regional service provided by C-TRAN and local bus and LRT service provided by TriMet. Both C-TRAN and TriMet provide special access and shared mobility services (i.e., paratransit, on-demand ridesharing, neighborhood shuttles, and vanpools) in the study area. Tables detailing each of these routes and their service assumptions (headways) are available in the Transportation Technical Report.

Table 3.1-9 shows the existing 2019 transit trips served by C-TRAN and TriMet in the study area. Approximately 4,800 people travel across the Columbia River via bus each weekday on routes using either I-5 or I-205. For transit trips between Vancouver and Portland on I-5, buses operate along with other vehicles in general-purpose travel lanes. On I-205, C-TRAN buses operate on the shoulder when peak-period congestion warrants. As a result, congestion impacts bus travel times and the reliability of trips, which are key measures of service quality for transit systems.

Table 3.1-9. Existing 2019 Average Weekday Transit Ridership

Organization	Transit Service	Regional System	Study Area Routes [a]
TriMet	Local Bus	189,200	50,400
	Light-Rail	122,000	13,200
	Westside Express Service (Commuter Rail)	1,400	N/A
	Total	312,600	63,600
C-TRAN	Local Bus	10,400	7,100
	The Vine BRT	4,500	4,500
	Regional Bus	2,100	1,500
	Express Bus	2,900	2,400
	Total	19,900	15,500

a Includes boardings for entire route, not just the portion within the study area.
BRT = bus rapid transit; N/A = not applicable

Transit travel time within the study area varies by time of day. For all trips between Vancouver and Portland, congestion on I-5 affects both transit travel time and the reliability of transit trips. Currently, only transit trips destined for downtown Portland have the possibility of a one-seat ride (i.e., a single ride with no transfers) on express buses that operate in mixed traffic on I-5. Total transit travel times (including in-vehicle, walking, and waiting) range between 38 and 65 minutes southbound during the AM peak period and between 46 and 71 minutes northbound during the PM peak period. Nearly all of the transit travel times currently require a transfer to complete the trip exclusively on transit. Transfer time is included in the travel times as walk and wait time but is generally perceived as being more onerous than initial walk and wait or in-vehicle time.

Active Transportation

Active transportation facilities in the study area include sidewalks, on-street bicycle facilities, and shared-use paths. The analysis of these facilities extended over 3 miles beyond the study area to account for local network conditions and the potential for active transportation modes to reach the Interstate Bridge from locations outside of the study area.

In Portland, the width and condition of active transportation facilities vary. Most existing sidewalks are between 4 and 6 feet wide, but there are areas with no sidewalks, as well as segments with missing connections. The Portland bicycle network in the study area comprises a mixture of bike lanes and off-street shared-use paths. Part of the 40-Mile Loop Trail, which is planned to create a route around the Portland region, runs through the study area on the south edge of the Columbia River but has a gap within the study area.

Land uses in the area south of North Portland Harbor (e.g., the Columbia Slough Watershed, Delta Park, the Expo Center, and industrial lands) have limited the overall roadway network development. As a result of large block spacing and historically lower standards, there are limited sidewalk connections. An incomplete network of shared-use paths connects to and through this portion of the study area, with some non-standard segments.

Bike lanes connect North and Northeast Portland with the North Portland Harbor bridge via N Denver Avenue, Martin Luther King Jr. Boulevard, and N Marine Drive. Access to the shared-use path on the North Portland Harbor bridge is circuitous and non-continuous on both ends of the structure (in North Portland and on Hayden Island). On Hayden Island, the path connecting the bridge with mainland Portland is narrow and does not meet applicable standards. The pedestrian network on the island is largely absent despite the grid-like nature of the street network.

The existing Interstate Bridge over the Columbia River between Vancouver and Hayden Island has substandard shared-use paths on the outside edges of the northbound and southbound bridge structures. While the design of each path is different, neither meets the American Association of State Highway and Transportation Officials (AASHTO) standards for shared-use paths. The "clear" (or unobstructed) widths of the paths on the existing bridges are less than 4 feet. The mixing of pedestrians and bicycles in this constrained space can result in safety conflicts and an uncomfortable traveling environment for many users. Still, an estimated 410 bicyclists and pedestrians, on average, make trips across the bridge daily.

In Vancouver, sidewalks are present in the downtown core and on most major arterials west of I-5, but gaps or non-standard facilities are present on several major routes. I-5 is a major barrier to pedestrian travel between Vancouver neighborhoods and destinations on the east and west sides of the freeway. Pedestrian facilities are provided at some I-5 crossing locations, but not consistently. The bicycle network in Vancouver comprises a mixture of shared roadways (designated bikeways in which people biking share the road space with cars and other vehicles), bike lanes, and off-street paved paths providing access to the Interstate Bridge.

Safety

For existing safety-related conditions in the study area, the IBR Program collected crash data records from WSDOT and ODOT from January 2015 to December 2019 (pre-pandemic). Within the study area, there were 2,270 total crashes on the I-5 mainline, ramps, and at study area intersections for the 5-year period evaluated, with rear-end crashes comprising about half of the total. Most crashes occurred between 6 and 9 a.m. and 12 to 7 p.m. About 38% of total crashes resulted in injury, with 2% fatal or serious. The analysis also found that crashes in both northbound and southbound directions are approximately two times more likely when a bridge opening and gate closure occurs than when it does not. The Transportation Technical Report details existing crash data by type, severity, and location, including crashes occurring during bridge openings and gate closures.

Transportation Demand Management and Transportation System Management

A variety of demand- and system-management programs and measures are currently in use in the study area. Demand-management programs can be categorized according to four basic strategies to alter transportation choices:

- Programs to improve public awareness of transportation choices.

- Programs to improve access to or availability of alternative transportation choices.
- Incentives and disincentives that cause changes in transportation choices by individuals.
- Institutional and organizational approaches, including employer-based or area-based programs, as well as transit-oriented or land use-based programs.

System-management measures and actions are used to increase the operational efficiency of the transportation system, especially the street and highway network, including signals and signal systems. These systems are owned or operated by the local agencies and the states and include:

- System monitoring and traveler information systems (e.g., web-based information systems, variable message signs).
- Facility management systems (e.g., active traffic management system, bus-on-shoulder operations, optimized signal systems, ramp meters, signal priority for special users, such as transit).
- Incident management systems (e.g., incident response and recovery teams).

3.1.3 Long-Term Effects

The long-term effects described in this section are for the year 2045. All regional travel demand modeling data is from the 2018 Regional Transportation Plan[2] (2018 RTP), jointly developed and adopted by Metro in 2018 and by Southwest Washington Regional Transportation Council (RTC) in 2019. Regional transportation plans identify and prioritize long-range transportation needs for all modes in the region. These plans serve as the blueprint for how transportation resources are invested and projects are selected for implementation and are the basis for planning efforts in the region. Year 2045 conditions incorporate the 2040 Financially Constrained assumptions adopted by both Metro and RTC with updates to extend the forecasts to 2045. Included in these updates are transit capacity constraints to better represent feasible transit ridership relative to transit investments described in the 2018 RTP.[3]

The evaluation of effects is organized by element of the transportation system for the No-Build alternative and Modified LPA and options. The Modified LPA is discussed in comparison to the No-Build Alternative. The base scenario modeled for the Modified LPA is a double-deck, fixed-span configuration, with one auxiliary lane and ramps at C Street. Three of the Modified LPA design options—those that would remove the C Street ramps, add a second auxiliary lane, and replace the Interstate Bridge with a new movable-span configuration—would operate differently than the Modified LPA in some categories and are discussed below where their impacts would differ. The other design options (i.e., single-level fixed-span configuration, centered I-5, I-5 shifted west, and park-and-ride site options) described in Chapter 2 of this Draft SEIS would not differ from the Modified LPA in terms of transportation impacts and are not discussed further.

[2] The transportation analysis for the No-Build Alternative and Modified LPA is based on the anticipated regional highway and transit networks and service levels for 2045 as informed by the 2018 Regional Transportation Plan jointly developed and adopted by Metro (Metro 2018) and RTC (RTC 2019). The traffic model applied to this analysis reflects pre-COVID conditions. New surveys and model development efforts that include post-COVID travel behavior are planned to be incorporated in the 2028 RTP update.

[3] The 2018 Regional Transportation Plan was jointly developed and adopted by Metro (Metro 2018) and RTC (RTC 2019).

Regional Transportation Impacts in 2045

Table 3.1-10 shows the daily measures of travel demand (VMT, VHT, and VHD) in year 2045 for the No-Build Alternative, the Modified LPA, and the Modified LPA (two auxiliary lane design option), based on the results from the regional travel demand model. The other design options under consideration have the same regional travel demand results as the Modified LPA and are not shown separately. Further details on the key elements of the design options can be found in Chapter 2, Description of Alternatives. The Transportation Technical Report has additional information on the regional model's assumptions. The regional model is based on the Metro and RTC Regional Transportation Plans with adjustments to better represent future conditions. This includes the underlying population and employment growth, land use factors, tolling, fare policies, parking, transit and highway capacity constraints, and other regional system investments that are based on the region's adopted regional transportation plans. All these factors influence the forecasts of future travel demand conditions, including the results for vehicle and transit demand in this corridor and across the region. Regional travel demand model assumptions are described in more detail in the Transportation Technical Report Appendix H.

Table 3.1-10. 2045 Weekday Daily Vehicle Miles Traveled, Vehicle Hours Traveled, and Vehicle Hours of Delay

Alternative	Study Area	Vehicle Miles Traveled	Vehicle Hours Traveled	Vehicle Hours of Delay
No-Build Alternative	Portland Metropolitan Region	59,042,000	1,803,600	65,500
	Traffic Subarea	14,349,500	439,600	24,900
Modified LPA	Portland Metropolitan Region	58,950,700	1,792,300	58,300
	Traffic Subarea	14,270,500	428,000	17,400
Modified LPA (Two Auxiliary Lane Design Option)	Portland Metropolitan Region	58,960,800	1,791,900	58,000
	Traffic Subarea	14,279,300	427,400	17,000
Change between No-Build and Modified LPA	Regional Difference	-91,300 (<-1%)	-12,100 (<-1%)	-7,300 (-11%)
	Subarea Difference	-79,000 (<-1%)	-11,600 (-3%)	-7,500 (-30%)
Change between No-Build and Modified LPA Two Auxiliary Lane Design Option	Regional Difference	-83,300 (<-1%)	-12,600 (-1%)	-7,600 (-11%)
	Subarea Difference	-70,900 (<-1%)	-12,200 (-3%)	-7,900 (-32%)
Change between Modified LPA and Modified LPA Two Auxiliary Lane Design Option	Regional Difference	10,100 (<1%)	-400 (<-1%)	-300 (<-1%)
	Subarea Difference	8,800 (<1%)	-600 (<-1%)	-400 (-2%)

Source: Metro/RTC Regional Travel Demand Model

Compared to the No-Build Alternative, the Modified LPA would decrease motor vehicle travel (measured by VMT) and travel times (measured by VHT) by 1% in the Portland metropolitan region and up to 3% in the traffic subarea (The traffic subarea includes a triangular area around I-5 from I-205 to I-84 on the west, I-205 from I-5 to I-84 on the east, and I-84 from I-5 to I-205 on the south). This is due to the transit improvements and the tolls assumed with the Modified LPA, with transit accommodating a larger share of the daily trips compared to the No-Build Alternative (see the section Daily Person Throughput). The Modified LPA with either one or two auxiliary lanes would result in an 11% decrease in delay (measured in VHD) in the Portland metropolitan region. The one and two auxiliary lane design options would result in a 30% and 32% decrease in delay in the traffic subarea, respectively, compared to the No-Build Alternative. The Transportation Technical Report includes more information on the modeling analysis and results.

Screenline Peak-Hour Traffic Volume Forecasts in 2045

The AM and PM peak-hour screenline volumes within the study area were analyzed using the regional travel demand model to determine the relative differences in traffic volumes between the No-Build Alternative and the Modified LPA. Below is a high-level summary of results from the screenline analysis. The Transportation Technical Report includes detailed figures and lists of the screenlines used for this traffic analysis.

- For the Vancouver east-west screenlines, the Modified LPA would result in increased volumes in the peak directions (southbound in the AM peak and northbound in the PM peak) for all screenlines compared to the No-Build Alternative (+4% to +11%). These forecast increases would be primarily on I-5 rather than on surrounding north-south arterial facilities, which for the most part would see decreases in volumes with the Modified LPA. These changes reflect the ability for more vehicles to be accommodated on I-5 during the peak period with the Modified LPA compared to the No-Build Alternative.
- Most eastbound and westbound screenlines in Vancouver would experience increases in both the AM and PM peak hours with the Modified LPA compared to the No Build Alternative (+2% to +31%). This is, in part, because of additional traffic using these facilities to access I-5 which shows up as higher volumes on I-5 for the north-south screenlines. Contributing to these increases, specifically, are SR 500 east of I-5 which has increases of just under 300 vehicles (approximately +20%) in the peak direction in both the AM and PM peak, and SR 14 east of I-5 which has increases of just under 200 vehicles (+7%) in the peak direction of the AM peak. SR 14 in the peak direction of the PM peak has less than 50 (+2%) vehicle difference.
- Compared to the No-Build Alternative, the Modified LPA and options would not see large changes in vehicle volumes on I-205 on any screenline location in the peak period (-3% to + 12%). Because there is not a significant shift to I-205 in the Modified LPA other east-west facilities such as SR 14, SR 500 and US 30/Lombard Street do not see significant increases either.
- For Portland screenlines capturing vehicles traveling north and south, the Modified LPA would increase vehicle volumes compared to the No-Build Alternative in the peak direction, but total changes are below 10%. The increases would occur on I-5 as well as on the arterials. Some of the changes would be related to Hayden Island area access and circulation changes that would occur with the Modified LPA. In a number of cases, the volumes would be lower than with the No-Build Alternative, particularly in the off-peak direction.

- For Portland screenlines capturing vehicles traveling east and west, nearly every facility in the peak and off-peak directions in the AM and PM peak have differences of fewer than 50 vehicles in the Modified LPA compared to the No-Build Alternative.
- The volumes in the peak and off-peak would not differ among the design options.

At a screenline level, these findings suggest that differences between the No-Build Alternative and Modified LPA are not substantial. Traffic volumes have been analyzed at an individual facility and intersection level as well and are summarized in the Arterials and Local Streets section of this chapter.

I-5/I-205 Travel Forecasts in 2045

Year 2045 volumes were developed using the four-step Metro/RTC regional travel demand model, with adjustments reflecting differences between observed existing traffic counts and the traffic volumes simulated by the Metro/RTC regional travel demand model. Year 2045 forecast volumes were developed for the No-Build Alternative and the Modified LPA. The forecast volumes would not differ among the design options. The Transportation Technical Report has additional information on the methods used and the results predicted.

Daily and Peak-Period Cross-River Demand Volume Forecasts in 2045

Both daily and during peak periods, the regional travel demand model predicts increased trips across the Columbia River by 2045, driven in large part by continued urban growth. Table 3.1-11 shows year 2045 average weekday traffic demand volumes for I-5, I-205, and total Columbia River crossings.

Table 3.1-11. 2045 Forecast Average Weekday Daily Traffic Volumes on I-5 and I-205

Location	Existing AWDT	2045 No-Build AWDT [a]	2045 Modified LPA AWDT [b]
Total River Crossing	313,000	400,000 (+28%)	389,000 (-3%)
I-5 Bridge	143,400	180,000 (+26%)	175,000 (-3%)
I-205 Bridge	169,600	220,000 (+30%)	214,000 (-3%)

Source: ODOT/WSDOT, Metro/RTC Regional Travel Demand Model, IBR Transportation Technical Report
a Percentages reflect change from existing conditions.
b Percentages reflect change from 2045 No-Build Alternative.
AWDT = average weekday daily traffic

In the 2045 No-Build Alternative, average weekday daily traffic volumes are forecast to increase 26% over 2019 conditions for the Interstate Bridge. Similar but slower growth is predicted during the peak periods.

The forecasts indicate that 45% of daily traffic would use the I-5 bridge and 55% would use the I-205 bridge in both the No-Build Alternative and the Modified LPA. The bridge splits would be similar for the No-Build Alternative and the Modified LPA and options due to the improvement in I-5 operations, congestion on both freeway corridors, addition of variable-rate tolling on I-5, addition of high-capacity transit in the I-5 corridor, and addition of active transportation facilities in the I-5 corridor.

The Modified LPA would have 3% lower traffic volumes crossing the river on I-5 and I-205 than the No-Build Alternative in 2045. This reduction is due to more investment in high-capacity transit to connect across the river into central Vancouver (LRT, express bus on shoulder, new park-and-ride lots and increased transit service levels), variable-rate tolls would be implemented on the I-5 Columbia

River bridges, and active transportation facilities would be improved. As noted above, average weekday daily traffic volumes are forecast to be similar across the design options. The Transportation Technical Report has additional description of the factors involved in forecasts of reduced traffic across the river, including tolling, shifts in travelers' choice of mode, or the potential for diversion.

In some locations, screenline vehicle volumes are slightly higher on I-5 and reduced on adjacent facilities under the Modified LPA compared to the No-Build Alternative. There are small changes to vehicle volumes on I-205 in the southbound peak direction (involving -50 to +200 vehicles) and slightly higher changes on I-205 in the off-peak direction (+450 to +500 vehicles) in the peak hour. The volumes would not differ among the design options.

I-5 Peak-Period Mainline and Ramp Volumes in 2045

The regional demand model was also used to predict peak-period mainline and ramp volumes by location, with refinements based on observed traffic volumes under current conditions. In general, ramps that have the highest proportion of demand relative to others in the existing condition would continue to have the highest proportion of demand relative to other ramps under the No-Build Alternative and the Modified LPA. Further detail about the forecast volumes at individual mainline locations and ramps can be found in the Transportation Technical Report.

No-Build Alternative

For southbound travel during the AM peak period and northbound travel during the PM peak period, hourly demand volume crossing the Interstate Bridge would increase between 17% and 30% under the No-Build Alternative compared to existing conditions. Hourly demand volume crossing the Interstate Bridge in the reverse commute period and direction would increase between 34% and 58% compared to existing conditions. Overall, the southbound mainline and ramp travel demand volumes would continue to be highest during the AM peak, and northbound mainline and ramp travel demand volumes would continue to be highest during the PM peak. However, in some locations near downtown Vancouver, such as Mill Plain Boulevard and the SR 14 ramps, there would be more balanced AM and PM peak volumes, with some on-ramps slightly higher during the off-peak period versus the peak period.

Modified LPA

Similar to the 2045 No-Build Alternative, southbound mainline and ramp volumes under the Modified LPA would be highest during the AM peak period and northbound mainline and ramp volumes would be highest during the PM peak period, except for some locations near downtown Vancouver, including Mill Plain Boulevard and the SR 14 ramps, which would see higher volumes (10% to 85%) during the off-peak period versus the peak period.

Hourly traffic volumes crossing the I-5 and I-205 Columbia River bridges in the peak period and peak direction (southbound during the AM peak period and northbound during the PM peak period) would be up to 10% higher in the Modified LPA compared to No-Build Alternative. Hourly traffic volumes crossing the bridges in the reverse commute direction (northbound during the AM peak period and southbound during the PM peak period) would be between 4% and 6% lower in the Modified LPA compared to the No-Build Alternative. The reason that the number of vehicles crossing the bridges would increase in the peak direction and decrease in the off-peak direction under the Modified LPA during the peak period is the cost of variable-rate tolls and the forecast congestion levels on both river

crossings. In the No-Build Alternative, congestion in the peak period and peak direction would continue to limit the traffic volumes on the Columbia River bridges.

Under the Modified LPA, the regional travel demand results reflect the additional person-moving capacity offered by transit and the improvements in traffic operations from the addition of an auxiliary lane in each direction. Tolling is predicted to reduce the *daily* demand volume crossing the river on the I-5 corridor, but the forecasts still assume growth in commute trips during peak periods in the peak direction, because these trips are less affected by tolls than periods with more discretionary trips. The result would be an increase in vehicle demand volume during the peak periods in the peak direction even though daily volume demand crossing the river on the I-5 corridor is decreasing.

All other design options would have similar peak-period traffic volumes as the Modified LPA, with the exception of the design option that would remove the C Street ramps. The design option which removes the C Street ramps would add between 300 and 600 vehicles per hour to the collector-distributor (C-D)[4] roadways and the Mill Plain Boulevard ramps during the peak periods.

Daily Person Throughput in 2045

Person throughput measures the number of people (as opposed to the number of vehicles) that a transportation facility carries. The number of vehicles (passenger cars and freight trucks) crossing the Interstate Bridge was multiplied by average vehicle occupancy assumptions to calculate total person throughput in vehicles. For all vehicle modes, the same average vehicle occupancy used to calculate existing (2019) daily person throughput was applied to future year vehicle volumes. The number of people crossing the bridge in transit (buses and light-rail) and via active transportation was included in the total number of people crossing the bridge to calculate 2045 daily person throughput for the No-Build Alternative and the Modified LPA.

The Interstate Bridge is forecast to carry 241,900 people under the No-Build Alternative and 251,100 people under all design options of the Modified LPA.

Daily person throughput across the I-5 Interstate Bridge is forecast to increase by 30.5% with the 2045 No-Build Alternative compared to the 2019 Existing Conditions. The person throughput with the Modified LPA and design options is forecast to increase an additional 3.8% compared to the No-Build Alternative. High-capacity transit, improved active transportation facilities, and variable-rate tolling under the Modified LPA would increase the number of people crossing the I-5 Columbia River bridges using transit or active transportation while reducing the daily number of vehicles. The increase in the number of transit and active transportation users compared to the No-Build Alternative would be greater than the decrease in the number of people crossing the Columbia River bridges in vehicles, resulting in a net increase in the number of people crossing the Columbia River bridges with the Modified LPA compared to the No-Build Alternative.

I-5 Operations in 2045

The 2045 I-5 operations analysis includes congestion estimates, peak-period speeds, peak-period travel times, LOS and V/C ratios, and impacts to local roads.

[4] A collector-distributer roadway parallels and connects the main travel lanes of a highway and frontage roads or entrance ramps.

Bottlenecks and Speeds in 2045

I-5 traffic performance within the freeway analysis area was evaluated using VISSIM during the 4-hour peak periods and estimated speeds during midday. Key information about forecast bottlenecks, including the location, time of day, duration, and extent of the congestion when speeds are below 45 mph, is summarized in Table 3.1-12 for the No-Build Alternative, Modified LPA, Modified LPA without C Street ramps, and the Modified LPA with two auxiliary lanes. This analysis shows the maximum levels of congestion at the peaks, but congestion levels would build over time and then dissipate as traffic demand volumes begin decreasing after peak periods.

To show the results in more detail, the Transportation Technical Report has maps of average vehicle speeds by segment and location, and it also shows the hours of congestion.

No-Build Alternative

In the southbound direction, the Interstate Bridge would be congested throughout the 4-hour AM and PM peak periods. Congestion at the bridge would continue to be caused by overall high traffic volumes, the structure's limited capacity, limited sight distance, substandard shoulders, short merge and diverge locations north and south of the bridge, high-volume on- and off-ramp flows north of the river, and high truck volumes.

Southbound congestion would span both peaks, from 5 a.m. until 9 p.m. (16 hours). This is an increase of 13 hours, compared to the 3 hours of southbound congestion under 2019 existing conditions. At times, congestion from the Interstate Bridge would extend north from the bridge beyond the I-5/I-205 interchange north of Vancouver, a distance of over 8 miles.

Beyond the study area, a regional southbound bottleneck at the I-5/I-405 split in North Portland would continue to affect I-5 operations backing up traffic toward the Interstate Bridge and into the Interstate Bridge congestion throughout the AM peak period and into midday from 5 a.m. to 1 p.m. (8 hours).

In the northbound direction under the No-Build Alternative, the Interstate Bridge bottleneck would remain the primary bottleneck and would be congested for most of the 4-hour AM peak period and all of the 4-hour PM peak period. The northbound congestion on the bridge is caused by similar factors as the southbound congestion and would last from 6 a.m. until 9 p.m. (15 hours). This is an increase of 6.25 hours over the 8.75 hours of congestion that exist in 2019. Congestion from the Interstate Bridge would extend south of the study area beyond the Marquam Bridge (over 10 miles) and combine with other northbound I-5 bottlenecks near downtown Portland.

Table 3.1-12. Future Year 2045 Average Weekday Bottleneck Summary When Speeds Are below 45 mph

Location	Metric	No-Build Alternative	Modified LPA	Modified LPA Without C Street Ramps	Modified LPA with Two Auxiliary Lanes
Northbound Existing Interstate Bridge/New Columbia River Bridges	Time of Day	7 a.m.–9 p.m.	12–9 p.m.	Same as Modified LPA	1:30–7:30 p.m.
	Duration of Congestion	14 hours	9 hours	Same as Modified LPA	6 hours
	Extent of Congestion	10+ miles	5 miles	Same as Modified LPA	0.75 miles
Southbound Existing Interstate Bridge/New Columbia River Bridges	Time of Day	5 a.m.–9 p.m.	6-10:45 a.m.	Same as Modified LPA	6:15–10:45 a.m.
	Duration of Congestion	16 hours	4.75 hours	Same as Modified LPA	4.5 hours
	Extent of Congestion	8+ miles	4.5 miles	Same as Modified LPA	1 mile
Mill Plain/SR 14 Collector/Distributor	Time of Day	N/A	6 a.m.–12 p.m.	6 a.m.–12 p.m.	7-11 a.m.
	Duration of Congestion	N/A	6 hours	6 hours	4
	Extent of Congestion	N/A	4 miles	4.5 miles	1.5 miles
I-5/I-405 Split in North Portland	Time of Day	5 a.m.–1 p.m.	5 a.m.–1:30 p.m.	Same as Modified LPA	Same as Modified LPA
	Duration of Congestion	8 hours	8.5 hours	Same as Modified LPA	Same as Modified LPA
	Extent of Congestion	5 miles	6 miles	Same as Modified LPA	Same as Modified LPA

Rose Quarter	Time of Day	1:30–9 p.m.	Same as No-Build	Same as No-Build	Same as No-Build
	Duration of Congestion	7.5 hours	Same as No-Build	Same as No-Build	Same as No-Build
	Extent of Congestion	1 mile	Same as No-Build	Same as No-Build	Same as No-Build

Source: IBR Transportation Technical Report
C-D = collector-distributor; N/A = not applicable

Modified LPA

During the AM peak period, overall congestion southbound would be reduced compared to the No-Build Alternative, but congested conditions would still occur. For the AM peak period, most segments of I-5 would operate with less congestion than No-Build, but congestion in North Portland would worsen approaching the downstream I-5/I-405 bottleneck in North Portland because traffic would no longer be as constrained by a bridge bottleneck. The combined congestion from the I-5/I-405 bottleneck in North Portland plus the bridge volumes would extend back into the study area as far north as the C-D system in Vancouver between Mill Plain Boulevard and SR 14. While traffic congestion on southbound I-5 through North Portland would be worse with the Modified LPA compared to the No-Build Alternative, the traffic volume demand forecasts are similar between the Modified LPA and the No-Build Alternative south of the IBR study area, and the Modified LPA would provide multimodal choices for users to avoid the downstream bottleneck near the I-5/I-405 split in North Portland via enhanced high-capacity transit, express bus options, and active transportation improvements connecting to the current active transportation system through North Portland.

During the PM peak period, there would be no southbound congestion at the bridge or to the north.

During the PM peak period, the northbound bottleneck at the Columbia River bridges would be reduced with the Modified LPA compared to the No-Build Alternative, improving northbound traffic flow at the bridges. However, the Columbia River bridges would still be a bottleneck for northbound traffic for 9 hours, with congestion forecast to occur between the Columbia River bridges and the I-5/I-405 split in North Portland with the Modified LPA. During the AM peak period, there would be no northbound congestion at the bridge.

Modified LPA Without C Street Ramps

Under the Modified LPA without C Street ramps, congestion would be the similar to the Modified LPA except for the southbound congestion at the C-D system in Vancouver. The removal of the C Street ramps would result in higher volumes at the Mill Plain Boulevard on-ramp to southbound I-5, and thus in higher demand volumes through the southbound C-D system. The higher demand through the southbound C-D would cause the congestion at the C-D off-ramp to extend further north (4.5 miles compared to 4 miles) than under the Modified LPA.

Modified LPA With Two Auxiliary Lanes

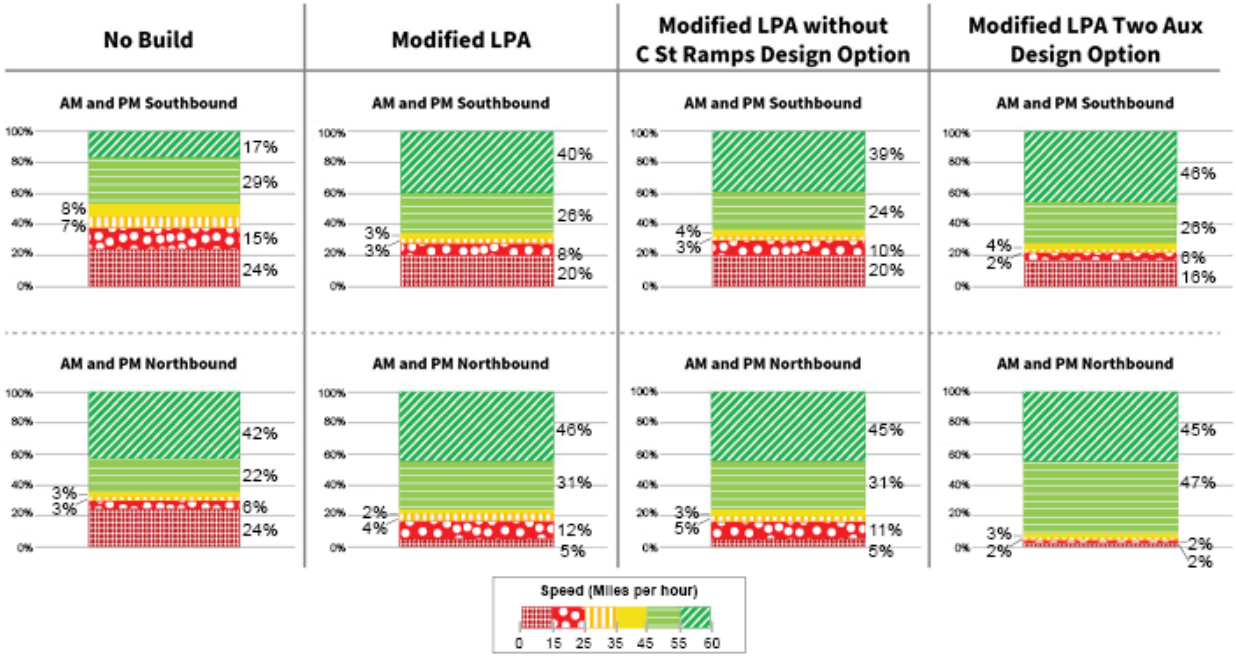
Under the Modified LPA with two auxiliary lanes, forecasted congestion during the AM peak would be reduced compared to the Modified LPA for the southbound direction. Within the areas where auxiliary lanes would be added approaching and across the new Columbia River bridges, operations would improve compared to the Modified LPA at the on- and off-ramps and there would be fewer hours of congestion and shortened backups. Peak-period AM congestion would last for 4 hours (compared to 6 hours with the Modified LPA) and would extend 1.5 miles (compared to 4 miles with the Modified LPA). Similar to the Modified LPA, no southbound congestion is forecast during the PM peak period.

Northbound PM peak-period congestion would be substantially reduced compared to both the Modified LPA and No-Build Alternative. Northbound PM peak congestion would be reduced from 9 to 6 hours but would only extend back less than 0.75 miles to Hayden Island, rather than 4.5 miles to the I-5/I-405 merge in North Portland under the Modified LPA. Similar to the Modified LPA, no northbound congestion is forecast during the AM peak period.

Congestion Index in 2045

Figure 3.1-3 provides a congestion index for No-Build Alternative, the Modified LPA, and the design options without C Street ramps and with two auxiliary lanes. The index aggregates the levels of congestion on I-5 during the 8 peak hours, including the 4-hour AM peak (6 to 10 a.m.) and the 4-hour PM peak period (3 to 7 p.m.). These indices are a summary of northbound and southbound congestion and how long any given section of I-5 in the analysis area is operating at a particular speed. Overall, all Modified LPA design options would improve conditions compared to the No-Build Alternative, and the addition of a second auxiliary lane would offer the highest level of improvement in reducing congestion, particularly for northbound travel.

Figure 3.1-3. Forecast I-5 2045 Peak Period Congestion Index



2045 Forecast Peak-Period Travel Times

I-5 travel time comparisons from I-405 in North Portland to I-205 generally mirror the congestion results described above, but they also provide an additional measure of how different the travel experience would be by alternative and design option, based on the time of day.

Table 3.1-13 through Table 3.1-16 show the 2045 forecast southbound and northbound I-5 average travel times between I-205 and I-405 in North Portland in the AM and PM peak periods. Southbound travel time differences are less varied than northbound travel differences, largely due to the constraints caused by backups at the I-5/I-405 split in North Portland.

- The southbound travel times during the 2-hour AM peak period would be 7% faster than the No-Build Alternative under the Modified LPA and the design option without C Street Ramps, while the two auxiliary lane design option would be 14% faster than the No-Build Alternative.

- The southbound PM peak period 2-hour travel time on I-5 between I-205 and I-405 in North Portland would be 52% faster than the No-Build Alternative under the Modified LPA and design options.
- The northbound AM peak period 2-hour travel time on I-5 between I-405 in North Portland and I-205 would be 28% faster than the No-Build Alternative under the Modified LPA and design options.
- The northbound travel times during the 2-hour PM peak period would be 38% to 40% faster than the No-Build Alternative under the Modified LPA and the design option without C Street ramps, while the two auxiliary lane design option would be 67% faster than the No-Build Alternative.

The Transportation Technical Report has hour-by-hour details, which provide more comparisons, including for periods when travel is closer to free-flow conditions.

Table 3.1-13. 2045 Forecast I-5 Weekday Southbound AM Peak-Period Average Travel Times

Alternative/Design Option	Peak 2-hour Average Travel Time (minutes)

Forecast 2045 Level of Service and Volume-to-Capacity Ratios

As described in the Transportation Technical Report, WSDOT uses LOS for its highway performance standard, and ODOT uses V/C ratios for mobility standards and performance targets. The ODOT performance standard depends on the implementation of project improvements. ODOT sets the V/C standard for acceptable performance for the No-Build Alternative at 1.1 for the peak hour and 0.99 for all other hours. For segments of I-5 in Oregon that are reconstructed as part of an infrastructure improvement project ODOT sets the V/C standard for acceptable performance at 0.75.

In general, the VISSIM freeway analysis performance measures (LOS and V/C ratios) show results similar to other measures (see the previous sections Bottlenecks and Speeds, Congestion Index, and 2045 Forecast Peak-Period Travel Times). Where bottlenecks are predicted and speeds and travel times are slow, the LOS and V/C ratios would be below standards. More detail on measures and locations is available in the Transportation Technical Report.

AM Peak Period

- Southbound I-5 approaching the Interstate Bridge would not meet WSDOT's mobility standard under the No-Build Alternative due to over-capacity conditions at the bridge. Similarly, the Modified LPA (including all design options) would not meet ODOT performance standards due to congestion spilling back from the downstream bottleneck at the I-5/I-405 split in North Portland.
- While northbound I-5 approaching the Interstate Bridge would not meet ODOT's mobility standard under the No-Build Alternative due to over-capacity conditions at the Interstate Bridge the Modified LPA and the design options would improve conditions on Northbound I-5 to meet design standards.
- Although the southbound C-D system between Mill Plain Boulevard and SR 14 in Vancouver would not meet performance standards in the southbound direction with the Modified LPA and all design options, the northbound C-D between SR 14 and Mill Plain Boulevard would meet performance standards.

PM Peak Period

- Southbound I-5 at the Interstate Bridge in the No-Build Alternative would not meet the WSDOT mobility standard, but the Modified LPA and the design options would improve conditions to meet design standards.
- Northbound I-5 in the No-Build Alternative, the Modified LPA, and the Modified LPA without C Street ramps would not meet ODOT's mobility standard. The Modified LPA with two auxiliary

lanes would improve most segments of I-5 to meet ODOT's mobility standard, but some segments near the Columbia River bridges would continue to not meet ODOT's mobility standard.

- Similar to the operations during the AM peak period, the southbound C-D system between Mill Plain Boulevard and SR 14 in Vancouver would not meet performance standards during the PM peak period with the Modified LPA and all design options but the northbound C-D between SR 14 and Mill Plain Boulevard would meet performance standards.

Freight Mobility and Access in 2045

Freight transportation in the Portland-Vancouver metropolitan region is estimated to increase substantially in the next 25 to 30 years, based on the 2022 *Washington Freight System Plan* (WSDOT 2022b) and the 2022 *Oregon Freight Plan* update (ODOT 2023). The Metro/RTC regional travel demand model forecasts increasing truck volumes, which are expected to exacerbate many challenges the state freight system currently faces, including those associated with traffic congestion and safety. Data from the Metro/RTC regional travel demand model forecasts that by 2045, trucks will comprise almost 15% of total trips across the new Columbia River bridges, which is an increase of 50% in truck traffic compared to 2019. This means that freight truck traffic would grow more quickly than general traffic under all alternatives and design options.

With the No-Build Alternative, trucks would be subject to the same delays as general-purpose traffic on I-5, as described above in the I-5 Operations section, as well as in the following discussion in the Arterials and Local Streets section.

Under the Modified LPA and the design options, I-5 in the study area would be improved to meet current design standards. While the elevation of the freeway lanes above the river would be higher than on the existing Interstate Bridge, the grades would still meet design standards for freight vehicles. Lane and shoulder widths would be increased, and highway ramps and interchanges would be rebuilt to meet current design standards. The one to two added auxiliary lanes would also better accommodate freight movements to and from the mainline lanes, especially at the interchanges serving the ports and industrial areas near the bridge. All of these factors were accounted for in the traffic operations models, which assumed a mix of freight and other vehicles. Overall, the Modified LPA would improve access, mobility, and safety for freight. The Modified LPA without C Street ramps would shift additional general-purpose traffic to the Mill Plain interchange, causing additional delay and congestion that could impact freight traffic traveling on the Mill Plain corridor compared to the Modified LPA. The Modified LPA with two auxiliary lanes would provide additional space on the I-5 mainline for trucks to get up to speed and merge with traffic in through lanes on the I-5 mainline, reducing disruptions to flows on I-5 mainline compared to the Modified LPA.

Bridge Openings and Gate Closures in 2045

No-Build Alternative

Under the No-Build Alternative, bridge openings and gate closures would occur at a frequency and for durations similar to existing conditions, assuming no major changes to the U.S. Coast Guard Bridge Permit. Bridge openings would avoid high traffic volume periods, but training and bridge maintenance activities would occur similar to existing conditions during the midday and overnight periods. However, as the durations of future congestion events would increase compared to existing conditions, the recovery periods associated with gate closures would be similarly extended, exacerbating overall congestion within the study area.

Modified LPA

The Modified LPA and all design options, except the single-level movable-span configuration, would eliminate the lift spans on the Columbia River bridges. Gate closures required for bridge openings and traffic stoppage events would no longer occur. Recovery times associated with bridge openings and gate closures would no longer contribute to the number and duration of congestion events.

The single-level movable-span configuration would require periodic bridge openings and gate closures that would interrupt traffic operations. For the years 2012-2023, the average number of bridge openings/gate closures was 257 per year with a range of 147 to 487 openings/bridge closures per year. Clearance of the bridge in the closed position would be higher in the single-level movable-span configuration than under the No-Build Alternative, thus allowing more vessels to pass without a bridge opening. There would likely be additional timing restrictions on when the bridge would be opened. Based on existing marine vessels transiting the Interstate Bridge, the number of bridge openings would be reduced to approximately 60 per year for marine vessels, 12 per year for maintenance, and between 0 and 55 openings per year for training purposes; however, this number of bridge openings could vary over time as maritime activities evolve over the 100+ year service life of the bridge. The total number of resulting openings would be less than with the No-Build Alternative, assuming that the U.S. Coast Guard would approve further restrictions on when bridge openings would be allowed.

Similar to the No-Build Alternative, daytime bridge openings under the Modified LPA with a movable-span configuration could impact traffic congestion for an hour or more; nighttime bridge openings would have less impact to traffic congestion. Transit and active transportation trips would also be affected. For transit, the openings would cause a system-level disruption in service, affecting operations for the Yellow Line to downtown Portland and other lines serving downtown Portland. Bus and rail connections would also be disrupted, increasing overall travel times for riders. Depending on when the disruptions occur, it could take hours for the system to recover.

Arterials and Local Streets in 2045

This section covers impacts to roadway network traffic patterns, study intersections, peak-hour volumes, and intersection operations under the No-Build Alternative and Modified LPA and design options. The Transportation Technical Report provides more detail on the analysis, while this section focuses on areas where impacts or benefits differ between the No-Build Alternative and the Modified LPA and design options.

Changes to Local Traffic Patterns

No-Build Alternative

Under the No-Build Alternative, other projects would be implemented that would modify interchange and arterial geometries in the study area, but no major changes affecting traffic patterns and circulation would occur. The No-Build Alternative would continue to require all Hayden Island traffic to access I-5, because no other local access route would be available.

Modified LPA

Within Oregon, all design options of the Modified LPA would similarly affect local traffic patterns within the Hayden Island, Bridgeton, and north and northeast Portland neighborhoods in the study area. The changes to local traffic patterns would primarily result from the revised Hayden Island and

Marine Drive interchanges and the proposed arterial bridge over North Portland Harbor. These improvements would alter access and circulation routes and patterns for the Hayden Island and Bridgeton neighborhoods but would also allow local access to be accommodated without requiring trips on I-5.

Within Washington, the Modified LPA would change local traffic patterns compared to the No-Build Alternative, primarily in the Esther Short and Arnada neighborhoods in downtown Vancouver. These changes would be the result of modifications to the interchanges in this area. Effects would be similar across design options except for the option without the C Street ramps, which would cause additional changes to traffic patterns by eliminating an access point to the downtown area.

The Transportation Technical Report includes a detailed description of local traffic pattern changes in the study area.

Intersection Operations

The local traffic analysis evaluated 80 intersections for the No-Build Alternative and 86 intersections for the Modified LPA. Due to interchange and access changes under the Modified LPA, some of the No-Build intersections would no longer exist, and other intersections would be added. The Transportation Technical Report provides details on these intersections, including the changes to traffic volumes, while discussion in this section focuses on locations where intersections would not meet agency standards in 2045.

The following summary identifies intersections that would operate below the applicable performance standards in 2045.

No-Build Alternative

All 80 study intersections would operate at or better than the intersection performance standards except for nine intersections. The first five intersections are in Vancouver and the four remaining intersections are in Portland.

1. Intersection #3 – 39th Street and Main Street (PM).
2. Intersection #5 – 39th Street and I-5 southbound on-/off-ramps (AM and PM).
3. Intersection #11 – Fourth Plain Boulevard and Main Street (AM).
4. Intersection #57 – Columbia Shores Boulevard and SR 14 eastbound off-ramp (AM and PM).
5. Intersection #58 – Columbia Shores Boulevard and Columbia Way (PM) .
6. Intersection #66 – Marine Drive and OR 120 (Portland Road) (PM).
7. Intersection #67 - Marine Drive and Force Avenue (PM).
8. Intersection #68– Marine Drive/Martin Luther King Jr. Boulevard and I-5 northbound/southbound on-/off-ramps (AM and PM).
9. Intersection #79 – Columbia Boulevard and Vancouver Way (PM).

Modified LPA and Modified LPA with Two Auxiliary Lanes

Under the Modified LPA with either one or two auxiliary lanes, there are 86 study intersections. All 86 study intersections would operate at or better than the intersection performance standards except for

eight intersections. The first five intersections are in Vancouver and the three remaining intersections are in Portland.

1. Intersection #3 – 39th Street and Main Street (PM).
2. Intersection #5 – 39th Street and I-5 southbound on-/off-ramps (AM and PM).
3. Intersection #11 – Fourth Plain Boulevard and Main Street (AM).
4. Intersection #57 – Columbia Shores Boulevard and SR 14 eastbound off-ramp (AM and PM).
5. Intersection #58 – Columbia Shores Boulevard and Columbia Way (PM).
6. Intersection #66 – Marine Drive and OR 120 (Portland Road) (PM).
7. Intersection #68 – Marine Drive/ Martin Luther King Jr. Boulevard and I-5 northbound/southbound on-/off-ramps (AM and PM).
8. Intersection #79 – Columbia Boulevard and Vancouver Way (PM).

In most of these cases, although the Modified LPA or Modified LPA with two auxiliary lanes would not meet the standard, it would perform the same as or better than the No-Build Alternative in terms of LOS or V/C ratio.

The park-and-ride options in downtown Vancouver would not notably alter the operating conditions for the Modified LPA under any of the design options.

Modified LPA Without C Street Ramps

If the C Street ramps were removed, a total of 14 study area intersections would operate below agency standards during the AM and/or PM peak hours compared to the Modified LPA, which would retain the C Street ramps. The removal of the C Street ramps would redirect all trips between downtown Vancouver and I-5 to the Mill Plain Boulevard interchange. The additional six intersections that would not meet agency standards in addition to those already identified in the Modified LPA are located in Subarea 2 and include:

1. Intersection #22 – Franklin Street & Mill Plain Boulevard (PM).
2. Intersection #24 – Washington Street and 15th Street (AM).
3. Intersection #25 – Main Street and 15th Street (AM).
4. Intersection # 28 – Columbia Street & Mill Plain Boulevard (PM).
5. Intersection #31 – Mill Plain Boulevard and Broadway Street (PM).
6. Intersection #34 – Mill Plain Boulevard at I-5 Northbound Ramps (PM).

In addition to the intersection-level impacts, the elimination of C Street ramps would increase queuing through the Mill Plain Boulevard and 15th Street couplet, affecting eastbound and westbound flows through the 15th Street/Mill Plain Boulevard couplet.

Transit in 2045

The long-term effects described in this section are for the year 2045. All regional travel demand modeling data is from the 2018 Regional Transportation Plan,[5] adopted by Metro in 2018 and by Southwest Washington Regional Transportation Council (RTC) in 2019 (2018 RTP).[6] Year 2045 conditions incorporate the 2040 Financially Constrained assumptions adopted by both Metro and RTC in the 2018 RTP, with land use updates to extend the forecasts to 2045. Included in these updates are transit capacity constraints to better represent feasible transit ridership relative to transit investments described in the 2018 RTP. Without accounting for capacity constraints of the regional transit system, the model would have generated estimates of transit ridership that could only be supported if additional capital investment projects were added to the 2018 RTP. The transit capacity constraint analysis is described in more detail in the Transportation Technical Report, Appendix H, Section 3.8.

The following section summarizes transit service effects in 2045 for the No-Build Alternative and the Modified LPA, including transit routing, ridership, station area mode of access, and transit transfer rates. Additional details about the transit networks, service and routing changes, and facilities are provided in the Transportation Technical Report. The report also has information on maintenance facilities, annual operating costs, and related factors.

For the purposes of this analysis, it is assumed the transit networks and service assumptions—except for those that are components of the IBR Program, including new LRT service and more frequent higher capacity express bus service on I-5—are the same for both the No-Build Alternative and Modified LPA. As described in more detail in Chapter 2, the Modified LPA would include service modifications and improvements in the study area—including new LRT and express bus service and facilities—as well as modifications to local transit service that would connect to these. A detailed description of the Modified LPA transit elements is in Chapter 2 of this Draft SEIS.

The effects of the Modified LPA on transit service would not differ substantially between the design options, with two exceptions. The design option without C Street ramps would result in small transit routing changes to access downtown Vancouver that would result in additional travel time for the express route in and out of downtown Vancouver as compared to the Modified LPA, and the two auxiliary lane design option would result in transit travel time improvements for all bus routes operating through the study area. The other design options are not discussed in this subsection because they would not affect transit service differently than the Modified LPA.

Amount of Service

The amount of service provided in the transit system can be measured by VHT in revenue service, daily VMT in revenue service, and daily place-miles of service. Table 3.1-17 shows average weekday totals

[5] The IBR Program used the Oregon Metro (Metro) regional travel demand model that is developed, maintained and implemented for projects in the Portland metropolitan region. The model is jointly developed between Metro, the Portland, Oregon metropolitan planning organization (MPO) and the Southwest Washington Regional Transportation Commission (RTC), the MPO for southwest Washington, The version of the model being used for the IBR Program, including planned regional highway and transit networks and service levels, was developed for the Regional Transportation Plan adopted in 2018 by Metro and in 2019 by RTC. The traffic model applied to this analysis reflects pre-COVID conditions. New surveys and model development efforts that include post-COVID travel behavior are planned to be incorporated in the 2028 RTP update.

[6] Regional transportation plans—such as the 2018 RTP—identify and prioritize long-range transportation needs for all modes in the region. These plans are the basis for planning efforts in the region, serving as the blueprint for how transportation resources are funded and projects are selected for implementation.

for all three of these measures for the model base year (2015) as well as for the 2045 No-Build Alternative and Modified LPA. Transit service assumptions (e.g., routes, headways) would not vary for the Modified LPA design options as compared to the Modified LPA except for a routing change on the Line 101 under the design option without C Street ramps which would change how this line enters and exits downtown Vancouver. The base year is included to provide a point of comparison of service levels under the No-Build Alternative and Modified LPA. As shown in Table 3.1-17, transit miles and hours in the No-Build Alternative increase over 50% as compared to existing conditions and place-miles increase just under 50%. This increase reflects the changes in the transit system planned in the 2018 RTP that are not part of the IBR Program. The Transportation Technical Report, Section 4.7 (and its appendix with the Travel Demand Modeling Methods Report), has further details on the factors driving the forecasts for increased ridership levels by 2045. Daily VHT and VMT are measured as time and distance, respectively, for transit vehicles in service on an average weekday. VMT would increase in 2045 with both the No-Build and the Modified LPA, with the additional growth for the Modified LPA due primarily to the extension of LRT and more frequent express service operating in bus-on-shoulder mode in the study area. Also, under the Modified LPA, VHT would decrease on local bus and increase on LRT and express bus by a similar number of hours, resulting in approximately the same total VHT compared to the No-Build Alternative.

Place-miles reflect the carrying capacity of the vehicles in service (seated and standing) for each bus or train and are calculated by multiplying the vehicle capacity by the VMT. Place-miles can highlight differences in total available capacity between alternatives as shown in Table 3.1-17. The Modified LPA would have more place-miles than the No-Build Alternative, in part because of the extension of LRT across the Columbia River and in part because additional express bus service between Vancouver and Portland would be provided under the Modified LPA.

The Transportation Technical Report Section 5.8 has additional discussion.

Table 3.1-17. 2015 and 2045 Average Weekday Corridor [a] Transit Service Characteristics

Measure	Mode	Existing (2015)	2045 No-Build Alternative	2045 Modified LPA
Transit VMT (miles)	Local Bus	9,250	13,500	11,900
	Express Bus	5,450	3,900	7,650
	LRT [b]	800	850	1,300
	BRT	0	5,300	5,250
	Total	**15,500**	**23,550**	**26,050**
	% Change [c]	**N/A**	**51.0%**	**9.5%**
Transit VHT (hours)	Local Bus	650	850	750
	Express Bus	200	150	250
	LRT	50	50	75
	BRT	0	300	300
	Total	**850**	**1,400**	**1,400**
	% Change [c]	**N/A**	**58.8%**	**0%**

Measure	Mode	Existing (2015)	2045 No-Build Alternative	2045 Modified LPA
Place-miles [d] (miles)	Local Bus	602,100	879,100	773,200
	Express Bus	545,300	388,900	763,300
	LRT[2]	225,400	247,300	380,300
	BRT	0	530,200	524,500
	Total	**1,372,800**	**2,045,500**	**2,441,300**
	% Change [c]	**N/A**	**49.0%**	**19.3%**

Source: Metro/RTC Regional Travel Demand Model, IBR Transportation Technical Report

a Excludes Portland central business district.

b For LRT, transit VMT is measured in train miles rather than in car miles.

c For the No-Build Alternative, the percentage change is the change compared to existing conditions; for the Modified LPA the percentage change is compared to the No-Build Alternative.

d Place-miles = transit vehicle capacity (seated and standing) multiplied by VMT. Bus capacity = 55, BRT and express bus capacity = 100, LRT capacity = 288 (LRT consists of two-car trains; each car can carry 144 people).

BRT = bus rapid transit; LRT = light-rail transit; N/A = not applicable; VHT = vehicle hours traveled; VMT = vehicle miles traveled

Regional Transit Ridership

The regional travel demand model for 2045, based upon the 2018 RTP, which was adopted by Metro in 2018 and by RTC in 2019 was used to produce estimates of ridership for both the No-Build Alternative and the Modified LPA. Included in the model for both the No-Build Alternative and Modified LPA are transit-capacity constraints to better represent feasible transit ridership relative to transit investments described in the 2018 RTP. The Transportation Technical Report has more details on the capacity constraint implementation along with a variety of ridership performance measures, including station boardings; the comparison here in the Draft SEIS focuses on the primary differences between the alternatives.

Travel Demand and Mode Choice

Table 3.1-18 shows the 2045 daily person trips and transit trips for the No-Build Alternative and the Modified LPA, including corridor and systemwide totals. Compared to existing conditions, the future growth rates for transit show higher use of transit for both the No-Build Alternative and the Modified LPA. The daily systemwide and corridor transit trips would be the same for all of the design options under the Modified LPA. The Transportation Technical Report Section 4.7 has further details on ridership levels and the services assumed, including total trips across the river on both I-5 and I-205. It also identifies the other system investments and regional planning assumptions related to the regional system ridership forecasted for both the No-Build Alternative and the Modified LPA.

Table 3.1-18. 2045 Weekday Daily Systemwide and Corridor Transit Trips

Measure	No-Build Alternative	Modified LPA
Total Regional Person Trips (all modes)	11,905,000	11,905,000
Total Regional Linked Transit Trips [a]	626,300	638,800
Regional Transit Mode Share	5.26%	5.37%

Measure	No-Build Alternative	Modified LPA
Total Regional Daily Unlinked Transit Boardings [b]	991,900	1,021,100
Percentage Change from No-Build	N/A	2.9%
Total Daily Regional Unlinked Light-Rail Boardings [b]	335,600	362,200
Percentage Change from No-Build	N/A	7.9%
Total Corridor Person Trips (All Modes)	3,249,500	3,250,200
Total Corridor Linked Transit Trips [a]	351,300	363,300
Percentage Change from No-Build	N/A	3.3%

Source: Metro/RTC Regional Travel Demand Model, IBR Transportation Technical Report

a Transit trips count each passenger only once between the origin and destination of their trip. Transit trips include all trips on any transit mode.

b Boardings count each time a passenger boards a transit vehicle; passengers who transfer between transit lines in a single "linked" trip count as multiple transit boardings.

LRT Station Use Levels and Mode of Access/Egress

Light-rail stations are accessed by transit (local, regional, and express bus, BRT, LRT) and by active transportation modes including walking, biking, and rolling. Trips by automobile are also reflected, primarily based on park-and-ride trips, but can also include drop-off or pick-up activities. The primary mode of access by station reflects key differences in the location of the station and the surrounding land uses served. Table 3.1-19 summarizes the predicted station use and mode of access and egress to the new LRT stations with the Modified LPA. The LRT station usage by mode of access for the design options would be the same for all Modified LPA design options. The Evergreen Station is expected to be the most-used station and the one with the highest level of access by transit. This reflects the station's connections to the C-TRAN system serving downtown, including BRT lines.

Table 3.1-19. 2045 Modified LPA Light-Rail Transit Station Usage (Boardings and Alightings) by Mode of Access and Egress, Year 2045

Station Location	Station Boardings/Alightings	Percentage of Total Boardings/Alightings	Percentage Non-Motorized [a]	Percentage Transfer	Percentage Park and Ride [b]
Hayden Island	3,300	15%	100%[c]	N/A	N/A
Waterfront	5,200	24%	25%	60%	15%
Evergreen/I-5	13,100	61%	16%	75%	10%

Source: Metro/RTC Regional Travel Demand Model, IBR Transportation Technical Report

a Non-motorized includes walking, biking and rolling.

b Analysis assumes park-and-ride facilities at Waterfront and Evergreen Stations. Park-and-ride numbers do not include numbers for drop-off (private vehicle, taxi, rideshare) or C-TRAN microtransit trips on The Current.

c 100% of trips are shown to come from non-motorized access because there was no transit connection or formal park and ride assumed in the Modified LPA for this station. As noted in footnote b to this table, the model does not include explicit assumptions about drop-off so while there will likely be some trips that come via that mode of access it is not reflected in the modeling.

Transit Travel Time

Transit travel times for both the AM and PM peak periods were calculated for the No-Build Alternative, the Modified LPA, and the Modified LPA with two auxiliary lanes. The other design options under the Modified LPA would have similar travel times to the Modified LPA.

The travel time summary in Table 3.1-20 shows the total transit travel time (including in-vehicle, walking, waiting, and transfer time) for trips between downtown Vancouver and four locations in Portland, including Hayden Island, Lombard Transit Center, Rose Quarter, and downtown Portland. The latter three locations in Portland provide access to connections for travel to other regional locations via transfer to and from the TriMet system. The Modified LPA and Modified LPA with two auxiliary lanes travel times are provided for both express bus and LRT where they both would provide service.

Express bus travel times include delays identified through the I-5 operational analysis above in the section, I-5 Operations in 2045, for both the No-Build Alternative and Modified LPA. This is especially notable for southbound trips in the AM peak hour through the area approaching the I-5/I-405 split in North Portland. Improved traffic flow under both the Modified LPA and the two auxiliary lane design option would allow more southbound vehicles to cross the new Columbia River bridges. This would result in more vehicles reaching the bottleneck at the I-5/I-405 interchange during the peak period, meaning that southbound buses running in traffic would experience higher levels of congestion approaching the bottleneck. As a result, southbound express bus travel times would be higher compared to the No-Build Alternative, which would continue to constrain vehicle trips at the Interstate Bridge. Differences in travel time between the Modified LPA and the two auxiliary lane design option would be primarily in the PM peak period in the northbound direction, where the Modified LPA with two auxiliary lanes would result in faster travel times (12 minutes) than the Modified LPA. LRT travel times would be similar for all Modified LPA design options.

The Transportation Technical Report includes additional information on the transit travel time analysis.

Table 3.1-20. 2045 Average Weekday AM and PM Peak Total Transit Travel Time for Selected Corridor Locations (minutes)

Origin/Destination	No-Build Alternative AM Peak SB	No-Build Alternative PM Peak NB	Modified LPA[a] AM Peak SB	Modified LPA[a] PM Peak NB	Modified LPA With Two Auxiliary Lanes AM Peak SB	Modified LPA With Two Auxiliary Lanes PM Peak NB
Between downtown Vancouver and Hayden Island	36[b]	21	17[c]	17[c]	17[c]	17[c]
Between downtown Vancouver and Lombard Transit Center	43[d]	41[d]	25[c]	25[c]	25[c]	25[c]

Origin/Destination	No-Build Alternative AM Peak SB	No-Build Alternative PM Peak NB	Modified LPA[a] AM Peak SB	Modified LPA[a] PM Peak NB	Modified LPA With Two Auxiliary Lanes AM Peak SB	Modified LPA With Two Auxiliary Lanes PM Peak NB
Between downtown Vancouver and Rose Quarter: • Express Bus[e] (no stops between downtown Vancouver and Rose Quarter)	43	62	52	38	52	26
Between downtown Vancouver and Rose Quarter: • LRT (includes 13 stations between downtown Vancouver and Rose Quarter)	N/A	N/A	37	37	37	37
Between downtown Vancouver and Pioneer Square (Portland central business district): • Express Bus[e] (includes two stops between downtown Vancouver and Pioneer Square)	48	67	59	45	59	33
Between downtown Vancouver and Pioneer Square (Portland central business district): • LRT (includes 16 stops between downtown Vancouver and Pioneer Square)	N/A	N/A	47	47	47	47

Sources: Metro/RTC Regional Travel Demand Model, IBR Transportation Technical Report
Note: Total transit travel times include 10 minutes of walk access (1/4 mile walk on either end of the trip at 3 mph average walk speed) in addition to initial and transfer (if applicable) wait time. Wait times are based on half the headway.
a Removal of the C Street ramps would require express bus transit to be rerouted to access downtown Vancouver via Mill Plain Boulevard. This would add travel time for express bus transit trips in and out of downtown Vancouver.
b Route 60 does not stop at Hayden Island southbound, so a trip from Vancouver to Hayden Island travels south to Delta Park and then back north to stop on Hayden Island.
c Travel time is on Yellow Line LRT.
d Route includes 60 Vancouver – Delta Park with transfer to Yellow Line LRT.
e Route includes Route 101 from downtown Vancouver – Rose Quarter or Pioneer Square.
LRT = light-rail transit; N/A = not applicable; NB = northbound; SB = southbound

Transit Reliability

Table 3.1-21 summarizes three measures of transit reliability in the corridor: (1) miles of exclusive or reserved right of way, (2) the number of passenger miles that would occur in the right of way, and (3) the percentage of passenger miles that would occur in the right of way. Under the Modified LPA, the extension of the Yellow Line from the Expo Center north to the new terminus at the Evergreen/I-5 station would be completely in its own guideway, and new shoulders proposed as part of the Modified LPA would provide bus-on-shoulder operations that are reserved for express buses. These both would

contribute to the increase in average weekday passenger miles in the Modified LPA as compared to the No-Build Alternative.

Table 3.1-21. 2045 Measures of Transit Reliability in the I-5 Corridor

Right-of-Way Measure	2045 No-Build Alternative	2045 Modified LPA
Miles of Exclusive/Reserved Right of Way	20.07	26.88
Average Weekday Passenger Miles	69,500	213,000
Percentage of Total Corridor Passenger Miles	12%	31%

On-time performance is an additional measure of reliability, particularly for multiline rail systems such as MAX. As part of ongoing regional system planning, TriMet previously conducted analysis using the Rail Traffic Controller model in 2018, which showed that on-time performance of the regional light-rail system would remain in an acceptable range under TriMet's performance policy when up to 56 trains per hour travel through the system where all lines converge at the Rose Quarter.

Key assumptions in the No-Build Alternative and Modified LPA that would affect on-time performance are defined below:

- To meet demand in the peak periods when ridership is highest under the No-Build Alternative, the Yellow line is assumed to operate at 10 minute frequencies. When combined with other LRT lines operating through the Rose Quarter (Blue, Red, and Green Lines), this results in 52 to 54 trains per hour (fewer than the 56 trains per hour threshold target at the Rose Quarter that has been identified as acceptable for on-time performance by TriMet).
- To meet demand in the peak periods when ridership is highest under the Modified LPA—with extension of the Yellow Line across the Columbia River to a terminus near Evergreen Boulevard in Vancouver—6.7-minute frequencies are assumed. When combined with other LRT lines operating through the Rose Quarter (Blue, Red, and Green Lines), this results in 58 to 60 trains per hour, which is 2 to 4 trains per hour over the target threshold at the Rose Quarter that was identified as acceptable for on-time performance by the TriMet-conducted Rail Traffic Controller model analysis. Because 6.7-minute headways under the Modified LPA would result in 2 to 4 more trains per hour over the threshold target, this would likely result in lower on-time performance.

Active Transportation in 2045

No-Build Alternative

As the region experiences increased population growth and development intensifies, more pressure would be placed on the Interstate Bridge's deficient existing active transportation facilities, including the shared-use path for walking, rolling, and riding between the two cities. For the bridge crossing itself, an increase in the volume of people traveling on the narrow and constrained paths would result in increased conflict between users sharing space along the paths, which are not wide enough for two-way travel or for people to pass each other. This deterioration in user experience would limit the potential for active transportation trips over the bridge and further reinforce the bridge as a barrier to active travel. Therefore, to be conservative, the No-Build evaluation assumes future average daily bridge trips would be the same as the existing 2019 conditions (410 daily trips).

Modified LPA

With the Modified LPA, future active transportation trips across the new Columbia River bridges are estimated to range between 740 and 1,600 trips per day. The Modified LPA would offer improved conditions for active transportation, improving capacity, access, safety, and user experience for trips across the bridge. These improvements would combine with the transit improvements offered by the Modified LPA to further improve mobility. Trains and buses would accommodate bicycle trips and allow active transportation travelers to use the new stations to reach a wider array of destinations on both sides of the river, compared to the No-Build Alternative. Measures for evaluating the perceived stress active transportation travelers experience would also improve.

The Modified LPA would include bicycle and pedestrian improvements for all ages and abilities on the new Columbia River bridges, as well as facilities to access these bridge connections. All Modified LPA design options would include a two-way shared-use path, approximately 25 feet wide in total, which would be designed to meet Americans with Disabilities Act (ADA) standards and would include other features to optimize user experience, safety, comfort, and directness. To prevent conflicts between path users traveling at varying speeds, the shared-use path would provide separate spaces for people walking and biking. The design elements of the path would buffer it from vehicle traffic, noise, and exposure to street debris and stormwater to provide a well-lit, attractive, and comfortable environment for all users. On each end of the bridge, the shared-use path would include improvements to existing and proposed network facilities and would also provide new connections that do not exist today.

In the Modified LPA, the shared-use path would be on the lower deck of the I-5 northbound bridge. The path would be at an elevation of 163 feet above the Columbia River due to waterway clearance requirements, compared to 90 feet for the existing Interstate Bridge. The path transition from the I-5 northbound bridge down to Columbia Way in Vancouver would require extensive ramp lengths to span the vertical distance at a grade that meets or exceeds ADA requirements. The design incorporates a helix ramp to make this transition, but this introduces considerable additional path length. Co-locating the shared-use path with the proposed Waterfront Station to provide additional elevator access down to Columbia Street/Columbia Way is a potential design solution that is being considered.

With the single-level fixed-span configuration, the shared-use path would be at an elevation of 135 feet above the river, while with single-level movable-span configuration it would be 120 feet above the river. While lower than the Modified LPA with the double-deck configuration, the paths in these design options would still be higher than under the No-Build Alternative; thus, all users must climb over a longer distance to get over the peak. The maximum grade for the fixed-span configuration would be 1.5% on the Washington side and 3% on the Oregon side; for movable-span configuration, these grades would be 4% and 1%, respectively.

All Modified LPA design options would include substantial bicycle and pedestrian improvements at reconstructed I-5 interchanges and crossings throughout the study area, as well as in areas around new transit stations. Where roadways are replaced or modified or where new roadways are developed (such as the new arterial bridge proposed over North Portland Harbor), active transportation facilities including sidewalks and bike facilities would meet applicable standards, at a minimum. These changes would reduce many of the perceived barriers to bicycle and pedestrian travel and would improve the connectivity of the active transportation network in North Portland and Vancouver within the study area.

The Transportation Technical Report has detailed listings and maps of the individual locations and facilities that would improve active transportation conditions with the Modified LPA.

Safety in 2045

The Enhanced Interchange Safety Analysis Tool (ISATe) was used to calculate the predicted frequencies of vehicle crashes on the I-5 mainline, ramps, and ramp terminal intersections within the IBR study area for the No-Build Alternative and the Modified LPA, including the design options. ISATe is based on the *Highway Safety Manual* (AASHTO 2010) predictive methodology for freeway facilities. The Transportation Technical Report includes additional detail on the results of the ISATe analysis, including predicted crash frequencies by design option.

No-Build Alternative

Crash patterns along the I-5 mainline, along ramps, and at ramp terminals within the IBR study area for the No-Build Alternative are anticipated to be similar to existing conditions, but crash frequencies are predicted to increase due to increased traffic volumes and increased hours during which I-5 is operating at capacity. The total number of crashes in the study area is predicted to increase by up to 28% by 2045 under the No-Build Alternative compared to existing conditions.

Modified LPA

ISATe was used to calculate the predicted crash frequency for the I-5 mainline, ramps, and ramp terminal intersections for the Modified LPA based on the proposed roadway geometry and estimated future traffic volumes. The results of this analysis can be compared directly to the No-Build Alternative analysis results to determine the change in predicted crash frequency.

The Modified LPA proposes substantial changes to the configuration of the network within the study area, including but not limited to new or removed ramps, reconfigured interchanges, and access point changes. These changes would make I-5 more consistent with modern design standards and would reduce weaving, thereby improving safety. As a result, the Modified LPA is predicted to reduce total crashes by 13% compared to the No-Build Alternative. The Modified LPA with the fixed-span configurations would also eliminate the movable span from the Columbia River bridges, the openings of which are correlated with an increased likelihood of crashes, while the No-Build Alternative would maintain the movable span. However, the effect of eliminating the movable span cannot be quantified within the predictive analysis, and it is likely that the predicted number of crashes within the study area is underestimated in the No-Build Alternative predictive analysis. Therefore, the fixed-span configurations would likely result in a larger reduction in crashes (above 13%) by reducing the congestion that would result from bridge openings.

The Modified LPA without C Street ramps design option would eliminate access between I-5 and C Street, removing two ramps and a ramp terminal intersection. The vehicles that would have previously used the C Street ramps would instead use the Mill Plain Boulevard interchange. While more traffic traveling through the Mill Plain Boulevard interchange could increase the likelihood of crashes at the Mill Plain Boulevard interchange ramps and intersections, the removal of the C Street northbound off-ramp and southbound on-ramp would reduce the number of crashes at the C Street interchange ramps and intersections due to the removal of the interchange.

The Modified LPA with two auxiliary lanes design option is predicted to reduce crashes over the Modified LPA with one auxiliary lane by up to 4% as a result of reduced congestion. This reduction in crashes assumes a fixed-span configuration.

The Modified LPA with a single-level fixed-span configuration would have similar safety performance to the Modified LPA.

The Modified LPA with a single-level movable-span configuration would maintain movable-span operations, but otherwise it would have the same geometry and traffic volumes as the Modified LPA. As described previously, while the safety effects of the movable-span configuration cannot be quantified, this configuration is associated with a higher likelihood of crashes. It is therefore likely that the movable-span configuration would perform slightly worse (i.e., experience more crashes) than the Modified LPA, but it would perform better (i.e., would experience fewer crashes) than the No-Build Alternative due to the reduction in traffic congestion.

Transportation Demand Management and Transportation System Management in 2045

TDM and TSM systems would continue to be available to reduce travel demand and maximize system efficiency, and are generally already incorporated in the analysis of impacts and performance for all alternatives and design options discussed in the preceding section.

Under the No-Build Alternative, existing TDM and TSM programs would continue to support trip reduction and shifts from single-occupancy vehicle use to more transit and active transportation. Existing established TSM programs including system monitoring and traveler information systems, facility management systems, and incident management systems would be maintained and advancements in technologies and infrastructure programs identified in the 2018 RTP.

The Modified LPA, under all design options, would develop physical infrastructure and provide operations that support non-single-occupancy vehicle modes for travel needs in the study area. These would include:

- Expanded connections and more frequent transit service via the extension of the MAX Yellow Line with three new stations in the study area, plus new express bus and more frequent feeder routes, and I-5 median shoulders that accommodate bus-on-shoulder operations through the study area between Victory Boulevard in Portland to State Route (SR) 500 in Vancouver (5 miles).
- New and improved bicycle and pedestrian facilities that accommodate more bicyclists and pedestrians and improve connectivity, safety, and travel time.
- Variable-rate tolling on the Columbia River bridges.

The Modified LPA would also include facilities and equipment that could support or expand TSM programs, including:

- Replacement or expansion of traveler information systems.
- Active traffic management system expansion.
- Expanded use of ramp meters.
- Queue jumps or bypass lanes for transit vehicles at freeway ramp meters or bus-on-shoulder operations.
- Preferential traffic signal priority.
- Incident management.

Tolling and Diversion

The Modified LPA assumes that time-of-day variable-rate tolling on a set schedule would be in place for vehicles using the new I-5 Columbia River bridges. This means that tolls would vary by time of day, with higher rates during peak travel periods and lower rates at other times based on a set schedule. Medium and heavy trucks would be charged a higher toll than passenger vehicles. While final toll rates will be set by the Washington State Transportation Commission and Oregon Transportation Commission and may be different than what was assumed for this technical analysis, the rates used in the analysis are a reasonable approximation of values that would support the revenue-generation and congestion-management needs of the IBR Program.

Tolling on a highway often leads to diversion where drivers opt for alternative routes or transportation modes to avoid paying tolls. These diversion effects can result in several outcomes including reduced traffic congestion on tolled routes, increased traffic on parallel roads, or potential shifts to transit or active transportation modes, as well as changing where, or if, a trip is even made.

Total daily vehicle volumes crossing the Columbia River would be reduced by approximately 3% with all Modified LPA design options compared to the No-Build Alternative, resulting in fewer total crossings on both the I-5 and I-205 bridges. Along with tolling, high-capacity transit investments (even with transit capacity constraints applied to the model) in the Modified LPA would contribute to a higher number of transit trips crossing the Columbia River, resulting in an increase of 97% compared to the No-Build Alternative.

An assessment of the shift in traffic between the No-Build Alternative and the Modified LPA was completed to understand whether there would be diversion impacts to other facilities under the Modified LPA. These findings are discussed above under screenline analysis, and more details are found in the Transportation Technical Report and Appendix B to the Transportation Technical Report where individual facility changes are provided.

To assess the potential for diversion of traffic from I-5 to I-205 as a result of tolling the Columbia River bridges, the IBR Program completed a tolling diversion analysis. The analysis found that the addition of a toll to the Columbia River bridges in conjunction with IBR Program implementation would divert approximately 7,000 vehicles per day to I-205, compared to a scenario in which the IBR Program was implemented but the Columbia River bridges were not tolled. Because implementation of the IBR Program without tolling on the Columbia River bridges is not a potential scenario, this sensitivity test was only intended to provide information necessary to understanding how people would travel if the Modified LPA was implemented without tolling on the Columbia River bridges. In both scenarios (not tolling and tolling), traffic on I-205 would be reduced overall compared to the No-Build Alternative (a reduction of approximately 15,000 vehicles and 8,000 vehicles, respectively). This occurs because the number of new transit trips (as a result of the LRT extension to downtown Vancouver along with frequency and operational improvements to C-TRAN express bus) would exceed the number of trips that would choose to divert to I-205 to avoid the toll. This means there would not be diversion impacts to east-west routes that would have to be used to divert between I-5 and I-205 (SR 14, SR 500, US 30/Lombard Street). Additional details on the tolling diversion analysis are documented in the Travel Demand Modeling Report, which is an appendix to the Transportation Technical Report.

3.1.4 Temporary Effects

This section summarizes potential construction impacts for transportation modes and facilities affected by the construction of the Modified LPA, which includes construction of the new bridges and removal of the existing bridges. Impacts would be similar across all design options.

Regional Travel

Construction of the Modified LPA is anticipated to last 9 to 15 years, impacting all modes of transportation within the study area as well as adjacent corridors. In addition to I-5, several regional roadway facilities including I-205, SR 500, SR 14, I-405, and I-84 would be affected by construction as drivers may temporarily reroute I-5 trips to these other highways. The Modified LPA could require nighttime closure of regional roadways, interchanges, and local roads during construction. Construction-related truck traffic for delivery of materials, equipment and for removal of materials/debris from demolition could also increase congestion and delays, particularly during periods of major construction. Table 2-5 in Chapter 2 lists the expected durations of Modified LPA construction components.

All modes of travel on the I-5 mainline and interchanges within the study area would be affected by changes associated with construction (e.g., temporary detours, lane closures, reduced shoulder and lane widths, reduced speeds).

Freight Mobility and Access

Impacts of the Modified LPA to freight truck movements on mainline I-5 would be similar to impacts to general traffic. Temporary closures, detours, or restrictions on primary truck traffic access corridors between I-5 and the Ports of Portland and Vancouver container terminals and to other industrial/commercial locations could result in delays to freight traffic. Affected designated freight corridors include Marine Drive, Mill Plain Boulevard and Fourth Plain Boulevard.

Temporary access closures or access modifications for businesses could also occur, affecting freight (such as deliveries). If driveway closures are required, access to these properties would be maintained to the extent possible. With driveway closures, detours for freight would cause similar impacts compared to what is described for general-purpose traffic impacts.

During construction across active rail lines, there could be temporary closures that result in delays to freight train traffic. Coordination plans with the rail operators would be required.

Bridge Openings and Gate Closures

All highway and active transportation users would be affected during construction by ongoing bridge openings and gate closures of the existing Interstate Bridge, similar to existing conditions. This would include bridge openings for maintenance activities until traffic is shifted onto the new Columbia River bridges, but it could also include additional openings to accommodate construction equipment.

Arterials and Local Streets

Construction of the Modified LPA would require local road closures, lane closures, traffic detours, and property access modifications and closures. Construction staging plans would include coordination with local jurisdictions to minimize the effect of closures, including detour routes. If driveway closures are required, access to these properties would be maintained to the extent practical. If access to a

business could not be maintained during construction, the specific construction activity would be conducted during non-business hours where feasible.

Construction truck traffic would use approved truck routes, and where necessary, local roadways to access the construction areas. This could result in increased congestion, queues, and delays for local traffic and access. Delivery of large items would occur via truck routes. There would be limited direct access to construction areas via the I-5 mainline, although trucks may use I-5 to access construction areas. During construction there may be some short-term closures (night/weekend) to on- and off-ramps to accommodate construction activities. As the design and construction plans are advanced, there could be a need for direct access between I-5 and construction areas. If direct access is required, the IBR Program would coordinate with WSDOT, ODOT, and FHWA.

Transit Operations

Construction of the Modified LPA could involve lane closures, bus stop relocations, light-rail station closures, partial or full temporary closures of park-and-ride facilities, schedule adjustments, and sidewalk and bicycle lane impacts that could affect transit operations and/or access to transit within the study area.

Buses on existing routes could experience delays from increased congestion due to potential roadway or interchange closures. Buses that travel through downtown Vancouver may encounter temporary closures and reroutes as LRT guideway is installed and I-5 is reconstructed.

The existing TriMet MAX Yellow Line could be adversely affected during construction. The current Yellow Line travels along Denver/Expo Road and has two stations in the south end of the IBR study area. Construction along Expo Road and as part of the Marine Drive interchange may require temporary relocation or closure of the Yellow Line's station near Delta Park and its terminus station near the Expo Center. These temporary relocations, closures, or schedule adjustments could take place intermittently for up to 4 years.

Active Transportation

Construction of the Modified LPA could temporarily close sidewalks, bicycle facilities, and/or shared-use paths or reduce facility widths within construction areas. Active transportation travel could be affected within the study area, including in the Expo Center and Delta Park light-rail station area, during station and guideway construction. Limited opportunities are available for active transportation crossings of I-5, but existing crossings would be maintained to the extent practical. Active transportation facilities would be temporarily rerouted during intermittent and temporary closures.

Safety

Many of the construction modifications to facilities, routes and services would involve temporary conditions where safety would be an increased concern. Maintaining safety for travelers as well as construction workers is one of the primary elements of construction plans, including for traffic control. Traffic diversion caused by construction would lead to higher traffic volumes on detour streets. The higher traffic volumes could lead to a potential increase in collision frequency. In locations where there is no physical change to the roadway, the types of crashes would remain similar to existing conditions.

Transportation Demand Management and Transportation System Management

During construction of the Modified LPA, the impacts to facilities, traffic, transit and other modes would affect TDM and TSM programs and operations, and modifications would be needed.

Tolling and Diversion

During construction of the Modified LPA, pre-completion tolling would commence on the existing Interstate Bridge. During the pre-completion period while the new bridges are under construction, the existing Interstate Bridge is assumed to operate toll-free between 11 p.m. and 5 a.m. Diversion could occur during construction as people try to avoid pre-completion tolling or congestion from construction impacts. Depending on the origin and destination of the trip, this could increase travel times, modify the time of day a trip is made, or potentially change the route or mode that is chosen.

3.1.5 Indirect Impacts

The No-Build Alternative would not provide multimodal improvements assumed in regional transportation and land use plans, which seek to manage growth through coordinated land use and transportation actions that encourage transit-oriented development patterns in areas such as downtown Vancouver and Hayden Island. These multimodal improvements are intended to manage travel demand through higher use of transit, walking and biking as alternatives to vehicle use. As noted in Section 3.4, Land Use and Economic Activity, the complementary patterns of land use and transportation systems would be less likely to be achieved if the multimodal improvements of the IBR Program were not in place.

Under the No-Build Alternative, without these multimodal improvements, population and employment may not reach anticipated levels or occur within districts planned for higher density growth. Although denser growth patterns are already occurring in areas such as downtown Vancouver, future growth under the No-Build Alternative is expected to be more limited and less dense than under the Modified LPA, where development is expected to be focused around centers of multimodal activity like high-capacity transit stations. The lack of multimodal improvements under No-Build would also reduce the options available for travel via transit or active transportation. Thus, an indirect effect of the No-Build Alternative is that future trips would be more likely to continue to rely on driving rather than other modes. This continued high reliance on driving would, over time, tend to encourage more dispersed patterns of development, often referred to as urban sprawl. A sensitivity analysis was completed to assess whether a change in land use between the No-Build Alternative and the Modified LPA would result in a change to the transportation analysis. The analysis showed that a change in land use would not change the transportation analysis. See Section 3.4.4 for more discussion of indirect effects on land use.

Other potential indirect effects of the No-Build Alternative related to transportation include:

- Delays in local and regional freight transportation as a result of increased congestion on I-5, with potential economic implications (see Chapter 3.4, Land Use and Economic Activity).
- Increased pressure on bus service in Vancouver and rail service in Portland as demand increases without corresponding growth in infrastructure.
- Potential for severe regional congestion, with resulting economic and social effects, particularly if the existing bridge spans were damaged in an earthquake or other catastrophic event.

Completion of the Modified LPA, including improved highway facilities and safety on I-5, enhanced transit solutions (light-rail service and increased express bus service), and improved active transportation facilities, would improve regional transportation between Vancouver and Portland. Predicted improvements in congestion and travel times would help to reduce current impediments to freight mobility and provide greater travel time reliability for trucks crossing the bridge. Because of the importance of I-5 in West Coast freight transport, improved freight mobility across the Columbia River bridges could contribute to more efficient, reliable, and predictable operations at local, regional, and national ports as well as more reliable freight deliveries to local businesses and residences. These operational improvements could result in positive economic effects such as increased employment and tax revenues within the Portland-Vancouver metropolitan area.

Areas in proximity to new LRT stations could experience new development and/or redevelopment. This development would facilitate growth and increased land use density, as encouraged by local and regional land use plans. As described in Section 3.4.4, the provision of high-capacity transit is expected to support development in already urbanized areas of Hayden Island and downtown Vancouver, while reducing the potential for urban sprawl. The growth that would occur in these areas is accounted for in current growth targets, which anticipate the extension of high-capacity transit service. Thus, the indirect effects of the Modified LPA would be consistent with local and regional planning.

Increased development in areas near the IBR Program stations is anticipated in the regional travel demand model, which includes changes to overall transit ridership beyond the study area. The mode of access to and from stations may shift as a result of increased development near the IBR Program stations. This may result in a greater percentage of active transportation or transit transfers and a lower percentage of automobile access as population and employment densities increase within station area walksheds and bikesheds. Increased active transportation trips to stations, particularly if higher-density residential and commercial development occurs in surrounding areas, may involve increased travel along streets that lack ADA accessibility or facilities to accommodate active transportation. However, increased development and transportation activity along these streets could encourage infrastructure improvements by local jurisdictions.

Safety conditions and effects on TDM and TSM would be similar to those described under direct effects because the direct effects analysis already incorporates projected urban growth and increased transportation activity.

Tolling the new Columbia River bridges would result in changes to traffic and travel by alternative modes. Variable-rate tolling would be higher in the peak periods, and this, along with the improvements made on both the highway and transit components of the IBR Program, would result in less congestion on I-5 through the study area. Variable-rate tolling would include lower rates during times of day that are less congested, which would help minimize potential traffic diversion to the I-205 Glenn Jackson Bridge as well as arterial facilities in and around I-5 during these time periods. The potential for tolling diversion is discussed in Section 3.1.3 and in the Travel Demand Modeling Report, which is an appendix to the Transportation Technical Report.

3.1.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Mitigation

When traffic operations on new highway facilities and at local intersections do not meet the applicable agency standards, mitigation may be required. Mitigation measures are typically negotiated between the project sponsor (in this case, the IBR Program) and the transportation agencies with jurisdiction over the affected facilities. As possible mitigations are identified and considered, the IBR Program will determine whether additional environmental analysis is necessary. Because mitigation is developed on a program-specific level, potential mitigation for each category of transportation effects is discussed below.

Program-Specific Mitigation

I-5 Operations

Traffic impacts were determined for I-5 mainline and ramp segments in the freeway analysis area by comparing freeway and ramp operations for the No-Build Alternative and Modified LPA and the other design options against agency performance standards for the 2045 design year.

WSDOT maintains a performance standard of LOS D. Mitigation could be required for the study area freeway and ramp segments in Washington if (1) the Modified LPA or the other design options caused I-5 operations to degrade below this standard, or (2) this standard was not met under the No-Build Alternative, but the Modified LPA or the other design options caused I-5 operations to degrade by more than 10% compared to the No-Build Alternative.

ODOT's performance standard for new or rebuilt highway facilities is a 0.75 V/C ratio, compared to a 1.1 and 0.99 V/C ratio (highest hour and second highest hour respectively) for existing facilities. Therefore, freeway and ramp mitigation could be required if the Modified LPA or the other design options did not meet ODOT's 0.75 V/C ratio performance standard in Oregon.

Areas where I-5 operations would not meet ODOT's and/or WSDOT's standards include:

- With the Modified LPA and the other design options except the two auxiliary lane design option, I-5 northbound approaching the Columbia River bridges would not meet ODOT's mobility standard during the PM peak period due to over-capacity conditions at the new Columbia River bridges. Congestion from the bottleneck at the bridges would back up to the I-5/I-405 interchange and would last for approximately 9 hours.
- With the two auxiliary lane design option, I-5 northbound approaching the Columbia River bridges would improve compared to the other design options but would not meet ODOT's mobility standard during the PM peak period due to over-capacity conditions at the Columbia River bridges. Congestion from the bottleneck at the bridges would back up 0.75 miles to Hayden Island and last for approximately 6 hours.
- With all Modified LPA design options, I-5 southbound through the study area would not meet WSDOT's or ODOT's mobility standards during the AM peak period due to congestion spilling back from the I-5/I-405 bottleneck in North Portland. Congestion from the I-5/I-405 bottleneck in North

Portland would extend 6 miles north to the C-D roadway in Vancouver and last for approximately 8.5 hours.

- With all Modified LPA design options, the southbound C-D roadway between the Mill Plain and SR 14 interchanges would not meet WSDOT's mobility standard during the AM or PM peak periods. The congestion from the C-D roadway would reach I-5, but the extent to which this would vary depends on the design option. Congestion in the Modified LPA would extend 4 miles and last approximately 6 hours. Congestion with the two auxiliary lane design option would extend 1.5 miles and last approximately 4 hours.

Potential mitigation to meet ODOT's and/or WSDOT's performance standards on I-5 could include the following:

Modified LPA

- Provide an additional auxiliary lane northbound and southbound within the IBR Program limits, and/or the program and partners could implement more intensive demand-reduction and system-management strategies beyond what the IBR Program already includes (variable-rate tolling, improved transit and active transportation systems, and enhanced TDM and TSM systems).

Modified LPA and the Other Design Options

- ODOT will continue to work with partners to study the downstream bottleneck at the I-5/I-405 split in North Portland. This downstream bottleneck is a separate project that ODOT is looking into to understand causes and identify potential solutions.
- The southbound C-D roadway would be impacted by congestion spilling back from I-5 during the AM peak period, but even during the PM peak period when no downstream congestion is present, the C-D roadway would not meet WSDOT's mobility standards. Potential mitigation measures could include braiding the Mill Plain on-ramp and SR 14 off-ramp and possibly providing a slip lane to continue providing access for trips traveling from the Mill Plain interchange to SR 14.

Final mitigation measures will be determined and agreed upon with the appropriate agencies and partners. Where applicable, the IBR Program would work with these agencies to identify and obtain approvals for design exceptions. The Final SEIS and Record of Decision will include all mitigation commitments that have been finalized by the time of publication; however, some mitigation measures may not be finalized until further along in the project design process.

Bridge Openings and Gate Closures

Measures to minimize disruptions to I-5 operations, transit service, and active transportation associated with bridge openings and gate closures under the Modified LPA with a single-level movable-span configuration could include the following:

- Establish new bridge opening and gate closure timing limitations, which could include scheduled days and/or times that avoid peak periods for passenger vehicles and trucks, in coordination with the USCG.
- Incorporate bridge opening and gate closure limitations into transit service schedules.
- Disseminate information concerning bridge openings and gate closures to the public, businesses, travel organizations, freight industry, and mariners.

Arterials and Local Streets

Traffic impacts were determined for arterials and local streets by comparing the overall intersection operations (LOS or V/C ratios) for the No-Build Alternative, the Modified LPA and design options against the agency operational standards. Mitigation could be required for study intersections that would meet agency performance standards under the No-Build Alternative but would operate below agency performance standards under the Modified LPA and design options. Mitigation could also be required if intersection operations that did not meet agency standards under the No-Build Alternative were degraded by more than 10% under the Modified LPA and design options.

Any potential mitigation measures will be determined and agreed upon with the appropriate agency. ODOT and WSDOT could contribute a proportionate share toward identified mitigation to improve intersection performance as agreed to with the local jurisdiction. The Final SEIS and Record of Decision will include all mitigation commitments that have been finalized by the time of publication; however, some mitigation measures may not be finalized until later in the project design process.

Local traffic impacts and mitigation would be similar among the Modified LPA design options except for the Modified LPA design option without C Street ramps, as described below.

Modified LPA and Two Auxiliary Lanes Design Option

No intersections in the Modified LPA or two auxiliary lane design option would require mitigation improvements because intersection operations are not worsened compared to the No-Build Alternative. As part of final design, a traffic analysis would be conducted to confirm the SEIS analysis and identify any mitigation measures, if necessary. Final mitigation will be determined and agreed upon by the IBR Program and the affected agency.

Modified LPA Without C Street Ramps

Six intersections in the Modified LPA design option without C Street ramps could require mitigation improvements and are summarized below. The impacts are caused by the additional traffic volumes accessing the Mill Plain Boulevard/15th Street east-west couplet due to the elimination of I-5 access via the C Street ramps.

1. Mill Plain Boulevard and Franklin Street.
2. 15th Street and Washington Street.
3. 15th Street and Main Street.
4. Mill Plain Boulevard and Columbia Street.
5. Mill Plain Boulevard and Broadway Street.
6. Mill Plain Boulevard and I-5 northbound on-/off-ramps.

Mitigation of this congestion could include retaining the C Street ramps or adding additional lanes or turn-pockets at study intersections. As part of final design, additional traffic analysis would be conducted to confirm the SEIS analysis and refine mitigation and design measures, as needed. Final mitigation will be determined and agreed upon by the IBR Program and the affected agency.

Transit Reliability

In the course of considering mitigation, an updated on-time performance analysis in the Rose Quarter may be completed. Final mitigation measures will be determined and agreed upon with the

appropriate agency and partners as needed. The IBR Program could contribute a proportionate share toward identified mitigation to improve on-time performance at the Rose Quarter. The Final SEIS and Record of Decision will include all mitigation commitments that have been finalized by the time of publication; however, some mitigation measures may not be finalized until later in the project design process.

Tolling and Diversion

Analysis indicates that the Modified LPA and options with tolling included would not result in permanent adverse impacts to other modes or cause diversion to other facilities that would require mitigation. If toll rates set by the Washington State and Oregon Transportation Commissions are different than what has been evaluated, impacts to other facilities or modes have the potential to increase.

Temporary Effects

Regulatory Mitigation

Construction activities would comply with ODOT and WSDOT requirements for maintenance of traffic. More specific measures related to maintenance of traffic are discussed in the Program-Specific mitigation section below. The Transportation Technical Report identifies additional potential mitigation measures and best practices such as for signage, traffic plans and control, access, communications, and safety.

Program-Specific Mitigation

Study Area Travel

- The IBR Program would develop a work zone transportation management plan (TMP) and a maintenance of traffic plan to address facilities and their modes of transportation. These plans would be prepared during subsequent design and construction phases for agency approvals. The plans would describe staging, access, facility, lane or shoulder closures and transitions, hauling, traffic management (including general-purpose traffic, transit, bicycle, and pedestrian traffic), detours, lane modifications, incident management, traffic control, closure details, and coordination and communications plans and would cover other construction zones or activities. Plans would be developed to meet applicable agency standards. The Program would coordinate with agencies with jurisdiction for review and applicable approvals.

Freight Mobility and Access

- Mitigation for freight and mobility would be an element of the work zone TMP identified above. In addition, the IBR Program would coordinate with all facility owners to notify them of facility or access closures. Construction information would be provided to affected jurisdictions. Similar information would be provided to WSDOT and ODOT for use in the states' freight notification systems. The IBR Program would provide information in formats required by WSDOT and ODOT.
- To minimize impacts to freight rail operations, the Program would coordinate with the railroad owners and rail operators and would obtain all applicable required permits. Construction would be limited to the times approved and coordinated with freight rail operators.

Bridge Openings

- During IBR construction, the IBR Program would coordinate with the U.S. Coast Guard, the ports, and other jurisdictions to minimize bridge openings and gate closures to minimize the impact to vehicles, active transportation, and transit. The work zone TMP would include coordination and communication with agencies, mariners, and the public for bridge openings and gate closures.

Arterials and Local Streets

- All minimization measures associated with constructing the Modified LPA would comply with local regulations governing construction traffic control and construction truck routing. The IBR Program would finalize detailed work zone TMPs in close coordination with local jurisdictions during the final design and permitting phases of the Program.

Transit Operations

- Transit service and facility modifications would be coordinated with TriMet and C-TRAN to minimize temporary impacts and disruptions to bus and light-rail facilities and service during construction. Detailed work zone TMPs and coordination/communication plans would be developed. This would include support for public information and communication throughout the construction period, including for periods where alternative routes, facilities or services would be needed to maintain service.

Active Transportation

- The work zone TMP would include specific measures to maintain access to active transportation facilities and users. The Transportation Technical Report has additional detail on potential measures for construction areas, signage, lighting, communications, safety and maintenance.

Safety

- The IBR Program would implement the latest safety technology during construction.

Transportation Demand Management and Transportation System Management

- The IBR Program would work with partner agencies on adapting and implementing TDM and TSM treatments during construction. Potential strategies could include the following:
  - Expanded transit service.
  - Vanpool/carpool program.
  - Telecommuting options.
  - Compressed work week/flexible work schedules.
  - Active transportation improvements and enhancements.

Tolling and Diversion

- The IBR Program would work with partner agencies to develop a detailed program and schedule for pre-completion tolling during construction.
- Diversion impacts during construction will be evaluated and potential mitigation will be discussed with partner agencies to offset any impacts.

3.2 Navigation

An important goal of the IBR Program is to meet the reasonable needs of navigation on the Columbia River for the 100+ year service life of the new Columbia River bridges. This section discusses existing river navigation conditions and evaluates the associated beneficial and adverse effects of the Modified LPA and the No-Build Alternative.

The Columbia River and North Portland Harbor are designated as federal navigable waterways. This designation signifies that all construction or alteration of bridges crossing these waterways must first receive approval from the U.S. Coast Guard (USCG), pursuant the General Bridge Act of 1946, as amended. Additionally, a Memorandum of Agreement (MOA) between USCG and FHWA and a Memorandum of Understanding (MOU) among the USCG, FHWA, FTA, and Federal Railroad Administration (FRA) state that environmental documentation must include a discussion of potential project impacts to navigation and a summary of ongoing coordination with USCG.

The information presented in this section is based on analyses found in the Navigation Impact Report (IBR 2022) and the Navigation Simulation Study (Appendix H).

3.2.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision, as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRA LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with navigation has been updated in this Draft SEIS to include:

- Changes to existing and prospective marine vessel navigation and marine freight shipments in both the main channel of the Columbia River and North Portland Harbor.
- Changes to USCG policy with 2016 updates to the USCG Bridge Permit Application Guide.
- 2014 MOU among the USCG, FHWA, FTA, and FRA to coordinate and improve bridge planning and permitting.
- 2014 MOA between USCG and FHWA to coordinate and improve bridge planning and permitting.
- New bridge configurations added for evaluation due to changed conditions, one of which would provide increased vertical navigation clearance (VNC).

The replacement bridges over the Columbia River and North Portland Harbor are the main Program component relevant to navigation considerations. The CRC LPA and IBR Modified LPA would both include a pair of double-deck fixed-span replacement bridges with 116 feet of VNC and 400 feet of horizontal navigation clearance (HNC) (a 300-foot channel plus 50 feet on either side for channel maintenance). The Modified LPA also includes two additional bridge configuration design options: a pair of single-level fixed-span bridges and a pair of single-level movable-span bridges. Consideration of the three bridge configurations involves coordination with the U.S. Army Corps of Engineers (USACE) and USCG regarding multiple navigation-related items; see Section 2.6 for a discussion of current and future actions necessary to reach resolution on an acceptable bridge configuration for the IBR Program.

Table 3.2-1 compares the impacts and benefits between the CRC LPA and the IBR Modified LPA and the changes listed above. Based on this analysis, the Modified LPA with fixed-span bridge configurations would have the same or similar effects as the CRC LPA on navigation; the Modified LPA with a movable-span bridge

configuration would provide more VNC than the CRC LPA. A detailed description of impacts and benefits to navigation from the Modified LPA and associated design options follows.

Table 3.2-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects on Navigation

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in the Draft SEIS	Explanation of Differences
River Navigation Clearance	Reduced vertical clearance in the Columbia River primary navigation channel (from 178 feet [during a bridge lift] to 116 feet). Increased horizontal clearance in the Columbia River primary navigation channel (from 263 feet to 400 feet [a 300-foot channel plus 50 feet on either side for channel maintenance]). Vertical and horizontal clearances for North Portland Harbor would remain unchanged.	Vertical and horizontal clearances on Columbia River navigation channels are the same as CRC for the double-deck fixed-span and single-level fixed-span configurations. Same horizontal clearance with an increased vertical navigation clearance to 178 feet with the single-level movable-span configuration. Vertical and horizontal clearances for North Portland Harbor would remain the same or similar.	A movable-span configuration design option was added to the Modified LPA to meet the USCG Preliminary Navigation Clearance Determination (2022). The I-5 bridge over North Portland Harbor would be replaced under the Modified LPA due to continued aging of the seismically obsolete existing bridge.
Federally Authorized Navigation Channel Location	Proposed changes to the location of the Columbia River primary navigation and barge channels.	Same as CRC.	N/A

Note: The CRC LPA and Modified LPA effects are as compared to a No-Build Alternative, unless otherwise noted.
CRC = Columbia River Crossing; LPA = Locally Preferred Alternative; N/A = not applicable; SEIS = Supplemental Environmental Impact Statement; USCG = U.S. Coast Guard

3.2.2 Existing Conditions

Columbia River

As one of the largest rivers in North America, the Columbia River is among the defining geographic features of the Pacific Northwest. It serves as an important part of the U.S. Maritime Transportation System corridor, and its resources have provided, and continue to provide, the economic and cultural foundations of Native American and western settlements.

The Columbia River headwaters are located in British Columbia, Canada, through which the river flows for approximately 425 miles before entering the continental U.S. in northeast Washington. From the U.S./Canada border it flows generally south to its confluence with the Snake River, where it turns west and forms the boundary between Washington and Oregon for the remainder of its course to the Pacific Ocean.

The Columbia River is an important natural resource and serves a vital role for power generation, irrigation, navigation, and recreational purposes. It is navigable for deep-draft vessels from its mouth to Portland, Oregon, and Vancouver, Washington, and for shallow-draft vessels to Lewiston, Idaho via the Snake River. The Columbia River's deep-draft navigation system provides for a 43-foot-deep by 600-foot-wide channel from inside the Columbia River Bar upriver to ports on both the Washington and Oregon sides of the river at

approximately river mile (RM) 106. The upriver end of this section of the channel, known as the Columbia and Lower Willamette, is just downriver from the existing Interstate Bridge.

From just downstream of the Interstate Bridge to the Snake River confluence near Pasco, Washington, the Columbia River is maintained as a shallow-draft system predominantly supporting tug and tow vessel traffic. The shallow-draft system has a maintained depth of approximately 17 feet. Just east of The Dalles is a BNSF Railway Bridge at Celilo Falls with a VNC of 79 feet, which is notably less than the bridge heights under consideration for the IBR Program.

Between the Interstate Bridge and the Celilo Falls BNSF Railway Bridge 95 miles to the east, many shoreline land uses are dependent on the Columbia River. Today, the Columbia River shoreline is often identified by local jurisdictions as a resource to be leveraged for river-dependent uses such as recreational, environmental, habitat, or economical purposes than with industrial marine, water-dependent uses.

Historically, the Columbia River for many Native Americans living in the Pacific Northwest was central to culture, sustenance, trade, and transportation. As EuroAmerican settlement traveled to the Pacific Northwest, river transport, commercial fishing and associated canneries, and agriculture developed along the Columbia River (OHS 2024a). When dams were constructed along the Columbia and Snake rivers in the 1900s, increased industrialization occurred and corresponded to increased movement of freight and agricultural products up and downriver. Shipbuilding operations, supporting industries, and employees were established along the Columbia River during World War II, including three Kaiser Shipyards in the Vancouver and Portland areas (OHS 2024b). Additionally, new and affordable hydroelectric power ushered in aluminum smelting operations, and new U.S. Bureau of Reclamation (USBR) irrigation projects spurred increased agriculture production in central/eastern Oregon and Washington. Navigation along the Columbia and Snake rivers grew tremendously during this time to support these economies. Over the 107 years of service life of the Interstate Bridge (northbound span opened in 1917 and southbound span opened in 1958), numerous bridge lifts have been conducted for mariners with large VNC requirements, including those requiring openings for clearances over 116 feet and up to 178 feet. Over time, industries along the river changed to a mix of marine and non-marine enterprises with a decreasing trend of commercial vessels on the Columbia River (USACE, USBR, BPA 2020); however, the capacity of the Columbia River to support marine development and transport remains similar to conditions after the dams were constructed.

The intrinsic value of the Columbia River is largely in its natural beauty, especially within the Columbia River Gorge located east of the Interstate Bridge. The most significant land use control is the 85-mile-long Columbia River Gorge National Scenic Area, which protects the natural beauty of the gorge and severely limits industrial development outside of existing incorporated communities in Oregon and Washington from roughly Troutdale, Oregon to Wishram, Washington.

Federally Authorized Navigation Projects

I-5 crosses the Columbia River via the existing Interstate Bridge and the North Portland Harbor bridge. Within the vicinity of the Interstate Bridge, there are four federally authorized navigation projects on the Columbia River: three federally authorized navigation channels that pass beneath the Interstate Bridge (the primary navigation channel, barge channel, and alternate barge channel) and the federally authorized Upper Vancouver Turning Basin located immediately downstream of the Interstate Bridge. This turning basin has historically provided a turning location for deep-draft ships navigating up to, but not beyond, the Interstate Bridge.

The primary navigation channel was authorized to accommodate ocean-going vessels past Bonneville Dam to The Dalles. This traffic never materialized, and the channel is currently maintained to a shallower depth consistent with current traffic. There is no federally authorized navigation channel within North Portland

Harbor in the vicinity of the Interstate Bridge. Table 3.2-2 summarizes the widths and depths of the federally authorized navigation projects within the study area.

Table 3.2-2. Widths and Depths of Federally Authorized Navigation Projects in the Study Area

Federally Authorized Navigation Channel	Authorized Width (feet)	Existing Horizontal Clearance (feet)	Authorized Depth (feet)	Maintained Depth (feet)	Current Waterway Depth (feet)
Primary Columbia River Navigation Channel (Vancouver to The Dalles)	300	263	27	17	30
Barge Channel	300	511	15	15	~21 to 25
Alternate Barge Channel	200	260	17	15	~21 to 25
Upper Vancouver Turning Basin	800	N/A[a]	35	35	~20 to 30

Source: IBR 2022

a Not applicable. The federal authorization for the Upper Vancouver Turning Basin includes dimensions of 2,000 feet long and 800 feet wide. Horizontal clearance as referenced for the other federally authorized projects in this table relates to distance between bridge piers for ships navigating beneath the bridge and therefore does not apply to the turning basin.

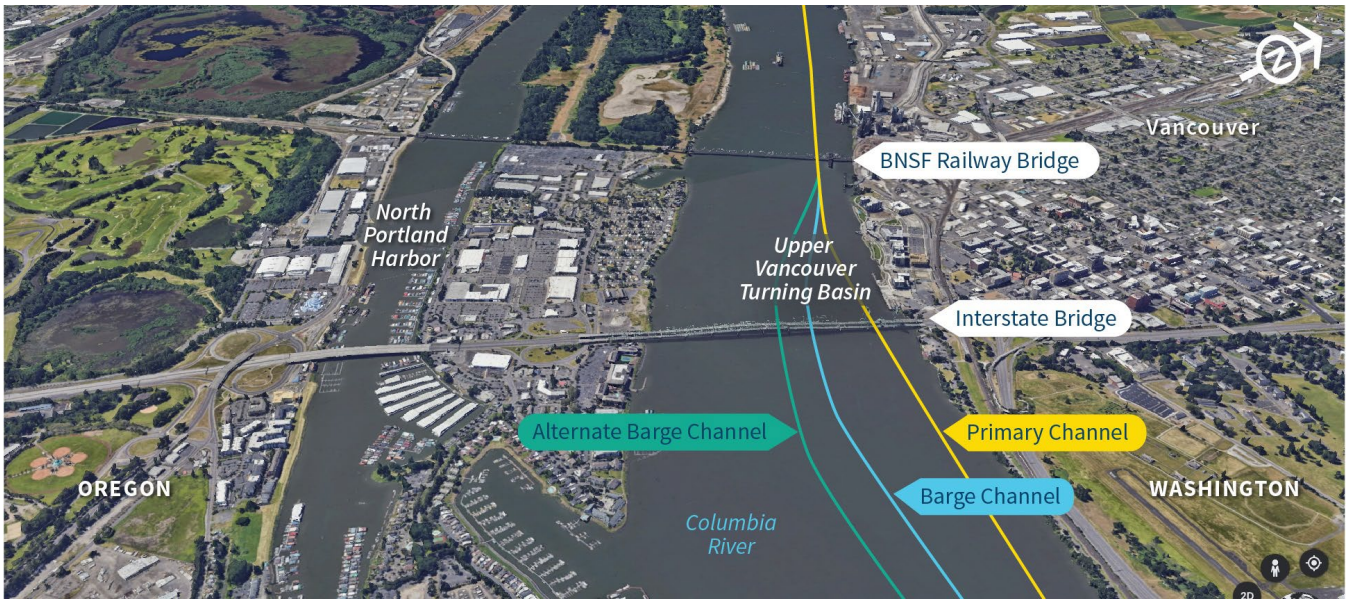
Vessel Operations and Navigation Clearance

Vessels that currently operate near and/or navigate beneath the Interstate Bridge include tugs and barges, recreational sailboats and powerboats, marine contractor barges with construction cranes and materials, cruise and passenger boats, dredges, government vessels, vessels transporting manufactured and fabricated goods, and others. More than 232,000 boat use days[1] occurred in 2017 in the Columbia River from the Interstate Bridge to the Bonneville Dam (approximately 39.5 river miles upstream).

Columbia River navigation is limited by horizontal and vertical clearances associated with the Interstate Bridge and North Portland Harbor bridge, the BNSF Railway Bridge that crosses the Columbia River to the west (downstream) of the Interstate Bridge, and a second BNSF Railway Bridge that crosses North Portland Harbor (see Figure 3.2-1). The alignments of the navigation channels factor into vessel passage of both the Interstate Bridge and the BNSF Railway Bridge. Figure 3.2-1 illustrates these alignments with different magnitudes of curvature between the two bridges. A variety of navigation factors, such as downstream or upstream transit, vessel/cargo load, vessel size and draft, weather conditions, water flow velocities, wind/wave conditions, and more are important considerations for vessel maneuverability and safety.

[1] Boat use days are calculated by multiplying the number of boats that use the river by the number of days of use. Therefore, one boat using the river 200 days would equal 200 boat use days, as would 200 boats each using the river for one day.

Figure 3.2-1. Existing Navigation Channels Under the Interstate Bridge and BNSF Railway Bridge



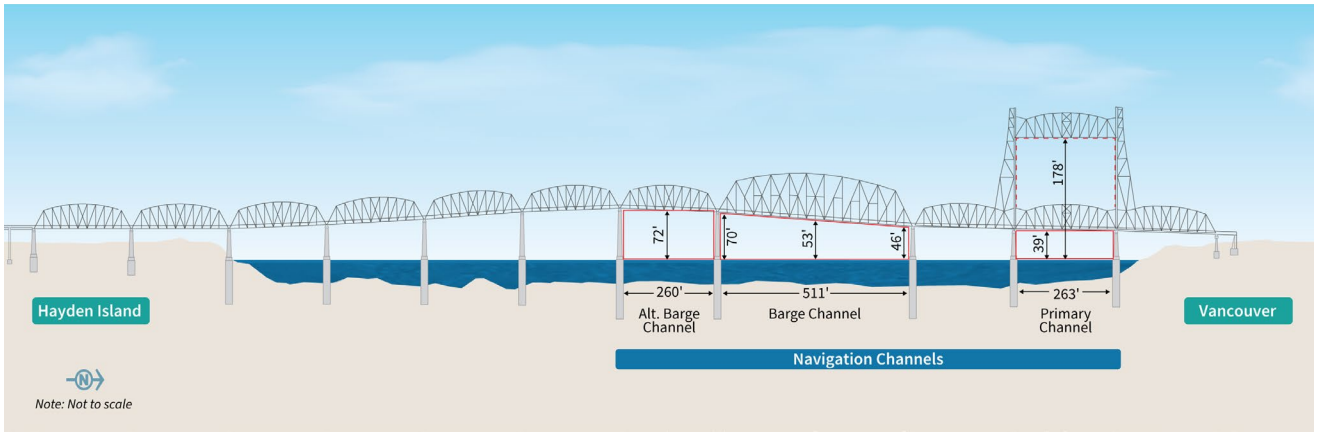
Due to the proximity of the Interstate Bridge and the BNSF Railway Bridge, vessel operators typically plan their route in consideration of navigation factors associated with both bridges. VNC and vessel cargo play a role in route options because USCG regulations specify that movable-span bridge openings are only allowed for vessels that are otherwise unable to pass under the bridge via alternate channels. For example, vessels that need less than 33 feet VNC (including adjustments for weather, water level, and other conditions) to pass the BNSF Railway Bridge may take a route outside the primary navigation channel. Vessels needing additional VNC require the BNSF Railway Bridge swing span to be opened and must use the primary navigation channel. This route is near the Washington shore (shown in Figure 3.2-1).

Figure 3.2-2 shows that when the Interstate Bridge lift spans are in the closed position, the vertical clearance within the primary navigation channel is 39 feet (as measured above 0 Columbia River Datum [CRD]).[2] When the lift spans are raised, the maximum vertical clearance is 178 feet. The barge channel lies under the wide span of the bridge and has an HNC of 511 feet and a vertical clearance ranging from 46 to 70 feet; however, vessels tend to use the southern half of this channel where the vertical clearance is the highest. The alternate barge channel has a HNC of 260 feet and a vertical clearance of 72 feet. Water levels dictate the available clearance at a specific time. Water levels vary seasonally based on flows and daily based on tidal influence. The average daily high is approximately 10 feet CRD and typically occurs in late spring. The average daily low is approximately 2 feet CRD and typically occurs in early fall.

For passage through the Interstate Bridge, vessels requiring more than 72 feet VNC must use the primary navigation channel with the opened lift spans; vessels that can pass with less than 72 feet of VNC can use one or more of the three channels without a bridge lift depending on vessel size and pilot choice. Interstate Bridge lift openings are currently restricted to avoid weekday peak highway traffic operations between 6:30 a.m. and 9:00 a.m. and between 2:30 p.m. and 6:00 p.m., excluding emergency bridge lifts. Thus, vessels that require a bridge lift must schedule their passage time outside these restricted time periods.

[2] Columbia River Datum is the plane of reference from which river stage is measured on the Columbia River from the lower Columbia River up to Bonneville Dam, and on the Willamette River up to Willamette Falls. Equals 1.82 feet above mean sea level (equivalent to National Geodetic Vertical Datum [NGVD]) at Vancouver, Washington (USACE 2014).

Figure 3.2-2. Existing Interstate Bridge Navigation Clearances



Note: all vertical VNCs shown are measured in feet above 0 CRD.

With the exception of some specialized vessels that use the Columbia River infrequently, most vessels require vertical clearances of less than 90 feet (see Table 3.2-3). As detailed in the IBR Program Navigation Impact Report (IBR 2022) issued in May of 2022, required openings of the Interstate Bridge declined by 45% from an average of 289 per year between 1997 and 2011 to 157 per year between 2012 and 2020. From 2012 to 2020, 58% of the bridge openings were for tugs, 17% for sailboats, and the remainder for other vessel types. These openings of the Interstate Bridge represent 5% to 7% of total river traffic based on openings of the downstream BNSF Railway Bridge and use of the locks at the upstream Bonneville Dam.

Table 3.2-3. Summary of Vertical Clearance Requirements and Frequency of Use

Vessel Type	Approximate Vertical Clearance Requirement	Approximate Annual Frequency
Tugs, Tows, and Barges	48 feet to 80 feet	> 500 trips
Sailboats/Recreation	63 feet to 90 feet	> 75 trips
Marine Contractors	40 feet to >175 feet	Varies
Dredges (U.S. Army Corps of Engineers dredge *Yaquina*)	102 feet	24
Marine Industrial	54 to >175 feet	Varies
Cruise/Passenger	50 feet to 80 feet	> 500 trips

Source: IBR 2022
Note: Vertical clearance requirements are based on vessel air draft (distance from water surface to highest point on a vessel) plus a 10-foot additional air gap (extra height allowance beyond the upper limit of air draft to allow a safety factor for vessel movements due to wind and waves). For marine contractors and marine industrial vessels, required clearance can vary based on the height of the cargo and/or construction equipment contained on the vessel.

For the Interstate Bridge, USCG has stated future navigation conditions clearance should not be less than existing conditions. In a June 17, 2022, Preliminary Navigation Clearance Determination, USCG stated that "any proposed new bridge would need to meet or exceed the existing VNC of the current I-5 twin bridges, 178 feet, and would preferably have unlimited VNC over the USACE-approved main navigation channel/project. Any side channels would require vertical clearances equal to or greater than 72 feet." Additionally, the Preliminary Navigation Clearance Determination states that any proposed bridge would

have an HNC requirement greater than or equal to that of the current or future permitted USACE federal navigation channel projects, and notes USACE may have additional requirements.

The federal navigation channels have various authorized widths. The authorized width of the Vancouver to The Dalles channel (i.e., the primary Columbia River navigation channel) is 300 feet. The authorized widths of the two side channels are 300 feet and 200 feet, respectively. The existing 263-foot HNC for the primary navigation channel beneath the Interstate Bridge, which is a function of bridge pier locations within the Columbia River, is less than the USACE-authorized channel width of 300 feet. The existing HNC was established when the original Interstate Bridge (current northbound span) was constructed, which was prior to federal authorization of the primary navigation channel.

Navigation is further affected by other bridges and structures that present obstructions to vessels. Upstream of the Interstate Bridge, this includes the following vertical clearances:

- I-205/Glenn L. Jackson Bridge, 136 feet (144 feet at center)
- Bridge of the Gods, 135 feet
- Hood River Bridge, 148 feet[3]
- The Dalles Bridge, 100 feet
- The Dalles Lock and Dam, 100 feet
- BNSF Railway Celilo Bridge, 79 feet

Downstream of the Interstate Bridge, this includes the following vertical clearances:

- BNSF Railway Bridge, Unlimited (39 feet when swing span closed)
- Lewis & Clark Bridge, 187 feet
- Astoria-Megler Bridge, 193 feet (205 feet at center)

North Portland Harbor

The North Portland Harbor, previously known as the Oregon Slough, is a 5-mile-long side channel of the Columbia River, located between Hayden Island and mainland Oregon. The waterway is bounded by a federal levee on the south bank and urban development and infrastructure on both shorelines.

North Portland Harbor supports marinas of floating homes and primarily noncommercial boats. North Portland Harbor does not include a designated navigation channel. It is largely traveled by recreational boaters and those accessing the water-oriented uses along the harbor. The HNC beneath the existing North Portland Harbor bridge is approximately 215 feet and a vertical clearance is approximately 35 feet. Farther west (downstream), large ocean-going cargo ships use North Portland Harbor to reach Port of Portland Terminal 6. However, they cannot travel farther upstream due to the depth of the waterway.

3.2.3 Long-Term Effects

No-Build Alternative

With the No-Build Alternative, navigation conditions would not change. Vessels requiring more than 72 feet of VNC would need to schedule passage through the Interstate Bridge around existing restrictions on lift-span operation. No additional timing restrictions on bridge lifts would be anticipated since the No-Build Alternative

[3] The Hood River Bridge, currently with a lift span providing up to 148 feet VNC, is proposed to be replaced with a fixed span that would allow for 90 feet VNC.

would not include light-rail transit. The primary navigation channel would remain in its current location and vessels would continue to use the same channels available today.

For navigation safety considerations, the No-Build Alternative would have the same safety considerations for mariners as existing conditions because the pier locations and navigation clearances would remain unchanged. Navigation simulations were conducted to evaluate existing, proposed future, and construction conditions for a variety of vessels (deep draft and shallow draft); upbound and downbound directions; daytime and nighttime conditions; various water flow conditions; loaded, light and unloaded cargo; and wind conditions. For additional detail on the navigation simulations, see Appendix H, List of Technical Reports, Navigation Simulation Study.

The mariners who participated in the vessel simulations indicated existing conditions can require careful maneuvering, especially with downbound direction and loaded cargo, to pass through both the Interstate Bridge and BNSF Railway Bridge due to the horizontal clearances of each bridge and the distance between the bridges.

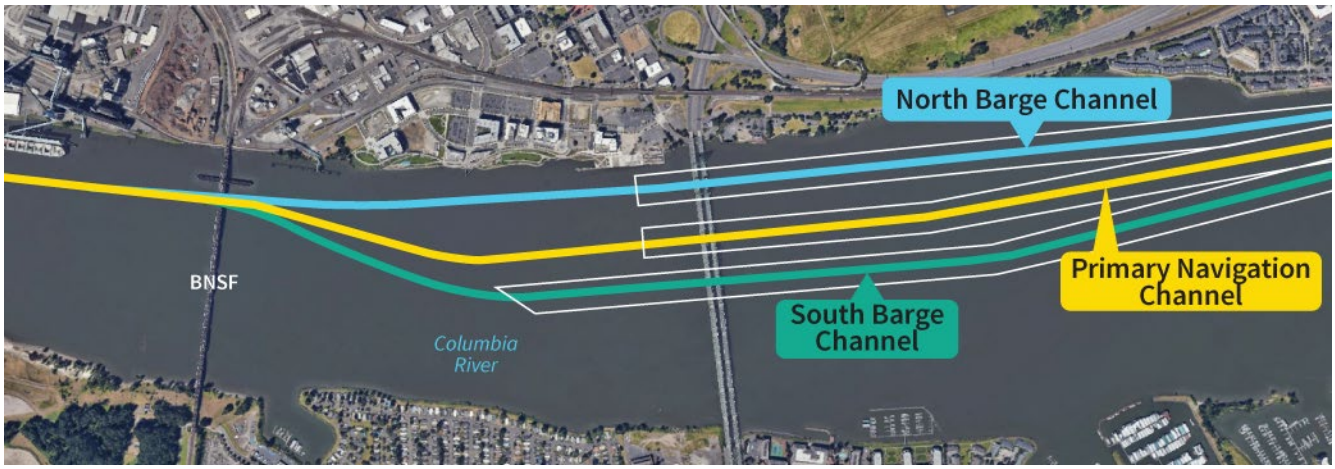
Without the seismic upgrades to the Interstate Bridge, a major earthquake could collapse or seriously damage one or both bridges, temporarily restricting or preventing navigation. Similar impacts to vessels navigating North Portland Harbor could occur if the bridge over North Portland Harbor is not replaced.

Modified LPA

Columbia River Navigation Channels

For all bridge design options under consideration for the Modified LPA, the routes that vessels would be required to take to pass through both the new Columbia River bridges and BNSF Railway Bridge would change due to the proposed relocations of the primary navigation channel and north barge channel (see Figure 3.2-3). All bridge configuration design options would modify the federally authorized navigation channels, switching the relative positions of the primary navigation channel and the barge channel from those shown in Figure 3.2-1. The north barge channel would be located closest to the Washington shore, while the primary navigation channel would be located one bridge span south at the bridge's highest point of vertical clearance. The south barge channel would continue to be in approximately the same location as the existing alternative barge channel.

Figure 3.2-3. Proposed Columbia River Navigation Channels under the Modified LPA



Navigation Clearance

The navigation clearance would change for all channels on the Columbia River:

- The north barge channel dimensions would be 100 feet VNC (fixed-span configurations) or 99 feet VNC (movable-span configuration) with 400 feet HNC. Most vessels and cargo would be able to pass under the new Columbia River bridges using the north barge channel with all bridge configurations. With a wider opening and higher vertical clearance, the north barge channel would provide improved navigation for most users compared to the existing primary navigation channel of the Interstate Bridge, except for vessels or cargo loads that require greater than 100 feet of clearance with the fixed-span configurations or 99 feet with the movable-span configuration and need to use the new primary navigation channel.
- The new primary navigation channel (center location) dimensions would be 116 feet VNC with 400 feet HNC (fixed-span configurations) and 92 feet VNC (closed position) to 178 feet VNC (open position) with 400 feet HNC for the movable-span configuration. Vessels that require more than 100 feet VNC (fixed-span configurations) or 99 feet VNC (movable-span configuration) would use this channel.
- The south barge channel dimensions would be 110 feet VNC (fixed-span configurations) or 90 feet VNC (movable-span configuration) with 400 feet HNC.

Currently, there are no planned new marine-dependent developments upstream of the Interstate Bridge; however, the Modified LPA with either the double-deck fixed-span or single-level fixed-span configuration would limit future navigation by introducing a permanent and complete obstruction to navigation upstream of the new Columbia River bridges for vessels or cargo loads with vertical clearance requirements greater than 116 feet. The Modified LPA with a single-level movable-span configuration would continue to provide unobstructed navigation for vessels requiring up to 178 feet of VNC.

Replacement bridges over North Portland Harbor would retain the same VNC as the existing I-5 bridge.

Navigation Safety

Columbia River navigation safety was evaluated by simulating future navigation conditions with varying vessel types, cargo loads, water flow conditions, wind conditions, transit direction, and other elements (Appendix H, Navigation Simulation Study). Simulations for deep-draft vessels were conducted with a vertical lift-span configuration in the open position; simulations for shallow-draft vessels were conducted with a vertical lift-span configuration in both open and closed positions. Simulations conducted for shallow-draft vessels would apply to the fixed-span configurations unless specialty cargo requiring greater than 100 feet VNC was transiting.

Because the construction of the new bridges would be to the west (downstream) of the existing Interstate Bridge, the distance between the BNSF Railway Bridge and the new Columbia River bridges would be reduced, resulting in a shorter available distance for vessels to align with the openings of the two bridges. However, the Modified LPA would include fewer bridge piers in the water and a greater distance between the piers and thus would provide greater HNC. This increased HNC would provide an opportunity for mariners headed downstream to position earlier to begin turning movements as they are transiting the new Columbia River bridges, compared to the current situation that does not allow them to begin turning until they have fully transited the Interstate Bridge. In addition, realigning the primary navigation channel from the north to the center channel would allow a greater passing distance between cruise vessels docked at Terminal 1 and transiting vessels. Overall, ship pilots and tug masters conducting the navigation simulations described the Modified LPA as providing more HNC to maneuver and reducing the number of direction changes to navigate between the new Columbia River bridges and the BNSF Railway Bridge. Specific pilot and tug master observations from the simulations are presented in Table 3.2-4. The Modified LPA for the double-deck fixed-span, single-level fixed-span, and vertical lift-span configuration design options includes spans of 465 feet, which meets the federally authorized channel width. Because the Modified LPA would require fewer

piers than the No-Build Alternative (six sets of in-water piers versus nine sets for the No-Build Alternative), the spans between pier sets would provide greater HNC and create fewer obstacles to navigation for all river users than would the No-Build Alternative.

Navigation safety for vessels transiting North Portland Harbor would remain unchanged as VNC and HNC with the replacement bridges would not decrease. However, the Modified LPA would increase the number of bridges crossing the North Portland Harbor from the single I-5 bridge that currently spans the harbor to five new bridges; thus, there would be additional piers in the water for vessels to navigate.

Table 3.2-4. Columbia River Navigation Simulation Pilot Observations for the Modified LPA

Draft	Direction	Pilot and Tug Master Observations
Deep-draft Vessels	Upbound	• Navigation channels were a significant improvement in the transition between the BNSF Railway Bridge and new Columbia River bridges as a result of a steady heading through the BNSF bridge toward where the pilot wants to be positionally approaching the Columbia River bridges. • With the proposed channel/bridge there is a single turn point between the BNSF Railway Bridge and Columbia River bridges compared to two corrections with the existing Interstate Bridge. • With the new Columbia River bridge piers, there is more maneuvering area compared to the existing Interstate Bridge piers where the clearance is more restrictive. • Passing through the existing Interstate Bridge, vessels come close to Vancouver and any vessels docked at Terminal 1 and are constrained from maneuvering on one side. Pilots expressed they had to “dig out” from the existing bridge channel. These conditions were mitigated with the proposed bridge span and center channel alignment for the deep-draft vessels (same observation made for downbound transit).
Deep-draft Vessels	Downbound	• The Modified LPA navigation channels and bridge piers allowed for more natural transition from the new Columbia River bridges to the BNSF Railway Bridge. The existing Interstate Bridge required a turn to the south and then another turn to the north, while the proposed bridge just required a single turn to the north to line up for the BNSF Railway Bridge. • Transit in the existing primary navigation channel with the existing bridge required a lot of rudder commands to maintain the intended track. • Increased clearance between bridge piers allowed more maneuvering room and allowed the pilots to start their turn earlier on the downbound passage (started the turn under the bridge) to set up for passage through BNSF Railway Bridge.
Shallow-draft Vessels	Upbound	• The approach to the north barge channel at the new Columbia River bridges is easier and improved from the existing conditions due to the new bridge piers shifting south, allowing the stern of the tug room to stay south rather than having to hold position on the north bank in existing conditions. • The additional width of the new bridge piers is an improvement from existing conditions. • The center channel (new primary navigation channel) was run with fog and nighttime conditions, independently, and no concerns were raised. This proposed center channel felt like a typical transit performed today.

Draft	Direction	Pilot and Tug Master Observations
		• For the south barge channel, it was noted the new channel was preferred over the existing due to the enhanced visibility from the higher low chord elevation of the bridges, a more gradual turn from the BNSF Railway Bridge to the new Columbia River bridges, and wider channel between the bridge piers.
Shallow-draft Vessels	Downbound	• The north barge channel transit at the new Columbia River bridges felt easier than existing conditions due to the proposed bridge piers shifting south making the transition to the BNSF Railway Bridge more natural. Additionally, with the new Columbia River bridges there would no longer be the need to wait for a bridge opening, which is a concern of the mariners as the new vertical clearance is sufficient for all 2-barge by 2-barge tows. • The center channel (new primary navigation channel) and bridge would be a substantial improvement from existing conditions both visually and spatially. The new center channel would limit the course correction needed between the new Columbia River bridges and BNSF Railway Bridge. The tug masters stated this channel would be the preferred channel to transit for both upbound and downbound transits. • For the south barge channel, it was noted that the proposed channel/bridge was easier than the existing conditions due to an easier transition from the new Columbia River bridges to the BNSF Railway Bridge, improving overall safety of the transit. • For specialty barges, tug masters thought maneuvers for the new Columbia River bridges and existing conditions were comparable with a preference for the new channel/bridge due to increased channel width.

Vessel and Operational Adjustments Associated with Columbia River Fixed-Span Bridge Configurations

The Modified LPA with either the double-deck or single-level fixed-span configuration would reduce the maximum VNC of the primary navigation channel from 178 to 116 feet. The IBR Program collected information on vessels traveling this section of the Columbia River to assess the existing clearance needs; the results were discussed and verified with vessel operators and the USCG. Vessel types, owners, names, and specifications were collected and analyzed to determine whether the Modified LPA with fixed-span configurations with a VNC of 116 feet would result in adverse impacts to these river users. In addition, information was also collected from marine industries along the Columbia River about large freight shipments that would be constrained by a fixed-span bridge.

Information on vessels that would be restricted by a 116-foot bridge under the Modified LPA is summarized in Table 3.2-5 and represents vessels transiting the Interstate Bridge during the 2012–2023 period. Five vessels and three industrial fabricators with large freight shipments may have vertical clearance requirements greater than the clearance provided by the Modified LPA with either fixed-span configuration. With the proposed fixed-span VNC of 116 feet, two marine contractor vessels (crane or derrick barges) would be unable to navigate beneath a fixed-span bridge. Two additional derrick barges and the USACE Dredge *Yaquina* would be restricted when the river level is at the ordinary high water level of 16 feet above CRD, which is approximately 1% of days in a typical year. If adjustments to taller vessels, large cargo, or business operations would be infeasible, then the fixed VNC of 116 feet would adversely affect the navigation capabilities of these vessel owners, as well as vessels and industrial businesses that ship cargo and require greater vertical clearance.

Table 3.2-5. River Users Restricted by a 116-foot Bridge under the Modified LPA Fixed-Span Configurations [a]

Type of Affected River Users	Number of Affected River Users	Limiting Factor	Required Clearance (feet CRD) [b]	Approximate Trip Frequency
Industrial fabricators	3	Fabricated materials shipped by barge	140–175	Less than 1 one-way trip per year
Marine contractors unable to pass all times of year	2	Crane boom heights	129–141	1–10 round trips per month
Marine contractors able to pass except during high water conditions (16 feet CRD)	2 [c]	Crane boom or gantry height	102–103	1–2 round trips per month
USACE Dredge *Yaquina*	1	Antenna height	102	1 round trip per month October through July; 2 round trips per month August and September

Source: IBR 2022

a Restrictions on vessel navigation beneath the new bridges were determined based on an OHWL of 16 feet above CRD. This level was exceeded at the Interstate Bridge less than 1.2% of days over the data period between 1972 and 2020.

b Required clearance includes a 10-foot air gap above a vessel's highest point, which provides a safety factor due to wave- and wind-induced movements in the vertical plane when vessels are transiting under the bridges.

c Both vessels have accommodations to lower crane booms/gantries and could implement them to transit during OHWL conditions.

CRD = Columbia River Datum; OHWL = ordinary high-water line; USACE = U.S. Army Corps of Engineers

Compliance with USCG Preliminary Navigation Clearance Determination

The Modified LPA with the single-level movable-span configuration over the Columbia River would continue to provide 178 feet or greater VNC. This configuration would meet the Preliminary Navigation Clearance Determination for the Columbia River issued by the USCG on June 17, 2022.

None of the bridge design options over the Columbia River with the fixed-span configurations would comply with the 2022 Preliminary Navigation Clearance Determination; thus, an updated Navigation Impact Report would need to be submitted and a revised Preliminary Navigation Clearance Determination from the USCG would be required to advance these design options (see Section 2.6, Additional Compliance Underway, for more discussion on this process).

The USCG issued a Preliminary Navigation Clearance Determination for North Portland Harbor on July 12, 2022, with which the Modified LPA is consistent.

Timing Restrictions on Columbia River Movable-Span Bridge Openings

Movable-span operations, and therefore Columbia River navigation, would potentially need to be restricted to minimize impacts to highway traffic and light-rail transit operations (see Section 2.6, Additional Compliance Underway, for more discussion on the rulemaking process to establish timing restrictions on movable-span openings). This would likely be more restrictive than the No-Build Alternative, as bridge openings are currently restricted during peak commute hours Monday through Friday to reduce impacts to highway traffic. The Modified LPA would include light-rail transit; thus, additional timing restrictions for this service would be considered. A factor to consider in determining changes to timing restrictions, is the number of projected

bridge openings. The increased HNC and VNC of the movable-span configuration would allow standard barges to transit all three of the navigation channels, including during high water conditions, without needing to request a bridge opening, thereby reducing the number of bridge openings. Extended timing restrictions on bridge openings could require vessel owners and cargo shipments to be scheduled at earlier or later times of day than are used today and under the No-Build Alternative. For more information on impacts to highway traffic and transit service from movable-span bridge openings, see Section 3.1, Transportation.

Future Maritime Transportation System demands and the associated need for bridge openings for the 100+ year service life of the bridge are difficult to predict because vessel traffic and river-level conditions vary from year to year and economic trends for maritime commerce may change over time. Under the Modified LPA with the double-deck fixed-span or single-level fixed-span configurations, future vessel traffic would be restricted to vessels that could navigate the 116-foot fixed-span, height-restricted navigation of the waterway. The Modified LPA with a single-level movable-span configuration would retain 178 feet VNC; all vessels and cargo that transit the existing Interstate Bridge would continue to transit in the future.

Upper Vancouver Turning Basin

Under the Modified LPA, the proposed Columbia River bridges would be constructed to the west of the existing Interstate Bridge. Consequently, all of the bridge configurations would shift the Upper Vancouver Turning Basin west by approximately 300-350 feet compared to the No-Build Alternative. This shift would continue to provide horizontal distance and vertical depth for vessels that have historically used this turning basin, allowing them to make similar turning movements in the future.

Summary of Long-Term Effects

Table 3.2-6 compares the long-term effects to navigation on the main stem of the Columbia River of the Modified LPA to the No-Build Alternative.

The new North Portland Harbor bridges proposed under the Modified LPA would not reduce or increase vessel navigation clearance from current conditions. In addition, mariners transiting the North Portland Harbor would continue to have an alternate route via the main channel of the Columbia River. Therefore, no long-term effects to navigation are expected to result from the new North Portland Harbor bridges.

Table 3.2-6. Summary of Long-Term Effects to Columbia River Navigation from the No-Build Alternative and Modified LPA

Navigation Component	No-Build Alternative	Modified LPA with Double-Deck or Single-Level Fixed-Span (Girder, Extradosed, Finback) Configurations	Modified LPA with Single-Level Movable-Span Configuration
Primary Navigation Channel	Location: North Width: 263 feet Height: 39 feet (closed) to 178 feet (open)	Location: Center Width: 400 feet Height: 116 feet	Location: Center Width: 400 feet Height: 92 feet (closed) to 178 feet (open)
North Barge Channel	Location: Center Width: 511 feet Height: 46–70 feet	Location: North Width: 400 feet Height: 100 feet	Location: North Width: 400 feet Height: 99 feet
South Barge Channel	Location: South Width: 260 feet Height: 72 feet	Location: South Width: 400 feet Height: 110 feet	Location: South Width: 400 feet Height: 90 feet
Navigation Safety	Primary navigation channel (north location) would provide straightest route to/from the BNSF Railway Bridge compared to existing barge (center) and alternate barge (south) channels	Wider HNC for all channels Reduced VNC for new primary navigation channel Increased VNC for the north barge channel and south barge channel Improve alignment with the BNSF Railway Bridge Increased visibility	Wider HNC for all channels Same or increased VNC for all channels Improved alignment with the BNSF Railway bridge Increased visibility
Number of In-water Pier Sets	9	6	6
Bridge Opening Restrictions	No lifts allowed on weekdays: 6:30 a.m. to 9:00 a.m. and 2:30 p.m. to 6:00 p.m.	N/A	Potentially more restrictions on openings allowed during weekday daytimes and early evenings [a]
Upper Vancouver Turning Basin	Approximately 2,000 feet long	Maintained length with an approximately 300-325-foot shift west	Maintained length with an approximately 350-foot shift west

Navigation Component	No-Build Alternative	Modified LPA with Double-Deck or Single-Level Fixed-Span (Girder, Extradosed, Finback) Configurations	Modified LPA with Single-Level Movable-Span Configuration
Seismic Resilience	Continued risks of impacts to navigation from potential earthquake events including the potential for the bridge failing and blocking or obstructing the navigation channels.	Increased seismic resiliency in event of potential earthquake reducing risk of bridge failure or collapse and blocking or obstructing the navigation channels.	Increased seismic resiliency in event of potential earthquake reducing risk of bridge failure or collapse and blocking or obstructing the navigation channels.
Demolition	N/A	Existing bridge foundation elements would be removed to a depth determined by the USACE to not pose a hazard to current or future dredging operations.	Existing bridge foundation elements would be removed to a depth determined by the USACE to not pose a hazard to current or future dredging operations.

a New bridge opening restrictions would require coordination with USCG and mariners. Federal rulemaking process would need to occur to modify current restrictions for long-term operations of the Modified LPA with a single-level movable-span configuration.

HNC = horizontal navigation clearance; LPA = Locally Preferred Alternative; N/A = not applicable; USACE = U.S. Army Corps of Engineers; USCG = U.S. Coast Guard; VNC = vertical navigation clearance

3.2.4 Temporary Effects

No-Build Alternative

No Program-related construction activities would take place under the No-Build Alternative that would have temporary effects to navigation.

Modified LPA

Construction of the Modified LPA includes the construction of the new bridges and removal of the existing Interstate Bridge. Construction activities would result in temporary effects to navigation on the Columbia River. During construction of the Modified LPA, some of the new piers, which are located outside of the current navigation channel, would not line up with the existing piers. Construction of the new bridge pier sets would occur one-by-one, resulting in changes to the three navigation channels at different points in time. For the estimated 4- to 7-year duration of construction, the existing Interstate Bridge would still be operational, and channels would be restricted by the presence of both the existing and constructed piers until demolition of the existing piers could occur. HNC could be further affected due to crane barges and other equipment present in the vicinity of the channel during pier construction. Smaller vessels and most recreational craft, which have limited horizontal and vertical clearance needs, would not be restricted from passing.

Construction would be staged so that at least one navigation channel would be open at a given time. A minimum unobstructed navigation clearance of 72 to 75 feet (vertical) by 150 to 200 feet (horizontal) would be maintained during construction. This clearance would meet vessel clearance needs of most waterway users; however, accommodations would be implemented to maintain safe passage through the construction area. Pilot and tug master feedback during the navigation simulations provided the following observations for the construction conditions:[4]

- The north barge channel/existing primary navigation channel felt like a typical transit through the existing north channel with more obstacles due to passing through two pairs of bridges. Overall, the mariner had limited concerns with this channel during construction.
- The navigation clearance limitations on the south barge channel, pilots/tug masters noted the channel is tight. As a result, until mariners are familiar with transiting this channel the 2-barge (length) by 2-barge (abreast) tows should be broken into a narrower 2-barge (length) by 1-barge (abreast) tow. For specialty barges, maneuvers should happen during daylight to have greatest visibility. Additionally, the deckhand would need to be on the barge constantly giving the tug captain distances throughout this transit, an assist tug would be required, and environmental conditions would need to be evaluated for each transit.
- All construction barges should have an active Automatic Identification System (AIS) signal and construction channel lines should be updated on the published navigation charts.

For vessels requiring greater than 72 to 75 feet VNC, advance coordination would be undertaken to seek opportunities to accommodate larger vessels and cargo with construction activities. Closures or restrictions on river traffic would need to be approved by the USCG and communicated in advance, enabling river users to accommodate their schedules without undue interruption. The majority of vessels currently using the navigation channel would be able to continue their use throughout most of the construction period. Larger

[4] The new primary navigation channel (center location) was assumed to have a minimum width of 200 feet and be limited to a vertical clearance of 43 feet during the simulated construction scenario. Thus, this channel would be closed as none of the design vessels would have sufficient clearance (see Appendix H, List of Technical Reports, Navigation Simulation Study, for additional details on the modeling assumptions for simulations).

vessels may require a tug to assist their navigation of the construction area, particularly if a vessel is traveling downriver with cargo.

The VNC restrictions during construction would prevent the *Yaquina* from navigating above the Interstate Bridge to conduct yearly maintenance dredging of the federal navigation channel. Without yearly maintenance dredging portions of the river could shoal and reduce the ability of vessels to navigate the federal navigation channel or could require reduced loads and vessel drafts. Modifications to the *Yaquina*, such as converting the fixed mast to a lowerable mast, use of alternative vessels, or changing dredging methods would be required to fulfill the USACE's navigation missions during these time periods.

While the size of vessels transiting the North Portland Harbor is more limited than those using the mainstem of the Columbia River, construction staging schemes would be devised for the Modified LPA to minimize adverse impacts to the vessels using North Portland Harbor. Construction in North Portland Harbor is not expected to occur at the same time as the Columbia River; thus, many vessels that typically transit North Portland Harbor could use the Columbia River as an alternate route. Restrictions and temporary closures of the navigation channel and the availability of the alternate route would be communicated to marinas and moorages on North Portland Harbor, as these are the primary users.

Temporary navigation effects under the single-level movable-span configuration would be similar in character to those described above but would be more pronounced because of the larger footings and piers on either side of the primary navigation channel and the additional construction time, materials, and equipment needed to construct this option compared to the fixed-span configurations.

See Section 3.2.6 for more discussion of staging and related construction-phase mitigation.

3.2.5 Indirect Effects

Under the Modified LPA with fixed-span configurations, vessels or cargo that would be height-limited and unable to transit beneath the new Columbia River bridges could have potential indirect effects on upstream marine-dependent uses. Based on state, port, and local jurisdictions' land use plans, these potential indirect effects would be expected to have limited, at most, impact on future upriver economic activity since there are few upstream opportunities for new or expanded commercial and industrial developments dependent on height-constrained vessels service (Appendix H. Navigation Impact Report). The Modified LPA with movable-span configuration would have no indirect effects to upstream marine-dependent uses.

The Columbia River waterway is currently authorized to a depth of 27 feet from the Interstate Bridge to The Dalles, approximately 83 river miles upstream, and could support greater navigation upriver from the Interstate Bridge than it currently does if the waterway were deepened from the currently maintained depth of 17 feet. However, no new marine-dependent developments are currently known to be planned upstream of the Columbia River bridges.

Constraints related to land use controls and business demand, rather than reducing the VNC from 178 feet (No-Build Alternative) to 116 feet (Modified LPA with fixed-span configurations), represent the primary factors that could potentially impact future commercial and industrial development upstream. Land use restrictions imposed by the Columbia River Gorge National Scenic Area, along with topography, transportation access parallel to shorelines (SR 14, I-84, the BNSF Railway, and the Union Pacific Railroad), and existing protected open spaces, are the limiting factors for future water-dependent commercial and industrial development. Overall, the Modified LPA is expected to result in little to no indirect impact to upstream marine-dependent land uses. See Section 3.4, Land Use and Economic Activity, for further discussion on indirect effects to land uses and the economy.

3.2.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

- Standards and regulatory measures to avoid or minimize long-term effects on navigation have been evaluated and screened. These measures have been incorporated during the development of the Modified LPA to the extent possible and will continue to be refined as the design progresses.

Avoidance Measures

The Modified LPA with a fixed-span configuration would have long-term effects to marine-based operations currently operating on the Columbia River, including five vessels and three upstream fabricators when shipping large cargo requiring VNC over 116 feet. Under the double-deck and single-level fixed-span configurations, these vessels and cargo shipments would be unable to transit beneath the new Columbia River bridges in either some conditions when river levels approach or exceed ordinary high water levels or be permanently precluded from transiting the bridge. The IBR Program would continue to coordinate with the affected vessel owners and river users to reach mutually acceptable decisions and agreements to avoid impacts through adjustments to vessels or business operations prior to publication of the Final SEIS.

Program-Specific Mitigation

In addition to regulatory requirements, potential Program-specific mitigation measures have been identified and will be developed with the Modified LPA design.

Specific mitigation for navigation includes:

- Provide obstruction marking and lighting to make the river crossing structures visible to river traffic. Design roadway or accent lighting on the bridges and surrounding interchanges to limit light or glare that could affect river navigation.
- Update navigation charts and other navigation publications to reflect changes to VNC and HNC for future river users.

Temporary Effects

Regulatory Requirements

To protect and minimize temporary effects on navigation during construction, standard and regulatory mitigation measures such as best management practices (BMPs) would be implemented. Construction BMPs applicable to the Modified LPA are discussed in Section 3.14, Water Quality and Hydrology.

Standard and regulatory mitigation measures for navigation include:

- Develop construction phasing and staging plans to help ensure that construction activities would be planned to maintain a minimum channel for navigation. The Construction Staging Plan would be reviewed and approved by the USCG Captain of the Port prior to construction. Coordination and approval by the USCG Captain of the Port would occur for changes to the three navigation channels at each of the different times bridge pier sets would be constructed. Closures or restrictions on river traffic would be communicated in advance, enabling river users to accommodate their schedules, tug and barge configurations, requirements for assist tugs, shipping marine freight by other modes (e.g., truck, rail), use of different vessels with lower vertical clearance, and other options during construction activities that disrupt navigation and enable USACE to fulfill its navigation missions.

- Provide Local Notice to Mariners throughout construction to provide information to tug operators, pilots, and the public.

Program-Specific Mitigation

- Make available an assist tug(s) to support safe navigation when vertical or horizontal clearances are reduced and assistance is needed to safely navigate the restricted channel.
- Conduct outreach to inform the navigation community, recreational boaters, and other river users of waterway restrictions and other construction activities that may restrict or otherwise change local navigation conditions.
- Provide information via local maritime publications, social media, local media, and other similar platforms.
- Provide signage and notices at boat ramps, water access points, marinas, and other locations frequented by river users to inform them of the construction activities and where additional information can be found on the Program.
- Notify individual vessel owners where information indicates they could be specifically impacted during construction.
- Require all construction barges to have active AIS signals and construction channel lines be updated on the published navigation charts.
- Modify the USACE Dredge *Yaquina* to have a lowerable mast or other feature to enable passage of the Interstate Bridge during construction.

3.3 Property Acquisitions and Displacements

This section identifies, describes, and evaluates short-term and long-term property and property rights effects for the Modified LPA. It also describes measures to help avoid, minimize, or mitigate adverse effects. The information presented in this section is based on the analysis described in the Acquisitions Technical Report, which provides information about each property acquisition and displacement.

3.3.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with property acquisitions and displacements has been updated in this Draft SEIS to include:

- Changes in land use as a result of new development and redevelopment in the area (e.g., closure of the Safeway on Hayden Island, new residential development, and development at the Vancouver Waterfront).
- Changes in the project footprint necessitated by changed conditions resulted in shifting the LRT alignment and modifying interchange designs.

Table 3.3-1 compares the impacts and benefits of the CRC LPA and the IBR Modified LPA. Based on the analysis described in this section, the effects of the Modified LPA would be similar to, but less than, the effects of the CRC LPA. Changes to the design of the CRC LPA have reduced the number of acquisitions and displacements. Key modifications that led to this reduction include replacing the full interchange on Hayden Island with a partial interchange and moving the LRT alignment adjacent to I-5 rather than along local streets in downtown Vancouver.

Table 3.3-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects Identified in this Section [a]	Explanation of Differences
Total Acquisitions (Full and Partial Acquisitions) [b]	217 parcels	Between 178 and 180 parcels	The reduction results from changes in land uses and design modifications necessitated by other changed conditions. Design modifications include replacing the full interchange on Hayden Island with a partial interchange and moving the LRT alignment adjacent to I-5 rather than in downtown Vancouver. One design option (Waterfront Park-and-Ride Site #3 Option) would result in the acquisition of 180 parcels, while the other design options would result in 178 acquisitions.

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects Identified in this Section [a]	Explanation of Differences
Total Residential Displacements [c]	59 units	Between 43 and 76 units	See above; one design option (Modified LPA with I-5 mainline westward shift) would result in the loss of 76 residential units, while the other design options would displace 43 units.
Total Commercial Displacements	69 businesses	Between 36 and 39 businesses [d]	See above; one design option (Modified LPA with I-5 mainline westward shift) would result in the loss of 39 businesses, while the other design options would displace 36 businesses. The Waterfront Park-and-Ride Site #3 Option would result in one additional business displacement.
Total Public Use Displacements	2 sites	1 sites	The reduction results from changes in land uses and design modifications necessitated by other changed conditions.

a Acquisition and displacement totals could vary slightly depending on design option chosen. Refer to Section 3.3.3 for more information.

b Does not include ODOT-owned property or right of way or City-owned right of way.

c Does not include the displacement of houseless individuals.

d Does not include the displacement of a billboard and a cellular phone tower.

CRC = Columbia River Crossing; EIS = environmental impact statement; LPA = locally preferred alternative; LRT = light-rail transit

3.3.2 Existing Conditions

This section describes vacancy and rental rates for residential, commercial, and industrial properties in the study area (Figure 3.3-1), which are indicators of the potential for finding viable sites for relocating displaced residents and businesses.

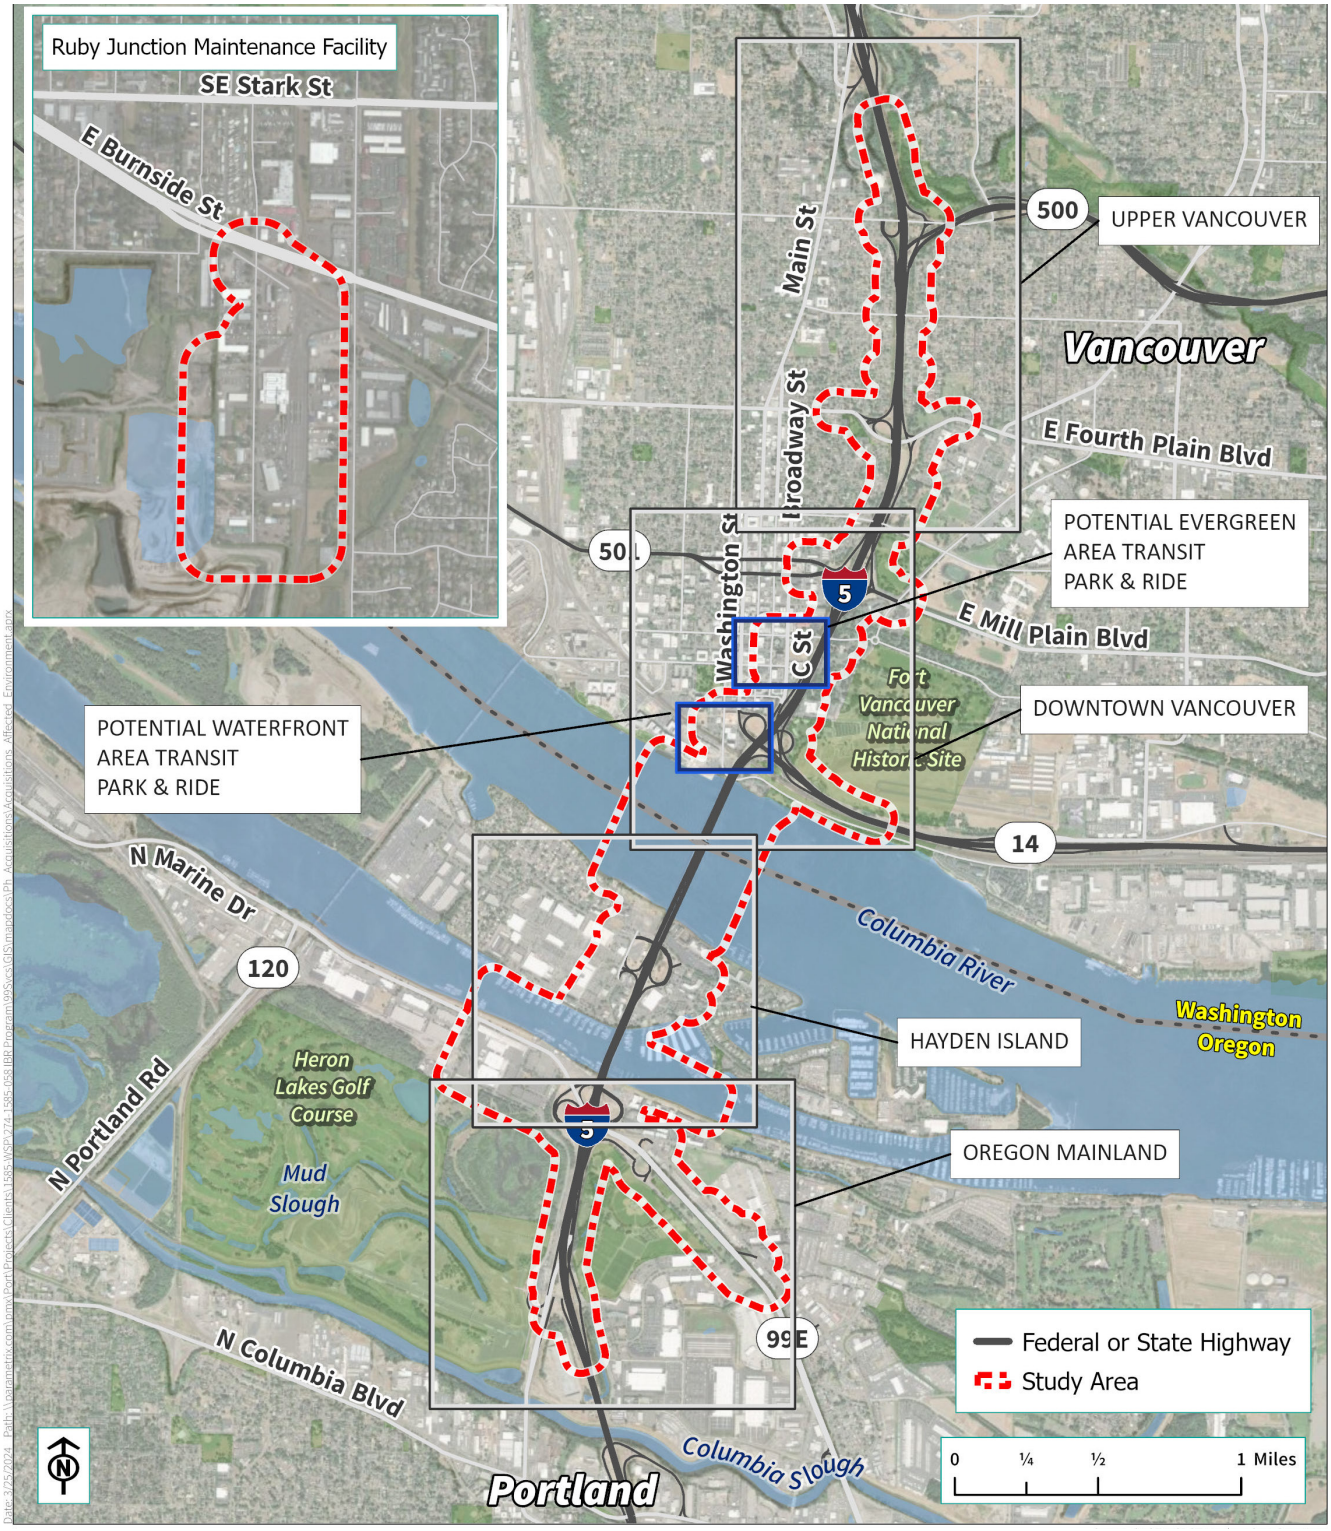
Portland-Vancouver Area

According to the Regional Multiple Listing Service, in July 2023 the Portland area (including Oregon suburbs but excluding communities in Washington) had a 2.5-month supply of homes for sale and a year-to-date median home sale price of $532,000. In the same month, Clark County had a 1.7-month home supply and a year-to-date median home sale price of $515,000.

In the second quarter of 2023, Vancouver had a 6.2% multifamily residential vacancy rate, with a rental rate averaging $1.81 per square foot per month (CoStar 2023). North Portland had a vacancy rate of 8.5% for multifamily residential rental units and a rental rate averaging $2 per square foot per month, while Northeast Portland had a vacancy rate of 6.9% and a $2.41 average rental rate per square foot per month.

Office space in the greater Portland-Vancouver metropolitan area was more available (22.2% vacancy rate) than either retail (4.5%) or industrial (2.6%) space (CBRE 2023). In the second quarter of 2023, the North Portland subarea, which includes Hayden Island, experienced an estimated 9.7% retail building vacancy rate, while the Vancouver subarea experienced an estimated vacancy rate of 5.8% (CBRE 2023).

Figure 3.3-1. Primary Study Area and Subareas



Portland-Vancouver metropolitan area vacancy rates were projected to decrease for retail and industrial space through 2025 and to increase for office space (SVN Bluestone & Hockley 2021b). The trend in increasing office space vacancies is likely due to more employees working from home rather than in traditional office settings. Additional office and retail spaces planned and currently under construction along the Vancouver waterfront could shift both vacancy and rental rates for the Vancouver subareas as they are completed.

North Portland Harbor, Portland, Oregon

In the North Portland Harbor area, a search of the active Regional Multiple Listing Service listings in August 2023 showed approximately 78 housing units listed for sale in the study area. Of that number, 34 were floating homes, 28 were condos, 6 were mobile homes, and 10 were conventional homes.

Gresham, Oregon

An analysis of vacancy rates was also performed for the area around the Ruby Junction Maintenance Facility in Gresham, Oregon (Figure 3.3-1). According to the Regional Multiple Listing Service, in August of 2023, the Gresham-Troutdale subarea had a median year-to-date sale price of $480,000. In the second quarter of 2023, the area had a 3.8% multifamily residential vacancy rate and an average rental rate of $1.49 per square foot for rentals (CoStar 2023).

3.3.3 Long-Term Benefits and Effects

No-Build Alternative

Under the No-Build Alternative, the existing interstate, local roads, and associated infrastructure would remain as they are today, and there would be no temporary or permanent acquisitions of properties.

Modified LPA

Property, including space underground (subsurface)[1] or in the air (airspace),[2] would be required to accommodate the proposed transportation facilities and their long-term operation and maintenance. Long-term operation and maintenance would require permanent acquisition, where the agency obtains complete ownership of the property, or a permanent easement, where the agency would obtain some rights to the land, air, or subsurface, but not would not assume full ownership. Both full and partial acquisitions could result in the displacement of residences, businesses, or public facilities from the parcel. Acquisition of property would typically occur through negotiated purchase or eminent domain.[3]

Construction and long-term operation and maintenance of the Modified LPA, including all design options, would permanently acquire approximately 47 acres of property, including approximately 4.3 acres in permanent subsurface easements, which are required for the potential installation of tie-back anchors associated with retaining walls. Under the Modified LPA with all design options, except the I-5 westward shift, this permanent property acquisition would be from a total of 178 parcels, with 46 full acquisitions and 132 partial acquisitions (Table 3.3-2 and Table 3.3-3). The I-5 westward shift would result in one less total acquisition. Figure 3.3-2 shows the potential property acquisitions for the Modified LPA in both Oregon and Washington, while Figure 3.3-3 shows a more detailed view of how acquisitions in downtown Vancouver would differ among design options. Acquisitions in Oregon would be the same for all design options. Detailed maps and a list of all properties identified for acquisition are included in Appendix A and Appendix B of the Acquisitions Technical Report.

[1] Subsurface lease requirements are preliminary and will be updated prior to construction.

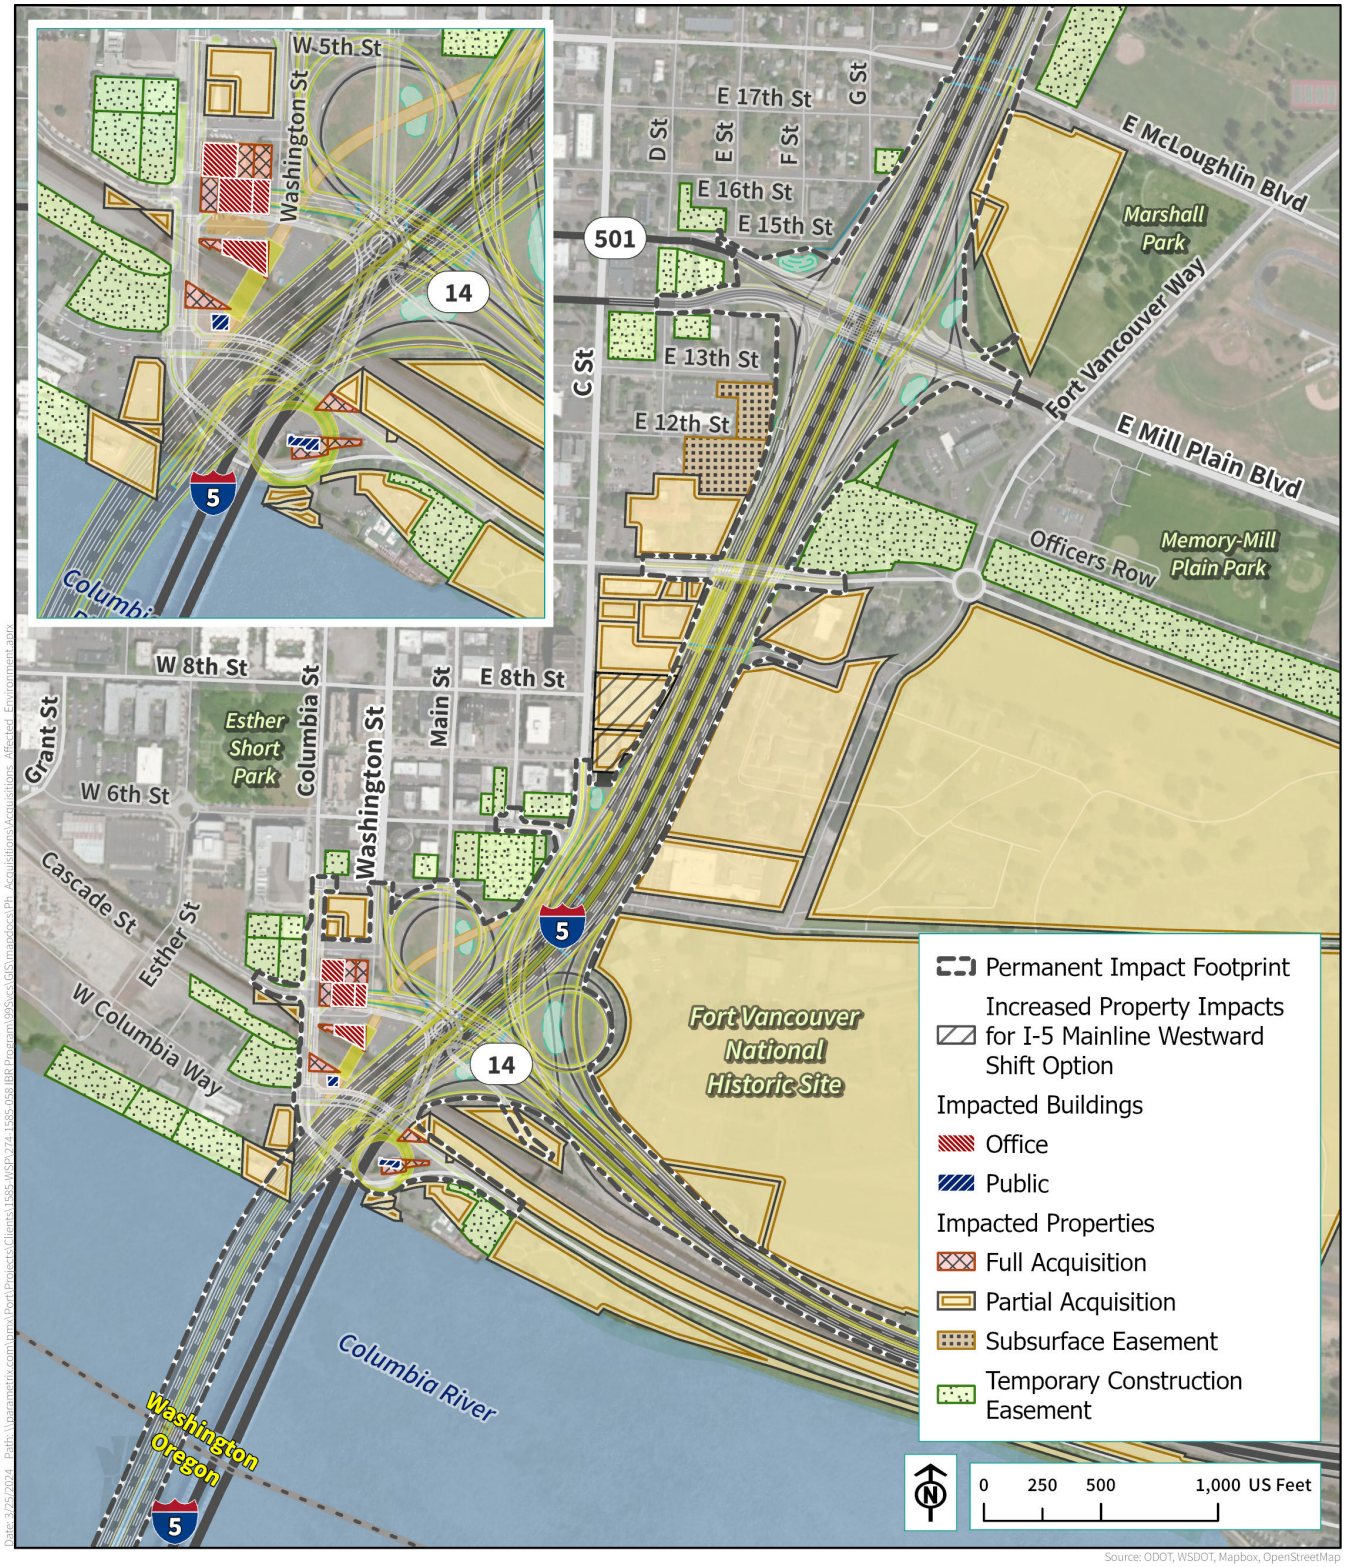
[2] Airspace leases have not been determined but will be identified prior to construction.

[3] In Washington, eminent domain is defined as the right of a government to acquire private property for public purpose following payment of just compensation to the property owner. In Oregon, "an authority may acquire, by the exercise of the power of eminent domain, any real property which it deems necessary for its purposes after adoption by it of a resolution declaring that the acquisition of the real property described therein is necessary for such purposes." Just compensation is required in both states.

Figure 3.3-2. Potential Property Acquisitions

Note: All design options would have similar impacts except the I-5 westward shift option. The increased property impacts associated with the I-5 westward shift option are denoted with a diagonal cross-hatched overlay, as shown in the legend. More detail is visible in Figure 3.3-3.

Figure 3.3-3. Detail of Property Acquisitions in Downtown Vancouver



Note: All design options would have similar impacts except the I-5 westward shift option. The increased property impacts associated with the I-5 westward shift option are denoted with a diagonal cross-hatched overlay, as shown in the legend.

Table 3.3-2. Summary of Permanent Property Acquisitions and Displacements for the Modified LPA in Oregon

Property Acquisition and Displacements	Type	Modified LPA Totals [a,b]
Parcels (count)	Full Acquisitions	25
	Partial Acquisitions	43
	Total	**68**
Displacement: Residential (number of dwellings)	Single-family	36
	Multifamily	0
Displacement: Commercial (number of businesses)	Retail, Services	23
	Office, Professional, Healthcare	1
	Lodging	0
	Other [c]	2
Displacement: Public Use (number of sites)	Public Service with Employees	0
	Religious/Community Center	0
	Park, Historic Site, Museum	0
	School	0
Permanent Acquisitions	Area Acquired	36.5 acres
Permanent Easements	Subsurface Easements [d]	0.1 acres
	Property Easements [e]	0 acres
Total of Permanent Acquisitions and Easements	**Total Area Acquired**	**36.6 acres**

a Parcel impacts, displacements, or total acreage, are only counted once when more than one mode (highway, transit, or bicycle and pedestrian) would result in the same or overlapping acquisition.

b Does not include ODOT-owned property or right of way or City-owned right of way.

c Includes a billboard at the Marine Drive interchange and a cellular phone tower.

d Subsurface easement requirements are preliminary and will be updated prior to construction.

e Airspace easements have not been determined but will be identified prior to construction.

LPA = locally preferred alternative

Table 3.3-3. Summary of Permanent Property Acquisitions and Displacements for the No-Build Alternative and the Modified LPA in Washington

Property Acquisitions and Displacements	Type	No-Build	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 [a,b]	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Centered I-5, without C Street Ramps	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift [a,b]	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5 [c]	Modified LPA with Single-Level [d] Fixed-Span or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 [e]

Property Acquisitions and Displacements	Type	No-Build	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 [a,b]	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Centered I-5, without C Street Ramps	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift [a,b]	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5 [c]	Modified LPA with Single-Level [d] Fixed-Span or Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 [e]
Permanent Easements	Airspace Easements [g]	0	Less than 1 acre	Less than 1 acre	Less than 1 acre	Less than 1 acre	Less than 1 acre
	Subsurface Easements [h]	0	4.2 acres	4.2 acres	3.6 acres	4.2 acres	4.2 acres
	Property Easements	0	0 acres	0 acres	0 acres	0 acres	0 acres
Total of Permanent Acquisitions and Easements [i]	**Total Area Acquired**	**0**	**10.6 acres**	**10.6 acres**	**10.9 acres**	**10.7 acres**	**10.9 acres**

a Parcel impacts, displacements, or total acreage, are only counted once when more than one mode (highway, transit, or bicycle and pedestrian) result in the same or overlapping acquisition.

b Does not include WSDOT-owned property or right of way or City-owned right of way.

c If coupled with the I-5 westward shift and a single-level fixed- or movable-span configuration, the two auxiliary lane option could require up to 11.1 acres of permanent acquisitions and easements.

d A single-level fixed-span or movable-span configuration would require partial acquisition of 0.2 acres from properties at the bridge approaches that would not be acquired with a double-deck bridge configuration.

e Reflects impacts for both the single-level fixed-span and movable-span configurations, regardless of bridge type.

f Properties requiring subsurface easements are included in the count of partial acquisitions.

g Airspace easements have been rounded up to 1 acre.

h Subsurface easement requirements are preliminary and will be updated prior to construction.

i The inclusion of the park-and-ride options would result in up to 1.5 additional acres of permanent acquisitions and easements at the Waterfront Park and Ride facility (Site 3) and up to 3.16 additional acres of permanent acquisitions and easements at the Evergreen Park and Ride facility (Site 1).

Aux = auxiliary; LPA = locally preferred alternative

Table 3.3-2 summarizes the permanent property acquisitions and displacements required for the Modified LPA in Oregon, and Table 3.3-3 summarizes property impacts for the Modified LPA design options in Washington. The design options within Washington would differ slightly in their impacts, as follows:

- The Modified LPA with double-deck bridge configuration, one auxiliary lane, with or without the C Street ramps, and centered I-5 would result in a total of 10.6 acres of permanent acquisitions and easements.
- The Modified LPA with two auxiliary lanes would require an additional 0.1 acres of permanent acquisition from the Fort Vancouver property on the east side of I-5 beyond what would be needed for the option with one auxiliary lane. The total permanent acquisition and easement area would be 10.7 acres. If coupled with the I-5 westward shift and a single-level fixed-span or movable-span configuration (regardless of bridge type), the Modified LPA with two auxiliary lanes could require up to 11.1 acres of permanent acquisitions and easements, which would be the highest-impact combination of the design options. The inclusion of the park-and-ride options would result in up to 1.5 additional acres of permanent acquisitions and easements at the Waterfront Park and Ride facility (Site 3) and up to 3.16 additional acres of permanent acquisitions and easements at the Evergreen Park and Ride facility (Site 1).
- The Modified LPA with a single-level fixed-span or movable-span configuration, regardless of bridge type, would require partial acquisition of 0.2 acres from properties at the bridge approaches that would not be acquired with a double-deck bridge configuration. Total permanent acquisitions and easements for this option would be 10.9 acres.
- In downtown Vancouver, the Modified LPA with I-5 mainline shift west would require the permanent acquisition of additional properties and associated displacements beyond those identified for the centered I-5 option. The shift would result in the full displacement of a multifamily property with 33 residential units on the northeast corner of E 7th Street and C Street. The property directly north of the apartment complex, which includes three commercial businesses, would also be fully acquired and the three businesses would be displaced. Total permanent acquisitions and easements would be 10.9 acres.

As described in Chapter 2, there are three site options for a new park and ride facility near the proposed Waterfront Station. Two of these sites (Sites 2 and 3) would require the acquisition of additional property beyond that needed for the highway and transit facilities. Site 2 would require full acquisition of one commercial parcel and no displacements. Site 3 would require full acquisition of four commercial parcels and displacement of one business. Site 1 would not require any acquisitions or displacements. Property impacts associated with the Waterfront Station park-and-ride options are shown in Table 3.3-4 and are in addition to the impacts identified in Table 3.3-3.

Two site options are being considered for a new park-and-ride facility near the proposed Evergreen Station. One of these sites (Site 1) would make use of an existing parking structure through a lease agreement; it would require the full acquisition of five commercial properties adjacent to the Vancouver Community Library, but no displacements. Site 2 would not require any acquisitions or displacements. Property acquisitions associated with the Evergreen Station park-and-ride facility are shown in Table 3.3-5 and are in addition to the impacts identified in Table 3.3-3.

Property owners, business owners, and residents affected by property acquisition and residential or business displacements would receive compensation and relocation assistance, as described in Section 3.3.6, Potential Avoidance, Minimization, and Mitigation Measures. Several types of properties or businesses may be difficult to relocate based on location and/or property type. These include small restaurants and taverns on Hayden Island, which rely on local patronage and may be difficult to reestablish elsewhere, as well as marine-oriented businesses adjacent to North Portland Harbor that require a waterfront location. Floating homes may also be difficult to relocate due to limited nearby moorage opportunities.

Table 3.3-4. Summary of Permanent Property Acquisitions and Displacements for the Waterfront Park-and-Ride Facility in Downtown Vancouver

Property Acquisitions and Displacements	Type	Site 1 [a,b,c]	Site 2 [a,b]	Site 3 [a,b]
Parcels (count)	Full Acquisitions	0	1	4
	Partial Acquisitions	0	0	0
	Total	**0**	**1**	**4**
Displacement of Use	Residential	0 units	0 units	0 units
	Office/Professional/Healthcare	0 businesses	0 businesses	1 business
Permanent Acquisitions	Area Acquired	0 acres	0.1 acres	1.5 acres
Permanent Easements	Property Easements [d, e]	0 acres	0 acres	0 acres
Total of Permanent Acquisitions and Easements	**Total Area Acquired**	**0 acres**	**0.1 acres**	**1.5 acres**

a Parcel impacts, displacements, or total acreage, are only counted once when more than one mode (highway, transit, or bicycle and pedestrian) result in the same or overlapping acquisition.

b Does not include WSDOT-owned property or right of way or City-owned right of way.

c Properties associated with Site 1 would be affected by IBR Program roadway and pedestrian improvements regardless of whether the site is developed as a park and ride.

d Airspace easements have not been determined but will be identified prior to construction.

e Subsurface easement requirements are preliminary and will be updated prior to construction.

Table 3.3-5. Summary of Permanent Property Acquisitions and Displacements for the Evergreen Park-and-Ride Facility in Downtown Vancouver

Property Acquisitions and Displacements	Type	Site 1 [a,b,c]	Site 2 [a,b,d]
Parcels (count)	Full Acquisitions	5	0
	Partial Acquisitions	0	0
	Total	**5**	**0**
Displacement of Use	Residential/Commercial	None	None
Permanent Acquisitions	Area Acquired	3.16 acres	0 acres
Permanent Easements	Property Easements [e,f]	0 acres	0 acres

Property Acquisitions and Displacements	Type	Site 1 [a,b,c]	Site 2 [a,b,d]
Total of Permanent Acquisitions and Easements	**Total Area Acquired**	**3.16 acres**	**0 acres**

a Parcel impacts, displacements, or total acreage, are only counted once when more than one mode (highway, transit, or bicycle and pedestrian) result in the same or overlapping acquisition.

b Does not include WSDOT-owned property or right of way or City-owned right of way.

c Properties associated with Site 1 would be developed as a joint venture between the IBR Program and the City of Vancouver.

d The existing parking structure would be used via lease with the existing owner.

e Subsurface easement requirements are preliminary and will be updated prior to construction.

f Airspace easements have not been determined but will be identified prior to construction.

- **Floating Homes in North Portland Harbor.** Up to 35 floating homes in North Portland Harbor would be displaced by the Modified LPA. Floating homes would be treated as personal property and would be relocated to moorages within the area if available. If the relocation study determines that sufficient replacement sites are not available, the floating homes would be purchased at fair market value and the occupants would be provided relocation assistance, which may include payments, if necessary, to acquire decent, safe, and sanitary replacement housing.

Acquisition of DOT-Owned Property

Construction of the Modified LPA would expand into existing WSDOT and ODOT (DOTs) right of way adjacent to I-5. The highway and transit improvements would also require the transfer of other DOT-owned properties located outside of the I-5 right of way. As this land is already owned by the DOTs, it is not counted as an acquisition in the total acreage requirements, although the displacement of the publicly owned facilities *is* included and disclosed in this document.

- **Businesses on Hayden Island.** More than one-quarter of the commercial businesses that would be displaced by the Modified LPA are located on Hayden Island. Although there are multiple vacant buildings on Hayden Island, including those in and around the Jantzen Beach Center, the island has limited capacity to accommodate the 15 businesses that would be displaced. As a result, while some of the displaced businesses would be able to reestablish on Hayden Island or nearby, many may have to relocate outside Hayden Island. Due to natural resource areas and zoning, small restaurants and taverns may not be able to find replacement sites on or near Hayden Island.
- **Marine Businesses in North Portland Harbor.** The marine businesses that would be displaced from the south shore of North Portland Harbor may be difficult to relocate given the limited waterfront space available and the in-water infrastructure these businesses need. These businesses may have to relocate to available sites upstream or downstream on the Columbia River or to sites on the Willamette River.
- **Shared Light Industrial and Residential Uses in Ruby Junction.** Three light industrial businesses would be displaced by the Ruby Junction Maintenance Facility expansion. Although replacement industrial property is available in the Gresham area, some of these displaced parties may have to relocate outside the Gresham area.

The Acquisitions and Displacements Technical Report includes more information on relocation considerations for various property types.

3.3.4 Temporary Effects

Construction of the Modified LPA would include the construction of the new bridges and removal of the existing Interstate Bridge. Constructing the highway, transit, and bicycle and pedestrian facilities of the Modified LPA would require acquisitions, easement, and leases beyond the permanent right-of-way needs. Temporary rights likely would be required for construction, staging areas, and potentially casting yards.

No-Build Alternative

Under the No-Build Alternative, the existing interstate, local roads, and associated infrastructure would remain as they are today. With no new infrastructure, there would be no temporary impacts to properties.

Modified LPA

Construction Easements

Construction easements beyond the permanent acquisitions and displacements reported in Section 3.3.3, Long-Term Benefits and Effects, would be required for the temporary staging of equipment and materials. Property used temporarily during construction would be returned to its owner once construction is complete. Table 3.3-6 summarizes temporary construction easements that would be needed in Oregon and Washington. Temporary easements would not differ among the design options.

Table 3.3-6. Summary of Temporary Construction Easements

State	Residential Properties	Commercial and Industrial Properties	Public Properties	Vacant/Parking Properties	Total Properties
Oregon [a]	1	8	3	3	**15**
Washington	35	16	11	9	**71**

a Expansion at the Ruby Junction Maintenance Facility would not require temporary construction easements.

Staging and Casting Areas

Regardless of the design options selected, staging areas include areas outside of the state or city right of way that could be temporarily acquired for uses such as material or equipment storage, stockpiling soils, or providing employee parking or temporary construction offices. Two sites have been identified as possible major staging areas, including a former I-5 WSDOT rest area (5 acres) and the vacant Thunderbird Hotel site on Hayden Island (3.5 acres).

Casting yards, if used, would be areas outside the state or city right of way that could be temporarily acquired for pre-casting of concrete segments for construction of the bridges and ramps. These areas would require barge access, in addition to road and/or rail access, and could also be used for storage of materials or equipment. The need for casting yards has not yet been determined and would depend on the bridge type and construction methods selected. The need for casting sites would be identified during later phases of project design or by a contractor, and the necessary environmental evaluation and permitting would be completed at that time.

3.3.5 Indirect Effects

Regardless of the design options selected, land uses and properties not directly impacted by the Modified LPA could experience indirect effects. Project elements such as realigned streets, active transportation improvements, and the addition of light-rail could change the viability of and demand for uses within and around the project footprint. Examples of such indirect effects could include denser, multiuse development around transit stations on Hayden Island and downtown Vancouver and additional commercial uses along newly developed roads near the Marine Drive interchange, on Hayden Island, and in downtown Vancouver. As described in Section 3.4, Land Use and Economic Activity, such development would be consistent with current local land use plans, which anticipate and encourage increased density in these areas. Indirect impacts to property could also occur during project construction as a result of road closures, noise, or other construction activities. Properties directly adjacent to acquired properties and to areas of active construction would be most likely to experience these types of impacts.

For additional information on potential Program-related indirect effects, see the Land Use and Economic Activity, Visual Quality, Parks and Recreation, and Noise and Vibration sections of this Draft SEIS.

3.3.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

Where property acquisition and residential or business displacements are unavoidable, those affected would receive compensation and relocation assistance from ODOT or WSDOT, depending on location. Property would be purchased at fair market value, and residential occupants displaced by the Modified LPA would be provided decent, safe, and sanitary replacement housing. Displaced households and businesses would be relocated per the Uniform Relocation and Real Property Acquisitions Policies Act of 1970, as amended (see sidebar). The Acquisitions and Displacements Technical Report includes more information on the provisions of the Uniform Act and the processes used to value properties and provide relocation assistance.

Providing Relocation Assistance

The Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended (Uniform Act) provides important protections and assistance for people affected by federally funded projects. Congress enacted it to ensure that people whose real property is acquired, or who have to move as a result of projects receiving federal funds, are treated fairly and equitably and receive assistance in moving from the property they occupy. The IBR Program and all project partners will follow the requirements of this act.

The Uniform Act provides measures to minimize the hardships of relocation for the occupants. For example, individuals cannot be displaced from their residences unless a comparable replacement residence is available, and individuals cannot be required to move less than 90 days after an offer to purchase has been made. Homeowners and tenants may receive payments for moving expenses and, if necessary, the increased cost of replacement housing. Businesses are also eligible for moving expenses and certain costs to reestablish their businesses. In addition, displaced individuals are offered advisory services to help them successfully relocate. This includes assistance in determining relocation needs, information concerning replacement properties, and timely written notifications of payment eligibility.

After the issuance of the Record of Decision for the SEIS, a Relocation Acquisition Management Plan would be prepared. The Relocation Acquisition Management Plan would contain a detailed analysis of available replacement properties and means for providing replacement housing for residential occupants displaced by the Modified LPA.

Program-Specific Mitigation

No Program-specific mitigation measures are proposed for long-term effects related to property acquisitions and displacements.

Temporary Effects

Regulatory Requirements

There are no specific regulatory requirements for mitigation of temporary property impacts.

Program-Specific Mitigation

As design progresses, the IBR Program would develop approaches to managing temporary construction easements as part of the overall right-of-way plan. The plan would identify measures that contractors would take to avoid, minimize, and mitigate impacts to property temporarily used for construction. Program-specific measures that may be included in the plan to minimize and mitigate for temporary effects related to property acquisition and displacements include:

- Mitigation for construction easements could include payment to property owners in exchange for the use of their property during construction. For example, one method for compensation would be to pay the equivalent of a rental based on the property valuation. Site impacts from temporary construction uses would be restored or compensated according to fair market or contributory value.
- Mitigation may be needed in areas where construction of the Modified LPA could block or impede access to residences or businesses. Continued access to properties during construction would be maintained to the extent possible. Specific provisions may include signage to let the public know that businesses are open and conducting construction during non-peak business hours.

3.4 Land Use and Economic Activity

Jurisdictions in the Portland-Vancouver region integrate transportation and land use planning to help ensure that major transportation improvements do not create unintended or unforeseen effects on land use patterns and the economy. Both Oregon and Washington have growth management laws to regulate land use and growth. The Modified LPA has been designed to accommodate the travel needs of existing land uses and support the region's anticipated growth and economic development. This section evaluates the potential effects of the Modified LPA on the region's land use planning goals and economic activity.

The information in this section is based on data in the Land Use and Economics Technical Reports (Appendix H), which contain greater detail and analysis of the information that follows.

3.4.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with land use and economic activity has been updated in this Draft SEIS to include:

- Updates to land use plans, policies, and regulations at the federal, state, regional, and local levels; updated zoning regulations for the Cities of Vancouver and Portland; updated environmental guidance for ODOT and WSDOT.
- Changes in businesses (e.g., closure of Safeway grocery store on Hayden Island).
- Land use changes in the study area, including development at the Vancouver Waterfront, changes in planned uses on Hayden Island, and recently constructed, altered, or removed buildings.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the light-rail transit alignment and modifying interchange designs.

Table 3.4-1 compares the impacts and benefits of the CRC LPA to those of the IBR Modified LPA. There are no impacts from the Modified LPA that would differ substantially from those of the CRC LPA.

Table 3.4-1. Comparison of CRC LPA Effects and Modified LPA Effects

Technical Considerations	CRC Effects Identified in the 2011 Final EIS	Modified LPA Effects	Explanation of Differences
Direct land use impacts (conversion of a land use to a transportation use)	Approximately 90 acres total (approximately 70 acres in Oregon and 20 acres in Washington).	Approximately 47 acres total (approximately 37 acres in Oregon and approximately 10 acres in Washington, including approximately 4 acres of subsurface easements). Totals would vary slightly among the Modified LPA design options, primarily in downtown Vancouver.	The reduction is due to both changes in land uses and design modifications necessitated by changes in land uses and other changed conditions, including replacing the full interchange on Hayden Island with a partial interchange and moving the light-rail transit alignment along I-5 (removing the proposed couplet in downtown Vancouver).
Consistency with land use plans and policies	Consistent.	Consistent.	N/A
Business displacements	Approximately 70 businesses and 900 employees displaced.	Between 35 and 39 businesses (depending on design option) and up to 758 employees displaced.	The reduction in business displacements and decrease in employee displacement are due to changes in existing businesses as well as design modifications necessitated by changes in land uses and other changed conditions, including replacing the full interchange on Hayden Island with a partial interchange and moving the light-rail transit alignment along I-5 (removing the proposed couplet in downtown Vancouver).
Regional economy	The CRC LPA was determined to be highly beneficial to the regional economy. Some larger vessels would no longer be able to pass under the proposed fixed-span configuration; however, the CRC project worked with those river users to develop measures to avoid economic impacts. With the suspension of the CRC	The Modified LPA would result in benefits to the trucking industry by reducing labor costs, improving safety, potentially improving vehicle operating costs, and reducing scheduling uncertainty. New transit connections in downtown Vancouver would improve travel time accessibility and broaden the pool of labor available along the corridor and in the region. For the Modified LPA with any of the three bridge configurations, marine commerce would be slightly improved for many vessels because	Although the terminology is different, the findings are generally consistent between the CRC LPA and the Modified LPA.

Technical Considerations	CRC Effects Identified in the 2011 Final EIS	Modified LPA Effects	Explanation of Differences
	project, these measures were cancelled.	the new Columbia River bridges would allow most vessels to pass without timing restrictions, providing more flexibility in operating schedules and reducing wait times. Passage of vessels or cargo that require more than 116 feet of vertical navigation clearance would be permanently eliminated under either of the two fixed-span configurations. The IBR Program is coordinating with these existing river users to develop measures to avoid economic impacts through vessel or cargo modifications and other accommodations. No permanent, adverse effects to vessels and cargo shipments would occur with the movable-span configuration. Potential economic effects to businesses and river users that could be constrained by the new Columbia River bridges' height could include increased costs from changes to production, additional freight shipment costs, increased assembly costs, and lost potential for future revenue from projects.	
Estimated reduction in property tax due to business displacement	Approximately $255,300 in Oregon (approximately $326,000 in 2022 dollars [a]). Approximately $12,100 in Vancouver (approximately $21,800 in 2022 dollars [a]).	Approximately $646,200 in Portland in 2022 dollars. Approximately $217,100 in Vancouver in 2022 dollars.	Property values and property tax revenues have increased across the region; hence, the estimated reduction in property tax revenues is larger for the Modified LPA even though fewer properties would be acquired.

Technical Considerations	CRC Effects Identified in the 2011 Final EIS	Modified LPA Effects	Explanation of Differences
Tolling	Variable-rate tolls would range from $1.00 to $2.00 in 2006 dollars. Tolling would likely be beneficial for freight-dependent businesses and businesses that rely on just-in-time deliveries because the predictability of travel times would improve. The collection of tolls would reduce the demand for vehicular capacity.	Variable-rate tolls would range from $1.50 to $3.15 in 2025 dollars/Fiscal Year 2026 dollars (Scenario B – Lower Tolls). Similar to CRC, tolling is expected to be beneficial for freight-dependent businesses and to result in an overall reduction in bridge crossings.	The Scenario B toll rates being evaluated for the Modified LPA are generally comparable to the Scenario 1 toll rates from the 2011 Final EIS after considering the effects of inflation.

a 2022 dollars were estimated using the Bureau of Labor Statistics Consumer Price Index inflation calculator.
CRC = Columbia River Crossing; EIS = final environmental impact statement; LPA = locally preferred alternative

3.4.2 Existing Conditions

Study Areas

Oregon's Statewide Planning Goals and Washington's Growth Management Act agree on general principles of compact urban form, preservation of rural areas, use of urban growth boundaries, and multimodal transportation systems. Regional plans tailor these goals for the Portland-Vancouver region, and local plans further refine these goals and implement them through zoning and development regulations.

The Portland-Vancouver region is located at the confluence of two navigable rivers—the Columbia and the Willamette—and is served by BNSF Railway and Union Pacific Railroad transcontinental rail lines, Portland International Airport, and marine terminals at the ports of Portland and Vancouver. The region's economic competitiveness depends in large part on its role as a gateway and distribution center for domestic and international markets.

The land use analysis considered primary and secondary study areas, shown in

Figure 3.4-1. The primary study area represents the area that would experience direct impacts from construction and operation of the Modified LPA. Because major transportation projects can affect regional growth trends and patterns, the secondary study area was identified to evaluate where indirect effects (e.g., traffic and development changes) could occur. The secondary study area extends from the I-5/I-84 interchange in the south to approximately where I-5 and I-205 meet in the north.

The potential for land use changes that could affect marine commerce is evaluated in the Navigation Impact Report. Appendix A of the Navigation Impact Report assesses existing commercial and industrial development and land uses along the Columbia River upstream of the Interstate Bridge to evaluate the potential for future development that could result in different vessels using the waterway. The appendix identifies properties along the Columbia River that currently have marine facilities available or have the potential for future development of such facilities. It concludes that there are few opportunities for new or expanded commercial and industrial development that would require the use of vessels too large to pass beneath the proposed new

Columbia River bridges. Section 3.4.5, Indirect Effects, provides more information on the potential for upriver marine facility development.

Figure 3.4-1. Land Use Primary and Secondary Study Areas and Existing Land Uses

Like the land use analysis, the economics analysis also considered two study areas (Figure 3.4-2). The primary study area is the same as the land use study area, while the secondary study area is composed of the seven-county Portland-Vancouver Primary Metropolitan Statistical Area (PMSA), which includes the counties of Clackamas, Columbia, Multnomah, Washington, and Yamhill in Oregon, and Clark and Skamania Counties in Washington. This larger area allowed the analysis to consider the potential regional economic effects of the Modified LPA.

Land Use

Oregon

The primary study area is largely composed of commercial land uses with smaller amounts of vacant land, multifamily residential, and parks/open space. The Oregon portion of the secondary study area is largely residential, with commercial activity on the major transportation corridors such as Interstate Avenue and Martin Luther King Jr. Boulevard. The southern portion of the secondary study area (Figure 3.4-3) includes the Lloyd District, which is a mix of residential and commercial land uses and includes regional facilities such as the Moda Center, the Veterans Memorial Coliseum, and the Oregon Convention Center. This area is a major employment center for the region, with several large office buildings housing the Bonneville Power Administration, State of Oregon, Metro and TriMet offices, the Lloyd Center Mall, and various small businesses.

The area of North Portland between N Columbia Boulevard and the Columbia River (Figure 3.4-4) is primarily industrial and commercial uses, but also includes multifamily housing, parks, public facilities, and open space. Some regionally important land uses in this area are the Portland International Raceway, the Expo Center, and an Amazon delivery facility that occupies the site of the former Portland Meadows horse racing track. This area includes the Columbia Slough, Hayden Island, and Delta Park, which contains large wetlands west of I-5 as well as a variety of recreational facilities. Currently, the TriMet MAX light-rail line ends at the Expo Center, just south of the Columbia River. Historically, the city of Vanport was located south of the Expo Center (see Section 3.8, Cultural Resources).

Hayden Island is only accessible via I-5, and N Hayden Island Drive is the main road within the island. The primary land use within this portion of the study area is commercial and includes the Jantzen Beach Center shopping mall and surrounding retailers. Residential land uses on Hayden Island include multifamily residential developments, manufactured homes, and floating homes in small marinas. The Columbia River, the boundary between Oregon and Washington, is lined on both sides by marinas, homes, hotels, restaurants, and public facilities.

The Land Use Technical Report contains a list with additional detail on recent and pending development within the Oregon primary study area. Since publication of the CRC Final EIS, six developments have been completed within the Oregon primary study area, while three are proposed and in various early stages of development permit review. Projects consist of retail commercial, multifamily residential, light industrial, and hotel uses.

Figure 3.4-2. Economic Analysis Primary and Secondary Study Areas

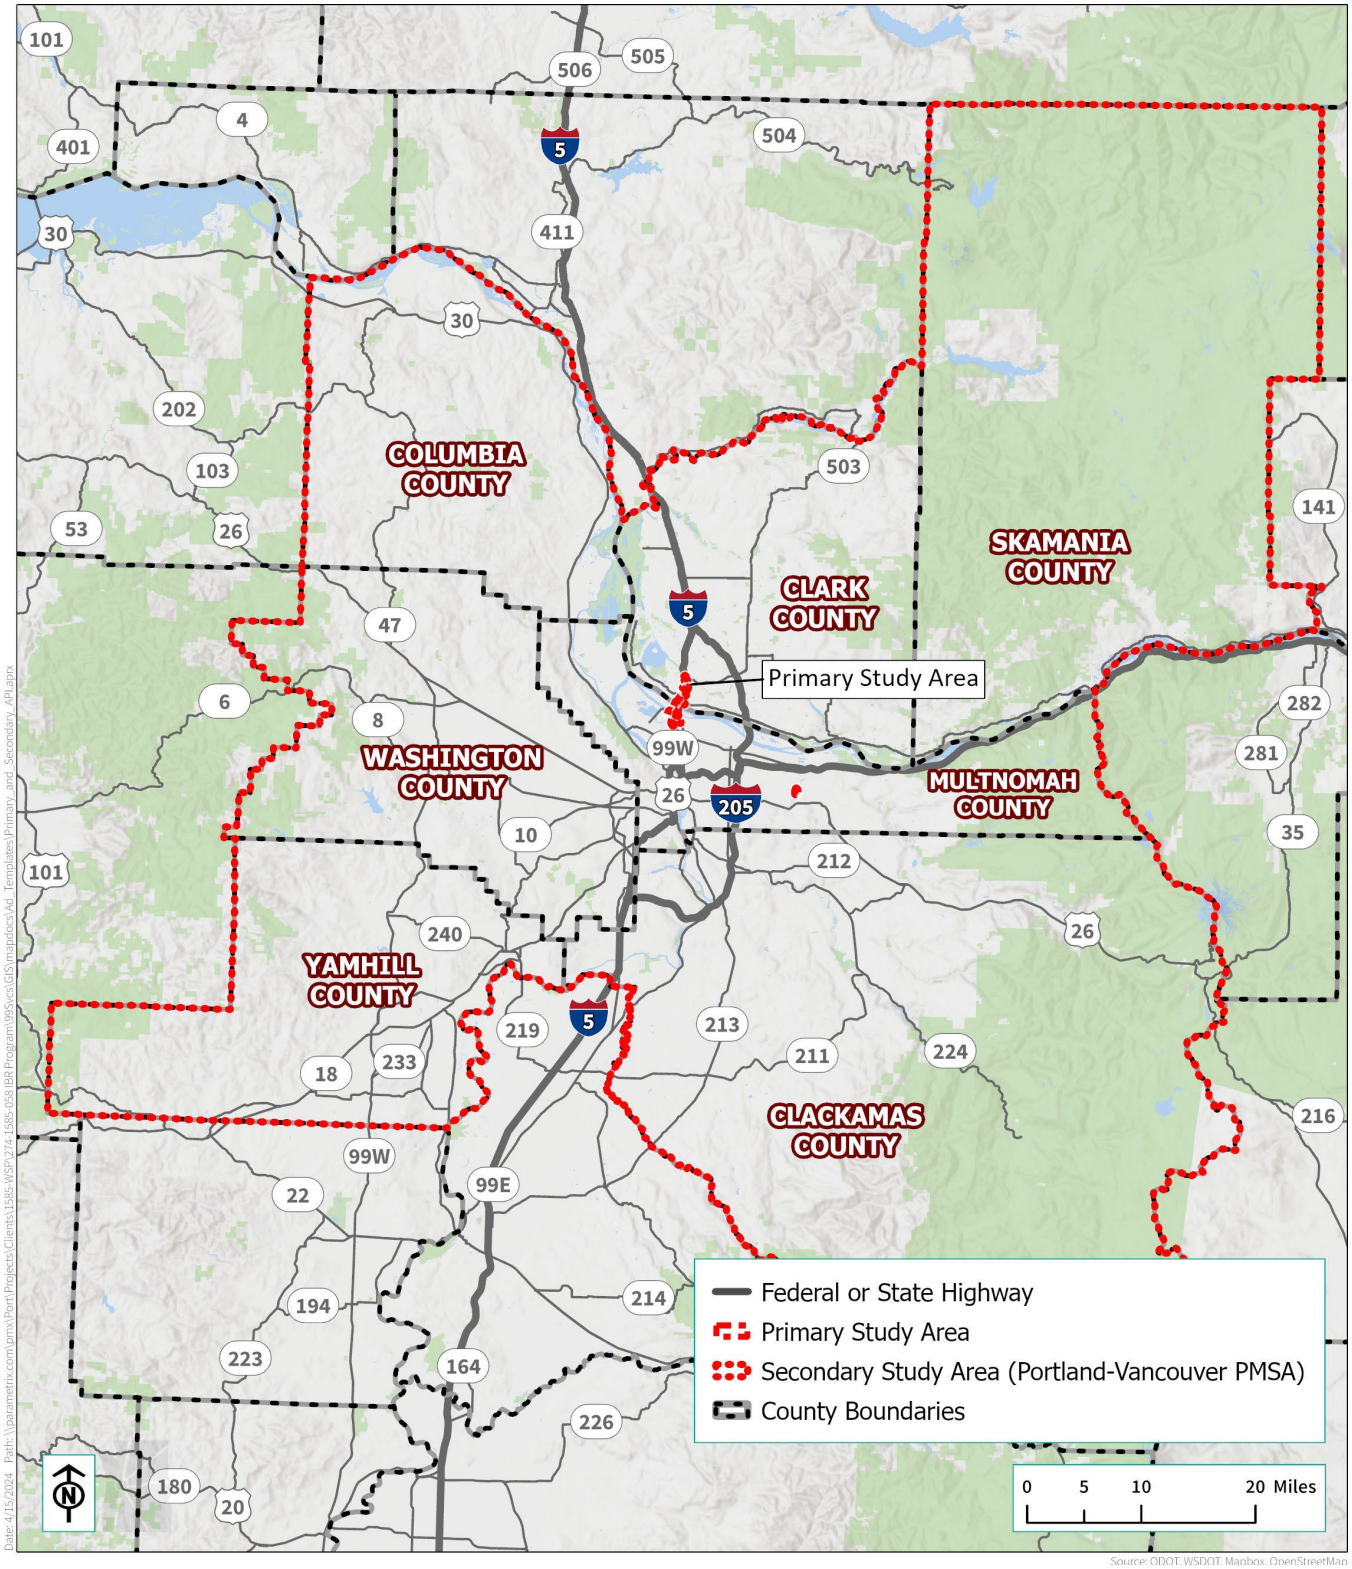

Figure 3.4-3. Existing Land Uses – Southern Portion of the Secondary Study Area

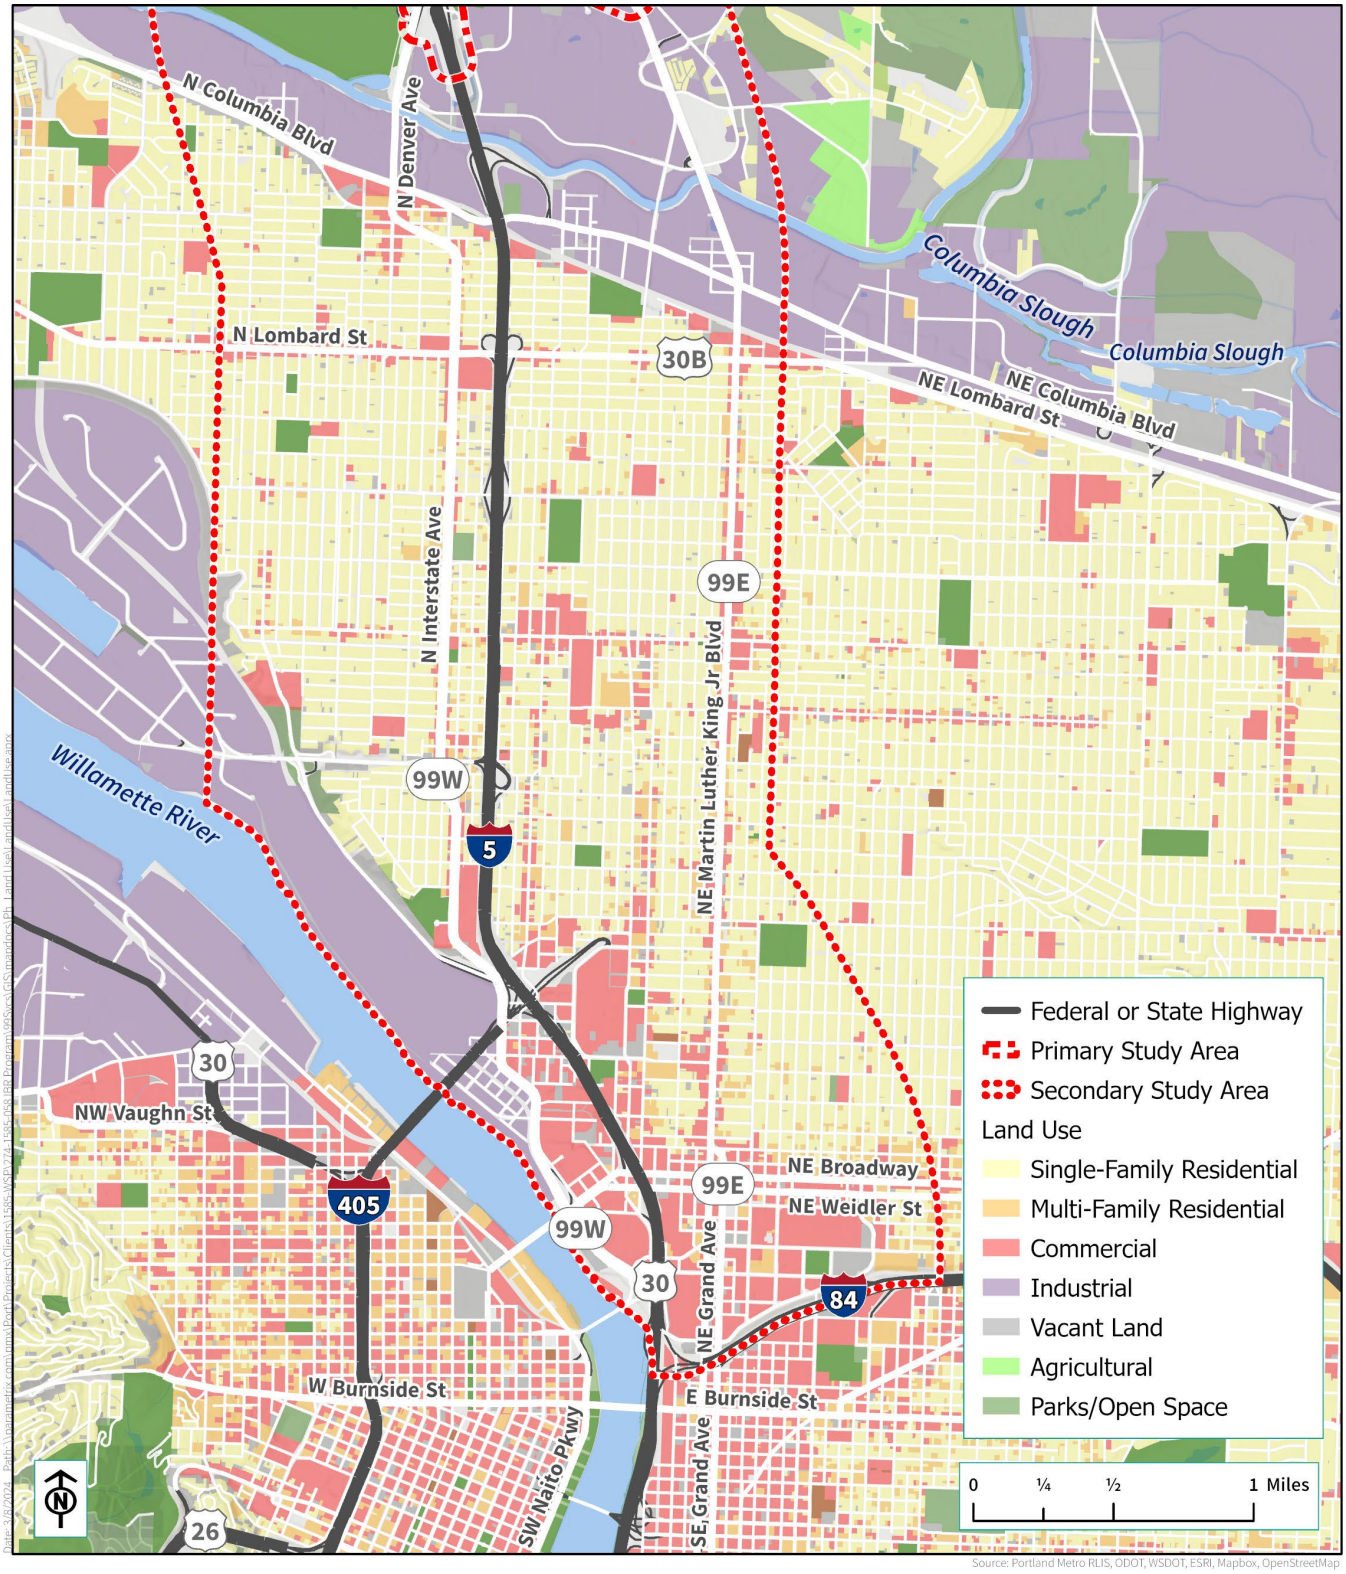

Figure 3.4-4. Existing Land Uses in North Portland, Hayden Island, and the Columbia River

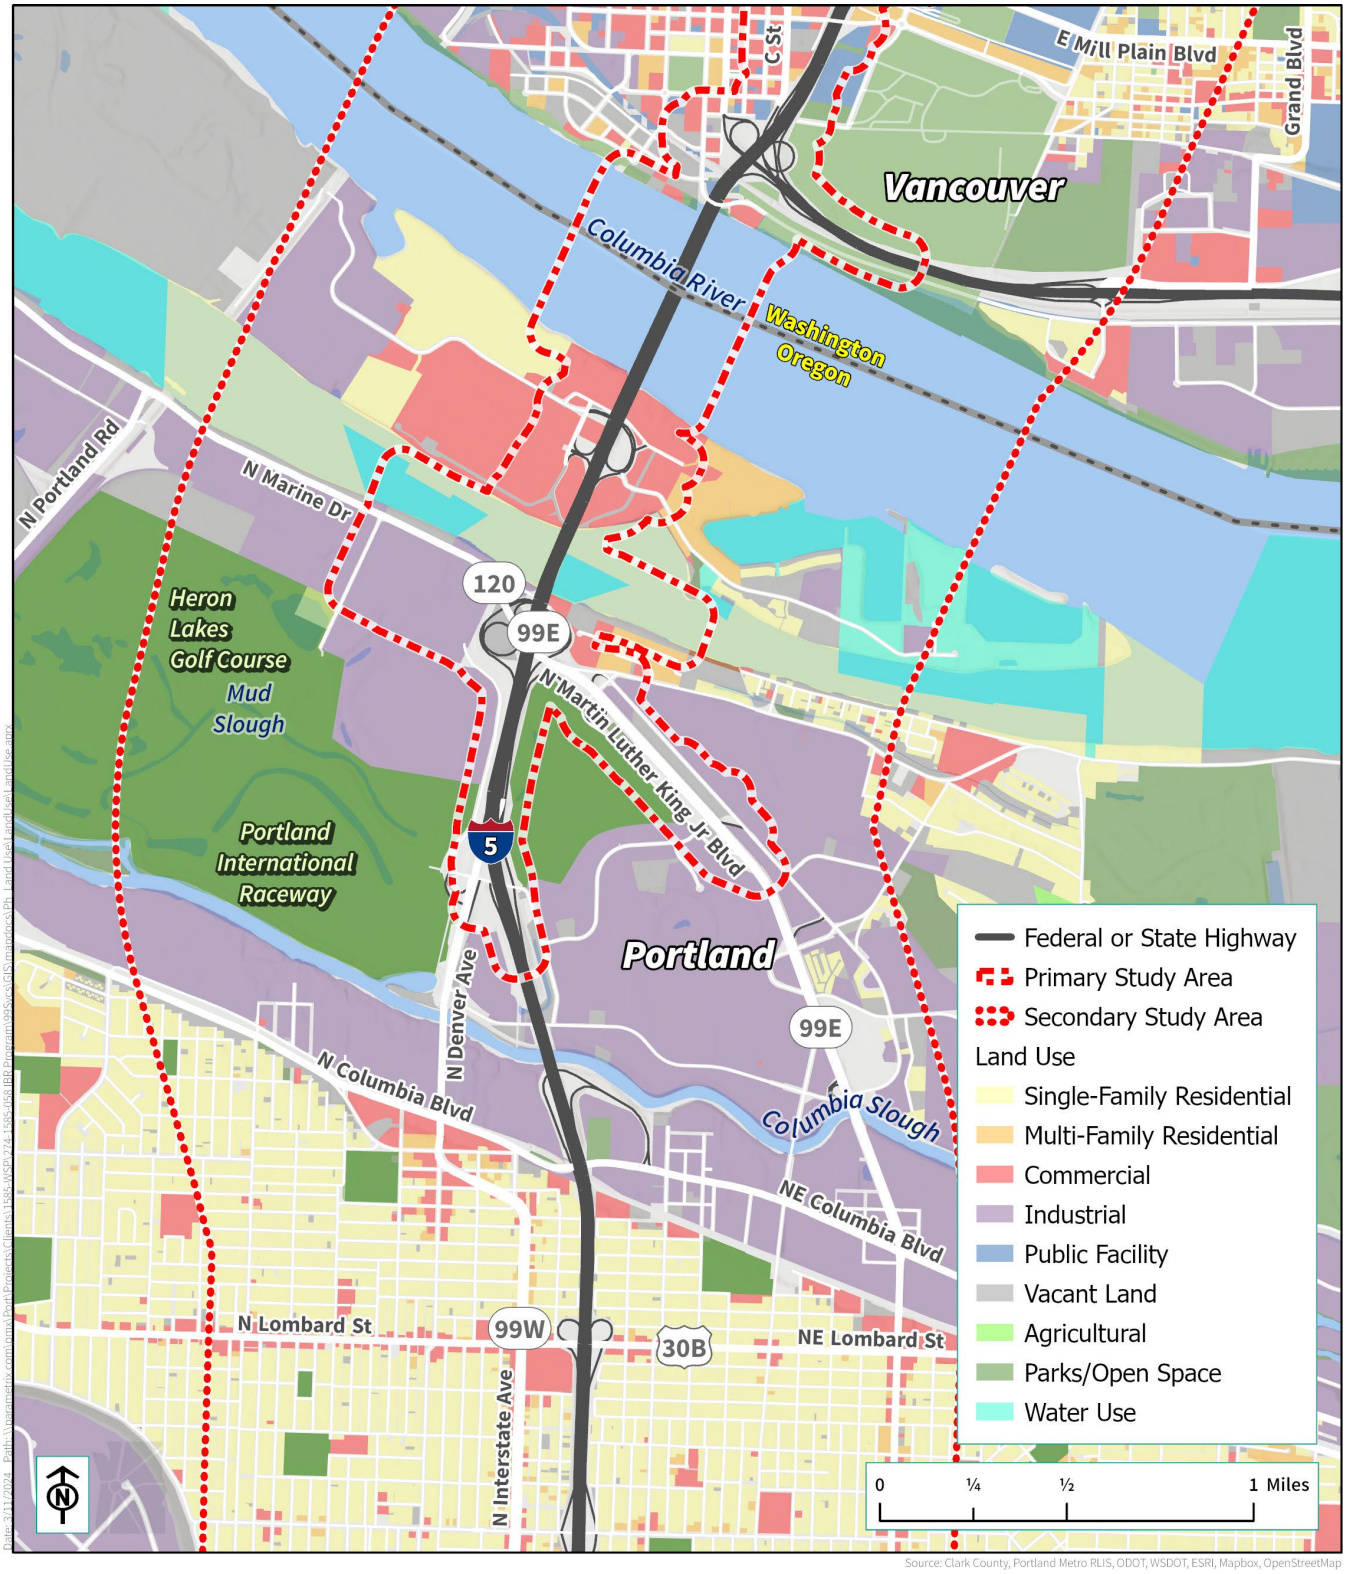

Washington

The Washington portion of the study area includes downtown Vancouver, residential areas, and the National Park Service property and the Vancouver National Historic Reserve (see Figure 3.4-5). Land uses are primarily commercial (including retail, offices, industrial, governmental) and residential. Community facilities include an Amtrak train station, C-TRAN bus rapid transit facilities (including Turtle Place Transit Station), Esther Short Park, the Vancouver Waterfront, and various government offices. The current I-5 corridor divides the downtown area, with the commercial/office center on the west and the Vancouver National Historic Reserve and Clark College on the east. E Evergreen Boulevard and E Mill Plain Boulevard provide east-west connections across I-5.

North of the central city, commercial development is centered on I-5 and Highway 99 (Figure 3.4-6). East and west of I-5, much of the secondary study area is single-family residential with some multifamily districts along major roadways. Public facilities, parks, and open spaces are located throughout the secondary study area. The Vancouver urban growth boundary is just north of the secondary study area, at the intersection of I-5 and approximately 209th Street.

The uptown commercial district (between Mill Plain and Fourth Plain Boulevards on Main Street) is a transitional area between downtown and the lower-density land to the north. The area contains primarily residential uses, with major transportation corridors supporting commercial uses. The current municipal boundary of the City of Vancouver is roughly along 63rd Street.

North of 63rd Street, and south of Salmon Creek and 119th Street, residential areas consist of large-lot single-family uses. The commercial areas (along Highway 99 and Hazel Dell Avenue) have frequent bus service but are primarily auto-oriented. Infill development of single housing units and very small subdivisions is being built on lots previously used as farmland. Commercial areas along 134th Street and Highway 99 are auto-oriented. This area includes a number of regional facilities: the Clark County Fairgrounds, the Clark County Amphitheater, and Legacy Salmon Creek Hospital. The Washington State University Vancouver campus is located just outside the secondary study area. I-5 and I-205 come together in this area, as do 134th Street, Salmon Creek Avenue, and Highway 99. Congestion from these major roadways has twice led to development moratoria in the area.

The Columbia Business Center is an industrial park located approximately 1.2 miles upriver from the Interstate Bridge. It was once the location of the Henry J. Kaiser Vancouver Shipyard established in 1942 as an emergency shipyard to build vessels for World War II. The last ship was delivered in 1946 and the shipyard was closed thereafter. The Columbia Business Center includes approximately 2.3 million square feet of space in 27 buildings and approximately 1.0 million square feet of leasable space. The Columbia Business Center provides both barge and rail access. The BNSF Railway mainline borders the north side of the property. The East Barge Slip is used to receive and ship fabricated steel products, construction materials, and supplies. The West Barge Slip is not active and as of 2021 there were no plans to improve it. There is a dock located just to the west of the West Slip, which is used by a marine shipyard services company.

The Land Use Technical Report contains additional detail on recent and pending development within the Washington primary study area. Since publication of the CRC Final EIS, 10 or more projects have been completed within the Washington primary study area, while 5 are under construction and 3 are proposed or in various stages of development permit review. These projects consist of several multifamily residential and mixed-use multifamily residential/commercial developments, along with commercial office, hotel, and public projects including a library and an elementary school.

Figure 3.4-5. Existing Land Uses in Downtown Vancouver

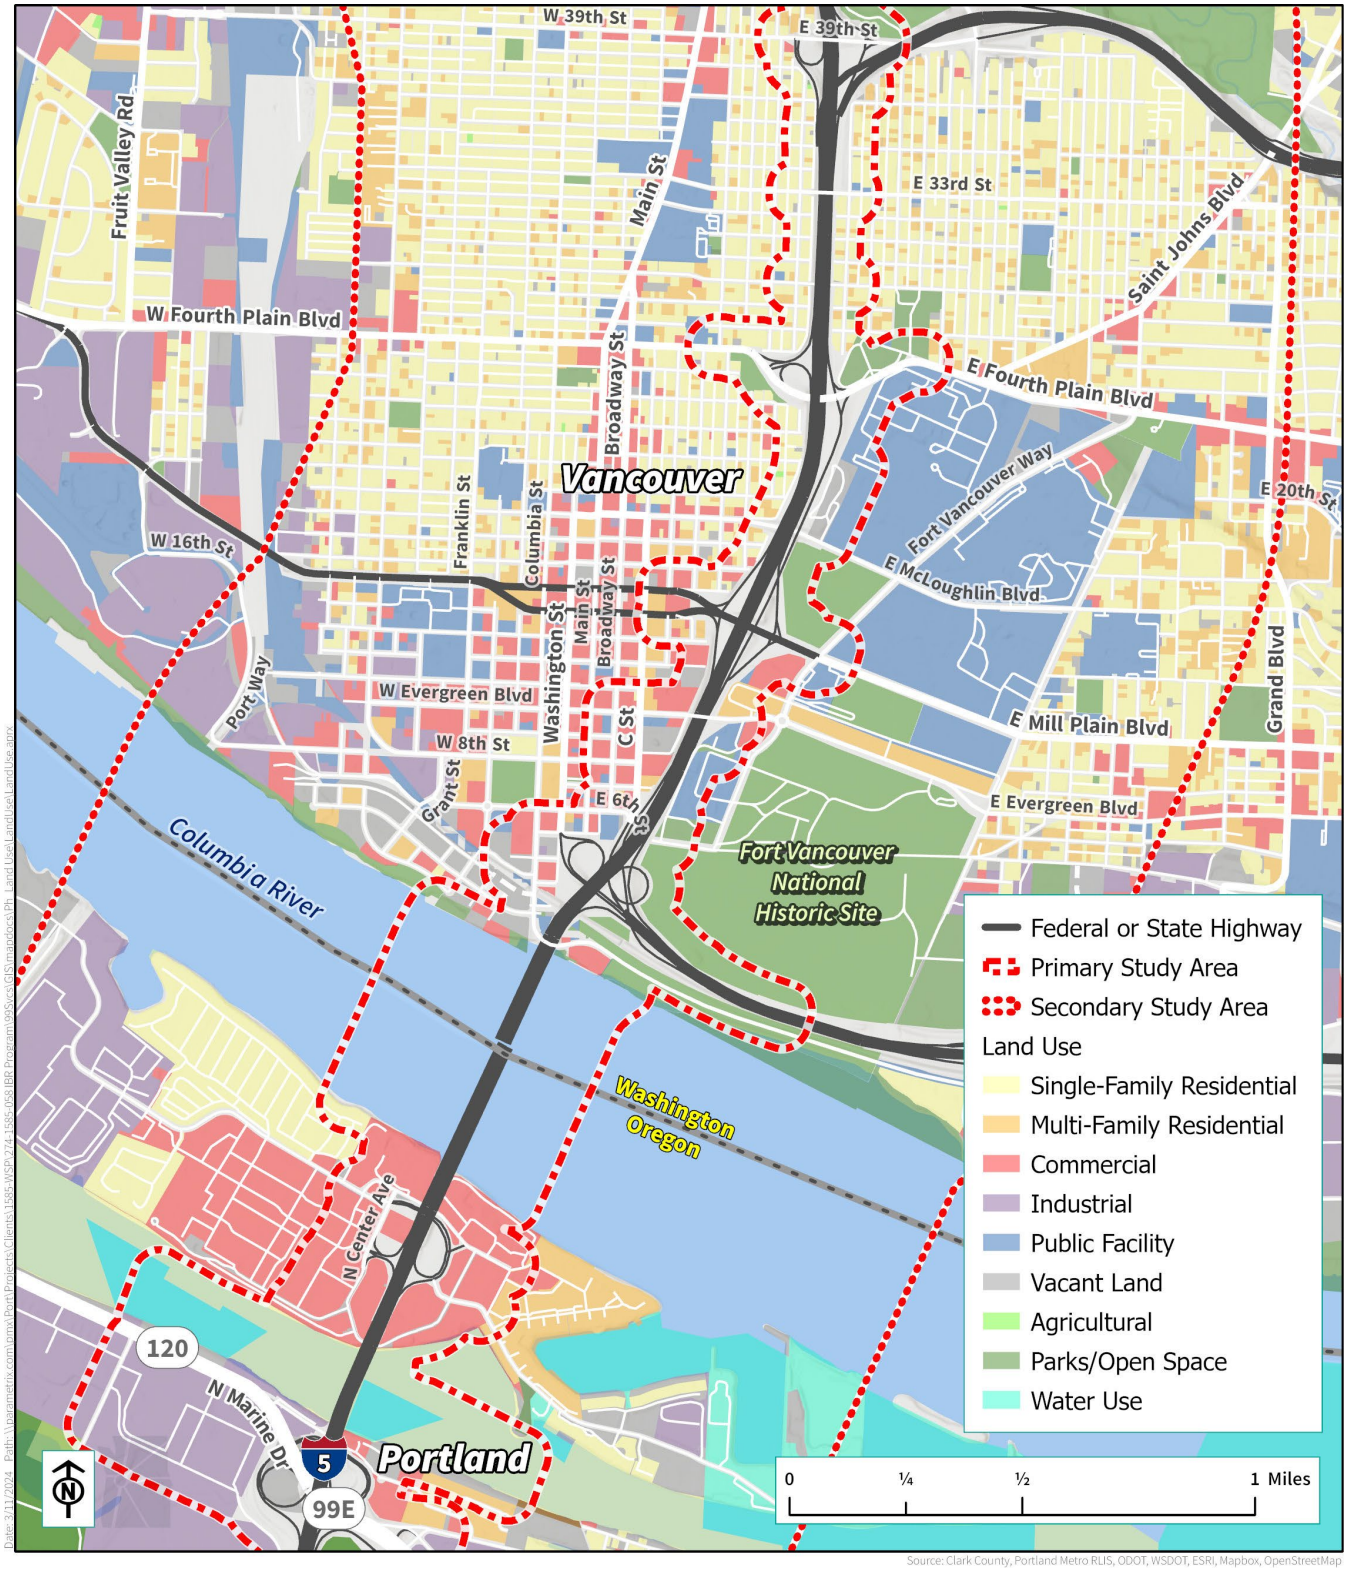

Figure 3.4-6. Existing Land Uses in North Vancouver and Clark County

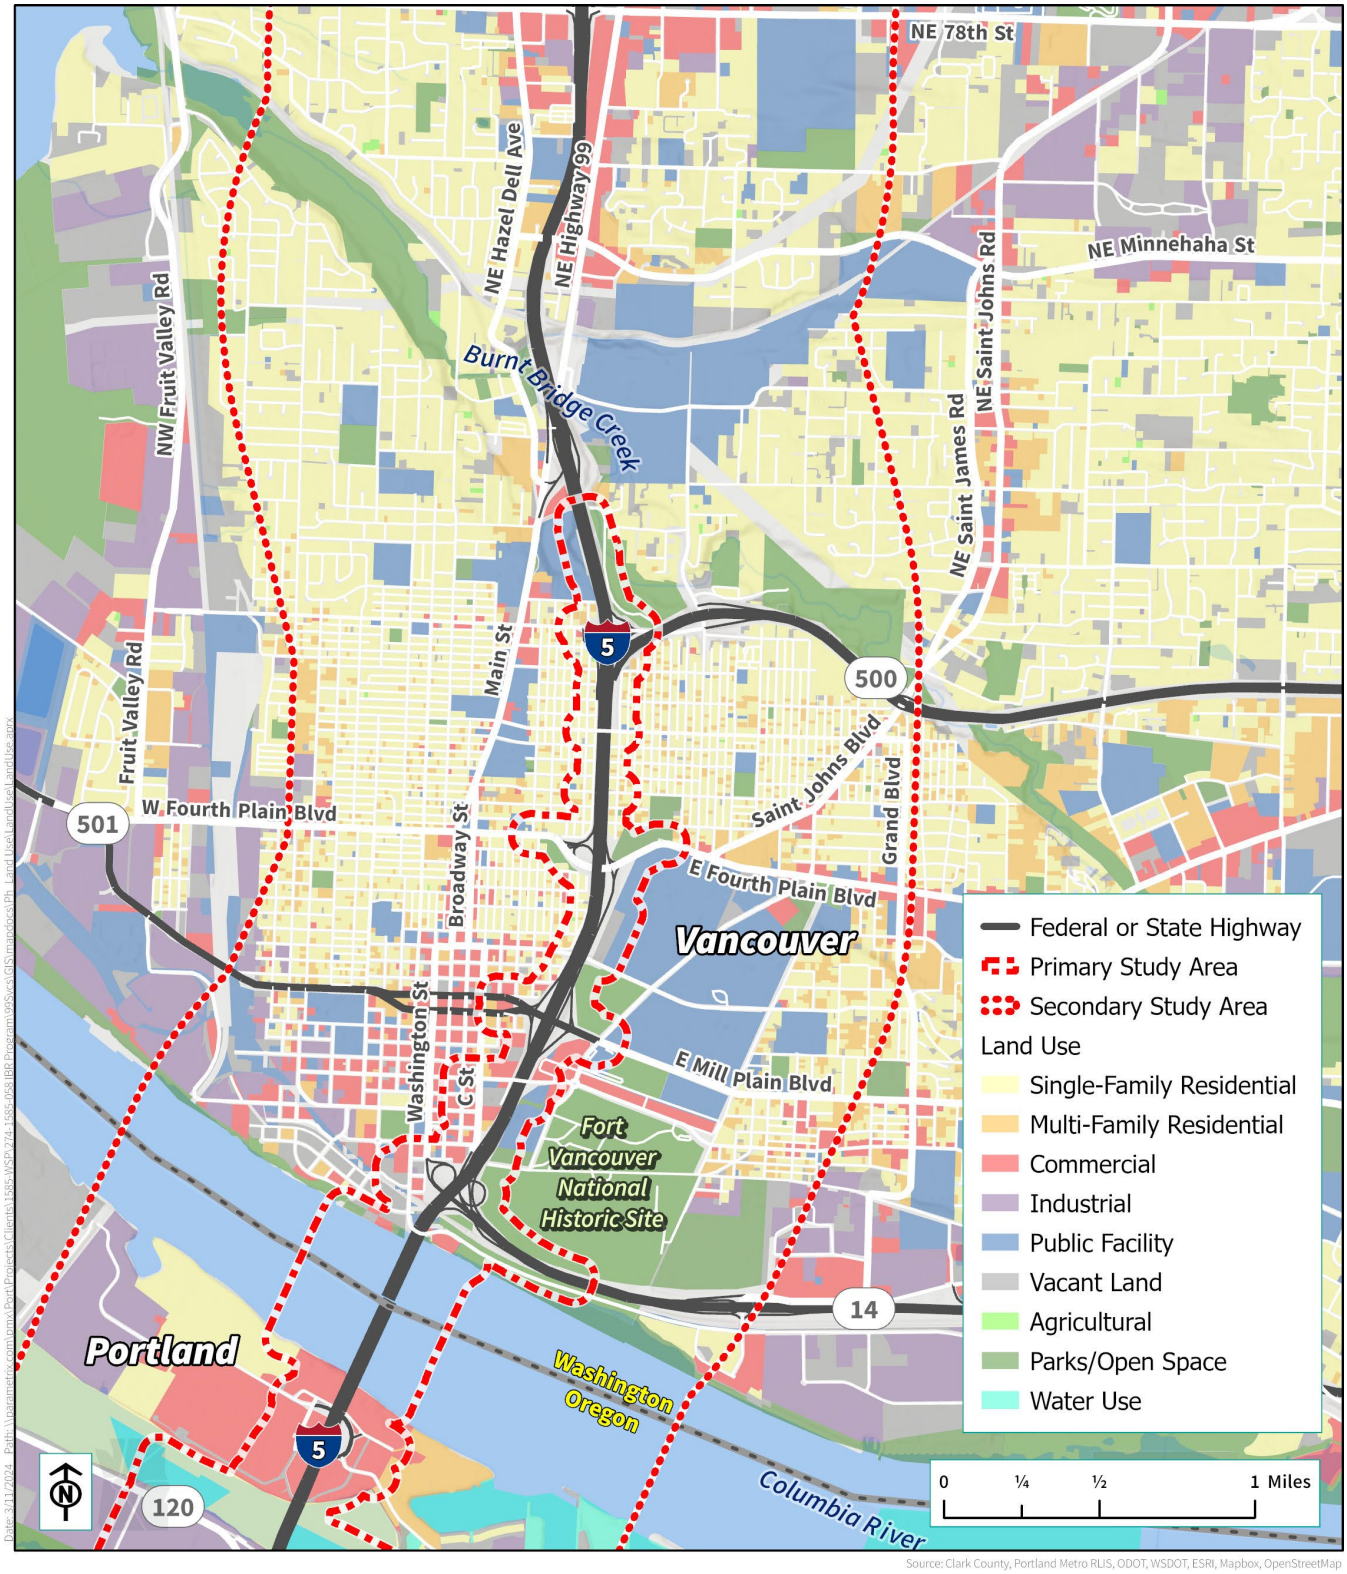

Economics

Regional Conditions

Many of the region's industries, including private marine facilities, depend on the movement of freight and reliable freight access to stay competitive locally and internationally.

From 2015 to 2020, the unemployment rate for the Portland-Vancouver PMSA, which includes Clark, Clackamas, Multnomah, Yamhill, Columbia, and Skamania Counties, trended lower than overall rates in Washington, Oregon, and the nation (BLS 2021). Unemployment spikes in 2009 to 2011 and in 2020 were caused by the economic recession and the pandemic, respectively. The most recent unemployment information (2021) shows a positive trend of economic recovery from the COVID-19 pandemic. Data on unemployment rates show 3.9% for the region, 4.7% for Oregon, 4.9% for Washington, and 4.8% nationally.

The number of jobs in the Portland-Vancouver PMSA increased by 301,160 (or 33.5%) between 2002 and 2019 (U.S. Census Bureau 2019); the largest increases were in health care and social assistance (3.2% increase) and professional, scientific, and technical services (1.5% increase). In the same time period, the largest decreases in employment share were in manufacturing (2.9% decrease) and retail trade (1.3% decrease). Of the Interstate Bridge commuters, 79% are residents of Clark County who work in the Oregon PMSA counties, and 21% are Oregon PMSA residents working in Clark County (U.S. Census Bureau 2018).

Table 3.4-2 lists the 10 largest employers in the Portland-Vancouver Metropolitan Statistical Area (MSA), which includes Clackamas, Multnomah, Washington, and Clark counties (as of September 2023). Each of these businesses depends on the region's transportation system to provide reliable movement of goods and services, and on the I-5 corridor to connect to Mexico, California, and Canada.

Table 3.4-2. Largest Employers in the Portland-Vancouver Metropolitan Statistical Area

Rank	Employer	No. of Employees
1	Providence Health System	23,100
2	Intel Corp.	22,328
3	Oregon Health & Science University	19,603
4	Nike, Inc.	15,522
5	Legacy Health System	13,087
6	Kaiser Permanente	12,514
7	Fred Meyer Stores	9,000
8	Portland Public Schools	7,111
9	City of Portland	6,753
10	Multnomah County	6,317

Source: Portland Business Journal 2023

In the Portland-Vancouver MSA, the median household income increased from $56,000 in 2010 to $75,000 in 2019, below the Washington median of $78,687 but above the Oregon and national medians, $67,058 and $65,712 respectively.

In 2012, the most recent year for available data, retail sales totaled $40.4 billion per year in the Portland-Vancouver MSA (U.S. Census Bureau 2012).

The ports of Portland and Vancouver are critical to the economic growth and prosperity of the region. The total annual tonnage moving through the two ports is expected to double from approximately 300 million tons in 2007 to almost 600 million tons in 2040 (Cambridge Systematics 2015). Commodities moved by trucks are expected to grow from about 200 million tons to about 400 million tons, though the percentage of total freight transported by truck is expected to remain roughly the same at 67%.

Approximately $133 million in commodity value was transported by trucks daily across the Interstate Bridge in 2019. The projected growth in truck traffic, along with passenger travel, has implications for the roadway network and capacity needs, as efficient and safe movement of products to and from the ports is needed to maintain their competitiveness. See the Economics Technical Report for more detail on the transport of commodities by mode through the Port of Portland and the Transportation Technical Report for more detail on freight moved by truck. Commodity transport by ship and tug/tow is also important to the regional economy. Inland navigation along the 360-mile Columbia Snake River System, Portland/Vancouver to Lewiston, Idaho, carried over 8.3 million tons of commercial cargo in 2020 (PNWA 2024). Recreational vessels, such as sailboats, powerboats, personal watercraft, and yachts modestly contribute to the regional economy.

As described in Chapter 2, the existing Interstate Bridge provides a maximum vertical clearance of 72 feet when closed and a maximum vertical clearance of 178 feet when the lift span is opened. Apart from a small number of specialized vessels that use the river infrequently, the majority of vessels require vertical clearances of less than 90 feet from the surface of the water to the bottom of the bridge deck. Required openings of the Interstate Bridge have declined from an average of 289 per year between 1997 and 2011 to 157 per year between 2012 and 2020. Approximately 58% of the bridge openings were for tugs, 17% were for sailboats, and the remainder were other vessel types. These openings are required for 5% to 7% of the total river traffic, based on openings of the BNSF Railway Bridge just downstream of the Interstate Bridge and use of the locks at the Bonneville Dam. Currently, bridge openings are restricted to non-peak commute hours to minimize stopping traffic on I-5.

Because the Portland-Vancouver region depends on the distribution of goods to broader regional, national and global markets, it is susceptible to long-term economic losses from traffic congestion.

Local Conditions

Table 3.4-3 presents Metro's recent and forecast population data for the primary study area, by state and for the four-county Portland-Vancouver Standard Metropolitan Statistical Area (SMSA).[1] Between 2015 and 2045, Metro forecasts that Portland-Vancouver SMSA will grow by an annual 1.4%, lower than the projected 2.7% growth for the Oregon portion of the study area, but slightly higher than the 1.1% forecast for the Washington portion.

Table 3.4-3. Population Forecast in the Primary Study Area

Area	2015	2045	Average Annual Growth Rate
Oregon (study area only)	61,362	110,128	2.7%
Washington (study area only)	60,228	80,323	1.1%
Portland-Vancouver SMSA	2,006,417	2,850,534	1.4%

Source: Metro 2021

[1] Forecast data provided by Metro includes the four-county SMSA, which includes Clark, Clackamas, Multnomah and Washington counties. The PMSA includes these four counties and also includes Yamhill and Columbia Counties in Oregon and Skamania County in Washington.

Between 2015 and 2045, the number of households in the Portland-Vancouver SMSA is forecast to grow approximately 1.5% per year; this is lower than the 2.7% projected for Oregon but higher than the 1.2% projected for Washington. Forecast household growth in the Portland-Vancouver SMSA is similar to population. However, the Metro forecast predicts a slight decrease in persons per household, declining from 2.36 in 2015 to 2.32 in 2045 (assuming no change in housing vacancy rates). Table 3.4-4 presents recent and forecast household data.

Table 3.4-4. Household Forecast in the Primary Study Area

Area	2015	2045	Average Annual Growth Rate
Oregon (study area only)	26,023	47,469	2.7%
Washington (study area only)	25,542	34,622	1.2%
Portland-Vancouver SMSA	850,898	1,228,679	1.5%

Source: Metro 2021

Table 3.4-5 presents employment forecast data for the Oregon and Washington portions of the primary study area and the Portland-Vancouver SMSA. Between 2015 and 2045, Metro forecasts total employment in the SMSA to grow by approximately 1.6% per year, slightly higher than the 1.1% forecast for Oregon and the 1.0% forecast for Washington.

Table 3.4-5. Employment Forecast in the Primary Study Area

Area	2015	2045	Average Annual Growth Rate
Oregon (study area only)	55,251	73,186	1.1%
Washington (study area only)	36,647	47,914	1.0%
Portland-Vancouver SMSA	1,072,925	1,592,290	1.6%

Source: Metro 2021

Both the City of Portland and the City of Vancouver rely on tax revenues to fund general services. Portland's largest source of revenue is property taxes (49%), as Oregon does not have a sales tax. In Vancouver, the largest source of revenue is business and occupation taxes (32%), followed by property tax and then sales tax.

Marine Commerce

The Columbia River has been a commerce route from time immemorial for Native Americans. European and European American contact with the Columbia River occurred around 1800 and prompted further exploration, trade, and settlement activities. The Interstate Bridge (existing northbound span) was built and opened in 1917, replacing a ferry system to transport people and goods across the river. The original bridge included a lift span to accommodate navigation for vessels and cargo with heights up to 178 feet. In 1958, a second bridge (existing southbound span) was completed and opened for traffic; this bridge was designed as a twin to the original bridge, including a lift span to accommodate navigation. For over 100 years, the Interstate Bridge has supported navigation on the Columbia River for commerce, recreation, and government agency missions.

Commercial vessels on the Columbia River include cruise vessels, tugs, tows, barges, and marine contractors' vessels. Several passenger cruise lines host tours up and down the Columbia and Snake Rivers and require frequent passage under the Interstate Bridge during the cruise season. Commercial tugs and barges have the highest share of river usage and transit year-round and accounted for approximately 54% of the bridge opening events across a 35-year study period. Tugs and barges are usually able to use the barge channel or alternate barge channel unless river and weather conditions are a factor or cargo requires additional vertical clearance. Tugs and barges will request an opening of the Interstate Bridge to provide sufficient vertical clearance or minimize safety hazards between the Interstate Bridge and the BNSF Railway Bridge downstream.

Marine contractors use vessels such as crane barges, dredges, and other construction equipment transported on the Columbia River. Transits of the Interstate Bridge are not limited to a particular time of year or frequency, as construction work is typically performed on an as-needed or contract basis. Whether the transport of construction equipment requires a bridge opening event depends upon the contractor's location and the location of the construction project. Construction equipment used by marine contractors accounted for an average of 17% of bridge opening events, ranging from no lifts (2013) to a high of 32% (1989 and 2000).

Existing horizontal and vertical obstructions limit the size of vessels on the Columbia River upriver of the Interstate Bridge. The BNSF Railway Bridge at Celilo Falls, located 95 miles upstream of the Interstate Bridge, has a vertical clearance of 79 feet in the raised position. Upstream from Celilo, several bridges and other obstructions such as power cables further limit the vertical clearance on the river to less than 79 feet. In addition, the Bonneville Locks and all other locks on the Columbia/Snake River system constrain navigation uses to a maximum width of 86 feet, which prohibits passage by ocean-going barges.

3.4.3 Long-Term Benefits and Effects

Table 3.4-6 summarizes the effects of the No-Build Alternative and the Modified LPA, and its design options, on land use and economics. Effects were evaluated for the Program analysis year of 2045. Additional information on the effects is provided in the sections that follow.

No-Build Alternative

Land Use

The No-Build Alternative would not address current deficiencies in the Interstate Bridge structure, design, or capacity. Existing land uses that rely on I-5 to travel within the region would remain vulnerable to high levels of congestion, unsafe conditions, and potential earthquake-induced failure. There would also be no high-capacity transit service to connect the regional centers of downtown Vancouver and downtown Portland, which would be inconsistent with the stated policies and goals of applicable regional transportation plans.

Under the No-Build Alternative, increased growth in the region by 2045 would result in traffic congestion that would impair road-based freight movement and reduce the region's productivity. This could indirectly impede the effective implementation of land use plans and hinder goals for economic development. A loss in the growth of local jobs could have impacts such as decreased property values, increased commercial vacancies, and reduced demand for downtown revitalization. Refer to Section 3.1, Transportation, of this Draft SEIS for more information on the No-Build Alternative traffic conditions.

Table 3.4-6. Summary of No-Build Alternative and Modified LPA Effects on Land Use and Economics

1	2	3	4	5	6	7	8
No-Build Alternative	**Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5**	**Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5**	**Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift**	**Modified LPA with Single-Level Fixed-Span Configuration, [a] One Auxiliary Lane, C Street Ramps, Centered I-5**	**Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5**	**Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, without C Street Ramps, Centered I-5**	**Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, Park-and-Ride Site Options**
• Existing land uses would remain vulnerable to high levels of congestion, unsafe conditions, and potential earthquake-induced failure. • No high-capacity transit, which is inconsistent with the stated policies and goals of regional transportation plans. • Congestion would impair freight movement and reduce area productivity, which could indirectly impact the implementation of land use plans and goals for economic development. • Loss in job growth could lead to decreased housing prices, increased commercial vacancies, and reduced demand for downtown revitalization.	• Converts approximately 47 acres of land to transportation use; currently primarily zoned industrial or commercial, with some land zoned residential. • High-capacity transit is consistent with state, regional, and local plans and policies. • Higher toll rates during peak periods would support regional and local policies for congestion and are not expected to change land use patterns. • Property tax revenues would be reduced compared to the No-Build Alternative. • Business displacements have the potential to impact 616 employees; affected businesses would be provided relocation assistance. • Bridge height would exclude up to eight existing users/vessels that require more than 116 feet of vertical clearance from passage underneath the new Columbia River bridges.	Similar to Column 2, except: • Slightly more acquisition of property at the Fort Vancouver National Historic Site. • Improved traffic operations (shorter duration and length of congestion, reduced travel times, and improved mobility options) compared to design options with a single auxiliary lane would result in improved mobility and access for freight and employment.	Similar to Column 2, except: • Larger areas of properties would be permanently acquired. • Additional 1 acre of permanent acquisition. • Additional three business displacements. • Potential to impact 142 additional employees.	Similar to Column 2, except: • Lower maximum bridge height and reduced highway grade would benefit freight vehicle speed compared to double-deck bridge, with corresponding economic benefits.	Similar to Column 2, except: • Bridge openings could interrupt vehicle and truck highway travel, transit service, and active transportation across the new Columbia River bridges. • No existing or future maritime vessels or cargo freight would be excluded from passage. • Lower bridge height compared to fixed-span configurations would allow fewer existing marine users/vessels to pass without a bridge opening. Movable-span operations, and thus river navigation operations, may have increased restrictions on bridge openings, which could impact marine commerce by restricting the times of day for large vessel movements.	Similar to Column 2, except: • Removal of the C Street ramps would result in traffic delay and increased travel times near the Mill Plain Boulevard interchange and in downtown Vancouver, which would have an economic impact on local businesses.	Similar to Column 2, except: Waterfront Station Locations: • Site1: Additional 0.1 acres acquired. • Site 3: Additional 1.5 acres of permanent acquisition; Potential to impact 53 additional employees. Evergreen locations: • Site 1: Additional 3.16 acres acquired, no displacement. • Site 2: No acquisition or displacement.

a The effects associated with the single-level fixed-span configuration would be the same for all bridge type options.

Economics

The No-Build Alternative would retain the existing Interstate Bridge and would only make minor preservation improvements to I-5 within the study area. Several local road projects are planned to improve freight mobility, access, and safety in the study area, and those would continue. The Interstate Bridge would increasingly serve as a bottleneck for southbound traffic, including freight traffic. Traffic operations forecasts indicate that congestion on the bridge on weekdays would last from 5 a.m. to 9 p.m., a total of 16 hours. In the northbound direction, congestion on the bridge would last 14 hours, from 7 a.m. until 9 p.m.

Under the No-Build Alternative, no businesses in Oregon or Washington would be displaced by right-of-way acquisition, and there would be no resulting decrease in property or sales tax revenues or jobs. However, increasing congestion on I-5 could result in significant economic effects, as planned economic development may occur more slowly with business owners reluctant to locate in an area with poor access and mobility for employees and customers. Freight reliability would decrease as congestion would continue to spread throughout the day. Customers could elect to shop in areas with better access and mobility.

Modified LPA

Most long-term effects on land use and economics would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Land Use

Long-term direct land use impacts are defined as converting land from its existing use to a transportation use. This analysis of direct impacts is based on acquisition data developed for the Modified LPA, as described in Section 3.3, Property Acquisitions and Displacements.

Approximately 47 acres of property would be permanently acquired for the construction and long-term operation and maintenance of the Modified LPA. The exact total would vary between approximately 47.1 acres and 47.5 acres, depending on the design option; variations in acquisition among the design options would occur only in the Washington portion of the study area. All design options would include approximately 4.3 acres in permanent subsurface easements, which are required for the potential installation of tie-back anchors associated with retaining walls.

Most of the land that would be acquired is currently zoned industrial or commercial, with some land zoned residential in upper Vancouver. Although these conversions would reduce the area of land available for non-transportation uses, they would comprise only a small portion of the total land in the Portland-Vancouver area and would not be substantial in a regional context. The acquisition of new right of way, displacement of active land uses, and other impacts would not lead to a significant change in the mix of land uses, land use patterns, zoning, or land use plans in the study area.

The transportation infrastructure associated with the Modified LPA, such as the extension of light-rail transit, would be consistent with the goals and policies of adopted land use plans as described in the “Consistency with Plans and Policies” section below and summarized in Table 3.4-10. Consistency with applicable land use plans and policies is also detailed in the Land Use Technical Report.

Oregon

Table 3.4-7 shows the change in land use from acquisitions in Oregon by zoning designation. The extent of direct land use impacts from property acquisitions would be the same for all of the design options. A total of 68 parcels, comprising over 37 acres, would be affected; 25 of these parcels would be fully acquired and 43 would be partially acquired. Partial acquisitions may not require the acquisition of buildings or affect the current use of the property. Partially acquired properties which require displacement of buildings or businesses may still leave a portion of the parcel available for redevelopment.

As described in Chapter 2, the construction activities associated with the Modified LPA would likely require both temporary and permanent modifications to portions of the Portland Metro Levee System, which is a system of federal flood control levees located along the south bank of the Columbia River/North Portland Harbor within the primary study area. Modifications may include activities to restore temporarily disturbed portions of the levees, permanent modifications where proposed infrastructure would intersect with the existing levees, or changes in access to the levees as a result of roadway reconfiguration. Modifications or improvements would be coordinated for consistency with the planned future condition of the levees under the Columbia Corridor Drainage Districts Joint Contracting Authority's Levee Ready Columbia project. The assessment of long-term effects to land use and economics associated with the Modified LPA presented in this section includes those associated with potential modifications to the federal levee system.

Table 3.4-7. Oregon Right-of-Way Acquisitions by Zoning Designation

Area	Zoning [a]	Acquisition Type	Parcel Count	Total Permanent Land Use Acquired (acres)
Oregon Mainland	CE	Full	1	1.59
	CM2	Partial	3	0.06
	IG2	Full	1	1.02
	IG2	Partial	13	7.42
	OS	Partial	4	2.13
Subtotal (Oregon Mainland)	N/A	N/A	**22**	**12.22**
Ruby Junction	HI	Full	4	4.41
	HI	Partial	2	0.26
	SC-RJ	Partial	1	0.31
Subtotal (Ruby Junction)	N/A	N/A	**7**	**4.98**
Hayden Island	CE	Full	17	10.88
	CE	Partial	11	7.26
	CM1	Full	2	0.27
	CM1	Partial	9	1.47
Subtotal (Hayden Island)	N/A	N/A	**39**	**19.88**
Totals	**N/A**	**N/A**	**68**	**37.08**

a Zoning designations shown for Ruby Junction are City of Gresham zoning designations; Oregon Mainland and Hayden Island are City of Portland designations.

CE = commercial employment; CM1 = commercial mixed use 1; CM2 = commercial mixed use 2; HI = heavy industrial; IG2 = general industrial 2; N/A = not applicable; OS = open space; SC-RJ = Ruby Junction Station Center – Ruby Junction Overlay; sq ft = square feet

Washington

Table 3.4-8 shows land use changes that would result from acquisitions in Washington according to zoning designation and design option. Each of the Modified LPA design options would affect approximately

110 parcels in Washington, but the number of acres acquired would vary by design option. Totals for each design option are shown below, with more detail provided in Table 3.4-8. See Section 3.3, Acquisitions, and the Acquisitions Technical Report for information on the locations of acquired properties.

- The Modified LPA with double-deck fixed-span configuration, one auxiliary lane, C Street ramps, and centered I-5 and the Modified LPA without C Street ramps would each acquire 10.6 acres of property, including 21 full acquisitions, 48 partial acquisitions, and 41 subsurface easements.
- The two auxiliary lane design option would have the same number of full and partial acquisitions and subsurface easements, but would require an additional 0.1 acres of property east of I-5 for a total of 10.7 acres of acquisition.
- The Modified LPA with any of the single-level bridge configurations or bridge types would also have 21 full and 48 partial acquisitions and 41 subsurface easements, but would require a total of 10.9 acres of acquisition to accommodate wider bridge abutments on the Vancouver shoreline.
- The Modified LPA with mainline westward shift would require 23 full acquisitions and 45 partial acquisitions as well as 41 subsurface easements. The total acquisition area would be 10.9 acres.

Up to two proposed park-and-ride facilities could be added to the Modified LPA in downtown Vancouver: one would be near Waterfront Station and one would be near Evergreen Station. Three sites are being considered for the Waterfront Station and two sites for Evergreen Station. Table 3.4-9 illustrates the potential land use changes by site option based on the acquisitions that would be required for each proposed park-and-ride facility.

Totals	Full Acquisitions	21 (3.2)	21 (3.2)	23 (4.5)	21 (3.2)	21 (3.2)
	Partial Acquisitions	48 (2.2)	48 (2.2)	45 (1.8)	48 (2.3)	48 (2.5)
	Total Permanent Acquisitions	**69 (5.4)**	**69 (5.4)**	**68 (6.3)**	**69 (5.5)**	**69 (5.7)**
	Subsurface Easement	**41 (4.2)**	**41 (4.2)**	**41 (3.6)**	**41 (4.2)**	**41 (4.2)**
	Air Space	**0 (1)**	**0 (1)**	**0 (1)**	**0 (1)**	**0 (1)**
	Total Permanent Acquisitions and Easements	**110 (10.6)**	**110 (10.6)**	**109 (10.9)**	**110 (10.7)**	**110 (10.9)**

a Modified LPA with and without C Street Ramps would have the same impacts. The footprint removed by removing the C Street Ramp is entirely within existing right of way.

b The Washington right-of-way acquisitions associated with the single-level fixed-span configuration would be the same for all bridge type options.

c (CPX) Central Park Mixed-Use; (CX) City Center; (R-9) Low-Density Residential District; (R-22) Higher-Density Residential District.

d A subsurface easement is a right given a party to use space underground, such as for buried electrical, cable, water or sewage line.

e For Upper Vancouver, all design options have the same impacts.

Table 3.4-9. Acquisition Impacts by Park-and-Ride Option

Property Acquisitions	Type	Waterfront Site 1 [a, b]	Waterfront Site 2 [a]	Waterfront Site 3 [a]	Evergreen Site 1 [a, c]	Evergreen Site 2 [a, d]
Parcels (count)	Full	0	1	4	5	0
	Partial	0	0	0	0	0
	Total	0	1	4	5	0
Area Acquired (acres)		0	0.1	1.5	3.16	0
Permanent Easements	Property Easements [e, f]	0	0	0	0	0
Total of Permanent Acquisitions and Easements		0 acres	0.1 acres	1.5 acres	3.16 acres	0 acres

a Does not include WSDOT-owned property or right of way or City-owned right of way.
b Properties associated with Waterfront Site 1 would be affected by IBR Program roadway and pedestrian improvements regardless of whether the site is developed as a park and ride.
c Properties associated with Evergreen Site 1 would be developed as a joint venture between the IBR Program and the City of Vancouver.
d The existing parking structure (Evergreen Site 2) would be used via lease with the existing owner.
e Subsurface easement requirements are preliminary and will be updated prior to construction.
f Airspace easements have not been determined but will be identified prior to construction.

Consistency with Plans and Policies

The Modified LPA's implementation of high-capacity transit would be consistent with state, regional, and local plans and policies and would help the region achieve anticipated development without expanding urban growth areas. In Oregon, state law requires ODOT to involve planning officials from affected jurisdictions in planning for transportation projects that require an environmental assessment or EIS. The Oregon Transportation Commission must also adopt a finding that the project is compatible with applicable comprehensive plans before the project design can be approved. Washington state law, while not explicitly requiring a consistency finding from the state's transportation commission, requires WSDOT to cooperate with city and county governments, planning agencies, transit agencies, and other appropriate local planning entities when planning improvements to highways of statewide significance, including the Interstate system. Appendix A, Agency and Tribal Coordination, provides detail on how the IBR Program has coordinated and collaborated with planning and regulatory agencies as part of the NEPA process. Table 3.4-10 summarizes relevant land use and transportation plans and policies that would apply to the IBR Program and discusses their compatibility with the Program. See the Land Use Technical Report for additional details on compatibility with applicable land use and transportation plans and policies.

Table 3.4-10. IBR Program Consistency with Relevant Land Use and Transportation Plans

	Plan	Description	IBR Program Consistency
State	Statewide Planning Goals (Oregon)	Directs all Oregon cities and counties to implement comprehensive land use plans that comply with statewide goals and guidelines.	Consistent with Goal 12, Transportation, which requires cities, counties, and the state to create a transportation system plan that addresses mass transit, air, water, rail, highway, bicycle, and pedestrian transportation. Among other objectives of Goal 12, the Modified LPA would: • Serve statewide, regional, and local transportation needs. • Serve the mobility and access needs of those who cannot drive and other underserved populations. • Provide for affordable, accessible and convenient transit, pedestrian, and bicycle access and circulation, with improved connectivity. • Help to reduce pollution from transportation to meet statewide goals to reduce climate pollution. • Facilitate the safe flow of freight, goods, and services within regions and throughout the state.
	Growth Management Act (Washington)	Requires local jurisdictions to implement a land use policy framework that reduces conversion of rural land to urban development.	Supports stated goals pertaining to transportation and infrastructure, including encouraging efficient multimodal transportation systems that are based on regional priorities and coordinated with county and city comprehensive plans. Also consistent with the Act's goals for providing infrastructure to urban areas and for directing high-density growth to urbanized locations.
Regional	2040 Growth Concept (Metro)	Defines regional growth and development in the Portland metropolitan region. Policies encourage efficient use of land, protection of farmland and natural resources, a balanced transportation system, a healthy economy, and diverse housing options.	Supports Metro's stated policy goals of providing a balanced transportation system and contributing to a healthy economy.

	Plan	Description	IBR Program Consistency
	Regional Framework Plan (Metro)	Identifies regional policies to implement the 2040 Growth Concept. Provides overall guidance for more detailed policies regarding several topics including regional transportation and mass transit systems, and coordination, to the extent feasible, of Metro growth management and land use planning policies with those of Clark County.	Includes IBR-related goals of developing a connected region through an integrated system of throughways, arterial streets, freight routes and intermodal facilities, transit services and bicycle and pedestrian facilities.
	2018 Regional Transportation Plan (Metro)	Establishes policies and priorities for all forms of transportation and anticipates the region's current and future transportation needs. Focuses on ensuring the region's transportation system works effectively, recognizing the importance of the movement of goods and services for the regional economy. The RTP adopted by Metro in December 2018 includes the same land uses and transportation projects as the RTP adopted by Clark County in March 2019 (as described below).[2]	The "I-5 Replacement project" is included on the financially constrained project list. This is earlier terminology used to reference the project now known as the IBR Program.
	Climate Smart Strategy (Metro)	States a regional strategy to realize local visions for land use and transportation while also reducing greenhouse gas emissions.	Seek opportunities to advance local and regional projects that best combine the most effective greenhouse gas emissions reduction strategies.
	Transportation Improvement Plan (TriMet)	Establishes transit improvement priorities and possible funding allocations. Includes a 5-year roadmap for the rollout of future services and programs to improve service in low-income communities.	Expands public transportation services with the extension of light-rail transit to Hayden Island and Vancouver, improved bus transit service, and station infrastructure improvements.
	20-Year Transit Development Plan (C-TRAN)	Plans for transit services in Clark County. Includes high-capacity transit planning, capital and technology improvements, and a financial plan.	Includes the IBR elements of light-rail transit and bus rapid transit improvements.

[2] The financially constrained *Regional Transportation Plan* adopted by the Metro Council in December 2018 (Metro 2018a) and adopted by the Southwest Washington Regional Transportation Council (RTC) Board of Directors in March 2019 is referred to as the "2018 RTP."

	Plan	Description	IBR Program Consistency
	2019 Regional Transportation Plan for Clark County (RTP)	Identifies future regional transportation system needs and outlines transportation plans and improvements necessary to maintain mobility within and through the region and access to land uses within the region. The RTP adopted by Clark County in March 2019 includes the same land uses and transportation projects as the as RTP adopted by Metro in December 2018 (as described above).	Includes IBR-related goals of providing reliable mobility for personal travel and freight movement by addressing congestion and transportation system bottlenecks
Local (Oregon)	Multnomah County Comprehensive Plan and Transportation System Plan	Describes policies that guide decisions made by the Land Use Planning Division, as well as the relationship between Multnomah County land use decisions and the policies adopted by the Metro Council and statewide planning agencies. The Transportation System Plan guides decisions about transportation system improvements over the next 20 years or more.	Supports the plan's goals of providing a safe and efficient transportation network.
	2035 Comprehensive Plan (Portland)	Continues the commitment to linking land use and transportation decisions. Seeks to improve Portland as a place that is walkable, bikeable, and transit-friendly with active main streets. Continues Portland's commitment to compact development with active employment centers, expanded housing choice, and access to parks and open space.	The IBR Program advances multiple goals articulated by the Transportation component of the Comprehensive Plan, including: • Create a coordinated, efficient, more affordable multimodal transportation system. • Reduce service disparities and achieve equitable access to all types of facilities and transportation modes. • Ensure safety of the most vulnerable users (people with disabilities, young people, the elderly). • Guide the location and design of new street, pedestrian, bicycle, and trail infrastructure.
	2035 Transportation System Plan (Portland)	Guides Portland's transportation system functions and investments. Ensures that new development and allowed land uses are consistent with the identified function and capacity of, and adopted performance measures for, affected transportation facilities.	Lists the I-5 Columbia River bridge replacement and interchange improvements as a financially constrained project to be completed within 1 to 10 years.

	Plan	Description	IBR Program Consistency
	City of Portland and Multnomah County Climate Action Plan	Sets a goal of achieving a 40% reduction in carbon emissions by 2030 and an 80% reduction by 2050 Identifies objectives and actions to be completed or significantly underway in the next 5 years, focusing principally on major actions to be taken to accelerate emission reductions.	Increases public transit opportunities, which is one of the overarching carbon reduction actions referenced throughout the plan.
Neighborhood or Area-Specific (Oregon)	Hayden Island Neighborhood Plan	Addresses the unique situation of the island while considering the best plan for its future. Recommends preserving existing uses while promoting new mixed-use development to meet future needs. Developed concurrently with the CRC project and specifically incorporates guidance for the CRC project.	The Modified LPA is consistent with the plan, supporting specific goals such as: • Light-rail transit to, and a station on, Hayden Island. • A light-rail transit alignment adjacent to the west side of I-5 instead of a separate alignment in order to minimize the barrier effects. • Access to local street systems south of North Portland Harbor without using the freeway.
	Bridgeton Neighborhood Plan	Addresses the neighborhood development challenges. Development consists largely of houseboats, rowhouses, and detached single-family homes. Significant wetland and riparian resources exist throughout the neighborhood as well.	Supports specific recommendations in the plan, including providing access to transit and providing for connectivity within the neighborhood and to the rest of the transportation network.
	Kenton Neighborhood Plan (as amended by the Kenton Downtown Plan)	Focuses on bringing back the Denver Avenue business district as a retail corridor.	Supports transportation recommendations including increasing the extent of the neighborhood's light-rail transit connectivity.
	Portland International Raceway Plan District	Sets a goal to preserve and enhance the special character and opportunities of the area, which includes natural areas to the west and "special event" uses to the east.	IBR development taking place within the district would be consistent with Chapter 33.566 of the Portland Zoning Code.
	East Columbia Neighborhood Natural Resources Management Plan	Promotes a consistent approach to development within this environmentally sensitive area. Prioritizes preservation of wetlands and wildlife habitats.	Modified LPA design would support policies concerning water quality, protection of wetlands/natural resource areas, and buffering of resources from development.

	Plan	Description	IBR Program Consistency
	Natural Resources Management Plan for Peninsula Drainage District No. 1	Promotes a consistent approach to development within the environmentally sensitive areas of the district.	Supports a MAX light-rail transit station for West Delta Park.
	Portland Interstate Corridor Urban Renewal Plan	Sets goals and objectives to improve livability, increase job opportunities, assist small businesses, and benefit from major infrastructure projects, including the Interstate MAX light-rail line.	Supports extension of light-rail.
Local (Washington)	Clark County Comprehensive Growth Management Plan	Represents the coordinated land use and transportation system plans for the county and seven cities.	Supports transportation and land use goals by providing a balance of transportation modes through the incorporation of bicycle and pedestrian facilities and high-capacity transit.
	City of Vancouver Comprehensive Plan	Guides growth for Vancouver. Encourages compact urban centers, transit, and supportive development regulations for areas along the defined high-capacity transit corridors identified along I-5 and SR 500.	Supports plan goals of connectivity, accessibility, and providing a range of transportation options.
	City of Vancouver Transportation Plan	Includes vision statements for the City's evolving transportation system emphasizing accessibility, system efficiency, connectivity, multimodalism, and a walkable community.	Increases public transit and provides greater multimodal opportunities.
	City of Vancouver Strategic Plan	Helps guide the City's decision-making and resource allocation.	Supports goals of developing and maintaining a safe, balanced, and innovative transportation system that will meet the needs of future generations.
	Vancouver City Center Vision and Subarea Plan	Divides the downtown into six planning areas with goals and guiding principles. Land use goals include focusing waterfront redevelopment on residential uses, with significant public access, recreation, cultural, hospitality, entertainment, and limited commercial uses.	Supports goals of ensuring that expansion of I-5 and Columbia River crossing improvements improve access to the city center and minimize potentially negative effects. Includes specific direction for the IBR Program, including a directive to integrate all modes of transportation, including high-capacity transit, bicycle, and pedestrian circulation, to achieve a true regional multimodal corridor.

	Plan	Description	IBR Program Consistency
	City of Vancouver Shoreline Master Program	Sets a program goal to protect natural values and functions of the shorelines while guiding and allowing appropriate development. New utility and transportation facilities must protect, enhance, and encourage development of physical and visual shoreline public access.	The IBR Program would comply with Shoreline Master Program requirements to protect shoreline ecological processes as well as preserve public access to the Columbia River shoreline.
Neighborhood or Area-Specific (Washington)	Downtown Vancouver Transportation System Plan	Addresses transportation conditions and plans from Fourth Plain Boulevard south to the Columbia River.	Includes specific directives to optimize MAX service into Vancouver, including such things as designating certain streets as transit streets.
	Central Park Plan	Calls for a unified sense of place by celebrating a shared historic landscape and emphasizing design of key features such as a “great street” network.	Includes CRC-specific language within the Plan’s vision statements that also applies to IBR: “the I-5 Columbia River Crossing improves access to Central Park from all parts of the city and region.”
	Port of Vancouver Waterfront Development Master Plan	Defines a vision for the Columbia River waterfront that is consistent with the Port’s mission to provide economic benefit to the community through leadership, stewardship, and partnership in maritime-related development.	Plan accounts for the Interstate Bridge replacement and its alignment relative to adjacent development.
	Highway 99 Sub-Area Plan	Covers the area from 63rd Street north to approximately 134th Street. serves as a guide for public investments and for Team 99, a group of business leaders in the corridor.	Notes that all planning efforts for the Highway 99 Subarea Plan will support the CRC project recommendations for high-capacity transit including light-rail or bus rapid transit. This also applies to the IBR Program.

Tolling

Tolling of cars and trucks that use the new Columbia River bridges is proposed as a method to fund the Modified LPA and encourage the use of transit and active transportation. Variable toll rates during peak periods would support regional and local policies for managing traffic congestion. Tolling is not expected to change land use patterns, because as discussed in Section 3.4.5, Indirect Effects, and the Land Use Technical Report, land use and development in the study area are governed by state land use and growth management laws, local land use plans and zoning regulations, and other controls. These require all development to be consistent with existing zoning and comprehensive planning in order to be permitted. Effective local plans and policies have been shown to control potential unplanned growth and land use changes resulting from transportation investments (CH2M Hill 2006; Tidd et al. 2013). See the Land Use Technical Report for a more detailed discussion.

Analysis using the Metro/RTC regional travel demand model showed an increase in transit mode share under the Modified LPA and design options relative to the No-Build Alternative as a result of both improved transit investment and the introduction of variable-rate tolling on the new Columbia River bridges. This shift to transit would reduce overall vehicle travel miles traveled across the Columbia River on an average weekday by approximately 1% compared to the No-Build Alternative. While tolling could divert some traffic from I-5 to I-205, the reduction in total vehicle trips because of toll and transit investments is expected to minimize any effect from diversion on traffic congestion. Therefore, tolling is not expected to induce changes in land use. See the Transportation Technical Report for a more detailed analysis of tolling effects.

Economics

Property acquisition for the Modified LPA would displace several businesses and their employees. The acquisition of taxable property for additional right of way would also decrease property tax revenues. The additional right of way acquired would include both full parcels, which would be removed from the tax rolls completely, and partial acquisitions. Business displacements and property tax revenue reductions are discussed in the subsections below.

The Modified LPA would also eliminate parking spaces, primarily at the Expo Center (386 of 2,160 existing stalls) and on Hayden Island (180 of 4,354 existing stalls). The Expo Center seldom requires the use of all 2,160 parking stalls, so no substantial reduction in parking revenue is expected. Any potential reduction in patronage during peak events due to loss of parking would likely be offset by the availability of the new light-rail transit service connecting the Expo Center with Vancouver. The parking loss on Hayden Island is a small fraction of available parking in the area; for businesses affected by parking loss, coordination with property owners would occur as the design progresses to minimize impacts to parking and site use. Overall, no significant economic impacts due to the elimination of parking are anticipated.

Business Displacements

Table 3.4-11 provides an estimate of the number of businesses, and their employees, that would be displaced due to land acquisition for the Modified LPA. See the Economics Technical Report for a description of the types of businesses affected.

Table 3.4-11. Business Displacements from the Modified LPA

Area	Businesses Displaced from Modified LPA Design Options with Centered I-5	Total Employees of Displaced Businesses from Modified LPA Design Options with Centered I-5	Businesses Displaced with I-5 Westward Shift Design Option	Total Employees of Displaced Businesses with I-5 Westward Shift Design Option
Oregon Mainland	7	41	7	41
Hayden Island	15	159	15	159
Ruby Junction	3	16	3	16
Downtown Vancouver	10	400	13	542
Upper Vancouver	0	0	0	0

Sources: IBR 2022b; Metro 2015

Compared to the Modified LPA with a centered mainline configuration, shifting the I-5 mainline west would displace an additional 3 businesses and 142 employees (in total, 13 businesses and 542 employees). Displaced employees may be impacted by longer commutes, depending on the availability of nearby space for the businesses to be relocated. None of the other design options, except park and ride sites, would have different number of business acquisitions.

If Site 3 were chosen for the Waterfront Station park and ride, an office building with approximately 53 employees would be displaced. None of the other park-and-ride sites would result in business displacements.

Property Tax Impacts

Table 3.4-12 presents the estimated reduction in property tax revenues associated with the Modified LPA. The tax effect of the partial acquisitions was calculated by multiplying the actual 2022 property tax collected for the parcel by an estimate of the percentage of the parcel taken. Estimated losses in property tax revenue are not substantial; in Multnomah County, losses attributable to the Modified LPA would account for less than 0.2% of annual revenues; estimated losses in Clark County would be between approximately 0.33% and 0.43% of annual revenues.

Table 3.4-12. Property Tax Reduction from the Modified LPA Design Options

Area	Estimated Assessed Value of Right of Way (millions) from Modified LPA	Property Tax Reductions (thousands) from Modified LPA	Percentage of 2022 County Budgeted Property Tax Revenues Lost as a Result of Modified LPA	Estimated Assessed Value of Right of Way (millions) from I-5 Westward Shift Design Option	Property Tax Reductions (thousands) from I-5 Westward Shift Design Option	Percentage of 2022 County Budgeted Property Tax Revenues Lost as a Result of I-5 Westward Shift Design Option
Oregon Mainland	$19.0	-$72.0	0.02%	$19.0	-$72.0	0.02%

Area	Estimated Assessed Value of Right of Way (millions) from Modified LPA	Property Tax Reductions (thousands) from Modified LPA	Percentage of 2022 County Budgeted Property Tax Revenues Lost as a Result of Modified LPA	Estimated Assessed Value of Right of Way (millions) from I-5 Westward Shift Design Option	Property Tax Reductions (thousands) from I-5 Westward Shift Design Option	Percentage of 2022 County Budgeted Property Tax Revenues Lost as a Result of I-5 Westward Shift Design Option
Hayden Island	$49.8	-$542.0	0.16%	$49.8	-$542.0	0.16%
Ruby Junction	$4.3	-$43.2	<0.01%	$4.3	-$43.2	<0.01%
Downtown Vancouver	$21.6	-$195.8	0.3%	$32.1	-$259.3	0.4%
Upper Vancouver	$2.6	-$21.3	0.03%	$2.6	-$21.3	0.03%

Sources: IBR 2022b; Multnomah County Tax Assessor 2022; Clark County Tax Assessor 2022

The I-5 mainline westward shift design option would only affect properties in downtown Vancouver, as shown in Table 3.4-12.

Table 3.4-13 presents the estimated property tax impacts associated with the park-and-ride sites that would result in impacts beyond those expected from the Modified LPA. Waterfront Site 3 is owned by the State of Washington, so there would be no loss of property tax associated with that potential impact. The reduction in property tax revenues from land acquired for Evergreen Station Site 1 would represent less than one-tenth of 1% of the total annual 2022 property tax revenues for Clark County.

Table 3.4-13. Clark County Property Tax Reductions

Park-and-Ride Station	Site	Estimated Assessed Value of Right of Way (millions)	Clark County Property Tax Reduction (thousands)	Clark County Budgeted 2022 Property Tax Revenues
Waterfront Station	3	$4.5	$0	0%
Evergreen Station	1	$6.0	-$58.2	0.08%

Washington Sales Tax Impacts

The displacement of businesses in Vancouver would result in a reduction of sales tax revenue. Detailed information on the amount of sales tax collected by these businesses was not available; however, it is not anticipated that the reduction would have a substantial economic impact given that most of the affected businesses would be commercial offices.

Impacts to Regional Economic Sectors

Economic Impacts of Delay

According to a study of the regional economic effects of transportation choke points (Cambridge Systematics 2003), five industries in the Portland-Vancouver region are particularly sensitive to road congestion: lumber/wood/paper, distribution/wholesale trade, transportation equipment/steel, farm and food products, and high-tech. These industries are particularly vulnerable to delay and decreased travel time reliability resulting from roadway congestion in the I-5 corridor. According to the study, congestion at the Interstate Bridge increases the cost of congestion delay to trucks. Reducing freight truck travel times by investing in transportation infrastructure improvements that increase access and decrease congestion would help maintain the efficiency of the area's freight movement on I-5. As well, travel time improvements would benefit all business and worker trips that travel through the I-5 corridor in the primary study area.

Commercial marine navigation includes similar products to those conveyed by road, which are transported under the Columbia River bridges both up and downriver. As with vehicle transportation, marine vessel transport products can be vulnerable to delays. Delays to some marine transport would occur with the single-level movable-span bridge configuration for vessels dependent upon bridge openings, as vessels may not be able to accurately time their arrival to outside the bridge opening time restrictions. No delays to marine transport would occur with either of the fixed-span configurations. However, vessels with vertical navigation clearance requirements of greater than 116 feet would permanently be unable to transit under the bridge for its 100+ year service life.

Effects of the Modified LPA on Freight Transport

Truck Transport

The Modified LPA would benefit the trucking industry by reducing travel times and increasing reliability, which in turn would reduce costs and improve efficiency for truck freight operators. As described in Section 3.1, Transportation, traffic operations on I-5 are expected to improve with the addition of one auxiliary lane and would improve even more with the addition of a second auxiliary lane. These improvements would enhance regional mobility and access, which would increase the competitiveness of the regional economy, reduce transportation costs for local businesses, and increase operational flexibility for businesses (e.g., deliveries, shipping, and business operations). However, if the C Street ramps at the SR 14 interchange were eliminated, additional traffic delay and longer travel times near the Mill Plain Boulevard interchange and in downtown Vancouver would have an adverse economic impact on local businesses in that area.

The single-level fixed-span configuration (all bridge type options) would have a lower maximum height and a reduced highway grade compared to the double-deck fixed-span configuration. The reduced grade would allow for improvements in freight vehicle speed. With the single-level movable-span configuration, the average number of bridge openings for vessels is anticipated to be less than 146 per year, which is the average number of openings for vessels over the past 12-year period (2012-2023). If future maritime use increases or decreases, the number of bridge openings may also deviate from recent historical patterns over the course of the 100+ year service life of the new Columbia River bridges. Future bridge openings would continue to cause delays and congestion for freight truck transport, with associated economic impacts that would offset the benefit provided by the reduced grade.

As described in Section 3.1, Transportation, under existing conditions, the average bridge opening and gate closure duration during the 5-year period (January 1, 2015, to December 31, 2019) was 11.6 minutes. While bridge openings are not allowed during peak highway traffic periods[3] except in emergency situations, they are

[3] Interstate Bridge lift openings are currently restricted to avoid weekday peak highway traffic operations between 6:30 a.m. and 9:00 a.m. and between 2:30 p.m. and 6:00 p.m., excluding emergency bridge lifts.

allowed before and after the peaks. Depending on the closure time and duration as well as traffic levels, it can take between 5 and 110 minutes for traffic to recover from a bridge opening and gate closure. An opening or closure just before the peak period can last even longer, affecting conditions throughout the peak traffic period. The single-level movable-span configuration would likely have increased restrictions on bridge openings to minimize impacts to vehicle traffic and transit compared to today's restrictions.

Marine Cargo Transport

Under the Modified LPA, each of the new Columbia River bridges would be built on six pairs of in-water piers, plus several pairs of piers on land. The new bridges under consideration in the Modified LPA include both fixed-span and movable-span configurations. As with the existing bridges, the new bridges would provide three shipping channels: a primary navigation channel and two alternate channels. Each of the three navigation channels would be 400 feet wide, which includes 50-foot maintenance buffers on each side of the navigation channels for all bridge configurations and bridge types currently under consideration. All bridge types of the fixed-span bridge configurations would provide approximately 116 feet of vertical navigation clearance over the primary navigation channel. The movable-span configuration would provide approximately 92 feet of vertical clearance in the closed position over the primary navigation channel (or 99 feet over the north barge channel) and 178 feet in the open position, compared to 72 feet in the closed position and 178 feet in the open position for the existing Interstate Bridge.

For a movable-span configuration, all current vessel traffic could pass beneath the new bridges; however, as noted above, the movable span could have more timing restrictions on bridge openings than the No-Build Alternative to minimize impacts to vehicle traffic and transit service. Construction of a fixed-span configuration with 116 feet of vertical navigation clearance would result in two vessels that currently transit under the Interstate Bridge and large cargo manufactured upstream by three industrial operations (fabricators) not being able to pass beneath the new bridges. The two vessels that would require a vertical navigation clearance greater than 116 feet include the Derrick Barge [DB] *Taylor*, which passes under the Interstate Bridge approximately 10 times per month, or 120 times per year; and, the DB *Freedom,* which makes approximately 10 trips under the bridge per year (based on 2012-2020 operations). On average during the 2012-2020 timeframe, about 2,600 commercial vessel trips occurred each year; therefore, the DB *Taylor* represents approximately 4.6% of total commercial vessel trips each year, while the DB *Freedom* represents approximately 0.3% of commercial vessel trips each year. Three additional vessels (DB *4100*, DB *General* and dredge *Yaquina*) would be restricted when the river level is at the ordinary high water level of 16 feet above Columbia River Datum, which is about 1% of days in a typical year. Each of these three vessels make approximately 12-28 trips per year. In summary, a total of five vessels and three fabricators would be adversely affected by any of the fixed-span configurations, whereas the movable-span configuration would allow passage for all current vessels and cargo. The IBR Program is committed to working with the owners and operators of these vessels to identify mutually acceptable measures to avoid or minimize economic impacts.

Vessels or cargo shipments unable to pass beneath a fixed-span configuration could result in economic impacts including increased production costs, reduced potential for future work, and reduced employment opportunities in the region. Affected fabricators could continue to seek contracts for products that exceed the bridges' vertical clearance but would require securing a downriver satellite site to complete final assembly and could incur higher costs.

Under the Modified LPA with any of the fixed-span configurations, other commercial vessels on the Columbia River such as cruise vessels and tugs/tows for the barges would continue operations. Under the Modified LPA with the movable-span configuration, all vessels currently using the Columbia River would be able to pass under the bridges, but the movable-span configuration would provide greater vertical clearance (92 feet over the primary navigation channel or 99 feet over the north barge channel) compared to the No-Build Alternative (72 feet over the alternate barge channel) when each is in the closed position, potentially allowing more

vessels to pass without requesting a bridge opening. If a bridge opening were required, these vessels would either need to revise their schedules to avoid restricted times for bridge openings or experience delay. See Section 3.2, Navigation, and the Navigation Impact Report for detailed discussion on the benefits and effects of the Modified LPA on vessel navigation.

Resulting economic benefits with the fixed-span configurations would be eliminating delays associated with the movable-span configuration and improving travel times for vehicles and transit service crossing over the river, which would no longer have interruptions from bridge openings.

The marine cargo transportation impacts listed above are a snapshot in time and represent current waterway usage. Over the 107 years of service life of the Interstate Bridge (northbound span opened in 1917 and southbound span opened in 1958), numerous bridge lifts have been conducted for mariners with large vertical navigation clearance requirements, including those requiring openings for clearances over 116 feet and up to 178 feet. It is difficult to predict maritime transportation system demands and associated needs for bridge openings for the 100+ year service life of the bridges, since vessel traffic and river-level conditions vary from year to year and economic trends for maritime commerce may change over time. Nevertheless, a fixed-span configuration with 116 feet of vertical clearance would permanently deny access under the bridges to mariners who require vertical clearances of greater than 116 feet for the 100+ year service life span of the bridges.

Rail Transport

The BNSF Railway mainline operates on an east-west alignment north of the Columbia River in Vancouver, between the river and downtown Vancouver. No long-term economic impacts to rail traffic operations would be anticipated as a result of the Modified LPA.

Other Considerations

New transit connections in downtown Vancouver would improve travel time accessibility and broaden the pool of labor available along the corridor and in the region.

Earthquakes could cause economic impacts by delaying or completely stopping the flow of freight, disrupting travel routes for employees traveling to and from work, and destroying billions of dollars in infrastructure. The Modified LPA would withstand a major seismic earthquake, minimizing these impacts to the greatest extent possible.

Tolling

The Modified LPA assumes a variable-price toll using two scenarios. These tolling scenarios are used to study the impacts of various toll rates related to Program funding and other traffic-related impacts. The IBR Program would not be setting toll rates; the Washington Transportation Commission and Oregon Transportation Commission have the authority to jointly set toll rates.

Scenario A (northbound and southbound tolls with a variable toll rate range of $2.15 to $3.55) estimates toll revenues, while Scenario B (a north and southbound toll with a variable toll rate range of $1.50 to $3.15) forecasts the impacts of tolling on traffic volumes for this NEPA analysis. The tolls are in Fiscal Year 2026 dollars and are assumed to escalate by 2.15% per year. Variable tolls are likely to be beneficial for freight-dependent businesses and businesses that rely on just-in-time deliveries because the predictability of travel would also increase. This benefit is somewhat offset by the higher toll charges truck movements would incur during peak periods; however, peak freight travel times tend to fall outside the peak periods for general-purpose traffic.

The application of a variable toll pricing scheme to the new Columbia River bridges would add an out-of-pocket cost to trips and is anticipated to result in an overall reduction in bridge crossings with the Modified LPA. With the proposed tolling scenarios, the highest annual cost of tolls for a typical driver making

an outbound and inbound trip 5 days a week, 50 weeks per year, would be approximately $1,625 (this assumes the driver pays $3.25 per trip under Scenario A in Fiscal Year 2022 dollars). The 2021 median household income was $78,476 for Portland and $67,462 for Vancouver (U.S. Census Bureau n.d.). The cost of tolls for traveling across the I-5 Columbia River bridges would constitute approximately 2% and 2.4% of the median household's income in Portland and Vancouver, respectively. According to the Consumer Expenditure Survey, administered by the Bureau of Labor Statistics, the average household spent approximately $10,961 on transportation expenditures in 2021, which is between approximately 14% and 16% of household income for Portland and Vancouver, respectively. The addition of toll fees would increase these percentages to approximately 16% of household income for Portland and 19% for Vancouver.

3.4.4 Temporary Effects

No-Build Alternative

Under the No-Build Alternative, the existing Interstate Bridge, I-5, local roads, and associated infrastructure would remain as they are today. With no new infrastructure, there would be no temporary impacts to land use.

The No-Build Alternative would not involve construction activities, which often result in temporary economic benefits from capital expenditures, opportunities for entering the labor market through construction jobs, the purchasing of local goods and services needed for construction, and construction employees spending money in the community. The No-Build Alternative would also not result in temporary adverse economic impacts such as limiting business visibility and access, traffic delays and detours, and noise.

Modified LPA

Most temporary effects on land use and economics would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Land Use

Construction of the Modified LPA, including construction of the new bridges and removal of the existing bridges, is expected to take between approximately 9 and 15 years overall. In most parts of the study area, impacts would not be continuous throughout this timeframe, but would be limited to the duration of active construction on a specific component of the Modified LPA. Because construction activities would be temporary, they are unlikely to have lasting impacts on land uses, land use patterns, or compliance with land use plans and policies. However, construction-related impacts from noise, dust, lighting (for nighttime construction), and traffic delays may have secondary impacts on land uses. For example, adjacent residential uses are particularly sensitive to the impacts of construction; commercial uses may also be affected if they rely upon easy access and a pleasant driving experience. For more information, please refer to the Noise, Air Quality, Visual Quality, and Transportation Technical Reports and Sections 3.1, 3.9, 3.10, and 3.11 of this SEIS.

Bridge construction would disturb existing land uses and associated activities on Hayden Island. The existing commercial use pattern on the island is predominantly auto-oriented big-box retail. Shoppers and visitors to the area would likely face delays, detours, and other inconveniences. Noise, dust, and vibration impacts may also reduce the shopping center's attractiveness to shoppers during construction, especially when compared to similar shopping centers nearby.

Although I-5 is only one of the ways to access the area, many land uses in downtown Vancouver, particularly businesses which rely heavily on pass-by traffic, could be negatively impacted by construction activities due to detours, unclear access, noise, vibration, and dust. However, construction activities would not change the zoning designation and land use; if a business were to close due to construction impacts, similar businesses

compatible with local zoning regulations, overlay districts, and land use plans would be expected to take its place.

A total of approximately 5.6 acres of temporary construction easements would be needed along the length of the Modified LPA. These areas would be used to access construction sites, store vehicles and equipment, and for other ancillary purposes. Areas required for temporary easements would be restored to their former condition and use at the end of the construction period.

Economics

Regional Temporary Effects

Construction has the potential to cause negative economic effects by blocking visibility and access to businesses and causing traffic delays and detours that increase travel times. Traffic congestion is already a common occurrence within the study area during peak hours. Construction activities and temporary detours could extend the peak duration, negatively impacting businesses whose employees commute via I-5. Likewise, the movement of freight, goods, and services could be negatively affected if construction activities make travel times longer or less predictable.

Construction of the new Columbia River bridges would also affect marine commerce on the river. Work on the new bridges is anticipated to take place over a period of approximately 4 to 7 years, with a general sequence of activities including initial preparation, installation of foundation piles, shaft caps, pier columns, superstructure, and deck. Construction barges would be anchored in the river, and support barges traveling to and from supply points could create conflicts with freight. Some likely effects on marine commerce include:

- There would be temporary closures or changes to the three navigation channels during construction of the proposed Columbia River bridges, but it is assumed that at least one navigable channel would remain open at all times for marine traffic.
- Commercial vessels may be provided with towing assistance during times where navigation is made difficult by construction activities.
- Vertical and horizontal clearance restrictions would be in place for portions of the construction period. Such restrictions would require U.S. Coast Guard concurrence. A temporary construction navigation envelope (height and width of unobstructed clearance for navigation) would be maintained during construction with a minimum clearance of 72 feet (vertical) by 150 to 200 feet (horizontal). During times when these minimum clearances are in effect, vessels requiring more than 72 feet of vertical navigation clearance would be unable to pass under the bridges; however, potential passage with reduced width or scheduled interim short-term openings could be coordinated with the bridge construction contractor.
- Temporary river travel restrictions are anticipated as barges are used to ferry materials to and from work sites.

Construction of the Modified LPA could also result in positive economic effects through increased employment and spending during construction. The extent of these effects depends on the source of funding and the makeup of construction work crews. Funds from local or regional sources are transfers of money that could be spent by residents and businesses on other economic activities in the region, and therefore do not add to the overall supply of funding in the regional economy. Conversely, federal or state funds that are new to a region can have a measurable economic effect, resulting in employment and income gains from construction. The federal government and the states of Oregon and Washington would provide the funds for the Modified LPA, thus resulting in some economic and employment benefits in the region that would otherwise not occur.

Local Temporary Effects

Roadway closures could affect local economic activity, depending on the location and duration. There is one temporary road closure associated with the Modified LPA; a portion of Jantzen Drive east and west of I-5 would be closed for approximately 8 months to allow for road and utility work. This section of roadway does not include any direct access points for businesses not permanently displaced by the Modified LPA. Access would remain open along N Hayden Island Drive and Center Avenue, but some out-of-direction travel could be required to continue to access businesses in the immediate vicinity of the closure.

In Washington, ramp closures associated with improvements to the SR 14 interchange would primarily affect traffic from downtown Vancouver to points east and the connection between Portland and downtown Vancouver on I-5. Alternate routes would be available to travel to these areas, but they would be more difficult and less direct. This could affect businesses in downtown Vancouver by increasing delivery times for goods and making it more difficult for employees and customers to reach downtown businesses. For more detail regarding local temporary economic effects due to construction, see the Economics Technical Report.

3.4.5 Indirect Effects

Most indirect effects on land use and economics would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Land Use

Indirect Effects on Local and Regional Land Use

Indirect effects on land use are associated with (1) the potential for the Modified LPA's transportation improvements to facilitate growth and development compared to the No-Build Alternative, and (2) the consistency of such potential growth and development with local and regional land use plans. This section evaluates both topics.

As described in Section 3.4.3, Long-Term Benefits and Effects, and Table 3.4-10, both Portland and Vancouver have accounted for future anticipated growth within their planning documents and provide strategies, visions, and goals to guide this growth. The plans provide for a development strategy to accommodate growth by increasing land use density, particularly in areas that would be served by high-capacity transit if the Modified LPA is implemented. Under the No-Build Alternative, light-rail would not be extended to Vancouver and express bus service across the Columbia River would be subject to delays caused by increasing congestion. Without high-capacity transit and associated light-rail stations on Hayden Island and in downtown Vancouver, the demand for higher-density development would be less likely to materialize, and the development strategy provided for in local land use plans may not be achievable. Vehicle, express bus, and active transportation would be the only mode option for crossing the Columbia River because high-capacity transit would not be available. Because the No-Build Alternative would have fewer transportation mode options to cross the river and would not include the LRT stations proposed under the Modified LPA, it would be less likely to support the increased development density provided for under the local planning documents. The Modified LPA would provide new light-rail service and improve the reliability of bus transit, which would facilitate the development strategy provided for in local planning documents, especially on Hayden Island and in Downtown Vancouver. This would support the plan to accommodate increased population growth through higher density development . The Modified LPA would not be expected to result in urban sprawl (scattered development on the periphery of urban areas) because the transit improvements would be provided in established urban areas, the local land use planning strategy to increase density is more likely to be achievable and the Columbia River bridges would be tolled. Because tolling increases the out-of-pocket cost of commuting, individuals have an incentive to shorten their commutes by living closer to alternative transportation connections, services and where they work (Brueckner 2001). As

described in Section 3.1, the transportation analysis also shows that tolling would cause some drivers to change to transit to avoid tolls.

The CRC EIS included an analysis of the project's potential for induced land use changes. The analysis used MetroScope, Metro's integrated land use and transportation model, to predict how the proposed changes in transportation infrastructure could influence the future distribution of employment and housing throughout the region. The modeling effort, which was completed in 2010, concluded that the CRC project would not significantly induce growth or sprawl. Compared to the No-Build Alternative, the model estimated that the CRC project, with tolling, would result in a 0.03% decrease in households in north Clark County and a 0.51% increase in households in the southern, more urban, half of the county (Conder 2010). Metro reviewed these findings in January 2024 and concluded they remain relevant to the Modified LPA.

The amount and timing of land use changes in transit station areas can be affected by transit ridership levels (e.g., higher ridership would be expected to increase land use development compared to lower ridership). Thus, the amount and timing of transit-oriented development in station areas would depend to some degree on transit ridership levels and other factors such as local economic conditions. Regardless of the pace of development, transit-oriented development would be consistent with existing planning and zoning that anticipates the future availability of high-capacity transit to support planned densities.

In conclusion, while the Modified LPA is expected to have the indirect effect of facilitating growth and development within the study area, the magnitude and location of this development would be consistent with all local and regional land use plans. Conversely, the No-Build Alternative would not encourage as much dense, transit-oriented development, and congestion resulting from over-capacity transportation facilities could inhibit the region from accommodating planned levels of growth.

Indirect Land Use Effects Related to Navigation

The Navigation Impact Report (IBR 2022) evaluated the potential for future land use changes upstream of the Interstate Bridge that could affect marine commerce based on city, port, state and federal land use and other management plans, which typically have planning horizons of 10 to 20 years. The report identified properties along the Columbia River that currently have marine facilities available or have the potential for future development of such facilities. It concluded there are few opportunities for new or expanded commercial and industrial development that would require the use of vessels too large to pass beneath the proposed new fixed-span Columbia River bridges. The number of suitable properties is limited by political and geographic constraints on land along the Columbia River waterfront, which include the Columbia River Gorge Natural Scenic Area designation, parallel transportation routes (SR 14, I-84, Union Pacific Railroad, and BNSF Railway), steep topography, and existing recreational and open space uses. The types of industrial uses that currently generate or could generate marine vessel traffic in the future are located within urban areas and typically within established industrial parks (e.g., Columbia Business Center, Port of Cascade Locks Industrial Park).

Per current planning documents, there are no known planned developments within the study area that would create additional navigation activities that would be adversely affected by the new Columbia River bridges with either the double-deck or single-level fixed-span configurations. If new marine-based businesses were to develop upstream of the new Columbia River bridges over their 100+ year service life, either fixed-span bridge configuration would limit their activities to a maximum vertical navigation clearance of 116 feet. The single-level movable-span configuration would continue to provide at least 178 feet of vertical clearance, and therefore would pose no additional limitations to future activities or marine development beyond those posed by the existing Interstate Bridge.

Economics

Indirect economic impacts may result from the displacement of local businesses if remaining businesses find it difficult to attract or retain customers because complementary businesses no longer exist. The long-term

magnitude of this impact would depend on the potential to relocate displaced businesses in the same neighborhood and the extent and types of infill and redevelopment that occurs. This in turn depends on a number of factors such as regional economic trends and market conditions, the willingness of businesses to relocate, available building space for lease during the relocation process, and community and city support for redevelopment.

Improved travel times for vehicles and improved transit options would have a positive impact on workers and business trips in the project area, reducing delay and the time cost of travel.

The types of economic activity dependent on marine navigation upriver of the bridge is not anticipated to change considerably in the near future. Most of the commercial river traffic in the shallow-draft upriver section of the Columbia/Snake system would continue to be dominated by barged shipments of grain, petroleum products, wood products, and other bulk products for domestic consumption and export. It would be highly unlikely the nature or composition of upriver navigation would change as a result of the Modified LPA. River depth and other existing, permanent height and width constraints limit the size and draft of vessels capable of upriver navigation, and the availability of suitable waterfront properties for industrial development is, and is expected to remain, extremely limited for the next 20 or more years. As a result, the Modified LPA would be expected to have limited, at most, impact on future upriver economic activity.

3.4.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

As described in Section 3.3, Property Acquisitions and Displacements, property acquisition and residential or business displacements would be mitigated under the provisions of the Uniform Relocation and Real Property Acquisitions Policies Act of 1970, as amended. Those affected would receive compensation and relocation assistance from ODOT or WSDOT, depending on location. Property would be purchased at fair market value, and residential occupants displaced by the Modified LPA would be provided decent, safe, and sanitary replacement housing. The Acquisitions and Displacements Technical Report includes more information on the provisions of the Uniform Act and the processes used to value properties and provide relocation assistance.

The IBR Program would continue to work with the U.S. Coast Guard and the U.S. Army Corps of Engineers to help ensure that the potential for effects on river users is addressed through the agencies' permitting processes.

Program-Specific Mitigation

The Land Use Technical Report also identifies several measures which, although they are not specifically land use mitigation, would support the Modified LPA's compatibility with existing land uses:

- The use of interchange area management plans to guide development within the vicinity of interchanges.
- Mitigation for effects to historic resources, including demolition of the existing Interstate Bridge.
- Avoidance of potential land use conflicts by planning and designing efforts to support integration of park-and-ride facilities with current and planned land uses in downtown Vancouver.

Temporary Effects

Regulatory Requirements

Construction best management practices would be used to avoid or minimize indirect construction effects on land use and economics, such as dust, noise, and aesthetic impacts. These measures are discussed in the analyses of air quality (Section 3.10), noise and vibration (Section 3.11), and visual quality (Section 3.9).

Program-Specific Mitigation

Land Use

- Monitor noise levels on a regular basis during construction near noise-sensitive receptors located closest to construction activities to reduce disturbance to nearby land uses, and confirm compliance with noise thresholds set by local jurisdictions as well as the conditions of any noise variances obtained.
- Schedule and manage construction activities to minimize community disruption to the greatest extent feasible.
- Implement mitigation measures for temporary impacts on residents as discussed in Section 3.3, Property Acquisitions and Displacements.
- Carefully plan construction of the Modified LPA to phase work in such a way that reduces or avoids complete closure of affected roadways and access points to nearby businesses. Necessary detours would be routed to reduce travel times and signed to reduce confusion. Construction would be planned to keep business access points open as much as possible and would be well signed. A construction communication plan could be developed to inform travelers about detours and road closures and would direct them to businesses.

Economics

- Reduce impacts to local businesses by implementing a phased construction schedule that avoids complete closures of roads and access points to local businesses. A construction communication plan could be developed to inform travelers about detours and road closures and would direct them to businesses.
- Design construction schedules to minimize temporary impacts to BNSF Railway lines and service frequency.
- Provide outreach to businesses affected by construction and use assistance programs to help mitigate potential negative construction-related effects.
- Coordinate with the Ports of Portland and Vancouver and associated businesses to identify ways to minimize delays for commercial freight vehicles during construction.
- To keep freight moving during construction, the IBR Program would conduct outreach to businesses in areas with high volumes of freight traffic to determine access and site circulation needs and maintain access as needed.

3.5 Neighborhoods and Equity

This section summarizes the IBR Program's benefits and impacts to neighborhoods and the broadened view of equity priority communities.

Transportation infrastructure substantially influences neighborhoods and communities. Highways and transit connect people with their homes and daily destinations, while local streets and paths provide circulation for drivers, bicyclists, and pedestrians within their neighborhoods. New or modified transportation infrastructure can improve these connections, such as by improving commutes for nearby residents and increasing community investment. It can also negatively change a community's character, for example by displacing neighborhood resources and increasing noise levels for residents adjacent to the highway. Thoughtful planning and design of transportation infrastructure can increase benefits to surrounding communities and reduce negative impacts.

The IBR Program defines **equity priority communities** as those who experience and/or have experienced discrimination and exclusion based on identity or status. The IBR Program provides a two-part definition for equity:

1. **Process equity** means that the IBR Program centers and prioritizes access, influence, and decision-making power for equity priority communities in establishing objectives, design, implementation, and evaluation of success.
2. **Outcome equity** is the result of successful process equity and is demonstrated by tangible transportation, community, and economic benefits for equity priority communities.

Terms and Definitions

As defined by the IBR Program, **Equity priority communities** refer to populations who experience and/or have experienced discrimination and exclusion based on identity or status, including:

- Black, Indigenous, and People of Color
- Tribal Governments
- People with disabilities
- Communities with limited English proficiency
- Persons with lower incomes
- Houseless individuals and families
- Immigrants and refugees
- Young people (under 25 years of age)
- Older people (65 years or older)

Together, process equity and outcome equity contribute to addressing harmful impacts and removing longstanding injustices experienced by equity priority communities.

The information in this section is based on the IBR Neighborhoods and Populations Technical Report and Equity Technical Report.

3.5.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with neighborhoods and equity has been updated in this Draft SEIS to include:

Neighborhoods

- Updated demographic information, neighborhood characteristics, and community resources within the study area.
- Changes in land uses such as development at the Vancouver Waterfront, planned uses on Hayden Island, and recently constructed, altered, or removed buildings.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the LRT alignment and modifying interchange designs.
- Updated analysis of the Modified LPA and design options, which were necessitated by changed conditions.
- Updated analysis of long-term, short-term, direct, indirect, and cumulative effects on Oregon and Washington neighborhoods resulting from the Modified LPA.

Equity

- Prepared a new Equity Technical Report based on the IBR Program Equity Framework.
- Applied the Climate and Economic Justice Screening Tool (CEQ 2023) to assist identifying equity priority populations.
- Incorporated directives from Presidential Executive Order (EO) 13985: Advancing Racial Equity and Support for Underserved Communities Through the Federal Government (2021) and Presidential EO 14096: Revitalizing Our Nation's Commitment to Environmental Justice for All (2023).
- Developed a public engagement plan that targets equity priority communities and evaluated benefits and burdens to these communities to support the U.S. Department of Transportation's Justice40 Initiative as part of Presidential EO 14008: Tackling the Climate Crisis at Home and Abroad (2021).
- Coordinated and engaged with the newly chartered Community Advisory Group and Equity Advisory Committee per the IBR Equity Framework and also updated public engagement efforts.
- Identified long-term, short-term, direct, indirect, and cumulative effects to equity communities resulting from the Modified LPA and design options.

IBR Equity Framework

The IBR Program is committed to centering equity by developing a shared understanding of what the Program seeks to achieve and how it will be achieved. IBR Equity Framework outlines the Program's approach and tools it will use to advance equity.

Table 3.5-1 compares the impacts and benefits to neighborhoods and equity between the CRC LPA and the IBR Modified LPA. While the CRC Final EIS evaluated neighborhoods, equity was not explicitly studied.

The impacts associated with the Modified LPA do not differ substantially from those of the CRC LPA. Both the CRC LPA and the Modified LPA would be consistent with neighborhood plans, both would have lower emissions for all Mobile Source Air Toxics and criteria pollutants than under existing conditions, I-5 travel times and reliability would improve, and access to transit, bike, and pedestrian facilities would increase. A detailed description of impacts and benefits to neighborhoods and equity from the IBR Modified LPA and associated design options follows.

Table 3.5-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects on Neighborhoods and Equity

Technical Considerations	Technical Subgroup	CRC Effects Identified in the 2011 Final EIS	Modified LPA	Explanation of Differences
Displacements	Residential	59	43 for most design options. One design option that shifts I-5 west in downtown Vancouver would displace 33 residential units in the Esther Short neighborhood, resulting in 76 total residential displacements.	Modified LPA design changes would reduce residential property acquisition, except the I-5 westward shift design option, which would increase displacements compared to the CRC LPA. Key design changes include replacing the full interchange on Hayden Island with a partial interchange and moving the LRT alignment closer to I-5 (removing the proposed couplet in downtown Vancouver).
	Business	69	36 for most design options. One design option that shifts I-5 west in downtown Vancouver would displace three commercial businesses at the Regal City Center Complex, resulting in 39 total business displacements.	Commercial property acquisitions would also decrease due to the Modified LPA's smaller footprint.
Neighborhoods	Access to resources	• Displacement of Hayden Island Safeway and bottle return.	• None identified.	The Safeway grocery store (including a pharmacy and bottle return) closed after the CRC project was suspended. A new Target store, replacing some of these services, was constructed outside the Modified LPA footprint.
	Community cohesion	• Improved cohesion with light-rail and transit-oriented development. • Would result in residential and commercial displacements.	• Similar to the CRC LPA, but with fewer commercial displacements; residential displacements would be less than under the CRC LPA for all design options except the I-5 westward shift design option.	Impacts of the CRC project and the Modified LPA for Hayden Island are similar and would affect community cohesion despite benefits from improved transit, bicycle, and pedestrian connections. Due to differences in design footprint, the

Technical Considerations	Technical Subgroup	CRC Effects Identified in the 2011 Final EIS	Modified LPA	Explanation of Differences
		• Reduced access to restaurants, wage-earning jobs on Hayden Island.		CRC project would have caused more commercial displacements and, except for the I-5 westward shift design option, more residential displacements.
	Noise and vibration	• 110 residential equivalent impacts after mitigation.	• 122 residential equivalent impacts after mitigation.	Noise impacts would increase with the Modified LPA. Differences between CRC and the Modified LPA result from changes in highway footprint at the I-5/SR 500/39th Street Interchange and in Oregon, as well as changes in transit alignment and proximity of alignment to the direct fixation trackway in downtown Vancouver.
	Tolling	• Tolling would increase overall household transportation costs and would require a higher share of income for low-income populations. Transponder mitigation for low-income populations would offset this impact. • Tolls would reduce travel times and improve travel time reliability.	• Similar to CRC LPA. • Toll rates and policies, including a possible low-income toll program, would be jointly set by the OTC and WSTC. Both commissions have supported the study of a low-income toll program, including how such a program could be implemented in each state. They will work together to determine how to approach this for the IBR Program.	Although changes in external economic conditions over time (e.g., inflation) may have influenced household costs related to tolling, the effects would be similar between CRC and the Modified LPA.

Technical Considerations	Technical Subgroup	CRC Effects Identified in the 2011 Final EIS	Modified LPA	Explanation of Differences
Equity	High-capacity transit	N/A [a]	• All equity priority communities would experience increased access to jobs and services via transit. • Three equity priority communities are estimated to see greater increases in access than their counterparts.	New analysis completed for the Modified LPA.
	Highway and driving improvements	N/A	• 18% to 20% more jobs accessed during AM peak and 3% during midday (on average) for all equity priority communities living in the Program area.	New analysis completed for the Modified LPA.
	Houseless populations	N/A	• Residential displacement for those living within existing or to-be-acquired right of way.	New analysis completed for the Modified LPA.
	Long-term displacement potential	N/A	• Potential for increased costs of housing and other necessities due to improved amenities and livability, which in turn could lead to displacement of lower-income residents.	New analysis completed for the Modified LPA.
	Tolling	N/A	• New toll requires higher proportion of income for low-income drivers. • Toll rates and policies, including a possible low-income toll program, would be jointly set by the OTC and WSTC.	New analysis completed for the Modified LPA.

Note: Residential Equivalent = used to equate the use of common outdoor areas to individual outdoor use areas for parks or other nonresidential household uses. The calculation includes the usage factor of the area, the number of uses, and the equation of users to residences.

a The CRC project EIS did not identify, define, or evaluate impacts/burdens and opportunities to equity populations.

CRC = Columbia River Crossing; LPA = locally preferred alternative; LRT = light-rail transit; N/A = not applicable; OTC = Oregon Transportation Commission; WSTC = Washington State Transportation Commission

3.5.2 Existing Conditions

The IBR corridor includes a 5-mile segment of I-5 approximately between the SR 500 interchange in Washington and the I-5/Columbia Boulevard interchange in Oregon, as well as the Ruby Junction Maintenance Facility in Gresham, Oregon.

Terms and Definitions

Community resources and cohesion. Community resources typically include educational, religious, health care, cultural, and recreational facilities. Community cohesion measures how well residents can connect with one another within their community. These connections can occur at gathering places such as schools, community centers, parks, or transit stations. High home ownership rates and active neighborhood associations also contribute to cohesion.

Neighborhoods

The study area includes 15 neighborhoods in the cities of Portland, Gresham, and Vancouver (Figure 3.5-1).

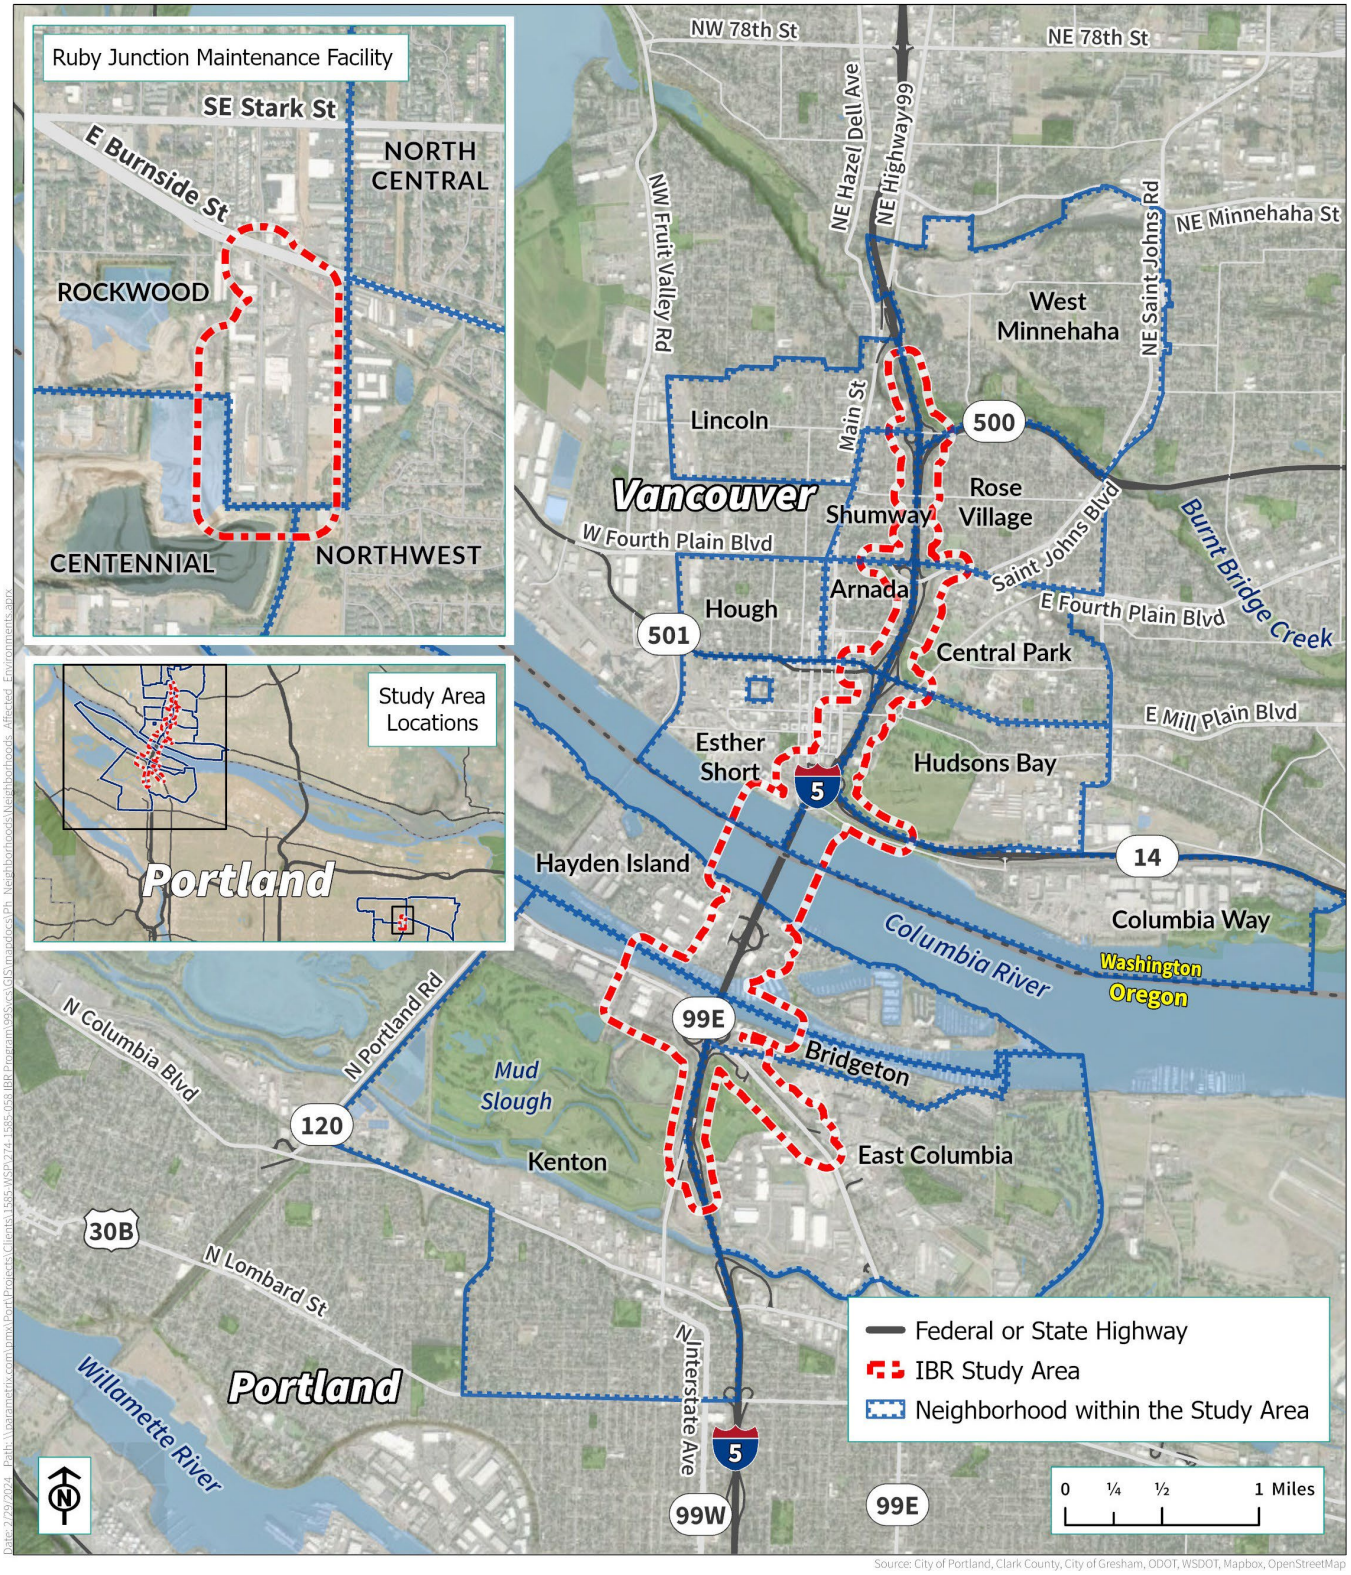
- Portland
  - Bridgeton
  - East Columbia
  - Hayden Island
  - Kenton
- Gresham
  - Rockwood
- Vancouver
  - Arnada
  - Central Park
  - Columbia Way
  - Esther Short
  - Hough
  - Hudson's Bay
  - Lincoln
  - Rose Village
  - Shumway
  - West Minnehaha

Data that help identify the overall neighborhood character and equity priority communities, which are detailed in the IBR Neighborhoods and Populations Technical Report, include:

- Total population.
- Household size.
- Demographics of equity priority communities compared to city and county.
- Median assessed home value.
- Crime rate statistics.
- Inventory of community resources.
- Neighborhood cohesion.

Analysists primarily used 2022 U.S. Census data for the analysis. Other data sources are provided in the footnotes to the tables in this section.

Figure 3.5-1. Neighborhoods in the Study Area



Neighborhood Demographics

Each neighborhood has a unique character formed by its residents, community resources, businesses, and landmarks. Table 3.5-2 through Table 3.5-7display the race/ethnicity, demographic, and age characteristics of study area neighborhoods in Oregon and Washington. For Oregon neighborhoods, data for Portland and Multnomah County are provided for comparison. For Washington neighborhoods, data for Vancouver and Clark County are provided for comparison. Several distinctions within the demographics of the study area are summarized as follows:

The IBR Program is consulting with 10 federally recognized Indian Tribes. While there are no reservations within the IBR study area, these tribes are sovereign nations that have identified an interest in the Program and the project area. Enrollment data is held and managed by the tribes and therefore is not incorporated into this report. However, tribal members living within the IBR study area are reflected in the U.S. Census data, but they are not specifically identified by tribal affiliation.

People with disabilities. The disabled population rate varies across study area neighborhoods. The Esther Short neighborhood reports a 25% disability rate, likely due to the senior housing in the area. All other neighborhood disability rates fall between about 11% and 19% (see Table 3.5-5).

Older adults and children. The Columbia Way neighborhood has the largest rate of people over 65, with 38.6%; all other study area neighborhoods have a rate between 6.5% and 26%. The Columbia Way neighborhood has the lowest percentage of children (age 18 or younger), at 3.2%, while the Rockwood neighborhood has the highest percentage of children, at 28.3% (see Table 3.5-6 and Table 3.5-7).

Car ownership. The neighborhoods vary in their reliance on automobile transportation. Thirty percent of households in the Esther Short neighborhood report not owning a car. The Hough neighborhood also shows relatively low rates of car ownership; 20% of the residents do not own a car. All other neighborhoods have a rate of households without a car between 2.1% and 16.5% (see Table 3.5-4 and Table 3.5-5).

Table 3.5-2. Race/Ethnicity for Oregon Study Area Neighborhoods, Portland, and Multnomah County

Study Area Neighborhood	Total Population	White Alone	Black or African American Alone	American Indian and Alaska Native Alone	Asian Alone	Native Hawaiian and Other Pacific Islander Alone	Some Other Race Alone	Two or More Races	Hispanic or Latino Alone
Hayden Island	2,373	76.5%	0.8%	2.1%	0.9%	0.4%	<0.1%	4.2%	15.0%
Bridgeton	701	69.4%	21.1%	1.9%	0.1%	<0.1%	0.0%	4.3%	3.1%
East Columbia	1,141	52.7%	16.8%	0.1%	16.2%	1.0%	0.0%	5.6%	7.7%
Kenton	7,626	67.6%	8.7%	0.6%	2.2%	0.9%	<0.1%	8.6%	11.4%
Rockwood	13,712	40.0%	7.5%	1.6%	6.4%	2.1%	<0.1%	3.6%	38.7%

Neighborhood Plans

Neighborhoods often define themselves and strengthen their identities through neighborhood plans, which are formally adopted by city-supported neighborhood associations. The Cities of Portland and Vancouver formally adopt these neighborhood plans as part of their respective comprehensive plans. All neighborhoods

in the study area have an adopted plan except for the East Columbia, Rockwood in Gresham, and Columbia Way neighborhoods.

Neighborhood plans typically include goals, objectives, proposed comprehensive plan and zoning changes, and an implementation strategy. Within the study area, neighborhood plans with goals relevant to potential benefits and impacts of the IBR Program include:

- Minimize the adverse impacts of increased density; support density adjacent to transit.
- Preserve existing housing stock; preserve historic character.
- Reduce transportation-related noises and odor; mitigate I-5 noise.
- Reduce speeding within the neighborhood.
- Enhance and maintain on-street parking, including bike parking.
- Maintain adequate transit service; support development of light-rail.
- Improve bicycle and pedestrian facilities and connections.
- Protect the Columbia River from contaminants.

Equity

For each equity priority community, Table 3.5-8 lists the percentage that population comprises in the Program area and the broader Portland-Vancouver metropolitan area.[1] People with disabilities, persons with lower incomes, and older adults make up a large share of the Program area population compared to the metropolitan area. Percentages of young people and immigrants and refugees are lower in the Program area than in the metropolitan area, while percentages of Black, Indigenous, and People of Color (BIPOC) and limited English proficiency populations are similar. Section 3.20, Environmental Justice, discusses existing conditions and potential long-term effects on low-income and minority populations.

Table 3.5-8. Percentage of Equity Priority Communities within the IBR Program Area and Portland-Vancouver Metropolitan Area

Community	Description	Percent Program Area Population	Percent Portland-Vancouver Metropolitan Area Population
Black, Indigenous, and People of Color	People selecting any race/ethnicity combination besides White/non-Hispanic on the census.	30%	31%
People with Disabilities	People living with a serious difficulty within four basic areas of functioning: hearing, vision, cognition, and ambulation.	15%	12%
Communities with Limited English Proficiency	People who indicate that they speak English less than very well.	6%	6%

[1] Because tribes are sovereign nations with members living throughout local communities across Oregon, Washington, reservations, the United States, and beyond, elements of equity for tribal governments are discussed separately from other equity priority communities, which can be evaluated, in part, with demographic data. Data for houseless individuals and families is not shown because the geographic area for which this data is available is too large to determine a count for the IBR Program area.

Community	Description	Percent Program Area Population	Percent Portland-Vancouver Metropolitan Area Population
Persons with Lower Incomes	People or households with income at or below 200% of the federal poverty level.	32%	24%
Immigrants and Refugees	People born outside of the United States (Foreign Born Population).	9%	13%
Young People	People under 25 years of age.	25%	29%
Older Adults	People 65 years of age or older.	18%	15%

Source: U.S. Census Bureau 2022, Tables B03002, S1810, C16001, C17002, DP02, Table B01001

The IBR Program is consulting with 10 federally recognized Indian Tribes. Tribal governments (federally recognized tribes) are sovereign nations as recognized by the U.S. Government, and consultation with federally recognized tribes occurs through a government-to-government consultation process that is separate and distinct from public and community outreach and comment. Because tribes are sovereign nations with members living throughout local communities, Oregon, Washington, reservations, the United States, and beyond, elements of equity for tribal governments are discussed separately from other equity priority communities, which can be evaluated, in part, with demographic data.

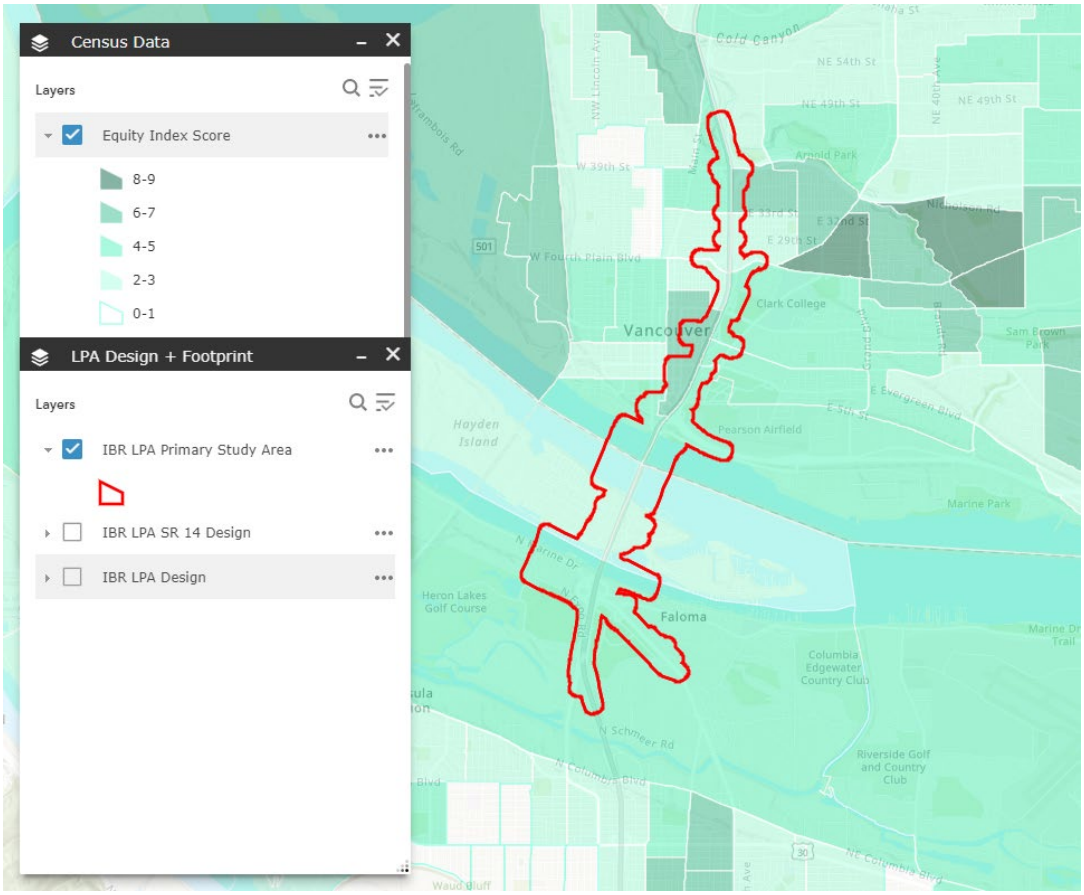
An equity index tool was developed to identify where equity priority communities live in the study area and the metropolitan region, with the exception of tribal governments (as noted above). The equity index assigns points to geographic areas (block groups or census tracts) in the study area that have an above-average percentage of equity priority populations compared to the metropolitan region. For example, 25% of the region's households are low-income according to census information (U.S. Census Bureau 2022), so a point was awarded to a study area block group if greater than 25% of households were low-income. Figure 3.5-2 shows a screenshot of this interactive web-based tool, showing that most equity priority communities are located in downtown Vancouver and east of the study area.

3.5.3 Engagement Activities and Consultation

Public Engagement Activities

Public involvement is important to data gathering, building trust, and developing viable solutions. Meaningful public involvement in the IBR Program included forming four advisory groups: the Community Advisory Group, Equity Advisory Group, Community Benefits Advisory Group, and Executive Steering Group. The advisory groups are composed of regional community members, who were identified and appointed to represent a diverse range of perspectives, as well as representatives from local agencies and community-at-large members. The IBR Program has been engaging with partner agencies, tribal governments, and community-based organizations since late 2020 and has been conducting more formal intentional community engagement since January 2021. This process is documented in the IBR Community Engagement Report (IBR 2021) and is described in Appendix B.

Figure 3.5-2. Screenshot of IBR Equity Index



Government-to-Government Consultation

WSDOT, ODOT, FHWA, and FTA are committed to government-to-government consultation with tribes on projects that may affect tribal rights and resources. The IBR tribal consultation process is designed to encourage early and continued feedback from, and involvement by, tribes potentially affected by the IBR Program and to ensure that their input is incorporated into the decision-making process. Although tribal coordination and government-to-government tribal consultation is being undertaken as a distinct outreach effort, tribal involvement is also occurring concurrently with agency coordination and public involvement. The government-to-government consultation goals and process are documented in Appendix A, Agency and Tribal Coordination.

3.5.4 Long-Term Benefits and Effects

Table 3.5-9 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on neighborhoods. Table 3.5-10 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on equity. Detailed analyses of the effects are provided in the following sections.

Table 3.5-9. Summary of No-Build Alternative and Modified LPA Effects on Neighborhoods

1	2	3	4	5
No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One or Two Auxiliary Lanes, with or without C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Single-Level Fixed-Span Configuration,[a] One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options
• No change to existing neighborhoods, community facilities, or social resources. Future development might not be fully consistent with goals that assume improved mobility and expanded transit access. Neighborhoods would not benefit from reduced congestion, improved mobility, and access to employment.	• Would not adversely affect community cohesion in neighborhoods, except for Hayden Island. Could increase cohesion in neighborhoods near the Community Connector. • Would affect the Hayden Island neighborhood's community cohesion, including displacement of floating homes and changes to views. Fourteen businesses would be displaced. However, neighborhood cohesion would be improved by a more continuous street system, improved pedestrian and bicycle facilities, and transit that increases connections for residents. • Construction-related impacts such as traffic diversion noise, temporary reductions in air quality, and sidewalk disruptions.	• Similar to Column 2 but with additional residential displacements in the Esther Short neighborhood.	• Similar to Column 2.	• Similar to Column 3, except that bridge openings would cause backups. The backups would reduce reliability for all travel modes, similar to the No-Build Alternative, which would negatively affect neighborhood cohesion by impairing access to community facilities and encouraging cut-through traffic in neighborhoods.

a The effects associated with the single-level fixed-span configuration would be the same for all bridge type options.

Table 3.5-10. Summary of No-Build Alternative and Modified LPA Effects on Equity

1	2	3	4	5
No-Build Alternative	**Modified LPA with Double-Deck Fixed-Span Configuration One Auxiliary Lane, With or Without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options**	**Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, With or Without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options**	**Modified LPA with Single-Level Fixed-Span Configuration, [a] One Auxiliary Lane, With or Without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options**	**Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, With or Without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options**
• Equity priority communities would not benefit from increased mobility and accessibility. • Would avoid short- and long-term displacement of residents and businesses. • Would avoid construction-related impacts such as traffic diversion, noise, temporary reductions in air quality, and cost burdens of tolling.	• Increased access to high-capacity transit, increased availability of active transportation, and highway and driving travel time reductions. The degree of benefits would vary by equity priority community. • Increase in job access for all demographic groups due to faster travel times. • Potential displacement of encampments of houseless populations, residential displacements, and additional transportation cost from tolling. There would be more residential displacements with the I-5 westward shift design option. • Construction-related impacts such as traffic diversion, noise, temporary reductions in air quality, and cost burdens of tolling. • Tolling would place a burden on low-income travelers.	• Similar to Column 2, but it would reduce delay and congestion on the Columbia River bridges to a greater extent, which would improve travel times for motorists, express bus riders, and emergency vehicles; slightly greater increase in jobs access for all demographic groups.	Similar to Column 2, except: • Users would experience a shorter distance to walk across the bridge. • Users may feel safer due to the extra security of being visible to passing vehicles.	• Similar to Column 4, except that there may be travel delays for transit and active transportation users due to lifts of the movable span. This would reduce the level of benefit that the Modified LPA would provide to equity priority communities.

a The effects associated with the single-level fixed-span configuration would be the same for all bridge type options.

No-Build Alternative

Neighborhoods

Under the No-Build Alternative, there would be no Program-related change to existing neighborhoods, community facilities, or social resources. Neighborhoods in the study area would continue to develop according to local and regional plans, though their development might not be fully consistent with goals that assume improved mobility in the I-5 corridor and expanded transit access; for example, the goals of the Hayden Island Plan would likely not be realized without the construction of a high-capacity transit station on the island. Section 3.4, Land Use, contains more information on local land use plans. There would be no changes in noise or vibration levels or transportation patterns that would change community cohesion, but study area neighborhoods would not benefit from reduced congestion, improved mobility, or access to employment opportunities from increased transit connectivity and improved active transportation connections.

Equity

The No-Build Alternative would not move the IBR Program toward its equity objectives. Equity priority communities would not benefit from increased mobility and accessibility resulting from construction of light-rail, active transportation facilities, or highway improvements.

In terms of potential burdens, the No-Build Alternative would avoid short- and long-term displacement of residents and businesses, as well as other construction-related impacts such as traffic diversion, noise, temporary reductions in air quality, and cost burdens of tolling. Above-average concentrations of equity priority communities were identified in each subarea where these impacts would occur.

Modified LPA

Most long-term effects on neighborhoods and equity would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Neighborhoods

Oregon

Potential effects on neighborhoods from the Modified LPA were assessed using six questions defined by the IBR Program to evaluate impacts and benefits. Table 3.5-11 summarizes the questions and answers for each Oregon neighborhood in the study area.

The Modified LPA is not anticipated to adversely affect community cohesion in most neighborhoods, except for Hayden Island. In the Hayden Island neighborhood, the Modified LPA is anticipated to adversely affect the neighborhood's community cohesion, particularly among the floating home community, where there would be changes to views and displacements of some floating homes. Fifteen businesses, and the 159 jobs associated with them, would be displaced, many of which are restaurants that provide places for neighbors to meet. In addition, bridge openings associated with the single-level movable-span configuration would cause backups that would reduce reliability for all travel modes, similar to the No-Build Alternative, which would negatively affect neighborhood cohesion.

However, neighborhood cohesion on Hayden Island would be improved by a more continuous street system, improved pedestrian and bicycle facilities, and transit that increases connections for residents under the Modified LPA. This assessment is described in more detail in the Neighborhoods and Populations Technical Report.

Table 3.5-11. Overview of Potential Effects on Oregon Neighborhoods

Potential Effect Question	Hayden Island	Bridgeton	East Columbia	Kenton	Rockwood
Will the Program displace people or community resources, including businesses?	Residential and business displacement	Business displacement	Impacts to Delta Park (loss of 1 acre of off-leash area)	Residential and business displacement	Business displacement
Will the Program create direct or indirect impacts to social services by displacing them?	No	No	No	No	No
Will the Program separate neighborhood residents from community resources?	No	No	No	No	No
Will the Program change travel such that it will affect access to community resources?	No	No	No	No	No
Will the Program change community cohesion?	Yes, positively and negatively	No	No	No	No
Is the Program consistent with existing neighborhood plan goals?	Yes	Yes	N/A[a]	Yes	N/A [a]

a This neighborhood does not have an approved neighborhood plan.

Washington

Table 3.5-12 summarizes the answers to the same set of questions for the study area neighborhoods in Vancouver. The Modified LPA is not anticipated to adversely affect community cohesion in these neighborhoods.

Table 3.5-12. Overview of Anticipated Effects on Vancouver Neighborhoods

Potential Effect Question	Rose Village	Hough	Arnada	Central Park	Esther Short	Hudson's Bay	Columbia Way
Will the Program displace people or community resources, including businesses?	No	No	No	Impacts to Marshall Park through land acquisition	Business displace-ments Residential displace-ments (design options)	No	No
Will the Program create direct or indirect impacts to social services by displacing them?	No	No	No	No	No	No	No

Potential Effect Question	Rose Village	Hough	Arnada	Central Park	Esther Short	Hudson's Bay	Columbia Way
Will the Program separate neighborhood residents from community resources?	No	No	No	No	No	No	No
Will the Program change travel such that it will affect access to community resources?	No	No	No	No	No	No	No
Will the Program change community cohesion?	No	No	No	No	No	No	No
Is the Program consistent with existing neighborhood plan goals?	Yes	Yes	Yes	Yes	Yes	Yes	N/A [a]

a This neighborhood does not have an approved neighborhood plan.

The Modified LPA would require the acquisition of a portion of Marshall Park in the Central Park neighborhood for a retaining wall along I-5. The retaining wall would displace horseshoe pits, landscaping, and trees that serve as a buffer between the community center and I-5; the current community center and senior center would remain. Compared to the centered mainline, the I-5 Mainline Westward Shift design option would require two additional property acquisitions: the Normandy Apartments, where 33 residential units would be displaced, and the Regal City Center complex, where three businesses would be displaced. This is a notable effect, especially for those living in these units. However, these displacements are not anticipated to substantially alter neighborhood cohesion because the Normandy Apartments are located at the edge of the neighborhood in an otherwise nonresidential area. Moreover, the displaced businesses, which are not considered community resources, make up a small portion of overall commercial property in the neighborhood.

Three sites are being considered for the Waterfront Park and Ride. Depending on the site selected, there would be up to four parcels acquired, with up to one business displacement. The potential displacement of a single business at the Waterfront Park-and-Ride site would not affect neighborhood cohesion. Two sites are being considered for the Evergreen Park and Ride; depending on the site, up to five parcels would be acquired, with no businesses or residential units displaced. For a more detailed analysis, see the Neighborhoods and Populations Technical Report.

The Modified LPA design options would have differing effects on travel reliability, congestion, and neighborhood cohesion, depending on their specific design elements. The single-level fixed-span and single-level movable-span configurations would have a lower profile than the double-deck fixed-span configuration at the bridge landing in downtown Vancouver. The single-level configurations would provide more flexibility in potential locations for the Vancouver Waterfront Station compared to the double-deck fixed-span configuration.

In addition, the single-level bridges would provide more opportunities for connection to residences and development, helping to maintain or improve neighborhood cohesion. However, bridge openings associated with the single-level movable-span configuration could cause backups that would reduce reliability for all travel modes similar to the No-Build Alternative. These backups could spill into neighborhood streets, limiting circulation within the neighborhood, impeding access to community facilities, and, thereby, negatively affecting neighborhood cohesion.

The design option eliminating the C Street ramps would redirect traffic from downtown Vancouver to the Mill Plain Boulevard interchange. This would result in additional traffic delay at intersections near the Mill Plain Boulevard interchange, which could reduce neighborhood cohesion in the Esther Short neighborhood by substantially increasing travel delay for residents and people accessing the neighborhood. These impacts would occur in an equity priority community.

Equity

This equity assessment looks at the distribution of benefits and burdens. Benefits from the Modified LPA to equity priority communities include increased access to high-capacity transit, increased availability of active transportation, and highway and driving travel time reductions. Burdens to equity priority communities include potential displacement of encampments of houseless populations, residential displacements, and the additional transportation cost from tolling.

Terms and Definitions

Counterparts: Those who are not members of a particular equity priority community. For example, the counterpart to the BIPOC community is the White, non-Hispanic population.

The Modified LPA would benefit equity priority communities with increased mobility and accessibility choices—specifically, the high-capacity transit and active transportation program elements. These new transportation improvements would help address existing gaps for those who depend on modes other than automobile transportation. While all members of the local community would have access to 40% more jobs via improved mode choices compared to the No-Build Alternative, the high-capacity transit analysis did identify some disparities in terms of distribution of benefits (i.e., increased access to jobs) between equity priority communities living in the study area and their non-equity priority counterparts. Three demographic groups—people with disabilities, persons with lower incomes, and older adults—would likely see greater increases in access than their counterparts during either or both the morning peak and midday hours. BIPOC communities, those with limited English proficiency, immigrants and refugees, and young people would experience an increase in accessibility, but the increase would be less than for their demographic counterparts. To address these disparities, the Program is working closely with C-TRAN to optimize the transit network and create convenient bus connections from the Evergreen Station to surrounding racially diverse neighborhoods.

Distribution of Benefits

High-Capacity Transit

The equity analysis used demographic and jobs data to examine how the Modified LPA's light-rail alignment would affect transit riders' mobility. Specifically, the analysis estimated how many jobs (a proxy for access to both employment and services) would be within a 45-minute trip on the 2045 transit network. The 45-minute threshold is consistent with a similar analysis conducted by the Portland Bureau of Transportation (Portland Bureau of Transportation 2020).

The equity analysis found that the degree of transit access improvements would differ across equity priority communities and the general population. Based on where members of equity priority communities currently live, three equity priority groups (people with disabilities, persons with lower incomes, and older adults) are estimated to see greater increases in access to jobs and services during either or both the morning peak and midday hours compared to their counterparts. Based on where they currently live, four equity priority groups (BIPOC communities, limited English proficiency, immigrants and refugees, and young people) would experience an increase in accessibility, but the increase would be less than for the general population. Table 3.5-13 shows the transit access improvements expected for equity priority communities in the study area.

Table 3.5-13. Transit Access Improvements for Equity Priority Residents: Percentage Increase in Jobs Access in a 45-Minute Trip

Equity Priority Community	Morning Peak Increase for Average [a] Member of Community (e.g., BIPOC)	Morning Peak Increase for Average Counterpart (e.g., White Non-Hispanic/Latino)	Midday Increase for Average Member of Community (e.g., BIPOC)	Midday Increase for Average Counterpart (e.g., White Non-Hispanic/Latino)
Black, Indigenous, and People of Color (BIPOC)	85%	107%	55%	68%
People with Disabilities	111%	96%	66%	59%
Communities with Limited English Proficiency	67%	100%	43%	61%
Persons with Lower Incomes	100%	92%	60%	60%
Immigrants and Refugees	71%	101%	46%	61%
Young People (under 25)	74%	102%	47%	64%
Older Adults (65+)	131%	87%	83%	55%

Sources: Metro 2045 Regional Model; U.S. Census Bureau 2020, 2022

Notes:

"Counterpart" is defined as someone who is not considered a member of the corresponding equity priority community. For example, the counterpart to members of the BIPOC community are those whose race/ethnicity combination is White Non-Hispanic/Latino; the counterpart to people with disabilities is people who do not have a disability, and so on.

Due to overlap within equity priority communities (i.e., individuals who belong to more than one community), the total increase in jobs for all equity priority community members cannot be determined.

a Average access is calculated based on residential distribution of each demographic group and weighted accordingly.

Estimated access improvements are similar when comparing equity priority communities and the general public at the regional level (i.e., the average resident of the four-county region in each group would see similar increases in access to jobs reachable within a 45-minute transit ride).

Demographic characteristics of residents within a half-mile walk of a station are largely similar to the Program area as a whole, meaning the stations serve equity priority communities at a level expected given where they live in the Program area.

Active Transportation

Active transportation components of the Modified LPA would support the equity objective to "improve mobility, accessibility, and connectivity, especially for lower-income travelers, people with disabilities, and historically underserved communities that experience transportation barriers." The facilities would provide new and safe connections for all people of all abilities and would improve the quality of existing connections.

Several of the Modified LPA design options would have different long-term effects on active transportation. Experiences could differ for the various age and ability levels, depending on grade, height, and distance of each option. The bridge configurations would have the following different impacts on active transportation:

- People walking, bicycling, or rolling on the shared-use path would be more exposed to noise from highway vehicles on the single-level fixed-span and the single-level movable-span configurations compared to the double-deck configuration. Blind and low-vision individuals could experience the greatest noise interference in their active transportation as they use sound to aid navigation.
- The single-level movable-span configuration would have a lower bridge height over the Columbia River than the double-deck fixed-span and single-level fixed-span configurations, which would decrease the length and steepness of the uphill and downhill grades for all users on the shared-use path.
- Some equity priority communities are more affected by discrimination and violence, and they might prefer the single-level fixed-span and single-level movable-span configurations because they provide visibility to active transportation users from passing vehicles, thereby potentially providing an increased sense of security. In comparison, with the double-deck fixed-span configuration, active transportation users would travel on the lower bridge deck and would not be visible from passing vehicles on the upper decks.
- With the single-level movable-span configuration, active transportation users could experience additional travel delays when bridge openings occurred. These delays would be similar to the No-Build Alternative. However, fewer bridge openings are anticipated with the Modified LPA single-level movable-span configuration because it would have increased vertical navigation clearance in the closed position that would allow more vessels to travel under the bridge in the closed position compared to the existing Interstate Bridge.

These differences in the experiences of active transportation users could adversely affect equity priority communities more than the general population—in particular, BIPOC, low-income, and people with disabilities—due to their greater reliance on modes besides driving.

Highway and Driving Improvements

As shown in Table 3.5-14, the Program area analysis estimates that, due to reduced congestion, within a 45-minute commute each demographic group would be able to reach an average of 18% to 20% more jobs during the morning peak and an average of about 3% more jobs during the midday (within a 45-minute drive) under the Modified LPA compared to the No-Build Alternative. This equates to an increase in access to about 180,000 to 197,000 jobs during the morning peak and 35,800 to 44,000 jobs during the midday.

As shown in Table 3.5-15, within the Portland-Vancouver metropolitan area, average access improvements from the Modified LPA would be 3% to 4% (an additional 30,000 to 37,000 jobs) during the morning peak and about 1% (an additional 11,400 to 13,700 jobs) during the midday compared to the No-Build Alternative. Estimated increased access to jobs would be similar between equity priority communities and the general public.

The addition of a second auxiliary lane in each direction would have a slightly greater increase in jobs access for all demographic groups due to faster travel times within the corridor from less congestion.

Table 3.5-14. Driving Access Improvements for Equity Priority Community Residents in the Program Area: Percentage Increase in Jobs Access with the Modified LPA Compared to No-Build Alternative (45-minute Travel Time)

Equity Priority Community	Morning Peak: Increase for Average Member of Community (e.g., BIPOC) [a]	Morning Peak: Increase for Average Counterpart (e.g., White Non-Hispanic/ Latino)	Midday: Increase for Average Member of Community (e.g., BIPOC)	Midday: Increase for Average Counterpart (e.g., White Non-Hispanic/ Latino)
Black, Indigenous, and People of Color	19%	19%	3%	3%
People with Disabilities	19%	19%	3%	3%
Communities with Limited English Proficiency	20%	19%	3%	3%
Persons with Lower Incomes	20%	19%	3%	3%
Immigrants and Refugees	19%	19%	3%	3%
Young People (Under 25)	20%	19%	3%	3%
Older Adults (65+)	18%	19%	3%	3%

a Average access is calculated based on residential distribution of each demographic group and weighted accordingly.

Tribal Government Consultation

In addition to the benefits associated with increased transit options and improved highway and active transportation, the government-to-government consultation process is encouraging improved and timely communication between the IBR Program and tribes. This process enables tribal governments to understand the Program, ask questions, and participate in issue identification and solution strategies, which could lead to protection of culturally sensitive resources, increased input into the design of the Program, and avoidance, minimization, and mitigation measures of potential impacts to resources valued by tribal governments.

Community Benefits

The IBR Program's Community Benefits Advisory Group is developing recommendations for community benefit efforts to achieve the greatest positive benefit to the communities in the Program area and broader region from the Program's work, in alignment with the Program's equity framework and community priorities. Recommendations from this advisory group will be shared with the larger community for input. This advisory group is collaborating with the Equity Advisory Group, Community Advisory Group, and the IBR Program to identify benefits that could be incorporated into the Final SEIS as mitigation strategies, construction contracts as design and construction specifications, or other documents as appropriate to ensure accountability for implementation of the community benefits.

Distribution of Burdens

Table 3.5-16 presents an analysis of the associated property impacts identified for each of the five geographic subareas and the specific equity priority communities affected by these property impacts. All subareas have high concentrations of multiple equity priority communities. The IBR Program has conducted outreach to potentially affected communities in each of these subareas and will continue to engage the community and consult with the Equity Advisory Group to identify and address potential impacts throughout the planning and design phases.

Table 3.5-16. Overview of Impacts to Equity Priority Communities in the Study Area

Study Area Subarea	Equity Priority Communities with Above-Average Representation [a]	Property Acquisitions and Displacements
Oregon Mainland	• BIPOC • Low-Income • People with Disabilities • Older Adults	• 4 single-family homes displaced (3 floating homes, 1 on land). • 5 retail/service businesses displaced. • 20 partial parcel acquisitions.
Hayden Island	• People with Disabilities • Older Adults	• 32 single-family homes displaced (all floating homes). • 15 retail/service businesses displaced. • 20 partial parcel acquisitions.
Downtown Vancouver	• Low-Income • People with Disabilities • Older Adults	• 10 office/professional/healthcare businesses displaced. • 31 partial parcel acquisitions.
Upper Vancouver	• BIPOC • Limited English proficiency • Low-Income • Older Adults • Young People	• 7 single-family homes displaced. • 33 multifamily units displaced (I-5 Mainline Westward Shift design option only). • 58 partial parcel acquisitions.
Ruby Junction	• BIPOC • Immigrants and Refugees • Low-Income • Young People	• 3 retail/service businesses displaced.

a Specific equity priority communities are listed where their percentage of the population is above average for the Portland-Vancouver metropolitan area in at least one census tract in that geographic area.

BIPOC = Black, Indigenous, and People of Color

Houseless Populations

The Modified LPA would likely displace houseless individuals and families staying in the study area during construction, including those living within existing or to-be-acquired right of way. While many experiencing houselessness either choose or are forced to relocate regularly, others remain in place for extended times when they have found a safe location with limited disturbances. Thus, the number of houseless people present in the study area who would be displaced at the time of construction is unknown. As design progresses and construction is scheduled, the IBR Program would continue to coordinate with local jurisdictions and aid organizations to determine potential impacts. Such impacts could include displacements of houseless individuals within the limits of construction; construction proximity impacts such as noise, vibration, and air pollution; and reduced access to food assistance and other resources as a result of construction-related closures or transit delays.

Tolling

The Modified LPA tolling program would place a burden on low-income travelers, who are disproportionately BIPOC. Toll rates and policies, including a possible low-income toll program, would be set jointly by the Oregon Transportation Commission and the Washington State Transportation Commission. Both commissions have supported the study of a low-income toll program, including how such a program could be implemented in each state. They would work together to determine how to approach this for the IBR Program.

3.5.5 Temporary Effects

No-Build Alternative

There would be no temporary effects to neighborhoods or equity priority communities under the No-Build Alternative.

Modified LPA

Most temporary effects on neighborhoods and equity would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Neighborhoods

On-site Construction

Construction of the Modified LPA includes construction of the new bridges and removal of the existing Interstate Bridge. Neighborhoods in the study area would experience temporary effects from construction of the Modified LPA. These effects would generally increase with proximity to construction areas and could include:

- Noise and vibration
- Dust and emissions
- Traffic delays, detours, and traffic spillover into neighborhoods
- Property easements for temporary construction staging areas
- Sidewalk disruptions and closures (which could impede access and mobility for disabled persons)

Neighborhoods near the construction activity, such as Hayden Island and Esther Short, would experience some of these effects over several years. Neighborhoods farther from the bridge construction could expect to experience effects over a shorter duration. Roadway and transit construction effects in other areas would cause traffic disruption and noise intermittently for several months.

Section 3.3, Property Acquisitions and Displacements, details the temporary easements that would be required to reconstruct sidewalks, build retaining walls, and other types of roadway features. None of these temporary easements would adversely affect neighborhood cohesion or livability.

Off-Site Staging Areas and Casting Yards

Most neighborhoods in the study area would not have temporary construction staging areas nearby. However, the Hayden Island neighborhood would experience temporary increases in noise levels, congestion on local roads, and reduced visual quality from the use of the Thunderbird Hotel site for staging because of its proximity to more densely populated areas. All neighborhoods in the study area could experience temporary noise and increases in truck traffic during construction, particularly in areas adjacent to I-5. Given that the potential construction duration could be up to 15 years, neighborhood quality and cohesion could be

adversely affected during construction for portions of neighborhoods adjacent to the corridor. However, construction effects in most neighborhoods are likely to be intermittent and temporary, since work would occur in different portions of the corridor at different times. See the Neighborhoods and Populations Technical Reports for a discussion of temporary effects for each neighborhood in the study area.

Equity

Table 3.5-17 summarizes temporary, construction-related impacts to equity priority communities.

Table 3.5-17. Overview of Temporary Effects to Equity Priority Communities in the Study Area

Study Area Subarea	Equity Priority Communities with Above-Average Representation [a]	Construction-Related Impacts
Oregon Mainland	• BIPOC • Low-Income • People with Disabilities • Older Adults	• Temporary increase in noise levels, reduced air quality (e.g., fugitive dust), and increase in truck traffic during construction, particularly in the areas immediately adjacent to I-5. • Temporary adverse effect on visual quality (e.g., construction equipment and activities blocking views, high-visibility signage, lighting during nighttime work). • Traffic detours and road closures. • Traffic spillovers in the Bridgeton, East Columbia, and Kenton neighborhoods.
Hayden Island	• People with Disabilities • Older Adults	• Temporary increase in noise levels, reduced air quality (e.g., fugitive dust), and increase in truck traffic during construction, particularly in the areas immediately adjacent to I-5. • Residents living in floating homes and the mobile home park may be particularly susceptible to air emissions due to their proximity to both the highway and transit alignments. • Temporary effects on visual quality. • Traffic detours and road closures.
Downtown Vancouver	• Low-Income • People with Disabilities • Older Adults	• Temporary increase in noise levels, reduced air quality (e.g., fugitive dust), and increase in truck traffic during construction, particularly in the areas immediately adjacent to I-5. • Temporary adverse effects on visual quality. • Traffic detours and road closures. • Temporary closures of east-west bicycle and pedestrian connections at SR 14, Evergreen Boulevard, and Mill Plain Boulevard.

Study Area Subarea	Equity Priority Communities with Above-Average Representation [a]	Construction-Related Impacts
Upper Vancouver	• BIPOC • Limited English proficiency • Low-Income • Older Adults • Young People	• Temporary increase in noise levels, reduced air quality (e.g., fugitive dust), and increase in truck traffic during construction, particularly in the areas immediately adjacent to I-5. • Temporary adverse effects on visual quality. • Traffic detours and road closures. • Temporary closures of east-west bicycle and pedestrian connections at McLoughlin Boulevard, Fourth Plain Boulevard, 29th Street, and 33rd Street. • Traffic spillovers in the Minnehaha, Rose Village, Central Park, Hudson's Bay, and Columbia Way neighborhoods.
Ruby Junction	• BIPOC • Immigrants and Refugees • Low-Income • Young People	• Temporary increase in noise levels, reduced air quality (e.g., fugitive dust), and increase in truck traffic during construction. • Temporary adverse effects on visual quality. • Traffic detours and road closures.

a Specific equity priority communities are listed where their percentage of the population is above average for the Portland-Vancouver metropolitan area in at least one census tract in that geographic area.

BIPOC = Black, Indigenous, and People of Color

3.5.6 Indirect Effects

Neighborhoods

As described in Section 3.4.1, the Modified LPA would have the indirect effect of facilitating growth within the study area compared to No-Build Alternative by providing new light-rail service and reducing traffic congestion for general-purpose and transit vehicles. The greatest potential effects on growth would be in proposed station areas, particularly in the Hayden Island and Esther Short neighborhoods, which have the greatest potential to support transit-oriented development. Such development is anticipated and encouraged in the adopted plans for these neighborhoods. Under the No-Build Alternative, light-rail would not be extended to Vancouver, and transit-oriented development would not occur. The Hayden Island neighborhood would have the greatest potential to experience indirect effects from the Modified LPA because transit-oriented development is planned to replace some of the dispersed, auto-oriented shopping centers that exist today. Creating a less auto-oriented environment for residents to travel between home and their services would provide more opportunities for residents to interact with one another and easily access potential new community resources. Similarly, if smaller-scale commercial services were to develop close to housing and transit, residents would be encouraged to use services provided in their neighborhood rather than leaving the island to access the same services.

In the Esther Short neighborhood, potential new transit-oriented development would add to cohesion in ways similar to those for Hayden Island. New housing and commercial services, particularly around light-rail transit stations, would give residents the opportunity to walk, bicycle, or take transit to services close to their homes, therefore providing more chances for residents to interact with one another and use community resources. Similar to the Hayden Island neighborhood, these changes would not occur under the No-Build Alternative, making it inconsistent with current planning for the area.

Although increased development density and intensity in these neighborhoods would be consistent with existing planning and zoning, these could still result in negative indirect effects, including increased noise, additional traffic on local streets, greater demand for public services, and changes in visual character.

Equity

Over time, there would be an increased risk of residential displacement in areas where the Modified LPA improves neighborhood amenities and livability, potentially increasing housing costs to unaffordable levels for lower-income residents. An analysis conducted in 2019 for the City of Vancouver as part of an anti-displacement plan identified downtown Vancouver, the Meadow Homes neighborhood, and the Maplewood neighborhood as particularly vulnerable to neighborhood change and residential displacement (City of Vancouver n.d.). Downtown Vancouver is home to high concentrations of BIPOC residents, low-income households, people with disabilities, and seniors. While Meadow Homes and Maplewood are not in the Program area, they are a short distance east and are also home to a large concentration of equity priority communities. These neighborhoods may be indirectly affected if development in nearby areas facilitated by the Modified LPA improvements leads to increased housing costs.

3.5.7 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Mitigation

- Comply with the Uniform Relocation Act. When displacement cannot be avoided, federal and state regulations require property to be purchased at fair market value and all displaced residents to be provided with replacement housing and relocation assistance. Federal regulations, such as the Uniform Relocation Act, and state statutes determine the standards and procedures for providing such replacement housing, based on the characteristics of individual households. Relocation benefit packages usually include replacement housing for owners and renters, moving costs, and assistance in locating replacement housing. Relocation benefits for businesses can include moving costs, site search expenses, and business reestablishment expenses.

Program-Specific Mitigation

Specific mitigation for effects on neighborhoods includes:

- The Modified LPA is anticipated to have an overall neutral effect on visual quality in study area neighborhoods. The IBR Program would work with residents and community members to understand impacts and avoid, minimize, or mitigate those impacts.
- The IBR Program would avoid and minimize impacts to community resources and neighborhood cohesion wherever feasible. Strategies to minimize impacts to neighborhood cohesion could include providing additional community gathering spaces such as pedestrian and bicycle facilities.

Specific mitigation for effects on equity includes:

- Work with residents and community members to understand impacts and avoid, minimize, or mitigate those impacts.
- Develop a package of community benefits, which may be captured in a variety of documents, including contract specifications, environmental documents, a potential workforce agreement and either a community benefits plan or report. Community benefits are likely to include a variety of investments and strategies to ensure workforce and contracting equity, enhance the local community, and offset burdens associated with construction and operation.

Temporary Effects

Regulatory Mitigation

Required measures to minimize construction impacts, such as construction best management practices, would also reduce impacts to neighborhoods and equity priority communities. These measures are used to address construction effects such as temporary easements, noise, dust, emissions from construction vehicles, and visual clutter. Best management practices applicable to the potential impacts described above in Section 3.5.5 are discussed in Section 3.3, Acquisitions and Displacements; Section 3.9, Visual Quality; Section 3.10, Air Quality; and Section 3.11, Noise and Vibration.

Program-Specific Mitigation

- Where feasible, implement nighttime construction schedules and shield nighttime lighting.
- Hold community meetings before construction starts to inform residents of the construction timeline, relevant staging plans, ramp and road closures, and detour plans.
- Use temporary signage, including variable message signs, to inform drivers of traffic delays because of construction or heavy equipment entering or leaving the highway.
- Provide signs for local business assistance alerting customers of continued operation and a hotline for construction information.
- Conduct regional outreach activities to provide information on construction-related impacts and detours that include communications to businesses, agencies, and community-based organizations within the greater Portland and Vancouver area. Traffic advisories and updates would be made available to the public to help make travel choices.
- Place communication and signage for temporary routes for pedestrians and biking well in advance of the detour areas. Wayfinding signage would be accessible, consistent, thorough, and maintained.
- Coordinate with affected property owners to minimize potential impacts to structures and access points during construction.
- Coordinate with local jurisdictions and other organizations offering services to people experiencing unsheltered houselessness in areas directly affected by construction activities. Services would be provided in advance of construction and could include harm reduction, access to health services, and emergency shelter or alternate housing options.
- Restore removed landscaping on properties following construction or as otherwise agreed within the property rights process.
- Pay property owners in exchange for the use of their property during construction.

3.6 Public Services and Utilities

Public services such as schools, emergency response services, government offices, and hospitals are vital to the health of a community and can be affected by large construction projects and changes to the transportation network. Similarly, utilities such as electricity, water, sewer, natural gas, telephone, data, fiber optic, and other communications services can be temporarily disrupted by construction activities. This section identifies the public services and utilities in the study area and evaluates the potential long-term and temporary effects of the Modified LPA on these resources. The information presented in this section is based on the Public Services Technical Report and the Utilities Technical Report.

3.6.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with public services and utilities has been updated in this Draft SEIS to include:

- Changes in development, population and employment, transportation, demographics, and other aspects of the built environment and urban setting.
- Changes in land uses such as development at the Vancouver Waterfront, planned uses on Hayden Island, and recently constructed, altered, or removed buildings.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the light-rail transit alignment and modifying interchange designs.
- Changes in transportation modeling and analysis.

Table 3.6-1 compares the impacts and benefits of the CRC LPA and the IBR Modified LPA. Based on the analysis described in this section, the effects of the Modified LPA would be similar to the effects of the CRC LPA. A detailed description of impacts and benefits to public services and utilities from the Modified LPA and associated design options follows.

Table 3.6-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects Identified in the 2011 Final EIS	Modified LPA Effects Identified in this Section	Explanation of Differences
Traffic effects on emergency services	The CRC LPA would improve traffic conditions on I-5; thus, response times for mobile public services relying on I-5 would be positively affected.	Similar to CRC LPA.	N/A
Displacement of public services	• ODOT Permit Station and Field Office, Clark Public Utilities building, and Clark College Annex would be displaced.	• Partial acquisitions would include property from FHWA Western Federal Lands office and Discovery Middle School.	The reduction in the displacement of public services is due to both changes in land uses and design modifications, including replacing the full

Technical Considerations	CRC LPA Effects Identified in the 2011 Final EIS	Modified LPA Effects Identified in this Section	Explanation of Differences
	• Partial acquisitions would include property from FHWA Western Federal Lands office, Discovery Middle School, Kiggins Bowl, and Clark College Athletic Annex. No uses would be displaced.	No uses would be displaced.	interchange on Hayden Island with a partial interchange and moving the LRT alignment along I-5 instead of a couplet in downtown Vancouver and past Clark College.
Utilities	Utilities would be protected in place or relocated.	Same as CRC LPA.	N/A

CRC = Columbia River Crossing; FHWA = Federal Highway Administration; LPA = locally preferred alternative; LRT = light-rail transit; N/A = not applicable; ODOT = Oregon Department of Transportation

3.6.2 Existing Conditions

Public Services

There are several medical centers, schools, solid waste management facilities, and other public service facilities in the study area, as shown on Figure 3.6-1 and Figure 3.6-2. Table 3.6-2 lists the types of services and the providers in the study area.

Both Portland and Vancouver operate fire and police stations in the study area. In addition, Portland, Clark County, and the U.S. Coast Guard have rescue and emergency services stations with watercraft and response teams serving the Columbia River. The Washington State Patrol and the Oregon State Police have jurisdiction over interstate and other state highways. There are mutual response agreements in place with emergency service providers outside of the study area to provide additional support when necessary, particularly for incidents on the Columbia River (Leek 2023; White 2021).

Emergency service providers designate critical emergency access routes for providing rapid response. I-5 is an important north-south access route through the area, and it is the only access route to and from Hayden Island. In Portland, other critical north-south access routes include N Interstate, N Vancouver, and N Williams Avenues and NE Martin Luther King Jr. Boulevard. In Vancouver, additional critical north-south access routes include NW Hazel Dell Avenue and SR 99. Table 3.6-3 describes the critical emergency access routes used by public service providers in the study area.

Four Portland schools serve students within the study area. Seven Vancouver School District schools and three other district facilities are located within or serve the study area. Two specialty schools that require special consideration in the design of transportation facilities, the Washington State School for the Blind and the Washington State School for the Deaf, are located outside of the study area but serve communities within the study area. While the main campus of Clark College, a private two-year junior college, is located outside of the study area, the Clark College Athletic Annex building is in the study area. Clark College athletic facilities at this location include tennis courts, a softball diamond, and a baseball diamond. The students, faculty, and staff that attend and support these schools rely on safe and efficient transportation facilities and services.

No other public services or facilities were identified outside the study area that would require special transportation considerations for service within the study area. See the Public Services Technical Report for further discussion.

Vancouver Fire Department Westside Station (2)	E Fourth Plain Boulevard, E 18th Street, Grand Boulevard.
Clark County Fire Marshal (District 6)	I-205, SR 99, and NW Hazel Dell Avenue.
West Precinct City of Vancouver Police	Main Street/SR 99, Fort Vancouver Way, P Street, SR 500 to I-205.
Clark County Sheriff's Office	NW Fruit Valley Road, NE Hazel Dell Road, NE St. Johns Boulevard, and NE Andresen Road (SR 500).

Sources: Lawson 2021; Leek 2023.

Utilities

Utilities in the study area are identified in Table 3.6-4.

Table 3.6-4. Utilities within the Study Area

Utility Owner	Type of Utility	Comments
AT&T	Communications	Local network services; cellular telecommunications antennae.
Clark Public Utilities	Power	Serves the area north of the Columbia River.
Comcast	Communications	Cable and fiber optic network.
Integra Telecom	Communications	Fiber optic network formerly owned by Electric Lightwave.
NW Natural	Natural gas	Natural gas service provider for the area.
Pacific Power & Light	Power	Generally serves the area east of I-5 and south of North Portland Harbor.
Portland, City of	Water, sewer, stormwater, and communications	None.
Portland General Electric	Power	Generally serves Hayden Island and the area west of I-5 and south of North Portland Harbor.
Qwest	Communications	General telephone service provider for the area.
Time Warner Telecom	Communications	Fiber optic network.
Verizon Wireless	Communications	Cellular telecommunications antennae.

Utility Owner	Type of Utility	Comments
Vancouver, City of	Water, sewer, stormwater, and communications	None.

Note: The list of utility owners is based on CRC project information. Later phases of the IBR Program will include additional studies and confirmation of utility providers and locations. The list will be updated and confirmed with appropriate regulatory agencies as the project progresses.

Several important utility lines cross the Columbia River and North Portland Harbor to provide service to Hayden Island. The presence of bridges across these two water bodies, combined with the narrow 2,200-foot width of Hayden Island at this location, result in a concentration of utilities along the I-5 right of way. Utilities in this area include:

- A water transmission main across the North Portland Harbor bridge (Portland Water Bureau).
- A main natural gas feed line across the North Portland Harbor bridge (NW Natural).
- An underwater power cable (Portland General Electric) and telephone lines located under the bed of North Portland Harbor, immediately west of the Interstate Bridge.
- Underground communication cables across North Portland Harbor, Hayden Island, and the Columbia River. A trunk line crosses the Columbia River, 500 feet east of the Interstate Bridge, and includes telephone, television, data, and fiber optic from multiple utility providers.

Other utility lines or structures in the study area, all in Vancouver, include water mains that cross I-5 at SE Columbia Way, 5th Street, Mill Plain Boulevard, 16th Street, McLoughlin Boulevard, E 29th Street, E 32nd Street, 39th Street, and 40th Street. Another major water line is located parallel to the western right of way line of I-5 between McLoughlin Boulevard and E 16th Street. The City of Vancouver Waterfront Pump Station is also within the study area.

ODOT, WSDOT, and TriMet maintain infrastructure in the study area for their agencies' uses, but do not provide direct service to the public. These utilities include power, stormwater, water, and sanitary sewer. These agencies also maintain signal and communication systems for transportation management and transit operations.

See the Utilities Technical Report for further discussion.

3.6.3 Long-Term Benefits and Effects

Long-term effects on public services are defined as physical changes to public service facilities such as medical facilities, police and fire facilities, or schools, as well as changes in traffic operations that could affect critical access routes or disrupt emergency vehicle response. Long-term effects on utilities are defined as permanent changes in utility service or availability.

Table 3.6-5 summarizes the effects of the Modified LPA, design options, and the No-Build Alternative on public services and utilities. Additional information is provided in the sections that follow.

Table 3.6-5. Summary of Modified LPA and No-Build Alternative Effects on Public Services and Utilities

1	2	3	4	5
No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, with or Without C Street Ramps, Centered I-5 or I-5 Westward Shift	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Single-Level Fixed-Span Configuration,[a] One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5
• Increased congestion on I-5 would increase delays in emergency response. • No change to utilities.	• Emergency service response time would be reduced with improved traffic conditions. • Utilities would be relocated or protected in place during construction and restored to full service following construction.	• Similar to effects listed in Column 2, but further reduced congestion and multimodal operations would lead to improved response times. • Same effects on utilities as listed in Column 2.	• Similar to effects listed in Column 2, but response times to transit and shared-use path incidents could improve because emergency vehicles would have better access to transit and active transportation facilities. • Same effects on utilities as listed in Column 2.	• Delays and disruptions to emergency response due to bridge openings would continue, but with less frequency than the No-Build Alternative. • Same effects on utilities as listed in Column 2.

a The effects associated with the single-level fixed-span configuration would be the same for all bridge type options.

No-Build Alternative

With the No-Build Alternative, no physical impacts to public services (including medical centers and school sites) are anticipated. There would be no change in intersection operations on critical access routes in Portland during either the AM or PM peak periods. In Vancouver, three intersections would not meet level of service standards during the AM peak period, and seven intersections would not meet level of service standards during the PM peak period, which could slow response times for emergency vehicles (see Section 3.1, Transportation, for further discussion). In addition, bridge openings to allow ship passage would continue to disrupt traffic and cause potential delays for emergency vehicles.

The No-Build Alternative would not involve any changes to existing utilities in the study area. However, damage to the Interstate Bridge from a seismic event could have adverse impacts to utilities located on or near the bridge and could hinder the provision of emergency services.

Modified LPA

Most long-term effects on public services and utilities would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Public Services

Effects on Public Service Facilities

Most public services would not experience direct long-term impacts to facilities as a result of the Modified LPA, including:

- Fire and life safety
- Solid waste management
- Postal service
- Cemeteries

The Modified LPA with C Street ramps at the SR 14 interchange would partially acquire the parcel that contains the FHWA Western Federal Lands office, north of 5th Street and immediately east of I-5. This would affect six marked parking stalls, adjacent asphalt and curbing, landscaping, parking area illumination, and an electronic swing gate. The Modified LPA without C Street ramps would move building access to the south from E 5th Street.

None of Portland Public Schools' facilities are near areas that would be directly affected by the Modified LPA. In Vancouver, the Modified LPA would directly affect Discovery Middle School, located at the northern end of the study area in the Lincoln neighborhood, with a minor acquisition of part of the southeastern portion of the parcel for a retaining wall. The retaining wall would require a permanent subsurface easement with some long-term surface use restrictions. No structures would be displaced, and the long-term use of the site would not be changed.

The property housing the Vancouver Police Department administrative offices, located east of I-5 and south of E Evergreen Boulevard, is planned for partial acquisition to accommodate I-5 and sidewalk improvements to E Evergreen Boulevard. No impacts to the building on the property are anticipated.

Traffic Effects on Public Services

Traffic congestion along critical emergency routes can cause delays for emergency service providers. The transportation analysis for the Modified LPA evaluated 2045 levels of service at 63 local street intersections along critical emergency access routes (46 in Vancouver and 17 in Portland). In Portland, all but one intersection along the critical emergency access routes would meet level of service standards in the AM peak

period with the Modified LPA; in the PM peak period, three intersections would not meet the standards. In Vancouver, three intersections would not meet level of service standards in the AM peak period with the Modified LPA; in the PM peak period, four intersections would not meet the standards. The design option to remove the C Street ramps would result in additional congestion in downtown Vancouver; under this option, five intersections would not meet level of service standards in the AM peak period, and eight intersections would not meet the standards in the PM peak period.

In Vancouver, the local streets with the most changes to level of service compared to the No-Build Alternative would be Main Street and 39th Street. During the AM and PM peaks, response times for mobile public services relying on Mill Plain Boulevard or 39th Street as critical access routes could increase. All design options of the Modified LPA would provide full-width shoulders on the new Columbia River bridges, which could improve response times by allowing emergency providers using I-5 to bypass congestion while crossing the Columbia River or accessing Hayden Island. The addition of an auxiliary lane would also reduce congestion and facilitate emergency response by improving traffic flow on I-5 through the study area. A second auxiliary lane would further reduce congestion and improve multimodal operations on I-5. This would lead to a decrease in response times for emergency vehicles using I-5 as an emergency route.

The fixed-span double-deck configuration would provide emergency access to the transit guideway and shared-use path on the lower decks of the Columbia River bridges for rescue trains and first responders. The single-level fixed-span configuration would improve emergency response times to transit and shared-use path incidents compared to the fixed-span double-deck configurations because all the facilities being located on a single level would allow response teams to access the incidents directly from the highway lanes. The single-level movable-span configuration would cause delays and disruptions to emergency response due to bridge openings, but with less frequency than under the No-Build Alternative.

See the Public Services Technical Report for further discussion of traffic effects on public services and the Transportation Technical Report for a full description of the traffic analysis completed.

Utilities

The Modified LPA would cross or be in close proximity to a number of major utility lines in Portland, on and near the existing Interstate Bridge, and in Vancouver. These include water supply, natural gas, and sewer mains, communications cables and infrastructure, a high-voltage electrical transmission line, a cellular antenna array, and, potentially, a wastewater lift station. Utility infrastructure on the North Portland Harbor bridge is particularly sensitive because in several cases these facilities are the only link between Hayden Island and the mainland.

Utilities affected by construction of the Modified LPA would either be protected in place or relocated. Once relocated, the utilities would be more robust and reliable. The effects would generally be similar across the design options, except that additional utilities at the park-and-ride locations at W 4th Street and W 3rd Street in downtown Vancouver could require relocation or replacement. No long-term adverse impacts to utilities are expected. See the Utilities Technical Report for additional information.

As noted in Section 3.6.2, the current analysis is based on CRC project information; later phases of the IBR Program will include additional studies and confirmation of utility providers and locations. As the design progresses, coordination with utility providers will be conducted to confirm there are no changes in impacts since the CRC EIS was prepared.

3.6.4 Temporary Effects

Temporary effects are defined as those that would occur during construction of IBR Program facilities. Construction of the Modified LPA includes the construction of the new brides and removal of the existing bridges. This could include traffic and access disruptions to public services and short-term service

interruptions resulting from utility relocation or protection measures. The duration of these effects would be limited to the active construction period.

No-Build Alternative

Under the No-Build Alternative, no temporary impacts to public services or facilities (including medical centers and school sites) are anticipated. The No-Build Alternative would not result in temporary utility disruptions from construction.

Modified LPA

Most temporary effects on public services and utilities would not differ among the Modified LPA design options. Where differences would occur, they are described in the subsections below.

Public Services

Traffic Effects on Public Services

Detours, increased delays, and traffic on streets with construction may cause response time delays for mobile public services including police, fire, medical emergency, school transportation, and solid waste services. In Portland, temporary effects on public services include increased delays for the fire services stationed on Hayden Island which must use I-5 when serving North Portland. Other services, such as law enforcement, would also experience delays accessing Hayden Island from North Portland or Vancouver. More information about traffic impacts during construction can be found in Section 3.1, Transportation.

Construction on emergency transportation routes may cause delays in emergency services' response times and must be communicated with those service providers in advance. Construction on school routes could cause delays for school transportation providers and advance coordination with school transportation services would be necessary. Construction noise and vibration may affect Discovery Middle School; Vancouver Innovation, Technology and Arts Elementary School; and the Athletic Annex at Clark College. More information can be found in Section 3.11, Noise and Vibration.

Temporary Construction Easements

Temporary construction easements would be needed from several properties that contain public service facilities. The buildings on these properties would not be affected, and their ongoing functions would not change.

- A temporary construction easement is planned for the northwestern corner of the City of Portland Fire Department property (Portland Fire & Rescue Station 17) on Hayden Island. No modifications to the building, parking lot, or driveway are planned.
- A temporary construction easement and a construction staging area would be needed on the western portion of the Clark College Athletic Annex and recreation fields property. The easement would not interrupt the function or public use of the recreation fields or modify the building on the western portion of the property. Chapter 4, Draft Section 4(f) Evaluation, has more information on this temporary construction easement.
- A temporary construction easement would be needed for the northwestern corner of the Clark Public Utilities District property, located on the east side of the existing northbound Interstate Bridge abutment. The building functions as an information center with energy conservation staff. Some landscaping would be lost, but there would be no modification to the building, parking lot, or access roads.

- A temporary construction easement is planned along the northwestern boundary of the Vancouver Division of Veterans Affairs Portland Health Care System. The impact would be limited to the northwestern corner of the site adjacent to East Fourth Plain Boulevard and the far western portion of the site along the I-5 frontage road.

Utilities

Temporary impacts to utilities during construction would result from the need to relocate the utilities or protect them in place to prevent damage from, or conflict with, new IBR infrastructure. The largest temporary utility impacts would occur in the area between Marine Drive and the SR 14 interchange. Between these interchanges, utilities are concentrated in a relatively narrow corridor parallel to or under I-5; the utilities would require temporary relocation during construction. Short-term service outages could occur as a result of utilities being relocated or while protective measures are implemented. Throughout the study area, utility providers would be contacted during design regarding temporary utility relocations and/or staging and sequencing provisions, many of which could occur in the early phase of construction, prior to heavy civil construction phases.

The following major utilities in Oregon on the North Portland Harbor bridge may be temporarily affected:

- A water main that supplies water to Hayden Island, including for fire flows, would be affected by a new span to accommodate the Jantzen Drive realignment.
- A natural gas feed main serving Hayden Island would be affected by the new North Portland Harbor bridges.
- Communication cables across the North Portland Harbor bridge, Hayden Island, and on the southbound Columbia River bridge, including several trunk lines, would be affected by the new North Portland Harbor bridges and Marine Drive and Hayden Island interchanges.

Additionally, underwater communication and power cables west of the North Portland Harbor bridge would be affected by construction of the new North Portland Harbor bridges and ramps. Sanitary sewer force mains crossing Marine Drive and Jantzen Drive could also be affected.

Other potentially affected utilities include:

- Water, power, gas, and communications infrastructure would be affected by Marine Drive interchange reconstruction.
- Electrical feeds and switches and the main gas feed adjacent to I-5 on Hayden Island would be affected by reconstruction of the Hayden Island interchange, construction of light-rail, and roadway realignments.
- The existing cellular antenna array in the vicinity of Jantzen Drive would be affected by reconstruction of the Hayden Island interchange.

Major utilities that cross I-5 in Washington and would be temporarily affected include:

- A sanitary interceptor sewer crossing I-5 around 5th and 6th Streets in Vancouver would be affected by construction of new ramps at the SR 14 interchange.
- Communications infrastructure, a sewage lift station and force main, and a high-pressure gas line between the SR 14 interchange and the Columbia River may be affected by bridge construction, improvements to SR 14, and local street improvements.
- A water supply main crossing I-5 at Mill Plain Boulevard would be affected by street reconstruction.
- A communications duct bank crossing I-5 at Fourth Plain Boulevard could be affected by the construction of additional lanes.

- A high-voltage electrical transmission line crossing I-5 at 33rd Street could be affected by over-crossing reconstruction. One or both poles at either end of the existing Interstate Bridges could conflict with construction of the new, longer Columbia River bridges.
- A water supply main crossing I-5 at McLoughlin Boulevard may be affected when the street is modified to allow for the widened highway and transit guideway, and by construction of the guideway S-curve between 17th Street and McLoughlin.
- A communications cable and duct bank crossing I-5 at Fourth Plain Boulevard would be affected by the construction of additional lanes.
- A sewage lift station at Columbia Street could be affected by new bridge foundations.
- A water supply main crossing I-5 at NE 40th Street would be affected by construction of a new ramp at NE 39th Street.
- Communication trunk lines on Washington Street south of W 6th Street would be affected by road reconstruction.

3.6.5 Indirect Effects

Public service and utility providers generally plan based on forecast population and development patterns found in the long-range comprehensive plans of the jurisdictions they serve. They evaluate future population growth and calculate needed future service increases such as increased numbers of police officers, new equipment, or new station locations. As described in Section 3.4, Land Use and Economics, the Modified LPA would facilitate growth in the study area, particularly in new light-rail station areas, in a manner consistent with local and regional land use plans. This, in turn, could result in increased demand for public services and utilities in areas where growth occurred. The increased service needs would be in urbanized areas where public services and utilities are already present; it is not anticipated that any extension of service to new geographic areas would be required.

3.6.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

- Oregon Administrative Rules Chapter 660, Division 11: Public Facilities Planning. Governing bodies are directed to avoid, minimize, and mitigate impacts to public services if possible.
- Growth Management Act (GMA) Revised Code of Washington 36.70A.030(33) defines public services. The GMA directs local governments to avoid, minimize, and mitigate impacts to public services.
- For utilities, ODOT and WSDOT would develop or modify agreements with affected utility owners to specify the locations of utilities within the right of way, access and maintenance requirements, etc.

Program-Specific Mitigation

Program-specific mitigation measures for effects on public services and utilities include:

- Implement feasible mitigation strategies for increased travel times along emergency service routes as described in Section 3.1, Transportation, of this Draft SEIS.

Temporary Effects

Regulatory Requirements

- Incorporate measures to maintain traffic flow and access during construction and to avoid and minimize temporary utility service disruptions into contract specifications.
- Comply with current federal Dig Once laws (23 CFR 645.307) and associated state regulations and guidelines, which require advanced coordination with the broadband/fiber industry to invite these providers to participate in highway improvement projects.

Program-Specific Mitigation

Program-specific mitigation for temporary effects on public services and utilities would include:

- Protect utilities in place where feasible and cost-effective.
- Work with utility providers to relocate utilities when protection in place is not feasible, with the goal of relocating facilities only once to reduce service disruptions.
- Work with service providers and the public to minimize temporary effects to the extent practicable. Advance communication with the impacted public services would be conducted to inform dispatchers and responders about planned road closures and detours. A preconstruction communication plan would be developed with affected emergency response groups and other public service agencies detailing how detour and road closure information would be provided to the services.
- Evaluate the need for backup on-call emergency services to transport patients during bridge construction to mitigate highway delays.
- Before construction, evaluate the need for backup on-call emergency services to transport patients during bridge construction to mitigate highway delays.
- Conduct public outreach campaigns before construction to ensure that detours and traffic routing plans during construction are available to public service providers and the communities they serve. Provide detour signs on routes typically used and signed to access public service locations.
- Coordinate closely with utility owners during project design to identify temporary facility needs and minimize temporary construction disruptions.

3.7 Parks and Recreation

Existing and planned parks and recreation facilities are important community resources that are highly valued by individuals, private organizations, and local governments. This section identifies, describes, and evaluates the long-term, temporary, and indirect effects of the No-Build Alternative and Modified LPA on park and recreation resources, including school facilities, interpretive or community centers, trails, open spaces, and sports fields. Additionally, this analysis examines potential impacts on recreational events and activities. An evaluation of the use of park and recreation resources in accordance with Section 4(f) of the U.S. Department of Transportation Act (49 United States Code [USC] 303) (referred to as "Section 4(f)") can be found in Chapter 4 of this Draft SEIS. An evaluation of impacts to park and recreation resources protected under Section 6(f) of the federal Land and Water Conservation Fund Act (referred to as "Section 6(f)") is included in Section 3.21 of the SEIS.

The information presented in this section is based on the Parks and Recreation Technical Report, which contains greater detail and additional analysis.

3.7.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with parks and recreation has been updated in this Draft SEIS to include:

- Updates to information on existing and planned park and recreation resources within the study area.
- Updates to information on federally and state-protected park and recreation resources.
- Changes in land uses such as development at the Vancouver Waterfront, planned uses on Hayden Island, and recently constructed, altered, or removed buildings.
- Updates to long-term and temporary effects of the Modified LPA.
- Updates to mitigation, in consultation with the agencies with jurisdiction, for the long-term and temporary effects of the Modified LPA.

Table 3.7-1 compares the impacts and benefits of the CRC LPA to those of the Modified LPA as a result of the changes listed above. Based on the analysis described in this section, the effects of the Modified LPA would be similar to those of the CRC LPA, but overall, the Modified LPA would have fewer impacts to parks and recreation resources than the CRC LPA.

Table 3.7-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Total acres of park and recreation resources acquired	4 acres	0.8 acres	The reduction in total acres acquired is primarily the result of reduced impacts to Fort Vancouver National Historic Site, Waterfront Park, Discover Historic Loop Trail, and Clark College

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
			Recreation Fields. These reductions are the result of design modifications, including straightening the bridge alignment and moving the LRT terminus from Clark College to Evergreen Boulevard.
Acres of acquired parkland within the Fort Vancouver National Historic Site	1.7 acres	0.4 acres	The reduction in impact is due to a slight westward shift in the I-5 mainline alignment, which also shifts the reconstructed loop ramp from I-5 northbound to C Street to the west.

CRC = Columbia River Crossing; EIS = Environmental impact statement; I-5 = Interstate 5; LPA = Locally Preferred Alternative; LRT = light-rail transit

3.7.2 Existing Conditions

Parks and recreation facilities were identified within the study area, which extends from approximately the SR 500 interchange in Washington and the I-5/Columbia Boulevard interchange in Oregon. North of the Columbia River, the study area generally terminates on the west side of I-5, expanding west into downtown Vancouver to include potential park and ride locations. The study area also includes the potential construction staging sites, identified in Chapter 2, and the Ruby Junction Maintenance Facility in Gresham, Oregon. Figure 3.7-1 shows the study area boundaries and the locations of parks and recreation facilities within or near the study area. Table 3.7-2 provides a description of these facilities, including their amenities.

The following parks are located nearby, but outside of the study area, and would not be affected by the Modified LPA:

- Lotus Isle Park (N Tomahawk Drive, east of I-5, Portland).
- Esther Short Park (W Columbia and 8th Streets, Vancouver).
- Leach Park (E 28th Street and K Street, Vancouver).
- Ike Memorial Dog Park (NE Ross Street and NE 15th Avenue, Vancouver).

Figure 3.7-1. Parks and Recreation Facilities in the Study Area

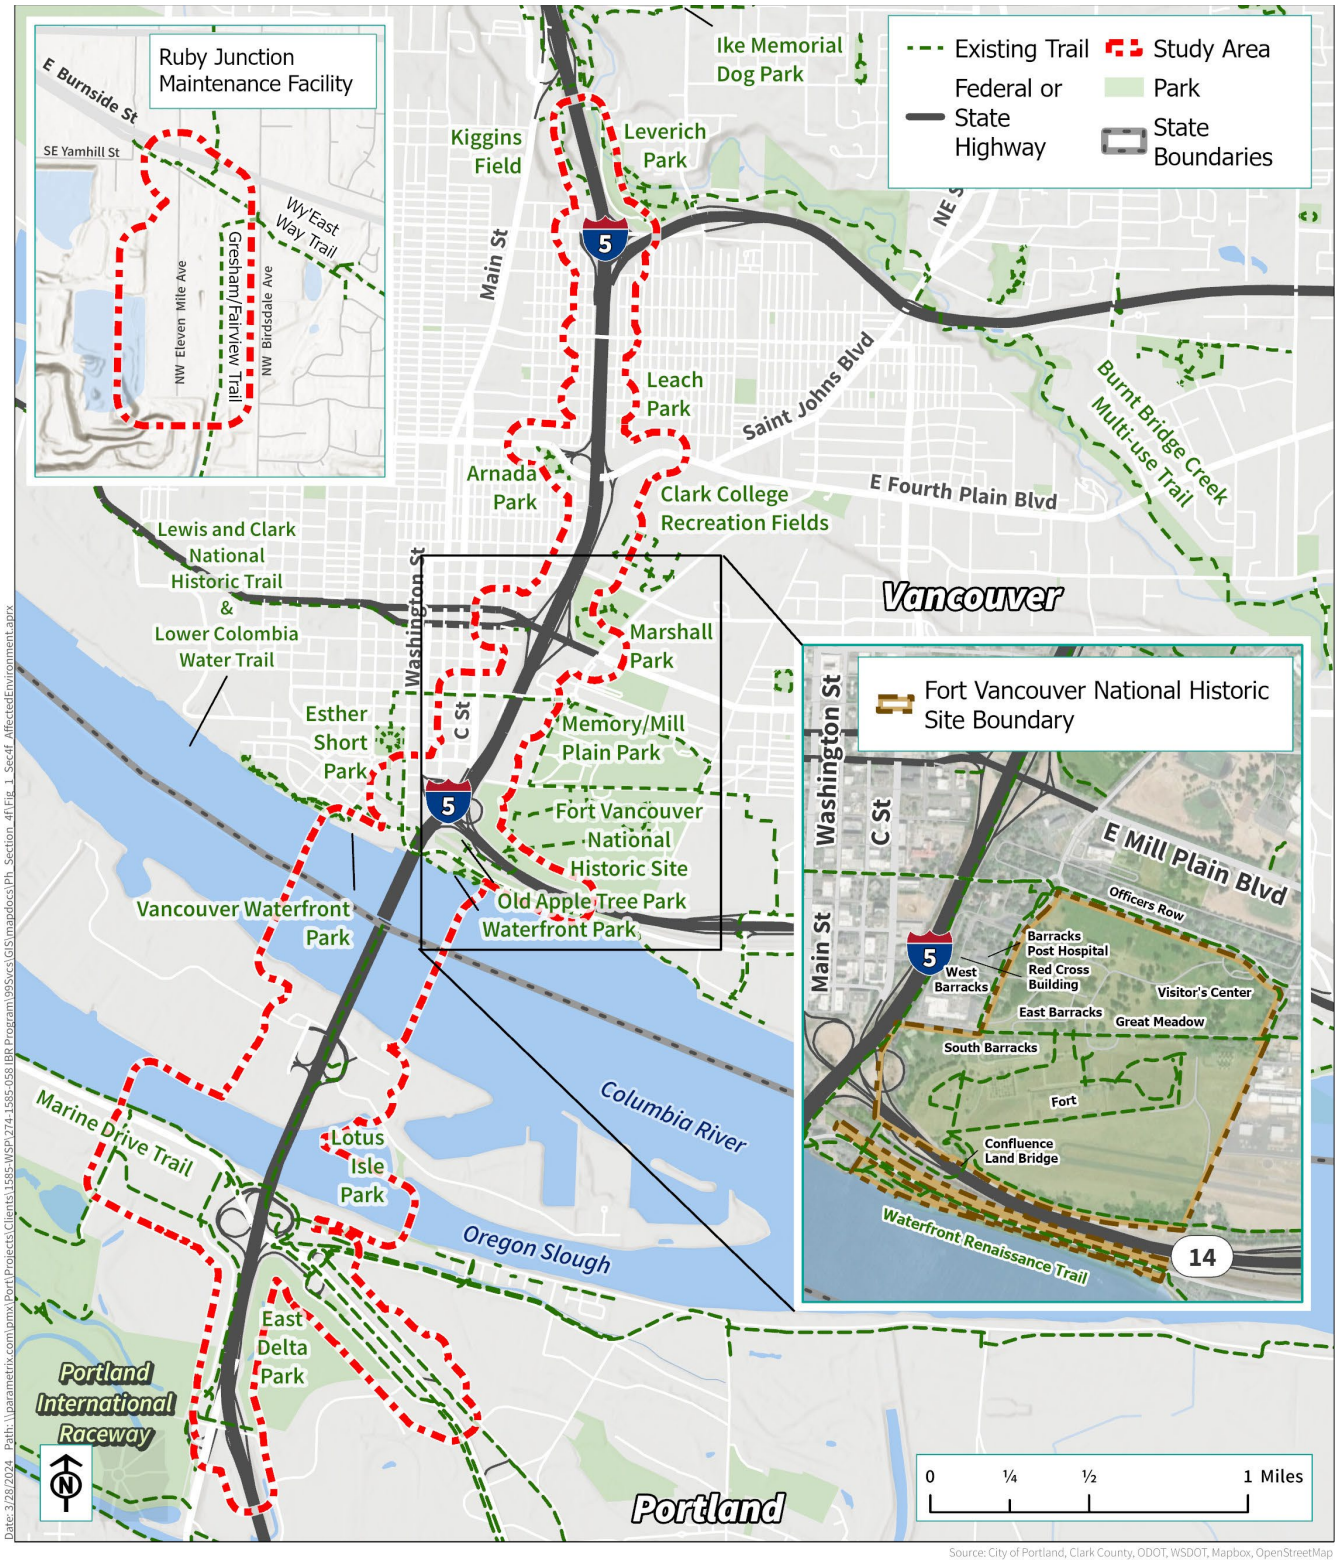

Table 3.7-2. Parks and Recreation Facilities – Location, Jurisdiction, and Amenities

Resource	Type	Location	Agency with Jurisdiction	Description and Amenities
East Delta Park	Regional park	N Denver and Martin Luther King Jr. Boulevard, Portland	PP&R	87.5 acres; softball and soccer fields, volleyball courts, nature trails, playground, control-line model aircraft flying field; off-leash area on ODOT property
Bridgeton Trail (Proposed)	Proposed multiuse trail	NE Bridgeton Road, Portland	PP&R and Prosper Portland	Proposed paved multiuse path paralleling NE Bridgeton Road and connecting to the Marine Drive Trail
Marine Drive Trail	Multiuse trail	I-5 to Kelley Point Park	PP&R	5.0-mile paved multiuse path connecting Marine Drive interchange and Kelley Point Park
Gresham/ Fairview Trail	Multiuse trail	NE Halsey Street to Springwater Corridor Trail	City of Gresham	3.29-mile-long trail starting at the intersection of Northeast Halsey Street at 201st Avenue and traveling south to the Springwater Trail at SW 10th Avenue
Wy'East Way Trail	Multiuse trail	Ruby Junction Station, Rockwood to Cleveland Station, Gresham	City of Gresham	2-mile-long, 12-foot-wide walking and bike path that runs along the MAX light-rail line from the Ruby Junction Station in Rockwood to the Cleveland Station in historic downtown Gresham
Lower Columbia River Water Trail	Recreational waterway	Columbia River	Not Applicable	Informally designated trail managed by Lower Columbia River Estuary Partnership. 146.0-mile recreational waterway from Bonneville Dam to Pacific Ocean
Lewis and Clark National Historic Trail	Recreational waterway	Columbia River	NPS	Recreational waterway
Columbia River Renaissance Trail (part of Discovery Historic Loop Trail)	Multiuse trail	115 Columbia Way, Vancouver	VPR&C	5.0-mile, 14-foot-wide multiuse paved trail starting at the intersection of Columbia Way and Columbia Street and traveling east to Marine Park and Wintler Park
Vancouver Landing at Terminal One	City amphitheater and public dock	River mile 106 on north shore of the Columbia River	VPR&C and Port of Vancouver	Public transient moorage facility/dock, amphitheater
Vancouver Waterfront Park	Public open space	115 SE Columbia Way, Vancouver	VPR&C	7.3 acres; completed in 2018, part of a 35-acre, high-density, mixed-use urban development – the Waterfront. Incorporates public open spaces with the Columbia River edge.

Resource	Type	Location	Agency with Jurisdiction	Description and Amenities
Old Apple Tree Park	City of Vancouver park	112 Columbia Way, Vancouver	VPR&C	1.3 acres; entrance to Confluence Land Bridge. The tree died in 2020, but interpretive signs, fencing, and the stump of the original tree remain.
Fort Vancouver National Historic Site	Includes a National Historic Site, Historic District	Between Columbia River and Mill Plain Boulevard east of I-5	NPS	209 acres (largely overlapping with the VNHR); historic interpretive sites and replica structures, multiuse trails, picnic tables, event and recreation fields, and reservable picnic shelter. Newly constructed main visitor parking lot and improvements to E 5th Street, including repaving, new sidewalks, reoriented parking spaces, and bicycle and pedestrian routes, completed in fall 2022. NPS is currently constructing a replica village dwelling in the western portion of the property. Waterfront Park, which NPS manages as a part of the Fort Vancouver NHS, includes passive recreation and viewing opportunities for the Columbia River and is crossed by the Columbia River Renaissance Trail.
Discovery Historic Loop Trail (includes portion of Waterfront Trail)	Multiuse trail and city sidewalks	Columbia River Waterfront, Fort Vancouver National Historic Site, downtown Vancouver	VPR&C/NPS	2.3-mile trail on paved multiuse paths and local streets
Marshall Community Center, Luepke Senior Center, and Marshall Park	Community center, senior center, and park	1009 E McLoughlin Boulevard, Vancouver	VPR&C	19.0 acres; community garden, play equipment, fields, gym, senior center
Clark College Recreation Fields	School recreation facility	1500 E Mill Plain Boulevard, Vancouver	Clark College	13.0 acres; operated by Clark College with soccer fields, softball fields, and tennis courts open to public
Arnada Park	Neighborhood park	610 E 25th Street, Vancouver	VPR&C	3 acres; gazebo, picnic shelter, play equipment, sports court, benches, and paved walkway
Leverich Community Park	Community park	39th and M Streets, Vancouver	VPR&C	16 acres; disc golf course, picnic areas

Resource	Type	Location	Agency with Jurisdiction	Description and Amenities
Burnt Bridge Creek Trail	Multiuse trail	North of SR 500 interchange, Vancouver	VPR&C	8.0-mile paved multiuse trail; portion extends through Leverich Park
Kiggins Bowl Sports Fields and Stadium	Sports venue	North of 39th Street, west of I-5, Vancouver	Vancouver Public Schools	3.0 acres; sports venue for Vancouver Public Schools and public

I-5 = Interstate 5; NHS = National Historic Site; NPS = National Park Service; ODOT = Oregon Department of Transportation; PP&R = Portland Parks and Recreation; SR = State Route; VNHR = Vancouver National Historic Reserve; VPR&C = Vancouver Parks, Recreation and Cultural Services

Planned Facilities

In Oregon, Portland Parks and Recreation (PP&R), in coordination with Prosper Portland, plans to construct a 0.5-mile trail section linking the Bridgeton neighborhood on North Portland Harbor with I-5. The proposed Bridgeton Trail would travel along the levee and underneath I-5, connecting to the Marine Drive Trail on the west side of I-5. In winter 2009, PP&R and Prosper Portland (known at the time as the Portland Development Commission) began acquiring trail easements from property owners. After these acquisitions are complete, work will begin to refine the trail design for construction.

Where are the regional multiuse trails?

Section 3.1, Transportation, contains a map showing the routes and connections of the region's nonmotorized multiuse trails.

The Portland Citywide Systems Plan maps a large portion of Hayden Island west of I-5 as a parks-deficient area and states that future park acquisitions are needed to serve residents in the area. The 2009 Hayden Island Plan recommends the development of future park spaces and increased recreational opportunities and conceptually identifies an area west of I-5.

In Washington, Vancouver Parks, Recreation and Cultural Services (VPR&C) has identified the area surrounding the Modified LPA as having a deficit in acquired and developed park acres. The City of Vancouver is therefore seeking to acquire new parks and expand current parks within the study area; currently, no specific sites have been identified.

Previously, Clark College had planned to develop athletic facilities on a parcel located immediately east of I-5 and north of McLoughlin Boulevard. This parcel, now owned by the State of Washington and maintained by Clark College, is currently used for college purposes such as parking for the athletic fields and is not open to the public.

The National Park Service (NPS) is coordinating with the City of Vancouver to increase connectivity between the Fort Vancouver National Historic Site (NHS) and downtown Vancouver. These plans include a pedestrian overpass between E Evergreen Boulevard and 7th Street. Within the study area, planned Fort Vancouver NHS park and recreation facilities include a replica Hudson Bay Company (HBC) historic village (HBC Village) and associated extensions to the existing trail system. The planned facilities would be tied to the historic village and the Confluence Land Bridge in the southwestern portion of the Fort Vancouver NHS near the I-5/SR 14 interchange, as well as a proposed new pedestrian crossing over I-5 connecting E 7th Street and Hathaway Road. This planned development would occur on land that was previously owned by the U.S. Army Reserve but transferred to NPS in 2012.

Recreational Events

Prior to the COVID-19 pandemic in 2020, recreational events taking place within the study area included several large ongoing events and festivals in the Fort Vancouver NHS. Although several previously ongoing events have not resumed, events that took place in 2022 included the Vancouver Summer Fest, a day-long festival that included live music, games, food and marketplace vendors, and a beer garden. The Fort Vancouver NHS also hosts ongoing interpretive events such as military history talks, cultural demonstrations, and a Junior Ranger program for children (Fort Vancouver NHS 2023). Esther Short Park, while located outside the study area, is a venue for numerous downtown festivals and events throughout the year, including the Vancouver Farmers Market, the Vancouver Brewfest, and the Vancouver Wine and Jazz Festival. In addition to the organized events taking place in parks within the study area, recreational fishing and boating occur in the Columbia River portion of the study area throughout the year.

3.7.3 Long-Term Benefits and Effects

No-Build Alternative

No long-term direct effects of recreational resources would occur under the No-Build Alternative. However, the No-Build Alternative would result in substantial traffic congestion along the I-5 corridor and would not improve transit, bicycle, and pedestrian access to parks and recreational facilities in the study area. The increased traffic congestion and limited transit, bicycle and pedestrian access would reduce the ability of community members to access and/or enjoy park and recreation resources. Large events in downtown Vancouver, such as festivals and events at the Fort Vancouver NHS, Vancouver Farmers Market, Vancouver Brewfest, and Vancouver Wine and Jazz Festival, would continue to have limited transit and active transportation access, particularly from Portland. Connections between the Marine Drive and Columbia River Renaissance Trails would not be improved, and the shared-use path on the Interstate Bridge would remain narrow and considerably less accessible.

Modified LPA

Each design option under the Modified LPA would have the same effects on the following park and recreation facilities, as described in Table 3.7-3. Table 3.7-4 compares the long-term effects on parks and recreation facilities from Modified LPA options where the effects differ. Table 3.7-5 summarizes the long-term effects from the No-Build Alternative and the Modified LPA and its design options.

Table 3.7-3. Long-Term Effects on Parks and Recreation Facilities from the Modified LPA (No Difference between the Design Options)

Resource	Description of Long-Term Effects from the Modified LPA
East Delta Park	• Total of approximately 0.2 acres permanently acquired. • Traffic noise levels could slightly increase. • Approximately 2.1 acres of ODOT right of way currently in park use reverting to highway use.
Bridgeton Trail (planned)	• No effects on this planned trail.
Marine Drive Trail	• Marine Drive interchange improvements would enable greater ease of future connection to the existing Marine Drive Trail. • Improved connections within and to Marine Drive interchange. • Portions of reconstructed trail would consist of replacement of existing sidewalks along north side of Marine Drive with 16-foot-wide multiuse trail.

Resource	Description of Long-Term Effects from the Modified LPA
Gresham/Fairview Trail	• No effects on this trail.
Wy'East Way Trail	• Approximately 140 linear feet of the trail, where it currently crosses the existing LRT tracks, would need to be reconstructed once construction of the new tracks and pavement for the Ruby Junction Maintenance Facility completes. The existing alignment of the trail would not change.
Columbia River Renaissance Trail (coextensive with Discovery Historic Loop Trail along affected portion)	• Realignment of up to 1,000 linear feet of trail underneath new Columbia River bridges landing (see Discovery Historic Loop Trail below). • Traffic noise levels are expected to slightly decrease with double-deck fixed-span configuration. Traffic noise levels may increase with the wider single-level configurations (all bridge type options). • Reduced number of connections between the Columbia River bridges and the water (from two to one). The connection would be wider and safer.
Vancouver Landing at Terminal One	• Changes in eastern and southern views due to new Columbia River bridges. • Improved active transportation connections to the park.
Vancouver Waterfront Park	• Changes in eastern and southern views due to new Columbia River bridges. • Traffic noise levels are expected to decrease.
Old Apple Tree Park	• Approximately 0.08 acres permanently acquired. • Less than 0.1 acres of airspace permanently acquired by easement.
Marshall Community Center and Park	• Approximately 0.6 acres permanently acquired. • Traffic noise levels from I-5 are predicted to increase slightly. • Long-term character, use, and enjoyment of the existing facilities would not be affected.
Clark College Recreation Fields	• Changes in westerly views. • Incremental increase in highway noise due to shift of I-5 closer to recreation fields.
Arnada Park	• Traffic noise levels could slightly decrease. • Long-term character, use, and enjoyment of the existing facilities would not be affected.
Leverich Community Park	• Changes in westerly views. • Traffic noise levels could slightly increase.
Burnt Bridge Creek Trail	• Traffic noise levels could slightly increase.
Kiggins Bowl Sports Fields/Stadium	• Less than 0.01 acres of property permanently acquired. • Approximately 0.3 acres of a permanent subsurface easement for retaining wall ties.

Table 3.7-4. Comparison of Long-Term Effects on Parks and Recreation Facilities from the Modified LPA Options

1	2	3	4	5	6
Facility	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, and Centered I-5	Modified LPA with Single-Level Fixed-Span[a] or Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Centered I-5, without C Street Ramps	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift
Lower Columbia River Water Trail	• Reduced navigational hazard with reduced number of in-water piers. • Traffic noise levels expected to slightly decrease due to increased bridge height over the Columbia River. • The Modified LPA with the double-deck fixed-span configuration and one auxiliary lane would have 173 linear feet of shading and coverage effects; a net increase of approximately 37 linear feet after the removal of the existing Interstate Bridge.	Similar to effects listed in Column 2, but: • Two auxiliary lanes would result in an additional 16 linear feet of shading and coverage effects (total of approximately 189 linear feet).	Similar to effects listed in Column 2, but: • The single-level fixed-span configuration would result in an additional approximately 80 linear feet of shading and coverage effects (total of approximately 253 linear feet) and a net increase of approximately 117 linear feet once the existing Interstate Bridge is removed. • The single-level movable-span configuration would result in an additional approximately 80 to 100 linear feet of shading and coverage effects (depending on the location); a net increase of 117 to 137 linear feet once the existing Interstate Bridge is removed.	• Reduced navigational hazard with reduced number of in-water piers. • Traffic noise levels expected to slightly decrease due to increased bridge height over the Columbia River. • Would have 173 linear feet of shading and coverage effects; a net increase of approximately 37 linear feet after the removal of the existing Interstate Bridge.	• Reduced navigational hazard with reduced number of in-water piers. • Traffic noise levels expected to slightly decrease due to increased bridge height over the Columbia River. • Would have 173 linear feet of shading and coverage effects; a net increase of approximately 37 linear feet after the removal of the existing Interstate Bridge.

1	2	3	4	5	6
Lewis and Clark National Historic Trail	• Reduced navigational hazard with reduced number of in-water piers. • Traffic noise levels expected to slightly decrease due to increased bridge height over the Columbia River. • The Modified LPA with the double-deck fixed-span configuration and one auxiliary lane would have 173 linear feet of shading and coverage effects; a net increase of approximately 37 linear feet after the removal of the existing Interstate Bridge.	Similar to effects listed in Column 2, but: • Two auxiliary lanes would result in an additional 16 linear feet of shading and coverage effects.	Similar to effects listed in Column 2, but: • The single-level fixed-span configuration would result in an additional approximately 80 linear feet of shading and coverage effects (total of approximately 273 linear feet) and a net increase of approximately 117 linear feet once the existing Interstate Bridge is removed. • Depending on bridge type, the single-level movable-span configuration would result in an additional approximately 80 to 100 linear feet of shading a coverage effects; a net increase of 117 to 137 linear feet once the existing Interstate Bridge is removed.	• Same as effects listed in Column 2.	• Same as effects listed in Column 2.
Discovery Historic Loop Trail (includes portion of Columbia River Renaissance Trail)	• Realignment of up to 2,750 linear feet of trail (1,000-foot portion of overlaps with affected length of the Columbia River Renaissance Trail). • Improved visitor experience from new and improved intersections, sidewalks, and	• Same as effects listed in Column 2.	• Same as effects listed in Column 2.	• The SR 14 interchange without C Street ramps design option would require approximately 174 fewer linear feet of permanent trail realignment along the Discovery Historic Loop Trail than the SR	• Same as effects listed in Column 2.

1	2	3	4	5	6
	bicycle lanes in downtown Vancouver portion. • Traffic noise levels are expected to slightly decrease on the Columbia River Renaissance Trail with the double-deck fixed-span configuration because the bridges would be shifted slightly to the west further from the trail. Traffic noise levels may increase with the wider single-level configurations which would be closer to the trail (all bridge type options). • Community Connector, which would span over I-5 and block traffic noise, would slightly reduce traffic noise levels on a portion of trail near and on Evergreen Boulevard.			14 with C Street ramps design option would.	
Fort Vancouver NHS	• Approximately 0.4 acres permanently acquired. • Traffic noise levels could increase due to shift in SR 14 interchange. • At Waterfront Park, changes in western and southern views due to new Columbia River bridges.	Similar to effects listed in Column 2, but: • The Modified LPA with two auxiliary lanes would require permanent acquisition of an additional 0.03 acres.	Similar to effects listed in Column 2, but: • The single-level fixed-span configuration would require permanent acquisition of an additional 0.02 acres.	• Same as effects listed in Column 2.	• The Modified LPA with the westward shift of I-5 would require an approximately 0.4-acre permanent easement from the Fort Vancouver NHS, a reduction of approximately 200 square feet from the Modified LPA design option that

1	2	3	4	5	6
					does not shift the I-5 mainline.

Note: Table does not include park and ride options because the potential park and ride areas are not near any of the parks and recreational facilities/resources. No long-term adverse direct effects are anticipated.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.

I-5 = Interstate 5; LPA = Locally Preferred Alternative; NHS = National Historic Site; ODOT = Oregon Department of Transportation; SR = State Route

Table 3.7-5. Summary of Long-Term Effects from the No-Build Alternative, Modified LPA, and Design Options on Parks and Recreation Facilities and Trails

1	2	3	4	5	6	7
Feature	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Single-Level Fixed-Span[a] or Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA Double-Deck Fixed-Span Configuration, One Auxiliary Lane, without C Street Ramps, Centered I-5	Modified LPA Double-Deck Fixed-Span Configuration One Auxiliary Lane, C Street Ramp, I-5 Westward Shift
Total acres [b] of park and recreation resources to be acquired (approximate) [c]	0 acres	1.3 acres	1.3 acres (+1,500 square feet compared to area of acquisitions stated in Column 3)	1.3 acres (+760 square feet compared to area of acquisitions stated in Column 3)	1.3 acres	1.3 acres (-200 square feet compared to area of acquisitions stated in Column 3)
Linear feet of trails to be reconstructed and/or permanently realigned (approximate)	0 acres	5,800 feet	6,000 feet	6,000 feet	5,700 feet	5,800 feet
Anticipated transit access to park and recreation resources in study area	No change.	Would improve access to some large regional parks.	Would improve access to some large regional parks.	Would improve access to some large regional parks.	Would improve access to some large regional parks.	Would improve access to some large regional parks.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.
b Does not include 2.1 acres of property permanently acquired from an off-leash area associated with East Delta Park but located in ODOT-owned right of way.
c Differences would be less than 0.1 acres between the design options.
I-5 = Interstate 5; LPA = Locally Preferred Alternative; N/A = not applicable; NHS = National Historic Site; ODOT = Oregon Department of Transportation; SR = State Route

East Delta Park

The Modified LPA would require permanent acquisition of approximately 0.2 acres of park land. Approximately 0.1 acres would be acquired from the western edge of East Delta Park to construct a wall supporting the I-5 northbound to Marine Drive interchange ramp.

A 2.1-acre area of ODOT-owned highway right of way north of N Union Court, which has previously been used as an off-leash dog area associated with East Delta Park, would be developed with a roadway connection between Oregon Route 99 E and N Union Court and a stormwater facility would be developed in place of the dog park. The off-leash dog area is currently closed. Because this area is highway right of way it is not included in calculations of parkland areas that would be acquired and converted.

Approximately 0.1 acres of PP&R-owned park land would be required to enable construction of the roadway connection between Oregon Route 99 E and N Union Court. This area is part of a small parcel located northeast of the main portion of East Delta Park that is not used by PP&R.

Portions of East Delta Park currently experience noise levels approaching FHWA noise abatement criteria, as discussed in Section 3.11, Noise and Vibration. Compared to the No-Build Alternative, the Modified LPA is predicted to slightly increase traffic noise levels in East Delta Park, due to the revisions to the I-5 northbound mainline and the N Marine Drive/NE Martin Luther King Jr. Boulevard interchange and roadways that would shift traffic noise slightly closer to East Delta Park. Portions of East Delta Park nearest to transportation noise sources are primarily ballfields, model aircraft flying areas, and other active recreation areas not dependent on a quiet environment.

The Modified LPA would result in improved access to East Delta Park via transit as a result of improvements at the Expo Center and the new light-rail connection to Hayden Island. Additionally, new active transportation facilities and improvements to the existing active transportation network throughout the Oregon portion of the study area would improve access to East Delta Park via active transportation modes. See Section 3.1, Transportation, and the Transportation Technical Report, for additional detail on these improvements.

Marine Drive Trail

The Modified LPA would realign and reconstruct Marine Drive, requiring approximately 3,000 linear feet of the 5-mile Marine Drive Trail to be demolished and rebuilt in a similar location. The rebuilt portion of the trail would be slightly widened to connect with a 16-foot-wide multiuse path along the north side of Marine Drive, which would replace the existing sidewalk. Following construction of the Modified LPA, the rebuilt portion of the Marine Drive Trail would extend through the Marine Drive interchange, connecting both sides of I-5 to the Expo Center light-rail station, East Delta Park, the existing portion of the Marine Drive Trail, and the crossing over North Portland Harbor to Hayden Island.

The existing network of paths within the Marine Drive interchange area is difficult for users to navigate; the greater connectivity and ease of travel provided by the trail improvements would be a benefit. The reconstructed portion of the Marine Drive Trail would be designed for forward compatibility with the proposed Bridgeton Trail, and a connection to the Bridgeton Trail is included in the Modified LPA design with an extension through the I-5 right of way.

Gresham/Fairview Trail

The expansion of the Ruby Junction Maintenance Facility in Gresham is not expected to affect the Gresham/Fairview Trail. The Gresham/Fairview Trail runs through the study area along the east side of the existing Ruby Junction Maintenance Facility, which would not be affected by the expansion to the west of the existing maintenance facility.

Traffic noise levels under the Modified LPA for the Gresham/Fairview Trail are expected to be the same or similar to the noise levels under the No-Build Alternative because the trail would still run along the east side of the existing facility.

Wy'East Way Trail

The expansion of the Ruby Junction Maintenance Facility in Gresham is expected to affect approximately 140 linear feet of the Wy'East Way Trail. The effects would be from new tracks and pavement that would be constructed for the Ruby Junction Maintenance Facility. Traffic noise levels under the Modified LPA for the Wy'East Way Trail are expected to be the same or similar to the noise levels under the No-Build Alternative because the trail would still run along the north side of the existing facility.

Lower Columbia River Water Trail

Users of the Lower Columbia River Water Trail (LCRWT) would benefit from the Modified LPA's replacement of the Interstate Bridge, as the number of pier sets in the Columbia River would be reduced from nine to six. The bridge piers can pose a navigational hazard to those using the trail for recreation and commercial purposes; therefore, fewer bridge piers would reduce navigation hazards. Compared to the No-Build Alternative, traffic noise levels along the LCRWT are expected to decrease with the Modified LPA because the bridge and highway traffic would be higher above the trail (over the Columbia River).

The Modified LPA with the double-deck fixed-span configuration and one auxiliary lane would result in approximately 173 linear feet of shading and coverage effects to the LCRWT. The demolition of the existing Interstate Bridge would remove approximately 136 linear feet of existing shading. Therefore, the Modified LPA with the double-deck fixed-span configuration and one auxiliary lane would result in a net increase of approximately 37 linear feet of shading to the LCRWT. Compared to the Modified LPA with the double-deck fixed-span configuration, the Modified LPA with the single-level fixed-span would result in an additional approximately 80 linear feet of shading and coverage effects on the LCRWT. The Modified LPA with the single-level movable-span would result in an additional approximately 100 linear feet of shading and coverage effects at the movable-span location and 80 linear feet elsewhere. Compared to the Modified LPA with one auxiliary lane, the Modified LPA with two auxiliary lanes would result in an additional approximately 16 linear feet of shading and coverage of the LCRWT.

The new Columbia River bridges would be visible from the LCRWT. See Section 3.9, Visual Quality, for more detail on visual effects.

Lewis and Clark National Historic Trail

As with the LCRWT, users of the Lewis and Clark National Historic Trail along the Columbia River would benefit from the reduced navigational hazard as a result of the Modified LPA. Compared to the No-Build Alternative, traffic noise levels along the LCRWT are expected to decrease with the Modified LPA because the bridge and highway traffic would be higher above the trail (over the Columbia River).

The Modified LPA with the double-deck fixed-span configuration and one auxiliary lane would result in approximately 173 linear feet of shading and coverage effects to the Lewis and Clark National Historic Trail. The demolition of the existing Interstate Bridge would remove approximately 136 linear feet of existing shading. Therefore, the Modified LPA with the double-deck fixed-span configuration and one auxiliary lane would result in a net increase of 37 linear feet of shading to the Lewis and Clark National Historic Trail. Compared to the Modified LPA with the double-deck fixed-span configuration, the Modified LPA with the single-level fixed-span would result in an additional approximately 80 linear feet of shading and coverage effects on the Lewis and Clark National Historic Trail. The Modified LPA with the single-level movable-span would result in an additional approximately 100 linear feet of shading and coverage effects at the movable-

span location and 80 linear feet elsewhere. Compared to the Modified LPA with one auxiliary lane, the Modified LPA with two auxiliary lanes would result in an additional approximately 16 linear feet of shading and coverage of the Lewis and Clark National Historic Trail.

The new bridges would be visible from the Lewis and Clark National Historic Trail. See Section 3.9, Visual Quality, for more detail on visual effects.

Columbia River Renaissance Trail

The Modified LPA would permanently realign approximately 1,000 linear feet of the Columbia River Renaissance Trail. Currently, the only access to the Columbia River Renaissance Trail from I-5 is via steep or circuitous paths extending from the north end of the Interstate Bridge to Columbia Way and then across Columbia Way. The Modified LPA would include a new multiuse path that would extend underneath the northbound Columbia River bridge and connect directly to the trail along the realigned Columbia Way.

The Modified LPA would reduce the number of connections between the Columbia River bridges and the waterfront from two to one, and the connection would be wider and safer than what currently exists, benefiting the Columbia River Renaissance Trail users. The Modified LPA with the double-deck fixed-span configuration is anticipated to result in lower traffic noise levels along the Columbia River Renaissance Trail than the No-Build Alternative because of the increased bridge height. The Modified LPA with the single-level fixed-span and the single-level movable-span configurations may slightly increase traffic noise levels due to the wider bridge span.

Discovery Historic Loop Trail

The Modified LPA, with the C Street ramps, would permanently realign approximately 2,750 linear feet of the Discovery Historic Loop Trail with construction of the new Columbia River bridges and demolition of the existing bridges. The elimination of the C Street ramps at the SR 14 interchange would reduce the permanent realignment of the Discovery Historic Loop Trail to approximately 2,579 linear feet—a reduction of approximately 174 linear feet. The affected portions of the Discovery Historic Loop Trail include approximately 1,000 linear feet where it shares an alignment with the Columbia River Renaissance Trail, with the impacts discussed above.

Users of the section of the Discovery Historic Loop Trail traversing downtown Vancouver streets would benefit from new and improved intersections, sidewalks, and bicycle lanes under the Modified LPA, which would result in an overall improvement in safety and enjoyment for users. Trail users would benefit from the Community Connector that would be constructed south of Evergreen Boulevard. This Community Connector would include off-street pathways for active transportation modes including pedestrians, bicyclists, and other micro-mobility modes, and public space and amenities to support the active transportation facilities – improving connections between downtown Vancouver and the VNHR and adding to the network of public spaces in the area. The Community Connector, which would span over I-5, would provide some reduction in highway noise when compared to existing sidewalks and bike lanes, which would further enhance the user experience when traveling this section of the Discovery Historic Loop Trail.

Project modifications would be visible from the Discovery Historic Loop Trail. See Section 3.9, Visual Quality, for more detail on visual effects.

Fort Vancouver National Historic Site

The Modified LPA, with the double-deck fixed-span configuration and one auxiliary lane, would require an approximately 0.4-acre permanent acquisition from the Fort Vancouver NHS. These permanent impacts would result from the modifications to the I-5/SR 14 interchange and the widening of I-5. The Modified LPA with the single-level fixed-span (all bridge type options) and single-level movable-span configuration would result in the permanent acquisition of an additional approximate 0.02 acres (approximately 762 square feet)

of park land at the Fort Vancouver NHS. The Modified LPA with two auxiliary lanes would result in the permanent acquisition of an additional approximately 0.03 acres of undeveloped park land at the Fort Vancouver NHS. Figure 3.7-2 shows the permanent and temporary impacts for each of the Modified LPA design options.

Traffic noise levels in the recreational portion of the Fort Vancouver NHS near the I-5/SR 14 interchange could increase slightly under the Modified LPA compared to the No-Build Alternative because highway infrastructure associated with the SR-14 interchange would shift slightly closer to the Fort Vancouver NHS.

The Modified LPA would not result in long-term direct effects on Waterfront Park, beyond changes in western and southern views from the new Columbia River bridges. These changes in views would not adversely affect the function or enjoyment of Waterfront Park.

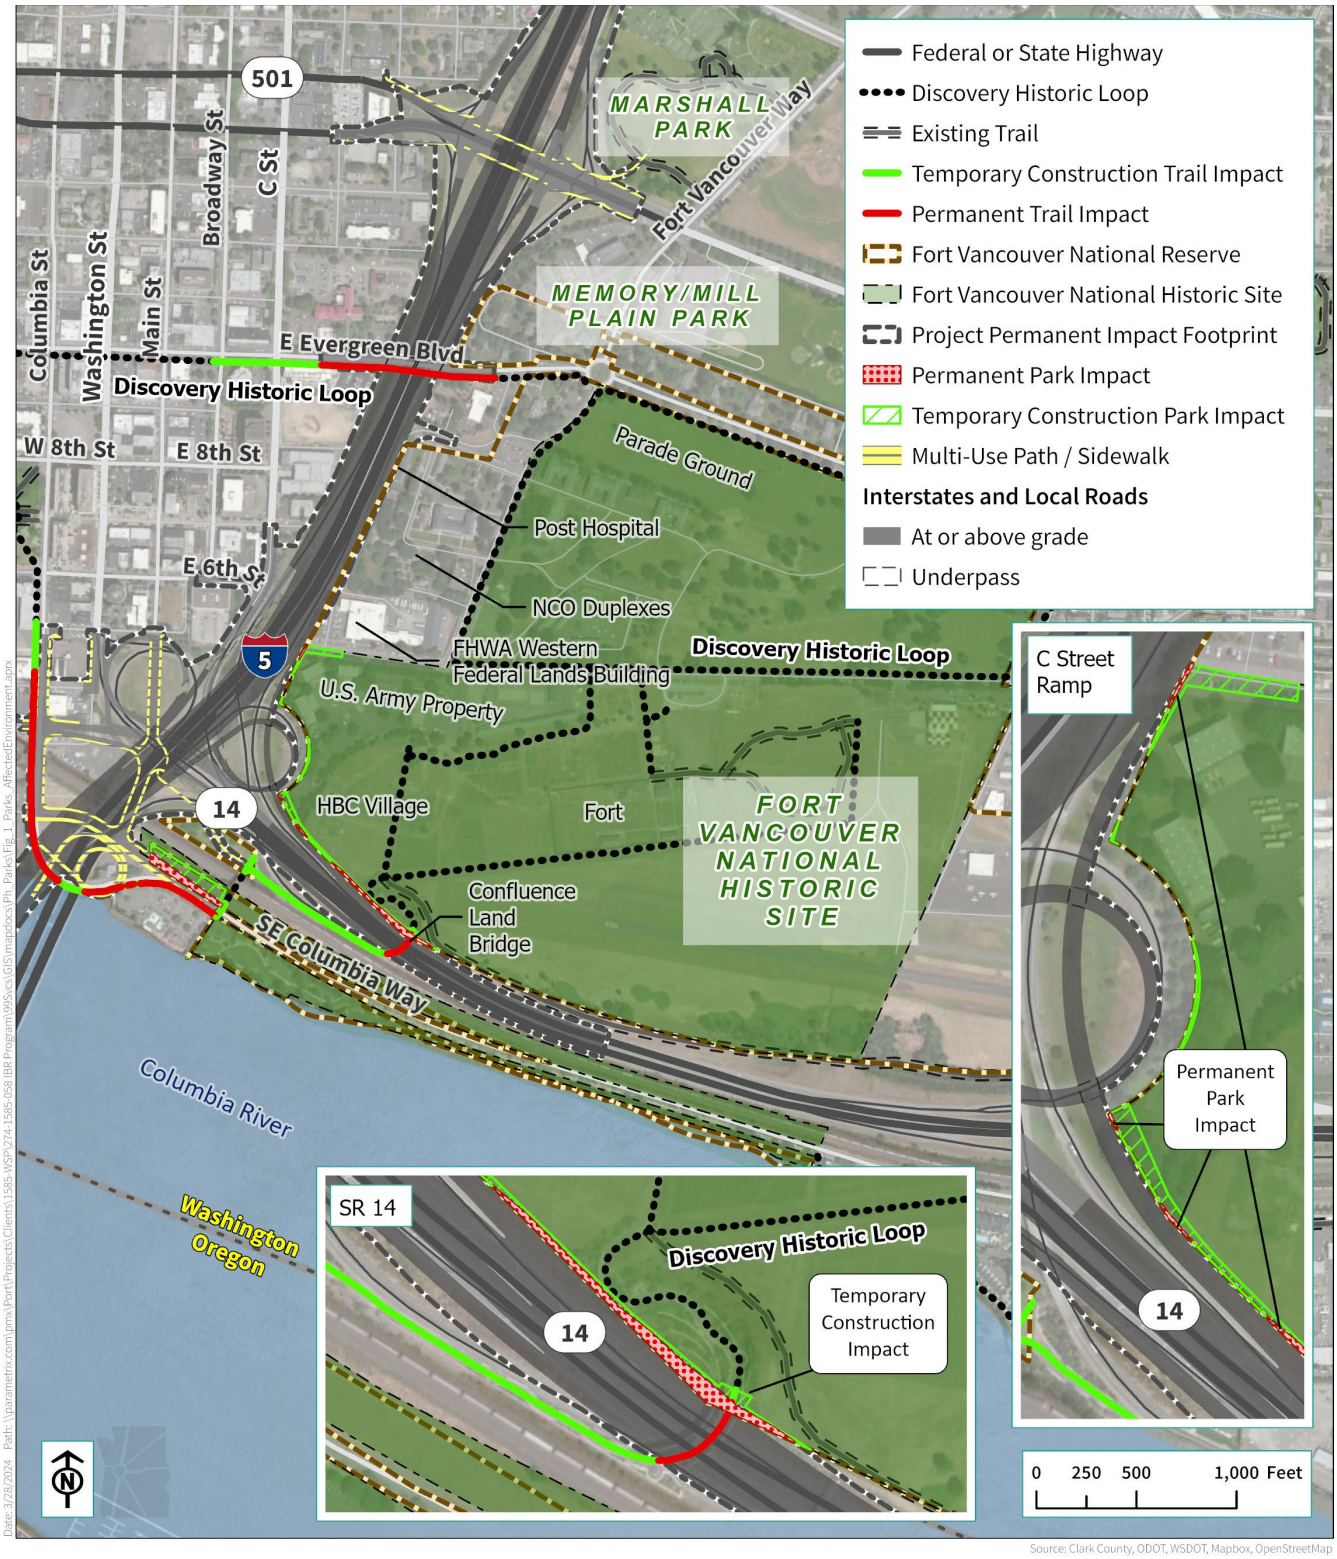
Old Apple Tree Park

The Modified LPA would permanently acquire approximately 0.08 acres from Old Apple Tree Park for a new shared-use path that would link Main Street and downtown Vancouver. Users of the Confluence Land Bridge, which extends over SR 14 and connects the Vancouver waterfront with the Fort Vancouver NHS, would benefit from this new path as they travel through the park.

The Modified LPA, with or without the C Street Ramps and with either the I-5 centered mainline or westward shift, would also require a permanent airspace easement (less than 0.1 acres) over the northwest corner of Old Apple Tree Park for maintenance of the I-5 northbound to SR 14 elevated ramp. This easement would provide WSDOT with the right to enter Old Apple Tree Park with equipment to perform routine inspections of the ramp structure. This easement is not expected to affect landscaping on the park property. The new I-5 northbound to SR 14 interchange ramp would be located within 5 to 10 feet of the park's northern boundary, closer to the park than the existing ramp. The ramp is not expected to adversely affect the forested buffer along the northern edge of the park, which would remain.

Traffic noise levels in Old Apple Tree Park are predicted to be slightly lower under the Modified LPA than under the No-Build Alternative because the new SR 14 ramp would be higher in elevation than the existing SR 14 ramp, reducing noise levels at grade within the park. In the case of the SR 14 without C Street Ramps option, traffic noise levels would be eliminated.

Figure 3.7-2. Fort Vancouver National Historic Site – Comparison of Modified LPA and Design Options



Marshall Community Center, Luepke Senior Center, and Marshall Park

The Modified LPA would require the permanent acquisition of approximately 0.6 acres of land from the parcel that includes the Marshall Community Center, the Luepke Senior Center, and Marshall Park. The area needed would be for a retaining wall associated with the elevated exit ramp from I-5 northbound to Fourth Plain Boulevard.

The permanent acquisition would displace up to four horseshoe pits and trees (both in state right of way and within the park boundary), including several large sequoia trees that serve as a buffer between the community center campus and I-5. The retaining wall would be located along the border of the parking lot, with a height of up to 20 feet. The existing parcel also contains a few medium-sized trees and provides a partial vegetative buffer between the park and I-5. Specific tree replanting requirements would be determined by the City of Vancouver Urban Forester during the tree removal permitting process.

Traffic noise levels from I-5 are predicted to increase slightly at Marshall Community Center, the Luepke Senior Center, and Marshall Park under the Modified LPA compared to the No-Build Alternative. The addition of the light-rail transit (LRT) line along the west side of I-5 is not expected to result in an increase in noise levels.

With the re-establishment of a vegetated buffer and replacement of trees and landscaping that would be removed between I-5 and the community center.

Kiggins Bowl Sports Fields and Stadium

The Modified LPA would require the acquisition of less than 0.01 acres of the Kiggins Bowl Sports Fields and Stadium property for a retaining wall near the southern access, along the east side of Discovery Middle School. This permanent acquisition would not displace park use. A permanent subsurface easement, totaling approximately 0.3 acres, would extend from the retaining wall to under the access road for the installation of long ties that would anchor the wall into the soil. This subsurface easement would not permanently affect the aboveground use of this area, but would limit excavation below a depth that would be determined based on the final design of the retaining wall.

3.7.4 Temporary Effects

No-Build Alternative

Under the No-Build Alternative, construction and associated construction-phase impacts such as use of park lands; traffic detours; temporary closures; and noise, dust, and vibration would not occur. Overall, there would be no foreseeable temporary direct effects or benefits to park and recreation resources from the No-Build Alternative.

Modified LPA

Construction of the Modified LPA includes construction of the new bridges and removal of the existing Interstate Bridge. Temporary effects of the Modified LPA on park and recreation resources include temporary easements on park land to stage construction and/or store materials; increased noise, glare, dust, and vibration; and temporary closures, detours, and congestion that could delay users traveling to parks or recreational activities. Temporary impacts on park and recreation resources are summarized in Table 3.7-6. The narrative following the table provides additional description for parks where more potentially substantial temporary effects would occur.

Table 3.7-6. Modified LPA Temporary Effects on Park and Recreation Resources

Resource	Description of Temporary Effects from Modified LPA
East Delta Park	• Approximately 0.2 acres temporary impacts for construction of retaining wall. • Detours required for active transportation and vehicles. • Increased noise and dust.
Marine Drive Trail	• Trail users diverted during construction to opposite side of Marine Drive and at times along south side of Portland Expo Center, resulting in approximately 360 feet of temporary impacts.
Gresham/Fairview Trail	• No temporary effects from construction.
Wy'East Way Trail	• Temporary trail detours and disruptions at NW Burnside Court and NW Eleven Mile Avenue / Wy'East Way.
Lower Columbia River Water Trail and Lewis and Clark National Historic Trail	• Recreational marine travel along the Columbia River would be limited. Safe passage route or detours, if necessary, to be provided through construction. • Possible temporary closure of near-shore areas to recreational use due to safety considerations.
Columbia River Renaissance Trail and Discovery Historic Loop Trail	• Increased levels of noise, dust, glare, and construction equipment emissions. • Long-duration closures of connections between downtown Vancouver and SR 14. Trail users diverted to Columbia Way to reach downtown Vancouver.
Vancouver Landing at Terminal One	• Less than 0.1 acres temporary impacts. • Temporary construction impacts from increased noise, changes in views of the Columbia River at I-5, and glare from construction lighting.
Fort Vancouver NHS	• Temporary construction easement on approximately 1 acre of the Fort Vancouver NHS, which would be adjacent to I-5 near the C Street ramp and E Fifth Street and near the Confluence Land Bridge, for construction of retaining wall. • Increased noise, vibration, and dust. • Temporary construction impacts from increased noise, changes in views of the Columbia River at I-5, and glare from construction lighting at Waterfront Park.
Vancouver Waterfront Park	• No temporary effects.
Old Apple Tree Park	• Temporary construction easement on approximately 0.2 acres. • Increased noise, glare from construction lighting, additional dust, and possibly debris entering the park. • Temporary increases in traffic levels along Columbia Way may affect trail users leaving or entering the park.

Resource	Description of Temporary Effects from Modified LPA
Marshall Community Center and Park	• Temporary construction easement on approximately 0.4 acres during construction. • Realignment and/or closure of accesses and potential temporary closure of access and portion of parking. • Increased noise/vibration, as well as glare from construction lighting.
Clark College Recreation Fields	• Increased noise, vibration, dust, and glare.
Arnada Park	• Less than 0.1 acres of temporary impacts for construction, affecting landscaped areas including grass and small trees. • Increased noise, dust, and glare.
Leverich Community Park	• Revised access and traffic movements on 39th Street during construction of the SR 500/I-5 interchange. • Increased noise, dust, and glare.
Burnt Bridge Creek Trail	• No temporary impacts.
Kiggins Bowl Sports Fields/Stadium	• Temporary construction easement on approximately 0.01 acres. • Increased noise, vibration, and dust.

East Delta Park

Under the Modified LPA, highway construction would require a temporary construction easement from approximately 0.2 acres from the western, eastern, and northern edges of East Delta Park. The affected area is covered by grass that is mowed periodically. The temporary construction easement would be required to gain access to the I-5 right of way to build a retaining wall that would support the I5 northbound bridge to the Marine Drive interchange ramp.

The duration of the temporary construction easement in East Delta Park is expected to be less than six months.

Construction activities would generate noise and dust and damage the grass where construction equipment would operate. All landscaping would be restored after construction. Detours for active transportation would reflect the Portland Bureau of Transportation guidance for detours around construction sites and would be maintained regularly. While detours may be required during some construction phases, vehicle access to East Delta Park would be maintained.

Wy'East Way Trail

The Wy'East Way Trail could experience trail detours and disruptions at NW Burnside Court and NW Eleven Mile Avenue / Wy'East Way.

Lower Columbia River Water Trail

During construction of the Columbia River bridges and the demolition of the existing Interstate Bridge, both recreational and commercial marine travel along the Columbia River would be limited. Users of the LCRWT would be provided with a safe passage route or detours, if necessary, through the construction zone. However, for safety purposes, it is possible that recreational travel through the study area would be limited at times and trail users may not be able to access some areas. For example, during construction or demolition of the shallow-water piers, near-shore areas may be closed to recreational use. Trail users in kayaks or canoes may not be able to venture into the mid-river detour routes that involve faster-flowing

water and possible interactions with motorized boats. This impact would be the same for the Modified LPA with or without the C Street Ramp options.

Temporary effects of the Modified LPA with two auxiliary lanes and the single-level fixed-span (all bridge type options) and single-level movable-span configurations would be similar to those described above.

Lewis and Clark National Historic Trail

Temporary impacts to the Lewis and Clark National Historic Trail would be the same as those described above for LCRWT.

Columbia River Renaissance Trail and Discovery Historic Loop Trail

Access under I-5 between downtown Vancouver and the Columbia River would be maintained throughout the duration of construction, though temporary detours and trail realignments would occur. The Columbia River Renaissance Trail would extend directly beneath the construction of the new Columbia River bridges and demolition of the existing Interstate Bridge. Trail users would experience increased levels of noise, changes in views of the Columbia River, glare from construction lighting, emissions from construction equipment, and possibly dust from construction activities.

Additionally, during construction at the I-5/SR 14 interchange, connections between downtown Vancouver and SR 14 would be closed for periods of time. Drivers and bicyclists attempting to make this movement would be detoured to enter and exit SR 14 at Exit 1 (Columbia House Boulevard) and would be required to travel along Columbia Way to reach downtown Vancouver. This would temporarily increase traffic levels on this street, which is adjacent to the Columbia River Renaissance Trail. This increase in traffic levels could pose a risk to trail users crossing into Old Apple Tree Park or crossing Columbia Way for another reason.

Fort Vancouver National Historic Site

The Modified LPA would temporarily affect approximately 1 acre of the Fort Vancouver NHS for construction of a retaining wall along I-5 in the western portion of the park, representing less than 1% of the 204-acre park.

The Modified LPA with two auxiliary lanes would require temporary disturbance of 0.96 acres of park land at the Fort Vancouver NHS. This is an approximately 0.03-acre decrease in temporary impacts from the Modified LPA with one auxiliary lane, because portions of the area of temporary impacts become permanent impacts with the addition of the second auxiliary lane. Compared to the double-deck fixed-span configuration, the wider structure associated with the single-level fixed-span (all bridge type options) and single-level movable-span configurations would shift some of the temporary impacts to permanent, resulting in a decrease of less than 0.1 acres (approximately 762 square feet) of temporary impacts at Fort Vancouver NHS.

The Modified LPA with the removal of the existing C Street ramps at the SR 14 interchange would temporarily affect approximately 0.98 acres) of the Fort Vancouver NHS, which would be adjacent to the West Barracks and at the west end of Officer's Row, for construction of a retaining wall along I-5. This would represent a minimal decrease (less than 0.02 acres) in temporary impacts compared to the Modified LPA. The westward shift of the I-5 mainline would also reduce the temporary impacts by approximately 0.02 acres.

Figure 3.7-2 shows the permanent and temporary impacts for each of the Modified LPA design options.

Waterfront Park west and east of the Columbia River bridges may experience temporary construction impacts such as increased noise, changes in views of the Columbia River at I-5, and glare from construction lighting. Waterfront Park users would be far enough to the west and east that they would not likely be affected by vehicle emissions and dust associated with construction.

Construction at the I-5/SR 14 interchange and along I-5 would temporarily increase noise, vibration, and dust that would distract from recreational activities, particularly for those seeking quiet.

Old Apple Tree Park

The Modified LPA would temporarily affect approximately 0.2 acres of Old Apple Tree Park during construction of the new I-5 northbound to SR 14 westbound off-ramp. Demolition of the existing ramp and construction of the new SR 14 westbound off-ramp would result in increased levels of noise, glare from construction lighting, additional dust, and possibly debris entering the park. Temporary increases in traffic levels along Columbia Way, as described above, may make it more challenging for trail users to leave or enter Old Apple Tree Park.

Marshall Community Center, Luepke Senior Center, and Marshall Park

The Modified LPA would require realigning the accesses to Marshall Community Center, Luepke Senior Center, and Marshall Park along McLoughlin Boulevard. This would result in temporary construction-related effects to approximately 0.4 acres along the western boundaries of the parcel. Access to and from the Marshall Community Center would be maintained during the duration of construction. One of the two access points may need to be closed for short periods to complete construction. During potential access closures, the one-way access between the two main parking lots would likely be signed for two-way traffic to allow for full use of the parking facility, which would likely require flaggers because this access is only one lane. Access closures would be coordinated with VPR&C.

Users of Marshall Community Center, Luepke Senior Center, and Marshall Park would likely experience increased levels of noise and glare from lighting for construction of the I-5 northbound exit ramp to Fourth Plain Boulevard.

Clark College Recreation Fields

Approximately 4.5 acres adjacent to the Clark College recreational fields would be temporarily affected by construction of the Modified LPA, which would affect landscaping (including grass and small trees) in this area. This temporary easement would occur west of the fields and is not expected to affect the recreational experience of users.

Similar to Marshall Community Center and Park, users of this facility would likely experience increased levels of noise and glare from construction lighting. Additionally, users attempting to access this facility from McLoughlin Boulevard may experience delays as they navigate through the construction on this street.

Arnada Park

Less than 0.1 acres of Arnada Park would be used for a temporary construction easement during construction of the Modified LPA, which would temporarily disturb landscaping (including grass and small trees). This landscaping would be restored per Program-specific mitigation measures. Users of this facility would likely experience increased levels of noise and glare from construction lighting.

Kiggins Bowl Sports Fields and Stadium

Construction of the retaining wall along the access to Kiggins Bowl Sports Fields and Stadium would temporarily affect less than 0.01 acres of the property. Construction is not expected to limit access by passenger vehicles, bicyclists, or pedestrians. The movement of heavier trucks and buses along this road could be restricted during installation of the underground tiebacks for the retaining wall. Every effort would be made to minimize closures of this access to large vehicles during times that have been identified by Vancouver Public Schools as high use times (e.g., September 1 through November 15). If closures are unavoidable and access to the stadium or fields is needed, an appropriate detour route would be established. This detour would be signed and would direct users to the northern access point from Main Street. The contractor would be directed to coordinate with the Vancouver Public Schools on planned access closures.

Construction along I-5 would temporarily increase noise, vibration, and dust that would distract from recreational activities, particularly for those seeking quiet.

3.7.5 Indirect Effects

The Modified LPA would include improved bicycle, pedestrian, highway, and transit access in North Portland and Vancouver, which could make access to parks and recreation resources easier and result in additional park users. New light-rail stations located within walking distance to the Fort Vancouver NHS would also improve access to nearby parks and recreation facilities.

As described in Section 3.4, transit-oriented development may occur along the new LRT line, consistent with local land use plans. Such development is frequently relatively high-density, with limited space devoted to yards or communal greenspace; residents of these developments may therefore have a greater per-capita demand for off-site recreational facilities. Greater demand, if it occurred, could result in increased use of existing parks and recreational facilities, which could potentially result in overcrowding at facilities that are already highly used.

3.7.6 Potential Avoidance, Minimization, and Mitigation Measures

The following regulatory and Program-specific measures are proposed to address long-term and temporary effects on parks and recreation facilities.

Long-Term Effects

Regulatory Requirements

- If tree removal is unavoidable, replace trees on site and in kind at appropriate replacement ratios in compliance with applicable requirements of Portland and Vancouver city code.
- Evaluate the feasibility and reasonableness of noise mitigation in accordance with WSDOT or ODOT criteria to shield park visitors and trail users from increased noise levels.

Program-Specific Mitigation

- If the acquired park land includes play equipment or other amenities, replace those features either in the same park or at one nearby.
- Coordinate specific tree removal permitting process and tree replanting requirements (location and type) for each park with the appropriate jurisdiction.
- Screen portions of the transportation improvements from view with trees, vegetation, or built screens.
- Explore retaining wall façade treatments to improve the visual quality, where feasible.

Temporary Effects

Regulatory Requirements

- In compliance with the City of Vancouver's tree conservation requirements (VMC 20.770.090, Tree, Vegetation, and Soil Protection During Construction) or City of Portland preservation standards for trees in development situations (PCC 11.50.040, Tree Preservation Standards) and Tree Plan requirements (PCC 11.50.020) protect trees on park property that would be close to construction activities from adverse impacts as directed by the agency managing the park land (the cities of Vancouver, Portland and Gresham, NPS, and the Vancouver Public School District).

- Employ best management practices, including those outlined in WSDOT and ODOT construction manuals, to minimize increased levels of noise, vibration, glare from construction lights, emissions from construction vehicles, or dust from demolition of existing structures.
- Comply with local ordinance requirements to provide additional protection for park users.

Program-Specific Mitigation

- Restore landscaping to its original condition and select plants that are resilient or adaptive to future climate conditions for new landscaping once construction is complete.
- Protect trees on park property that would be close to construction activities but not removed, as agreed to with the appropriate jurisdiction.
- Restore landscaping to as close as possible to its original condition once construction is complete.
- Establish detour routes based on work zone Transportation Management Plan.
- Schedule construction-related closures at public parks and recreation facilities to minimize effects on large events, as feasible.
- Provide notice to users of the recreational trails of the temporary limits on recreation in the Columbia River.
- Notify recreational anglers of temporary access restrictions to fishing areas and consider other coordination efforts, including working with the Washington Department of Fish and Wildlife and the Oregon Department of Fish and Wildlife to share closure information and distribute this information at locations that serve the fishing community.

3.8 Cultural Resources

This section analyzes the potential impacts of the Modified LPA to cultural resources in the Area of Potential Effects (APE; see Section 3.8.2) compared to the No-Build Alternative. In addition, this section describes design changes or new information obtained since 2013, existing conditions, project planning to avoid and minimize effects, and the ongoing process to develop a Programmatic Agreement (PA) to resolve adverse effects to historic properties (see Section 3.8.6). This section summarizes information in the Archaeology Technical Report and Historic Built Environment Technical Report, which were prepared to comply with NEPA, and summarizes compliance with Section 106 of the National Historic Preservation Act (NHPA; 54 USC 306101) and its implementing regulations at 36 CFR Part 800 (Protection of Historic Properties) (NHPA Section 106).

Evaluation of Cultural Resources

The evaluation of impacts to cultural resources in this section of the Draft SEIS uses terminology associated with Section 106 of the National Historic Preservation Act. Several new terms are introduced:

- **Area of Potential Effects (APE)** is used to represent the study area for cultural resources (see Section 3.8.2).
- **Direct Effects** to cultural resources are those caused by the undertaking at the same time and place with no intervening cause and regardless of type (e.g., visual, physical, auditory), and may be permanent or temporary.
- **Indirect Effects** to cultural resources are those caused by the undertaking that are later in time or father removed in distance but still reasonably foreseeable.

The term *cultural resources* refers to sites, buildings, structures, objects, and districts, which may also include traditional cultural properties (TCPs), historic properties of religious and cultural significance to Indian tribes (HPRCSIT), and cultural landscapes.[1] Cultural resources may be considered *historic properties* as defined in 36 CFR 800.16 if they are included in, or eligible for inclusion in, the National Register of Historic Places (NRHP). To be NRHP-eligible, historic properties must meet one or more NRHP significance criteria; possess integrity of location, design, setting, materials, workmanship, feeling, and association; and typically be 50 years of age or older. Resources meet the NRHP significance criteria if they:

- (Criterion A) are associated with events that have made a significant contribution to the broad patterns of our history.
- (Criterion B) are associated with the lives of persons significant in our past.

[1] TCPs are defined by the National Park Service (NPS) as properties that are eligible for the NRHP for their "association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community" (Parker and King 1992:1).

HPRCSIT is a term used in federal law and regulation to describe an historic property to which specifically a Native American tribe or Native Hawaiian organization attaches traditional religious and cultural importance and may be determined eligible in accordance with Section 101(d)(6)(A) of the NHPA (54 USC 302706a). Though conceptually similar, HPRCSIT are differentiated from TCPs because they must be associated with a Native American tribe or Native Hawaiian organization rather than a general "living community."

A cultural landscape is defined by NPS as "a geographic area (including both cultural and natural resources and the wildlife or domestic animals therein), associated with a historic event, activity, or person or exhibiting other cultural or aesthetic values" (Birnbaum 1992). Cultural landscapes are generally categorized as at least one of four types: historic sites, historic designed landscapes, historic vernacular landscapes, and ethnographic landscapes.

- (Criterion C) embody the distinctive characteristics of a type, period, or method of construction, or that represent the work of a master, or that possess high artistic value, or that represent a significant and distinguishable entity whose components may lack individual distinction.
- (Criterion D) have yielded, or may be likely to yield, information important in prehistory or history.

Certain categories of resources are typically not considered eligible for listing in the NRHP: cemeteries, birthplaces, or graves of historical figures, properties owned by religious institutions or used for religious purposes, structures that have been moved from their original locations, reconstructed historic buildings, properties primarily commemorative in nature, and properties that have achieved significance within the past 50 years (NPS 1995). However, these properties may qualify as NRHP-eligible if they are:

- (Criteria Consideration A). A religious property deriving primary significance from architectural or artistic distinction or historical importance.
- (Criteria Consideration B). A building or structure removed from its original location, but which is significant primarily for architectural value, or which is the surviving structure most importantly associated with a historic person or event.
- (Criteria Consideration C). A birthplace or grave of a historical figure of outstanding importance if there is no appropriate site or building directly associated with the figure's productive life.
- (Criteria Consideration D). A cemetery which derives its primary significance from graves of persons of transcendent importance, from age, from distinctive design features, or from association with historic events.
- (Criteria Consideration E). A reconstructed building when accurately executed in a suitable environment and presented in a dignified manner as part of a restoration master plan, and when no other building or structure with the same association has survived.
- (Criteria Consideration F). A property primarily commemorative in intent if design, age, tradition, or symbolic value has invested it with its own exceptional significance.
- (Criteria Consideration G). A property achieving significance within the past 50 years if it is of exceptional importance.

Archaeological sites are physical remnants of past human activity, including items left behind by past peoples (i.e., artifacts) and physical modifications to the landscape (i.e., features). Historic built environment resources are buildings, objects, structures, sites, or districts (NPS 1995). TCPs are places, landscape features, or locations associated with cultural practices, traditions, beliefs, lifeways, arts, crafts, or social institutions of a living community that meet one or more of the four NRHP significance criteria (Parker and King 1992). Historic districts may be composed of a collection of all or some of these resources—archaeological sites, historic built environment resources, and TCPs (NPS 1995).

Cultural resources may be listed in national, state, or local historic registers and may also be identified as important to a particular group during public outreach or formal consultation under Section 106. Project elements that occur on federal lands are also required to comply with the Archaeological Resources Protection Act of 1979 (ARPA; 16 USC 470) and the Native American Graves Protection and Repatriation Act of 1990 (NAGPRA; 25 USC 3001-3013). In Oregon, statutes that consider cultural resources include Archaeological Objects and Sites (Oregon Revised Statutes [ORS] 358.905 to 358.961), Permit and Conditions for Excavation or Removal of Archaeological or Historical Material on Public Lands (ORS 390.235), and Indian Graves and Protected Objects (ORS 97.740-97.760). In Washington, these laws include Archaeological Sites and Resources (Revised Code of Washington [RCW] 27.53), Indian Graves and Records (RCW 27.44), and Abandoned and Historic Cemeteries and Historic Graves (RCW 68.60). In addition, the City of Portland, the City of Vancouver,

and Clark County have ordinances and environmental policies that consider the preservation of cultural resources.

Section 106 of the NHPA requires federal agencies to consider the effects on historic properties of undertakings they carry out, assist, fund, permit, license, or approve and consult on anticipated effects on historic properties.

FHWA and FTA, co-lead federal agencies under Section 106, initiated consultation for the Modified LPA. In September 2020, FHWA and FTA extended formal letters inviting consultation on the IBR Program with 21 tribes and Native Hawaiian Organizations that consulted during the Columbia River Crossing (CRC) project. Through this initial effort, 10 federally recognized tribes expressed an interest in consultation. In February 2022, as a result of consultation with the National Park Service (NPS), letters were sent to an additional 17 tribes. None of those tribes accepted the invitation to consult. A complete list of consulting tribes and a summary of the IBR Program's outreach efforts is included in the Tribal Consultation section of Appendix A. In March 2022, FHWA and FTA contacted 48 points of contact from governments and organizations, sending information about the IBR Program and an invitation to be a NHPA Section 106 consulting party.

In correspondence dated February 7, 2023, FHWA and FTA notified consulting parties and consulting tribes that the IBR Program would be treated as a new undertaking under Section 106, provided maps depicting their determination of the APE, and initiated consultation on the PA. On February 8, 2023, the IBR Program solicited feedback from consulting parties on the APE during a consulting party meeting. The Oregon State Historic Preservation Office (SHPO) agreed with the definition of the APE in correspondence dated March 7, 2023, and the Washington Department of Archaeology and Historic Preservation (DAHP) agreed with the definition of the APE in correspondence dated March 10, 2023. In response to comments from consulting parties and in response to design modifications the APE was revised and FHWA and FTA provided documentation of the revised APE in correspondence to consulting parties dated September 8, 2023. FHWA and FTA provided documentation of additional revisions to the APE in correspondence to consulting parties dated December 27, 2023, and July 1, 2024. Section 106 consultation for the current undertaking is ongoing, including development of a PA. Stipulations in the PA will outline processes for continued consultation, phasing of additional historic property identification, evaluation, effect determination, and mitigation in accordance with 36 CFR Part 800. More detail is provided in Section 3.8.6, Mitigation and Programmatic Agreement.

From April 17 through May 18, 2023, a cultural resources online open house was held to provide an opportunity for public input on efforts to research and identify cultural resources in and near the APE. Information regarding the methods and process for public involvement is provided in Appendix B. Efforts to engage the public specifically related to the cultural resources online open house included advertisement on IBR social media and the home page of the IBR Program website, email notifications to Program partners and community organizations, postcard mailing to addresses in the Program vicinity, press release distribution, and promotion in the April 2023 IBR Program newsletter. In addition, IBR Program cultural resources staff participated in in-person neighborhood forums in May and June 2023 and have staffed virtual and in-person office hours to field questions from the public. Reports on historic properties and the Draft PA will be made available for review to the general public at the IBR project office and through online open houses. Documentation that includes sensitive information exempt from the Freedom of Information Act will not be readily available for public review pursuant to Section 304 of NHPA.

In addition to Section 106 compliance, historic properties that are NRHP-listed or determined to be NRHP-eligible are also subject to applicable state laws and Section 4(f) of the U.S. Department of Transportation Act of 1966 (49 USC 303). The Section 4(f) Evaluation is Chapter 4 of this Draft SEIS.

3.8.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC Locally Preferred Alternative (CRC was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with cultural resources has been updated in this Draft SEIS to include:

- Initiation of a new undertaking under Section 106.
- Updated APE based on changes to the construction footprint.
- Updated information on known historic properties within the APE in response to reduced construction footprint and expansion of historic built environment analysis to consider resources that would be 50 years of age at the time of the Modified LPA's anticipated completion date in 2032.
- Updates to direct and indirect effects of the Modified LPA and design options.

Table 3.8-1 compares the effects identified for the CRC LPA and the IBR Program's Modified LPA resulting from the changes listed above. As shown, changes to the design of the CRC LPA may result in fewer adverse effects on archaeological sites. Meanwhile, although the construction footprint of the Modified LPA is less than the CRC LPA in some areas, the number of historic built environment resources affected increased because the quantity of historic built environment resources assessed increased. Compared to 25 resources assessed by CRC, 39 resources were accessed for the Modified LPA. This increase is due to the following additions:

- Resources built between 1967 (the most recent resources evaluated in the CRC Final EIS) and 1982 were evaluated because they would be at least 50 years of age at the time of the Modified LPA's anticipated completion date in 2032.
- Both the northbound and southbound portions of the Interstate Bridge are assessed for effects in this Draft SEIS, while the CRC Final EIS evaluated only the northbound portion of the bridge.
- The CRC Final EIS considered the Vancouver National Historic Reserve (VNHR) as one property. This analysis refines that approach by separately considering the four historic districts and one historic site that are located within the boundaries of the VNHR, but previously documented separately as NRHP-eligible or NRHP-listed historic properties. These include Vancouver National Historic Reserve Historic District, Pearson Field Historic District, Vancouver Barracks Historic District, Officers Row Historic District, and Fort Vancouver National Historic Site. Portions of the VNHR are owned and managed separately by NPS and City of Vancouver.

A detailed description of effects on archaeological sites and historic built environment resources from the IBR Modified LPA and design options is provided in Section 3.8.3, Direct Effects.

Table 3.8-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section [a]	Explanation of Differences
Number of NRHP-listed or NRHP-eligible historic built environment resources adversely affected	3	12	• Pier 99 (OR 1, also referred to as Totem Pole Marina No. 2) would have been adversely affected under CRC but was demolished in 2023 by activities unrelated to the IBR Program. • Northbound portion of the Interstate Bridge would be adversely affected under both CRC and IBR. • Additional adverse effects of the I-5 southbound portion of the Interstate Bridge and the Normandy Apartments with the Modified LPA. • VNHR was previously assessed as one property. Under the IBR Program, four districts and one site, which are located within the boundary of VNHR but previously documented as separate historic properties, are assessed separately and found to be adversely affected separately. • Four previously unevaluated properties would be adversely affected, of which two were built between 1967 and 1982.[b]
Number of archaeological sites adversely affected	32	12	• Changes in project construction footprint reduced the number of adverse effects.

a Given the complexities of the IBR Program and the anticipated mix of construction contract delivery methods, additional cultural resource investigations completed consistent with a Section 106 phased identification process that will be stipulated in the PA are required and may result in changes to these totals. When executed, the PA will include stipulations that specify the process for continued consultation, evaluation, effect determination, and mitigation in accordance with 36 CFR Part 800. Current totals are based on Section 106 investigations completed at the time of document publication.

b These include Jantzen Beach Moorage (OR 111), Jantzen Beach Water Tank (OR 109), Harbor Shops (OR 107), and Bridge Substation (WA 1192).

CFR = Code of Federal Regulations; CRC = Columbia River Crossing; EIS = Environmental Impact Statement; IBR = Interstate Bridge Replacement; LPA = Locally Preferred Alternative; NRHP = National Register of Historic Places; PA = Programmatic Agreement; VNHR = Vancouver National Historic Reserve

3.8.2 Existing Conditions

This section describes the APE and summarizes baseline conditions in the APE, as described in the Archaeology and Historic Built Environment Technical Reports. These reports include context and background for the precontact and post-contact periods that inform the significance analysis of documented historic properties. In addition, this section presents the findings of archaeological and historic built environment investigations conducted to date to identify historic properties within the APE.

Area of Potential Effects

The APE is shown in Figure 3.8-1. The APE is defined as “the geographic area or areas within which an undertaking may directly or indirectly cause alteration in the character or use of historic properties, if any

such properties exist" (36 CFR 800.16(d)). The APE was established through FHWA's and FTA's consultation with SHPO, DAHP, 10 consulting tribes, and other Section 106 consulting parties.

The APE was delineated to account for direct and indirect effects. The APE includes the project footprint (limits of ground disturbance) of the Modified LPA plus a 100-foot buffer. In addition, it includes all areas within the NPS VNHR, as well as a non-contiguous area consisting of the property boundary for the Ruby Junction Maintenance Facility in Gresham, Oregon, and the C-TRAN Operations and Maintenance Facility in Vancouver, Washington. The 100-foot buffer from the project footprint account for potential visual or air quality effects, such as dust created during construction or noise or vibration effects, which could affect historic properties. Potential effects are assessed for historic properties on parcels crossed by the APE boundary, including parcels where only part of the historic property boundary is within the APE boundary. In total, the APE encompasses 1,094.07 acres, including 49.05 acres for the Ruby Junction Maintenance Facility and 1.79 acres for the C-TRAN Operations and Maintenance Facility.

Context

Precontact Period Background

While there is archaeological evidence that Native Americans inhabited the Pacific Northwest more than 10,000 years ago, the archaeological record for Native American land use in the lower Columbia River begins around 3,500 years ago. The scarcity of archaeological sites from earlier periods in the region is thought to be related to the submergence and burial of earlier archaeological sites as sea levels rose quickly during the early to middle Holocene epoch. The Holocene epoch is the period extending from around 12,000 years ago to the present. Numerous precontact archaeological sites dated to after around 3,500 years ago are located along the shores of the lower Columbia River, indicating widespread and persistent Native American occupation of the region at this time. At the time of European American contact, the shores of the Lower Columbia River in the vicinity of the APE were inhabited by Native peoples, with numerous villages located along the river between the outer coast and what is now referred to as The Dalles, as well as several ethnographically named places in the vicinity of the APE.

The Native American groups inhabiting the APE were part of an extensive network of villages, trade, and harvesting, fishing, and resource sites. The Native peoples practiced a seasonal mobility pattern in which they occupied winter villages inland before moving to spring fishing locations on the Columbia River and its tributaries. The river and its tributaries, in addition to providing important resources, also served as an important transportation route for these groups. While salmon was the primary staple, other fish were also harvested, including sturgeon, eulachon, smelt, and lamprey. Important fishing spots included the mouth of the Columbia River, the Columbia at The Dalles and at Hayden Island (in the APE), and on the Willamette River at Willamette Falls. Summer villages were centers of gathering and trade. Common trade goods included beaver, elk, and otter skins; whale blubber; plants, such as wapato, camas, and berries; obsidian, shell beads, and dentalium shell; and manufactured goods such as baskets. Later, Europeans introduced items such as wool blankets and copper kettles. Villages consisted of multifamily houses and other structures such as fish-drying sheds or scaffolds, sweat and menstrual lodges, and temporary dwelling houses. In the late summer and fall, small bands would begin to move inland to hunt game such as deer, elk, and fowl and gather roots, nuts, fruits, and berries while enroute to their winter villages.

The 10 federally recognized tribes, and one non-federally recognized tribe, consulting on the Program have been invited to prepare geographic and ethnographic context statements in lieu of standard context statements so the tribes can share information about the background of this region from their perspective and in their own words. Two federally recognized tribes have accepted this invitation. Preparation of these context statements is in progress. Completed context statements will be provided in an appendix of the Archaeology Technical Report. The IBR Program recognizes that the context statements prepared may not reflect the histories of those tribes that have chosen not to participate.

Figure 3.8-1. Area of Potential Effects

Post-Contact Period Background

Starting in the late 18th century, maritime expeditions by Europeans and European Americans began to interact with Native Americans along the Oregon coast and the mouth of the Columbia River. In 1792, a party

from the Vancouver expedition—a British expedition that circumnavigated the globe in the late 18th century—briefly traveled up the Columbia River from its mouth to Reed Island, passing through the APE. European and European American settlement of the region accelerated shortly after Meriweather Lewis and William Clark completed their overland expedition to the Pacific Coast in 1806. This expedition also passed through the APE.

The introduction of foreign diseases such as smallpox and malaria caused severe epidemics among Pacific Northwest Native populations in the late 1700s and periodic outbreaks throughout the 1800s. At the time of contact between Native peoples of the lower Columbia and Lewis and Clark's Corps of Discovery, populations had already declined considerably. Settlers then began arriving along the Oregon Trail in the 1840s. British agency in the region ended with the Treaty of Oregon in 1846, which settled competing colonial claims in favor of the United States.

A series of Pacific Coast, southwest Washington, and Willamette Valley treaties were negotiated between the United States and local Native American tribes between 1848 and 1855. The first treaties signed with the surviving tribes of western Oregon would have established several Indian reserves in the Willamette Valley. Congress never ratified these treaties due to opposition to the reservations by European American settlers. A second round of treaties, one of which included the Native peoples of the Clackamas and lower Willamette River drainages, was ratified, and two reservations (Siletz and Grand Ronde) were established by executive order shortly thereafter. With the creation of the reservations, federal troops began the process of relocating the Willamette Valley groups to the reservations.

Oregon

During the 19th century, Hayden Island was used by Native peoples and the Hudson's Bay Company (HBC). European American settlement along the Columbia River's southern bank remained sparse in the mid-1800s, as settlers migrating into the region along the Oregon Trail commonly continued south into the Willamette Valley to settle in the vicinity of Oregon City or in the Tualatin Valley. Homesteading in North Portland was hindered by the area's topography, which consisted of a series of swales, lakes, and wetland marshes. The Donation Land Claims of George W. Force and J. R. Switzler (encompassing the present-day site of the Interstate Bridge approach on the south bank of the Columbia River) during this period were noted by surveyors as frequently inundated. The area remained sparsely developed throughout the 19th century, with the only notable development being a single streetcar line extending northward from East Portland to the docks of the Vancouver-Portland ferry on the south shore of the Oregon Slough (now North Portland Harbor) near the east end of Hayden Island. Further development of this area began in the early 20th century, though it remained limited. Union Meat constructed a large-scale meatpacking facility on the south shore of the Oregon Slough near the west end of Hayden Island from 1907 to 1909, the neighborhood of Bridgeton was platted in 1912, and a ferry landing was constructed at nearby Columbia Beach in 1916. In addition to upland developments, small groupings of floating homes began to be developed along the Columbia Slough during this period, with concentrations in the vicinity of the Union Meat facility and Bridgeton. Navigation of the Columbia River was instrumental to 19th-century development of Portland. Vessels regularly sailed between the settlements of Astoria, Vancouver, and Portland, bringing in supplies and people and shipping out goods and raw materials. The U.S. Army Corps of Engineers (USACE) began to make modifications of Columbia River and Willamette River channels in the vicinity of the APE in 1867 and continued through at late 1800s and early 1900s, including survey, dredging, shoaling, and the construction of levees, dams, dikes, and revetments.

Over the first half of the 20th century, the area between the Columbia River and Columbia Slough to the south was gradually developed as an industrial district. Supported by federal reclamation projects beginning in 1913 and continuing through World War I, four drainage districts—from east to west, Sandy Drainage Improvement Company, Multnomah Drainage District No. 1, Peninsula Drainage District 1, and Peninsula Drainage District 2—were created, and newly available land turned over for agricultural uses. The four drainage districts (now collectively known as the Columbia Slough Drainage District), served an important role in the redevelopment of North Portland, Northeast Portland, Gresham, Fairview, and Troutdale.

Reclamation associated with these drainage districts and their associated levee infrastructure resulted in new productive land uses and improved public health through sewage flow controls. Industrial developments along the Oregon Slough gradually expanded southward. Parcels transitioned to uses such as heavy industry, boat building and repair workshops, recreational developments such as golf courses, and, farther to the east, the Portland-Columbia Airport (now Portland International Airport).

As vessels used on the Lower Columbia River grew in size, the U.S. Congress authorized USACE under the Rivers and Harbor Act of 1930 to increase the depth and width of the Lower Columbia River Federal Navigation Channel, expanding the navigation channel from Portland to the Columbia River's mouth and from Portland to the Bonneville Dam and Locks. Between 1915 and 1939, the Port of Vancouver and USACE constructed associated channel maintenance and navigations structures, including the Hayden Island Pile Dike System, built 1915-circa 1920s by Port of Vancouver; Vancouver Bar-Washington Side Pile Dike System, built 1915–1931 by Port of Vancouver and USACE; Upper Vancouver Bar – Oregon Bank Pile Dike system, built 1936–1939 by USACE; and the Lower Vancouver Turning Basin and Upper Vancouver Turning Basin, with the construction of both authorized by the Rivers and Harbors Act of 1933 and modifications authorized by amendments to the Rivers and Harbors Act in 1935 and 1937. The navigation channel from the Columbia River's mouth to the Willamette River was further expanded and additional modifications and repairs were made to its channel control and navigation structures in the 1960s under the Rivers and Harbors Act of 1962 (33 USC Public Law 87-874) to accommodate additional increases in shipping volume.

The onset of World War II and the rapid development of Portland's wartime industries created an acute need for wartime housing in the city. The area between the Columbia Slough and Columbia River and to the west of present-day I-5 was developed by Henry Kaiser, owner of the Oregon Shipbuilding Corporation, to provide housing for company workers; it became known as Vanport. When the housing development was completed in 1943, it included 703 apartment buildings and 17 multiunit dwellings, as well as a post office, schools, fire stations, a movie theater, social buildings, a library, an infirmary, a police station, and various other service and administration facilities. The population of Vanport increased exponentially, growing from 6,000 in January 1943 to a peak of 39,000 in August 1943.

A sizable percentage of Vanport's population were Black employees of Kaiser's shipyards, with 6,000 of Oregon's estimated 15,000 Black citizens residing in the Vanport development. Though it was never articulated as official policy, Vanport was a predominantly segregated community; Black residents were placed into a specific section of the city, and there are documented examples of overtly racist internal communications among the development's administering agencies. On May 30, 1948, when the levee protecting Vanport from Smith Lake broke, the community was flooded, many of its buildings and structures were destroyed, and 15 people were killed. Rather than attempt to rebuild, the City of Portland and state officials chose to demolish what remained of the settlement.

In the latter decades of the 20th century, the North Portland area gradually changed to include a variety of land uses. While industrial development remained along the Columbia River, large areas to the west of I-5 along the Columbia Slough are now occupied by the protected Smith and Bybee Wetlands Natural Area, Heron Lakes Golf Club, and Portland International Raceway. Land to the east of I-5 was redeveloped as small residential, commercial, and light-industrial developments, as well as recreational areas such as Delta Park and the Columbia Edgewater Country Club.

The earliest European American settlement of Hayden Island was the 1866 claim of Gay and Mary Jane Hayden. The Haydens reportedly constructed a property on the island, though 19th century surveyors never documented this property. By the turn of the 20th century, much of Hayden Island had been acquired by the Portland Electric and Railway Company (later the Portland Electric Power Company and then Portland General Electric) to prevent competitive developments to its ferry business between Portland and Vancouver. The Hayden Island Amusement Company (later Hayden Company and then Hayden Island Inc.) acquired portions of Portland General Electric's Hayden Island landholdings in the late 1920s and 1930s, developing a

portion of the island as the Jantzen Beach Amusement Park. During World War II, Hayden Island Inc. began a decades-long effort to develop Hayden Island as a residential and commercial center, culminating in the company's 12-year development plan, which spanned from 1968 to 1980 and included large-scale commercial developments such as the Jantzen Beach Center as well as numerous hotels, multifamily residential developments, and floating home moorages.

Washington

In the early 19th century, to better capitalize on regional commercial interests, the HBC established Fort Vancouver upriver of the mouth of the Columbia River. During this period, the HBC and the Northwest Company, another British trading company, utilized the Columbia River as a primary transportation route between their trading posts along the Columbia River and its tributaries. The fort was originally established in 1825 on high ground on the north side of the Columbia River, east of its current location. It was relocated in 1829 to its current location to be closer to the river. An extensive multicultural settlement known historically as Fort Vancouver Village or Kanaka Village, where most HBC employees lived, developed around the fort beginning in 1827. Following the Oregon Treaty of 1846, Fort Vancouver came under the jurisdiction of the United States. Shortly thereafter, a portion of Fort Vancouver became a military reservation. Over time, the reservation expanded to encompass much of the original Fort Vancouver footprint. This facility, originally referred to as Fort Vancouver and later referred to as the Vancouver Barracks, remained exclusively in use by the military until the 1940s, when it was designated as a national monument by NPS. Military use of the facility continued until 2012, though in a much-reduced capacity.

Beginning in the 1850s, the Vancouver townsite began to form to the west of Fort Vancouver on the former Donation Land Claim of Amos and Esther Short. In the later decades of the 19th century, Vancouver grew into the primary shipping point in Clark County for agricultural products and timber. Numerous rudimentary trails and roads from outlying settlements were developed, as well as several rail lines including the Spokane, Portland and Seattle Railway, a joint venture of the Northern Pacific Railroad and Great Northern Railway. Vancouver continued to expand into the 20th century, with small suburban residential and commercial areas established to the north of the original townsite and around the northern and eastern boundaries of Fort Vancouver.

In anticipation of a Great Northern Railway line connecting Vancouver to other Northwest cities such as Seattle, Portland, and Spokane, many of the residential areas closer to the original townsite were platted in the early 20th century. These included Columbia Orchard Lot in 1900, Swans Addition in 1905, Arnada Park in 1906, and Thompson's Addition in 1907. Following the completion of the Great Northern Railway line in 1908, Vancouver annexed other bordering areas, including the North Bank and Northern Pacific railyards to the west and Vancouver Heights, Lay's Addition, and portions of Irvington and Harney Hill to the east. New residents and commercial businesses poured into Vancouver, beginning a period of substantial growth that continued through World War I, which bolstered the city's shipyards and lumber mills.

Vancouver experienced a downturn during the late 1920s and into the 1930s, as agricultural declines and the Great Depression hampered local industries. The period's economic disruption was alleviated in part by federal programs such as the Civilian Conservation Corps, the western branch of which was headquartered in the Vancouver Barracks, which provided temporary employment for many of the city's unemployed workers. The construction of the nearby Bonneville Dam in 1938 provided additional employment opportunities for Vancouver residents, and the cheap energy it provided brought new industrial developments, such as aluminum product manufacturing, which helped to revitalize the local economy in the years leading up to World War II. The reindustrialization of Vancouver's economy during the war resulted in a second housing boom in the city, supported by the establishment of the Vancouver Housing Authority, a local governmental organization tasked with developing permanent housing for wartime (and later low-income) workers.

The completion of I-5 in 1955 bisected the city, separating the military reserve of Fort Vancouver and its adjacent suburban areas from the main portion of the city and its residential neighborhoods to the north. In the late 1950s, urban renewal programs were proposed to redevelop sections of the city. These programs removed older residential developments and replaced them with new uses. Within the APE, urban renewal projects included the conversion of lands within the Esther Short neighborhood along the Columbia River to light-industrial uses and the demolition and reconstruction of historic residential areas. These programs of urban renewal led to a backlash in the late 1960s, causing the city to change its policy from demolition to improvement. Fort Vancouver was also redeveloped by NPS during this period. In 1961, the U.S. Congress changed the name of the Fort Vancouver National Monument to the Fort Vancouver National Historic Site and increased its authorized boundaries. The Fort Vancouver National Reserve was established by the U.S. Congress in 1996 and encompassed much of the original military reserve on the east side of I-5 and added the City of Vancouver and U.S. Army properties as part of the Fort Vancouver National Historic Site.

While the local political movement that grew out of the urban renewal programs of the 1950s and 1960s led to increased community-led commercial growth and housing in Vancouver's suburban areas, its downtown core suffered from commercial decline in the later decades of the twentieth century. In the 1990s and early 2000s, the City pursued public-private partnerships aimed at downtown revitalization, including improvements at and around Esther Short Park and conversion of the mid-twentieth century industrial waterfront to mixed commercial and residential uses.

Previous Cultural Resources Studies

Archaeological investigations in the vicinity of the APE began in 1947, within the boundary of HBC Fort Vancouver. Several additional archaeological studies were performed in Fort Vancouver in the late twentieth century and early twenty-first century, including extensive excavations in advance of the reconstruction of I-5 and SR 14 from 1974 to 1982 and an ongoing public archaeology field school administered by NPS.

Numerous cultural resources studies in support of private, local, and state projects have been performed within and adjacent to the Washington portion of the APE during the late twentieth and early twenty-first centuries. These studies have covered much of the Washington portion of the APE. Comparatively few cultural resources studies have been performed on the Oregon portion of the APE.

On the Washington portion of the APE, between 2006 and 2012 archaeological background research and survey conducted for the CRC project and APE documented 32 archaeological sites. The CRC project surveys included an underwater survey under the existing Interstate Bridge within the Washington portion of the CRC APE. No underwater archaeological sites were documented during this survey. No archaeological survey was performed within the Oregon portion of the CRC APE.

Geoarchaeological investigations, consisting of both rotosonic borings and ground-penetrating radar, were performed in support of the CRC project within both the Washington and Oregon portions of the CRC APE. These investigations revealed widespread and thick deposits of fill in Oregon and thick deposits of fill in portions of the Washington CRC APE. In both the Oregon and Washington portions of the CRC APE, several locations were identified as having the potential for encountering deeply buried archaeological deposits.

Precontact and Historical Archaeology

In the Pacific Northwest, **prehistoric or precontact archaeology** is associated with Native American peoples, culture, and settlements (Little et al. 2000). **Historical archaeology or post-contact archaeology** is defined by NPS guidance as dating from after the beginning of European American settlement of the area and addresses both European American and Native American peoples, culture, and settlement, within the historic period (Little et al. 2000). However, historical or post-contact archaeology is understood to be inclusive of all people, cultures, and settlement, within the historic period.

Historic built environment background research and survey was conducted for the CRC project between 2005 and 2013. The CRC project surveyed 877 resources constructed prior to 1967. Of these, 201 were identified as NRHP-listed or considered eligible for listing in the NRHP. In Oregon, four properties were identified as previously listed or eligible for listing in the NRHP, and one property was determined eligible as part of the CRC study. In Washington, 24 properties were identified as previously listed in the NRHP and 172 properties were determined eligible for listing in the NRHP as part of the CRC study.

Cultural Resources Identified

Archaeological Sites

For the purposes of this analysis, an archaeological site was considered if it is listed in the NRHP, is eligible for the NRHP, or has not been formally evaluated for listing in the NRHP. Archaeological sites determined not eligible for the NRHP were not considered for this analysis.

A review of archaeological resource data available on the Washington Information System for Archaeological and Architectural Resources Database and the Oregon Archaeological Records Remote Access identified 34 archaeological sites within or directly adjacent to the APE. These resources include 14 eligible for listing in the NRHP and one as-yet unevaluated resources.[2] Nineteen additional archaeological sites within or adjacent to the APE were previously determined not eligible for listing in the NRHP and are therefore not included in the count of archaeological sites. Additional information about the 14 eligible and one unevaluated archaeological sites is summarized in Table 3.8-2, below. Since location information relating to archaeological sites is protected under federal and state law, figures depicting specific resource locations are not provided.

While archaeological studies were previously performed for the CRC project, additional studies are in progress to verify known archaeological resource presence and dimensions, and to identify unrecorded terrestrial and marine archaeological sites. Further studies will be performed through phased identification as allowed under Section 106 of NHPA (36 CFR 800.4 (b)(2)) and would be stipulated in the Section 106 PA. The IBR Program would disclose anticipated effects, if any, to terrestrial or marine archaeological sites identified through phased identification and offer the public opportunities to comment through methods such as online open houses, listening sessions, community briefings, community working groups, and public comments submitted by email or telephone.

Oregon

No archaeological sites have yet been documented within or directly adjacent to the Oregon portion of the APE.

Washington

Fifteen archaeological sites have been documented within the Washington portion of the APE. Table 3.8-2 summarizes key information about these resources. Of these archaeological sites, 14 are eligible for listing in the NRHP and one remains unevaluated.

[2] Of the 14 eligible and one unevaluated archaeological sites, 12 are located within the Modified LPA and have the potential to be impacted by construction-related physical ground disturbance (45CL152, 45CL160, 45CL162, 45CL163, 45CL300, 45CL514, 45CL653, 45CL910, 45CL918, 45CL920, 45CL921, and 45CL922). Three resources (45CL217, 45CL400, and 45CL582) are located within the APE but outside the Modified LPA. See Section 3.8.3, which addresses direct effects.

Table 3.8-2. Archaeological Sites within the Washington Portion of the Area of Potential Effect

Trinomial	Management	Resource Name	IBR NRHP Eligibility Status	Resource Type
45CL152	Historic Trust	Providence Academy	Eligible	Multicomponent: historic structural features, privies, trash pits, refuse scatter, lithic materials.
45CL160	City of Vancouver	Officers Row	Eligible	Historic structural features, debris, refuse.
45CL162	City of Vancouver, NPS, and FHWA Western Federal Lands	Vancouver Barracks	Eligible	Historic structural features, debris, refuse.
45CL163	NPS	Fort Vancouver National Historic Site	Eligible	Multicomponent: historic fort, debris, precontact lithic material, bones, charcoal, fire-altered rocks, and features.
45CL217	Veterans Affairs	Post Cemetery	Eligible	Cemetery.
45CL300	VNHR	Fort Vancouver Village	Eligible	Multicomponent: historic fort village, debris, structural remains, lithic material.
45CL400	Underwater, WA DNR	Quartermaster East/Benoit Site	Eligible	Submerged multicomponent: historic refuse, precontact net weight, trade bead.
45CL514	Private	Killian Pacific	Eligible but portions no longer extant	Historic structural features, refuse scatter related to City Blocks 24 and 25.
45CL582	City of Vancouver	Vancouver Convention Center	Eligible	33 features and seven yard middens associated with City Block 62 and north half of City Block 66.
45CL653	City of Vancouver	N/A	Unevaluated	Historic refuse scatter.
45CL910	WSDOT	N/A	Eligible	Historic structural features, refuse scatter.
45CL918	WSDOT	N/A	Eligible	Multicomponent: historic trash pits, refuse, lithic debitage.
45CL920	WSDOT	N/A	Eligible	Historic structural features, refuse scatter.
45CL921	WSDOT	N/A	Eligible	Historic structural features; foundations, refuse, trash pits.
45CL922	WSDOT	N/A	Eligible	Historic trash pits, refuse scatter, human dental remains.

DNR = Department of Natural Resources; N/A=Not Available; NRHP = National Register of Historic Places; NPS = National Park Service; VNHR = Vancouver National Historic Reserve; WSDOT = Washington Department of Transportation

Historic Built Environment Resources

For the purposes of this analysis, a historic built environment resource was considered if it is listed in the NRHP or is eligible for the NRHP. Historic built environment resources determined not eligible for the NRHP were not considered.

For the purposes of this undertaking, and in consultation with Oregon SHPO and Washington DAHP, historic built environment resources with construction dates in or prior to 1982 were identified as historic-age resources requiring evaluation because they would be 50 years of age at the time of the Modified LPA's anticipated completion date in 2032. Therefore, resources within the APE constructed between 1967 (the year that the CRC survey analysis concluded evaluation) and 1982 have been added to the evaluation. Survey fieldwork to support preparation of Section 106 Documentation Forms for Individual Properties and preparation of the Historic Built Environment Technical Report was conducted in January 2023 and August 2023. Survey methodology included review of resources on any parcel crossed by the APE boundary.

The IBR Program review of historic built environment resources identified 36 historic properties in the APE constructed prior to 1982 that are listed in the NRHP or considered eligible for listing in the NRHP. These properties are summarized in Table 3.8-3 (Oregon), Table 3.8-4 (Interstate Bridge), and Table 3.8-5 (Washington). Appendix C to the Historic Built Environment Technical Report, Section 106 Documentation Forms for Individual Properties, provides the detailed evaluation for the NRHP eligibility status.

Oregon

The IBR Program review of historic built environment resources in Oregon identified seven historic properties eligible for listing in the NRHP. Of these seven properties, two were previously identified as NRHP-eligible historic properties, and five were not previously identified. These properties are summarized in Table 3.8-3 and depicted in Figure 3.8-2.

Interstate

Three identified historic built environment resources—the northbound and southbound portions of the Interstate Bridge and the Lower Columbia River Federal Navigation Historic District—span the Columbia River between Oregon and Washington. The northbound Interstate Bridge was previously listed in the NRHP. The southbound Interstate Bridge is considered eligible for listing in the NRHP. The Lower Columbia River Federal Navigation Historic District was recommended eligible for listing in the NRHP through consultation with the USACE. Additional detail about these resources is provided in Table 3.8-4 and are shown in Figure 3.8-3.

Washington

The IBR Program review of historic built environment resources in Washington identified 26 historic properties listed in or eligible for listing in the NRHP. This includes eight historic built environment resources previously listed in the NRHP and 22 eligible for listing in the NRHP. These properties are summarized in Table 3.8-5 and are shown in Figure 3.8-4 and Figure 3.8-5.

Traditional Cultural Properties

Formal consultation, as defined in 36 CFR 800.3, with consulting tribes and other consulting parties is ongoing. As of this writing, no traditional cultural properties have been identified in or adjacent to the APE, either during the previous CRC project Section 106 process or the current Section 106 review.

Table 3.8-3. Oregon Historic Built Environment Resources

Map ID	Resource ID	Property Name	Previously Identified (Yes/No)	NRHP Eligibility Status	Year Built	Address	Description
OR 2	663154	Columbia Slough Drainage Districts Historic District	Yes	Eligible (2023 IBR recommendation); Eligible (2011 determination); Criteria A and C	1916–1960	Various	System of levees, dikes, and ditches along the Columbia Slough.
OR 155[a]	N/A	East Vanport Commercial Center	No	Eligible (2023 IBR recommendation); Criterion A	1938	10850 N Denver Avenue	Northwest regional-style department store (sport facility).
OR 56	50293	Portland Assembly Center	Yes	Eligible (2023 IBR recommendation); Not eligible (2009); Criterion A	1924	2060 N Marine Drive	Complex of architecturally indistinct exposition halls associated with regional agricultural and social events and gatherings, and site of Oregon's only Temporary Assembly Center for Japanese American interred during WWII.
OR 111	N/A	Jantzen Beach Moorage	No	Eligible (2023 IBR recommendation); Criterion A	ca. 1960s	1501 N Jantzen Avenue	Large-scale moorage consisting of 175 floating homes and associated docks and infrastructure.
OR 109	N/A	Jantzen Beach Water Tank	No	Eligible (2023 IBR recommendation); Criteria A and C	1970	N Center Avenue	Cylindrical two-story steel water tower.
OR 107	N/A	Harbor Shops	No	Eligible (2023 IBR recommendation); Criteria A and C	1980	11915 N Center Avenue	Second phase strip mall type development associated with Hayden Island, Inc.'s large-scale planned commercial development.
OR 120[a]	N/A	Hayden Island Yacht Club Clubhouse	No	Eligible (2023 IBR recommendation); Criteria A and C	1972	12050 N Jantzen Drive	Modern-style (Northwest Regional and Shed-style elements) clubhouse.

a While the resource boundary shown in Figure 3.8-2 is outside the APE, the parcel boundary for this property crosses the APE and the resource is considered in this study.
APE = Area of Potential Effects; ca. = circa; Dr = Drive; N = North; N/A = Not Available; No. = Number; NRHP = National Register of Historic Places; VNHR = Vancouver National Historic Reserve

WA 900	20458	Covington House	Yes	NRHP-listed (1972); Criterion C	ca. 1848	4201 Main Street	Hall-and-Parlor-Pioneer Log-style residence.

a VNHR Historic District (WA1357) includes archaeological resources as contributing components. Archaeological resources that contribute to the historic district are identified in Table 3.8-2, including 45CL160, 45CL162, 45CL163, and 45CL300.
b While the resource boundary shown in Figure 3.8-4 is outside the APE, the parcel boundary for this property crosses the APE and the resource is considered in this study.
APE = Area of Potential Effects; IBR = Interstate Bridge Replacement (Program); N/A = Not Available; NRHP = National Register of Historic Places; VNHR = Vancouver National Historic Reserve.

Figure 3.8-4. Washington Historic Built Environment Resources – South

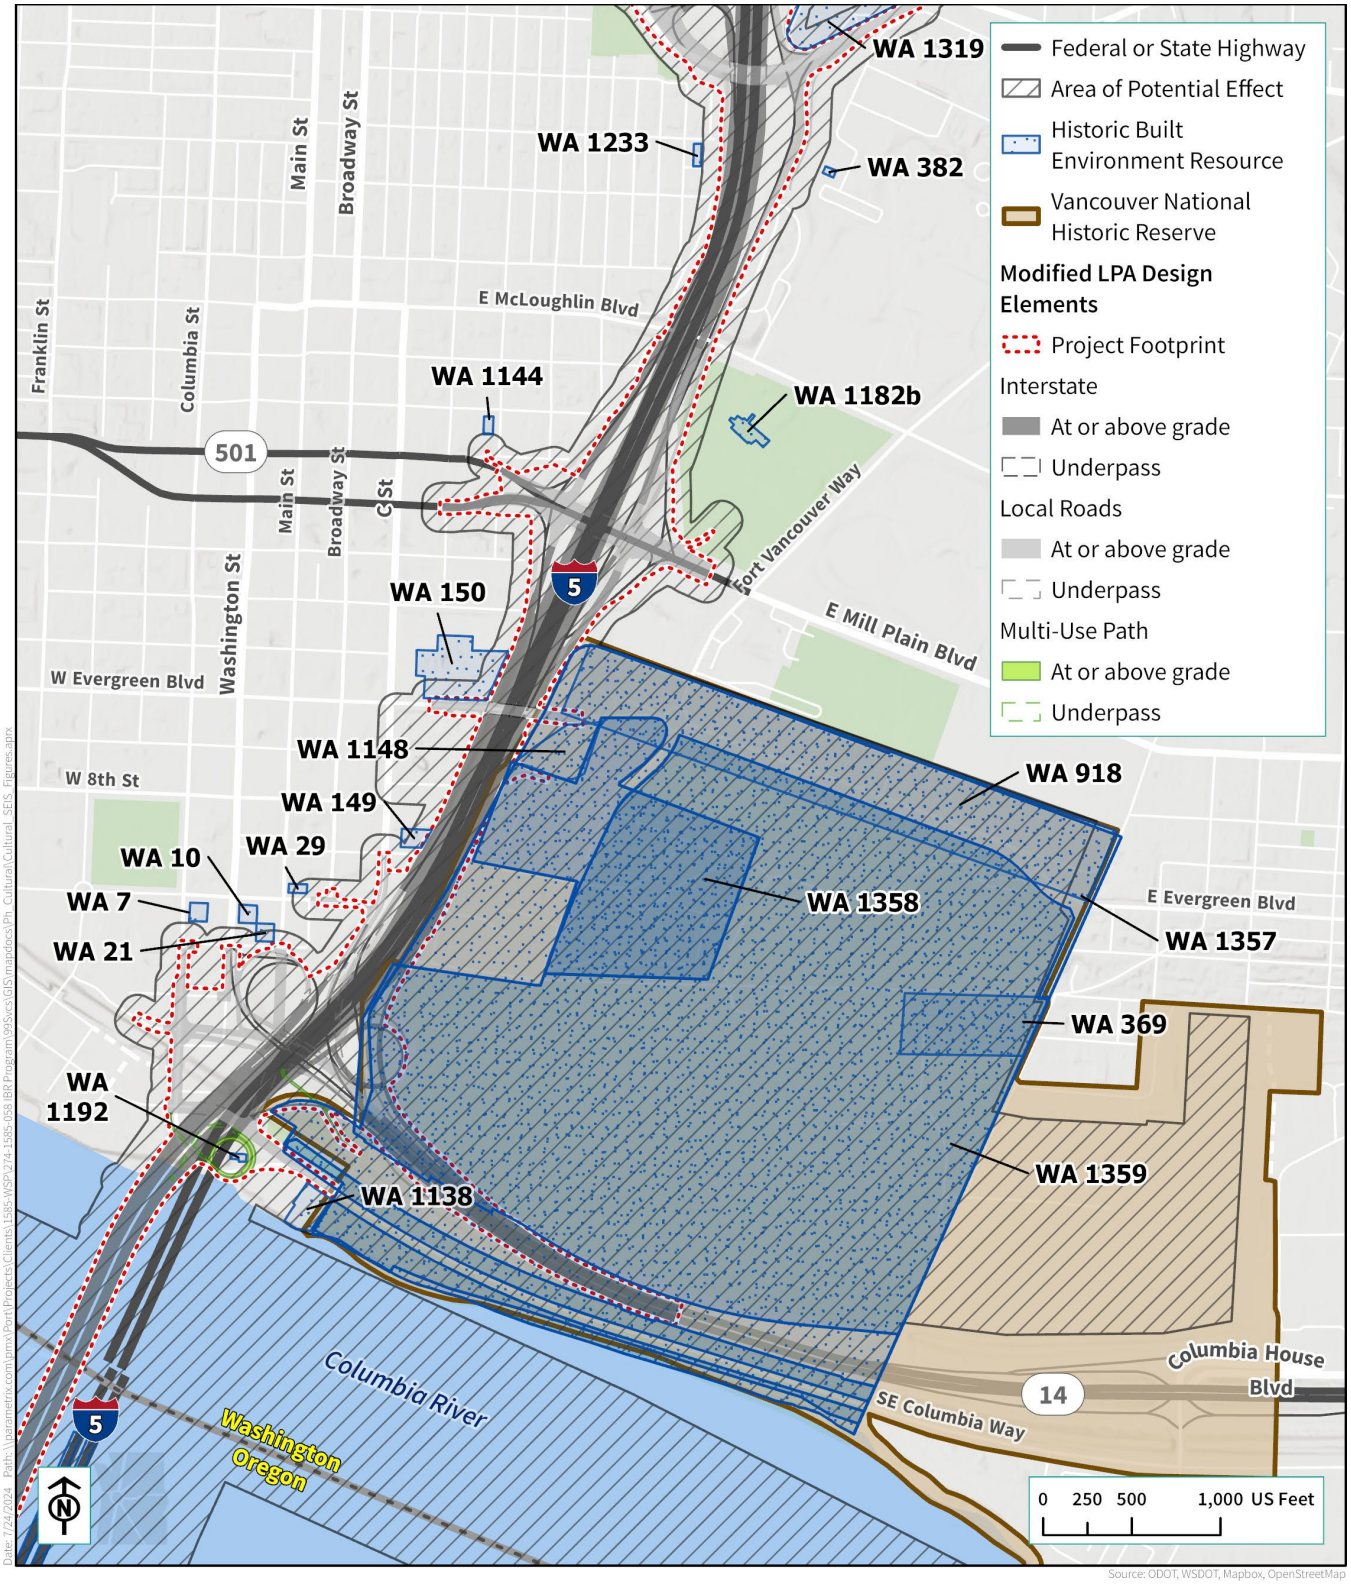

Figure 3.8-5. Washington Historic Built Environment Resources – North

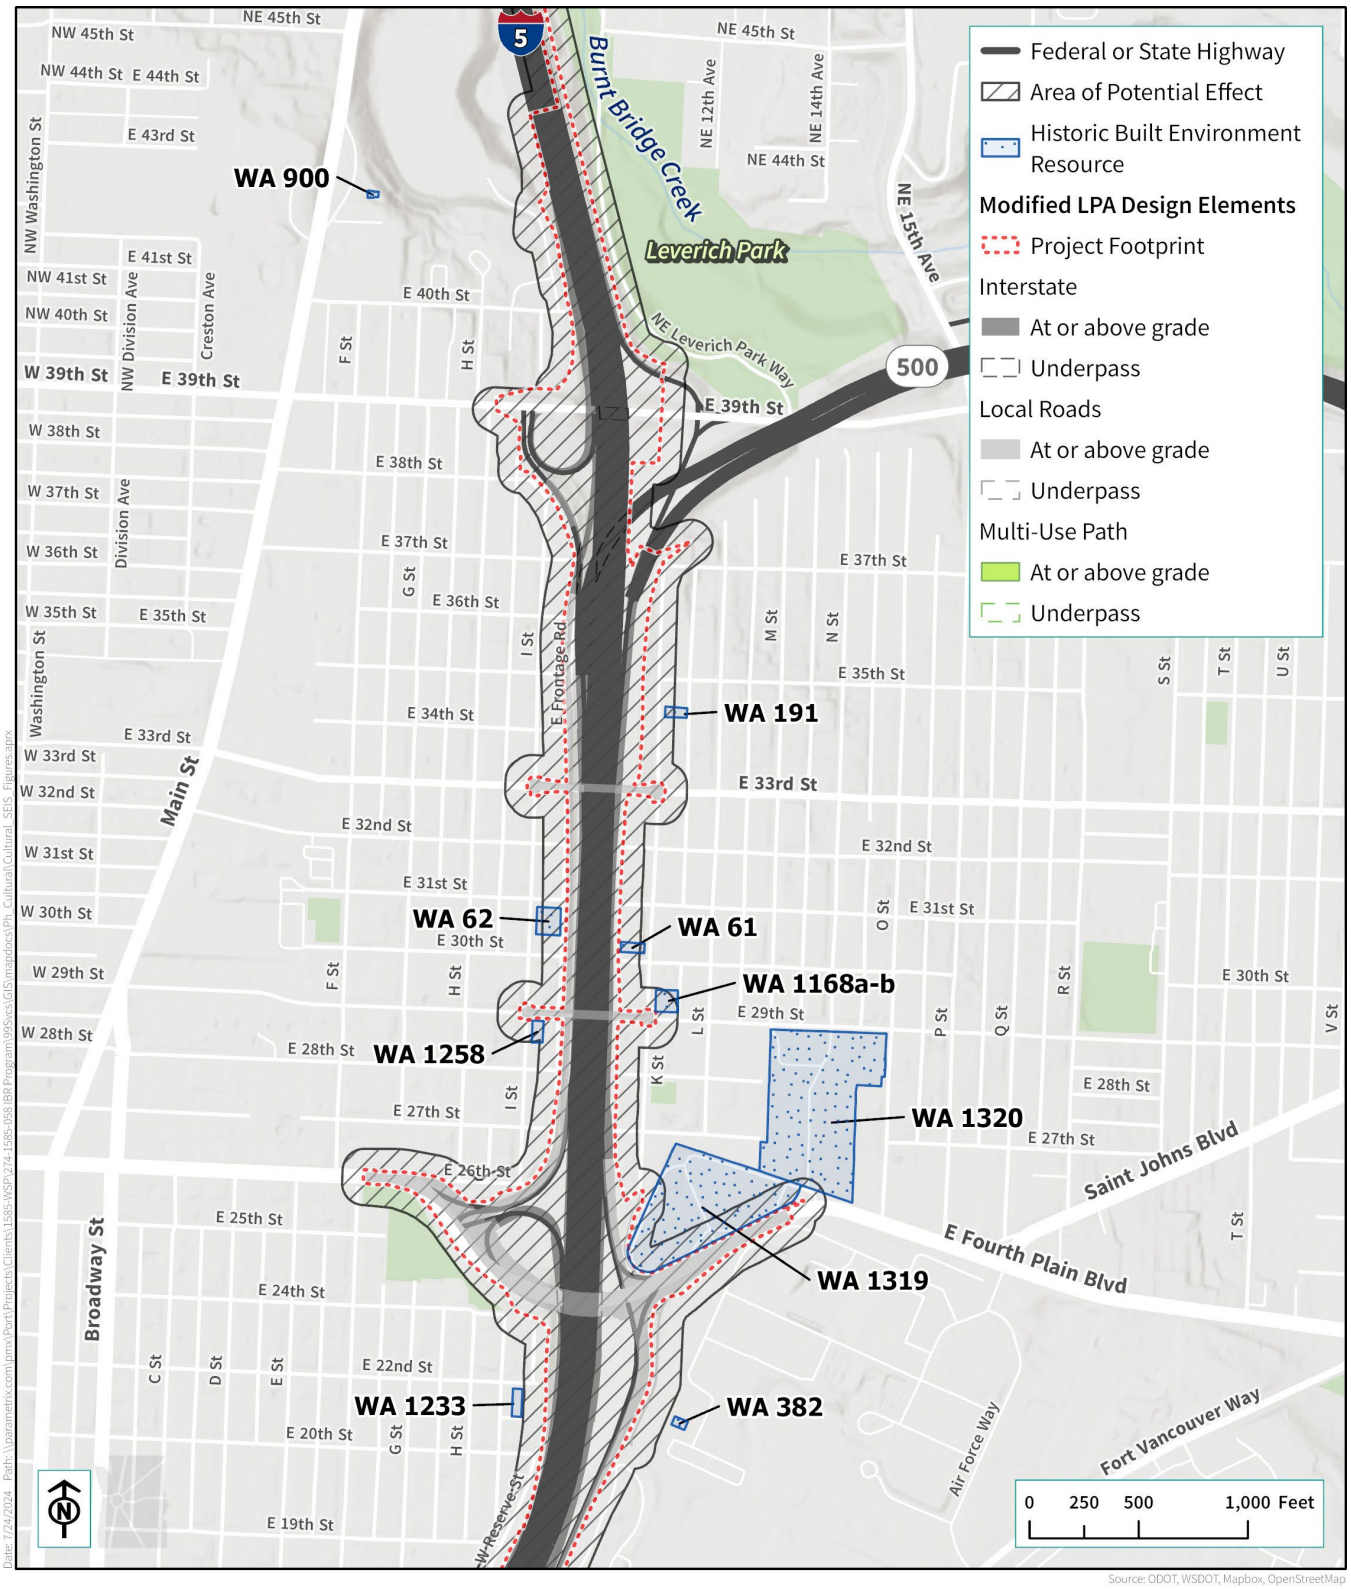

3.8.3 Direct Effects

Direct effects on historic properties are described below for the No-Build Alternative and the Modified LPA. Direct effects under Section 106 are based on "…causality, and not the physicality, of the effect. This means that if the effect comes from the undertaking at the same time and place with no intervening cause, it is considered 'direct' regardless of its specific type (e.g., whether it is visual, physical, auditory, etc.). 'Indirect' effects are those caused by the undertaking that are later in time or farther removed in distance but are still reasonably foreseeable" (ACHP 2019). Indirect effects are discussed in Section 3.8.4.

Direct effects assessed include, but are not limited to, physical or atmospheric effects that permanently alter, damage, or destroy historic properties; visual effects from permanent introduction of new visual elements that diminish or remove the characteristics that make a cultural resource eligible for listing in the NRHP; effects to historic properties from air quality, noise, or vibrations that are the result of Modified LPA operations that diminish or remove characteristics that make a cultural resource eligible for listing in the NRHP; and construction easements that permanently occupy part or all of a historic property for the purposes of project construction and operation.

Under 36 CFR 800.5(a)(1), an adverse effect on a historic property would occur if an undertaking altered, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association.

Table 3.8-6 summarizes the effects of the No-Build Alternative, Modified LPA, and design options[3] on cultural resources. Detailed analysis of the effects is provided in the following sections.

Table 3.8-6. Summary of No-Build Alternative and Modified LPA Effects on Cultural Resources

Resource	Modified LPA (All Design Options)	No-Build Alternative
Number of NRHP-listed or NRHP-eligible historic built environment resources affected	12	0
Number of archaeological sites affected	12	0

LPA = Locally Preferred Alternative; NRHP = National Register of Historic Places

The No-Build Alternative would retain the existing infrastructure, and the existing Interstate Bridge, which consists of two distinct historic properties (OR 50; WA 381a and OR51; WA 381b), would continue to operate as they do today. Projected increases in traffic volumes would potentially result in increased congestion and delays for all travelers, as well as additional costs and uncertainty for all businesses that rely on this corridor for freight movement. Additionally, needs for repair and maintenance would potentially increase as the bridge ages, and the bridge would remain vulnerable to mechanical failure or damage from a seismic event. Under the No-Build Alternative, construction and associated construction-phase activities such as traffic detours; temporary closures; and noise, glare, dust, and vibration would not occur. The No-Build Alternative would

[3] In cases where the effects analysis is the same for all Modified LPA design options, the various design options are not separately addressed in the Modified LPA Direct Effects Analysis column of Tables 3.8-7, 3.8-8, and 3.8-9.

have no permanent or temporary effects to historic properties, including archaeological sites and historic built environment resources, but it would fail to address present and future travel demand, mobility needs, and safety considerations in the APE.

Modified LPA

Archaeological Sites

Construction-related physical ground disturbance is anticipated to be the primary source of potential permanent and temporary direct effects to archaeological sites. An example of an adverse effect would include physical destruction of or damage to all or part of the archaeological site.

As described in Section 3.8.2, Existing Conditions, the APE contains 15 archaeological sites; 14 eligible for listing in the NRHP and one unevaluated. These resources are located within the Washington portion of the APE. Of these, 12 are located within the Modified LPA and have the potential to be impacted by construction-related physical ground disturbance (45CL152, 45CL160, 45CL162, 45CL163, 45CL300, 45CL514, 45CL653, 45CL910, 45CL918, 45CL920, 45CL921, and 45CL922). Additionally, archaeological and geoarchaeological studies performed in support of the CRC project also highlight the potential for encountering as-yet-undocumented archaeological sites in previously unsurveyed areas and in deeply buried contexts at specific locations across the APE. Archaeological field studies to determine the dimensions, depths, and contents of known and as-yet-undocumented archaeological sites relative to the anticipated areas of ground disturbance associated with the Modified LPA have not yet been performed. These studies would be performed in accordance with stipulations under the IBR Program's Section 106 PA (see Section 3.8.6, Mitigation and Programmatic Agreement for more information) once it has been executed. Based on the anticipated nature and extent of ground disturbance associated with the Modified LPA, it is anticipated that construction would damage or destroy portions of 12 archaeological sites located within the Modified LPA's limits of construction within the APE. Potential effects to archaeological sites would be essentially the same across all design options.

Historic Built Environment Resources

Direct effects to the historic built environment analyzed herein, include those that would result in physical destruction or damage to the property or any part of the property that contributes to its historic significance; permanent changes within the property's setting that would alter characteristics that contribute to its historic significance; and the introduction of permanent visual, atmospheric, or audible elements that would diminish the integrity of the property's significant historic features. Work within temporary construction easements and staging areas, as well as temporary effects associated with construction such as noise, dust, and traffic congestion, were also analyzed given they are anticipated to be the primary sources of temporary effects to historic built environment resources.

The potential direct effects to the historic built environment are summarized in Table 3.8-7 for resources located in Oregon, in Table 3.8-8 for interstate resources located along the Interstate Bridge where it crosses the Columbia River, and in Table 3.8-9. for resources located in Washington. The Modified LPA would result in permanent direct effect to 12 historic built environment resources – three in Oregon, two interstate properties, and seven in Washington. This would include:

- Jantzen Beach Moorage (OR 111)
- Jantzen Beach Water Tank (OR 109)
- Harbor Shops (OR 107)
- Interstate Bridge northbound (OR 50; WA 381a)
- Interstate Bridge southbound (OR 51; WA381b)

- Bridge Substation (WA 1192)
- Normandy Apartments (WA 149)
- Vancouver National Heritage Reserve Historic District (WA 1357)
- Officers Row Historic District (WA 918)
- Pearson Field Historic District (WA 369)
- Vancouver Barracks Historic District (WA 1358)
- Fort Vancouver National Historic Site (WA 1359)

Potential direct effects to historic built environment resources would differ among design options for two historic properties:

- Normandy Apartments (WA 149).
  - The Modified LPA with centered I-5 mainline would not result in physical destruction of Normandy Apartments, but would result in permanent changes to the property's setting from construction of the elevated light-rail transit alignment that would contribute to an adverse effect to this historic property. See Figure 3.8-6.
  - The Modified LPA with the westward shift of the I-5 mainline would result in physical destruction of the Normandy Apartments, and would result in permanent changes within the property's setting as a result of construction of the elevated light-rail transit alignment that would contribute to an adverse effect to this historic property. See Figure 3.8-6.
- Vancouver National Historic Reserve Historic District (WA 1357).
  - The Modified LPA with the centered I-5 mainline would result in physical destruction or damage to part of the property by demolishing a portion of the contributing Army Road System on E 5th Street where it terminates against I-5. In addition, noise and vibration effects would affect contributing components of the historic district, and construction of the new bridges and ramp structures would affect the historic district's setting, resulting in an adverse effect to this historic property. See Figure 3.8-7 and Figure 3.8-8.
  - The Modified LPA with the westward shift of the I-5 mainline would not require demolition of a portion of the contributing Army Road System on E 5th Street where it terminates against I-5. However, noise and vibration effects would affect contributing components of the historic district, and construction of the new bridge and ramp structures would affect the historic district's setting, resulting in an adverse effect to this historic property. See Figure 3.8-7 and Figure 3.8-8.

The property-specific Section 106 effects assessments found in Appendix D of the Historic Built Environment Technical Report, Finding of Effect Forms, provide the detailed analysis for the Modified LPA direct effects analysis.

Figure 3.8-6. Design Options Comparison – Normandy Apartments (WA 149)

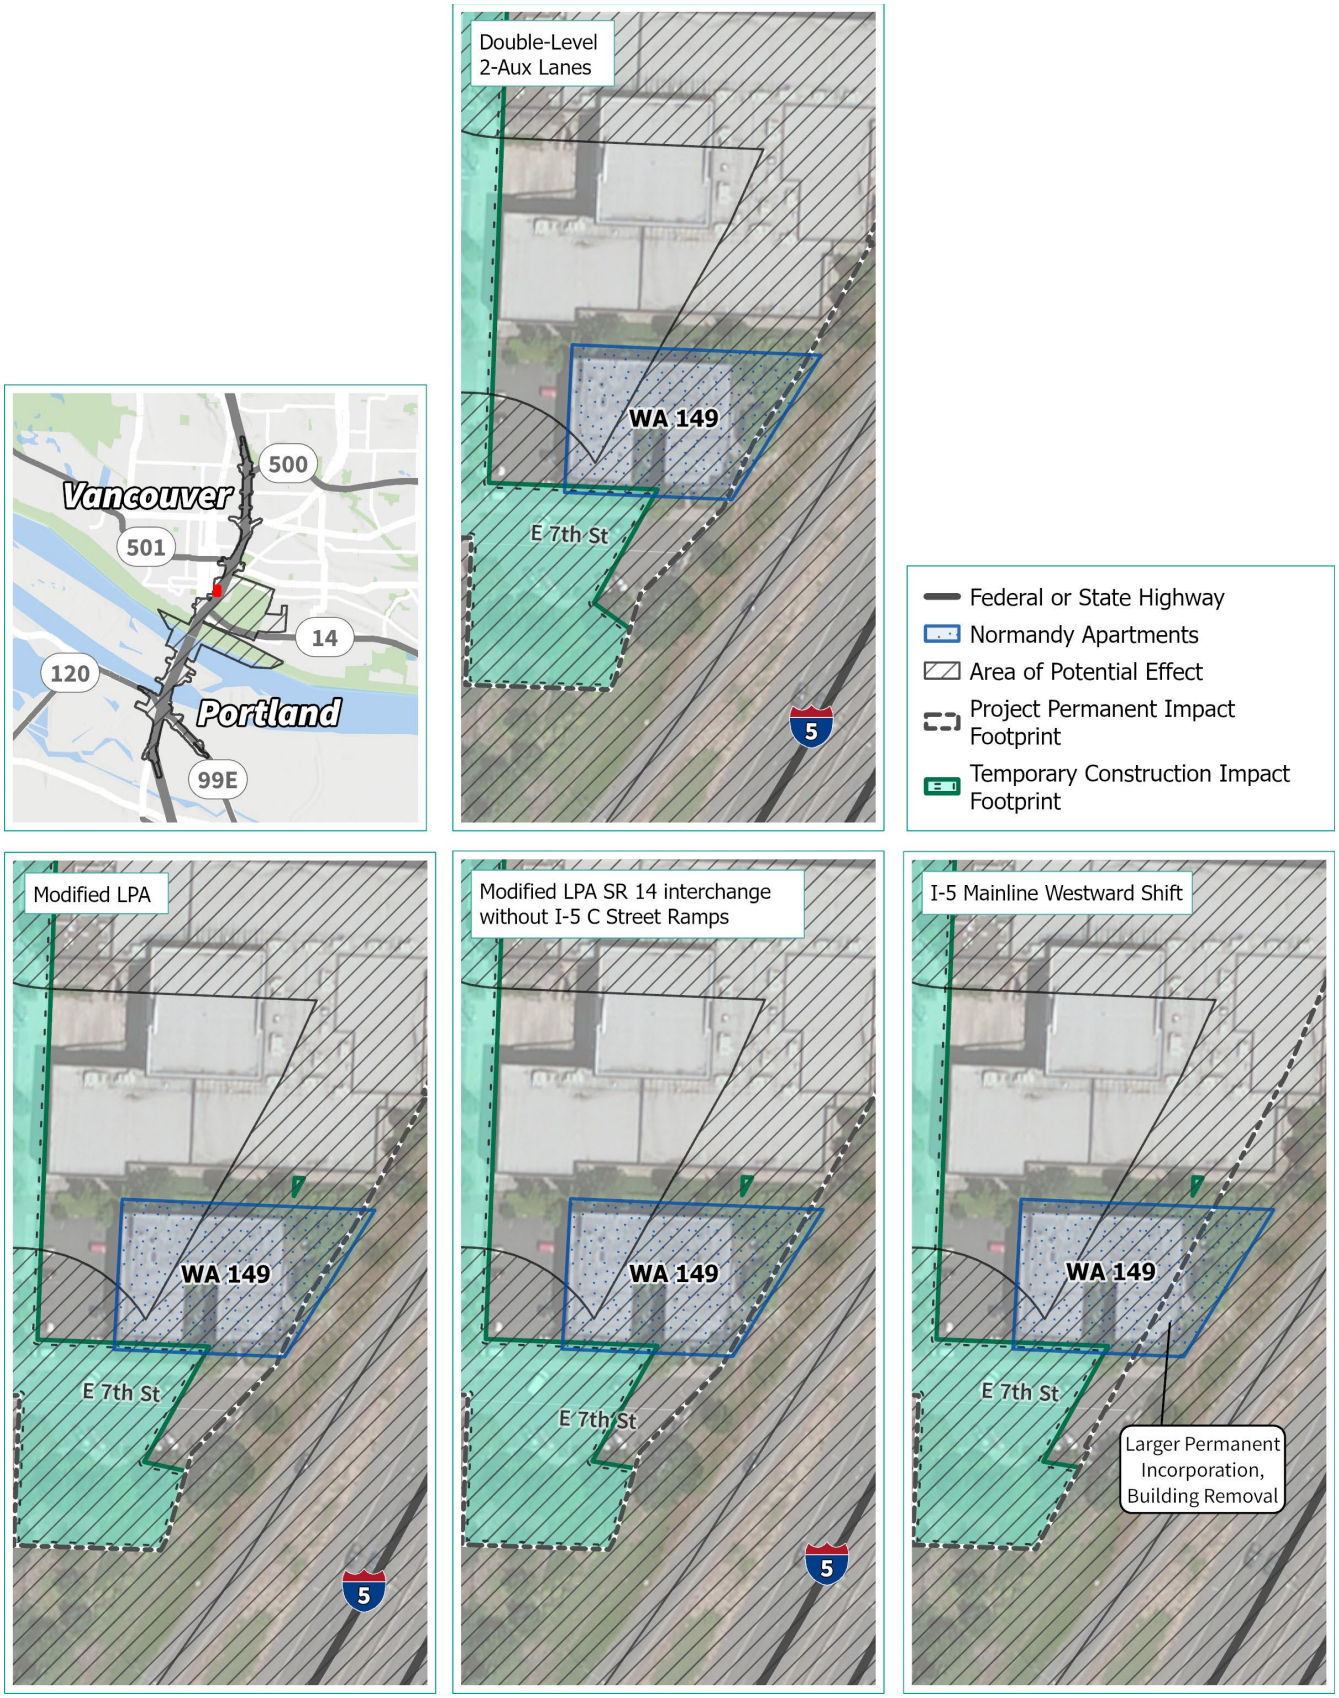

Figure 3.8-7. Design Options Comparison – Vancouver National Historic Reserve Historic District (WA 1357), South

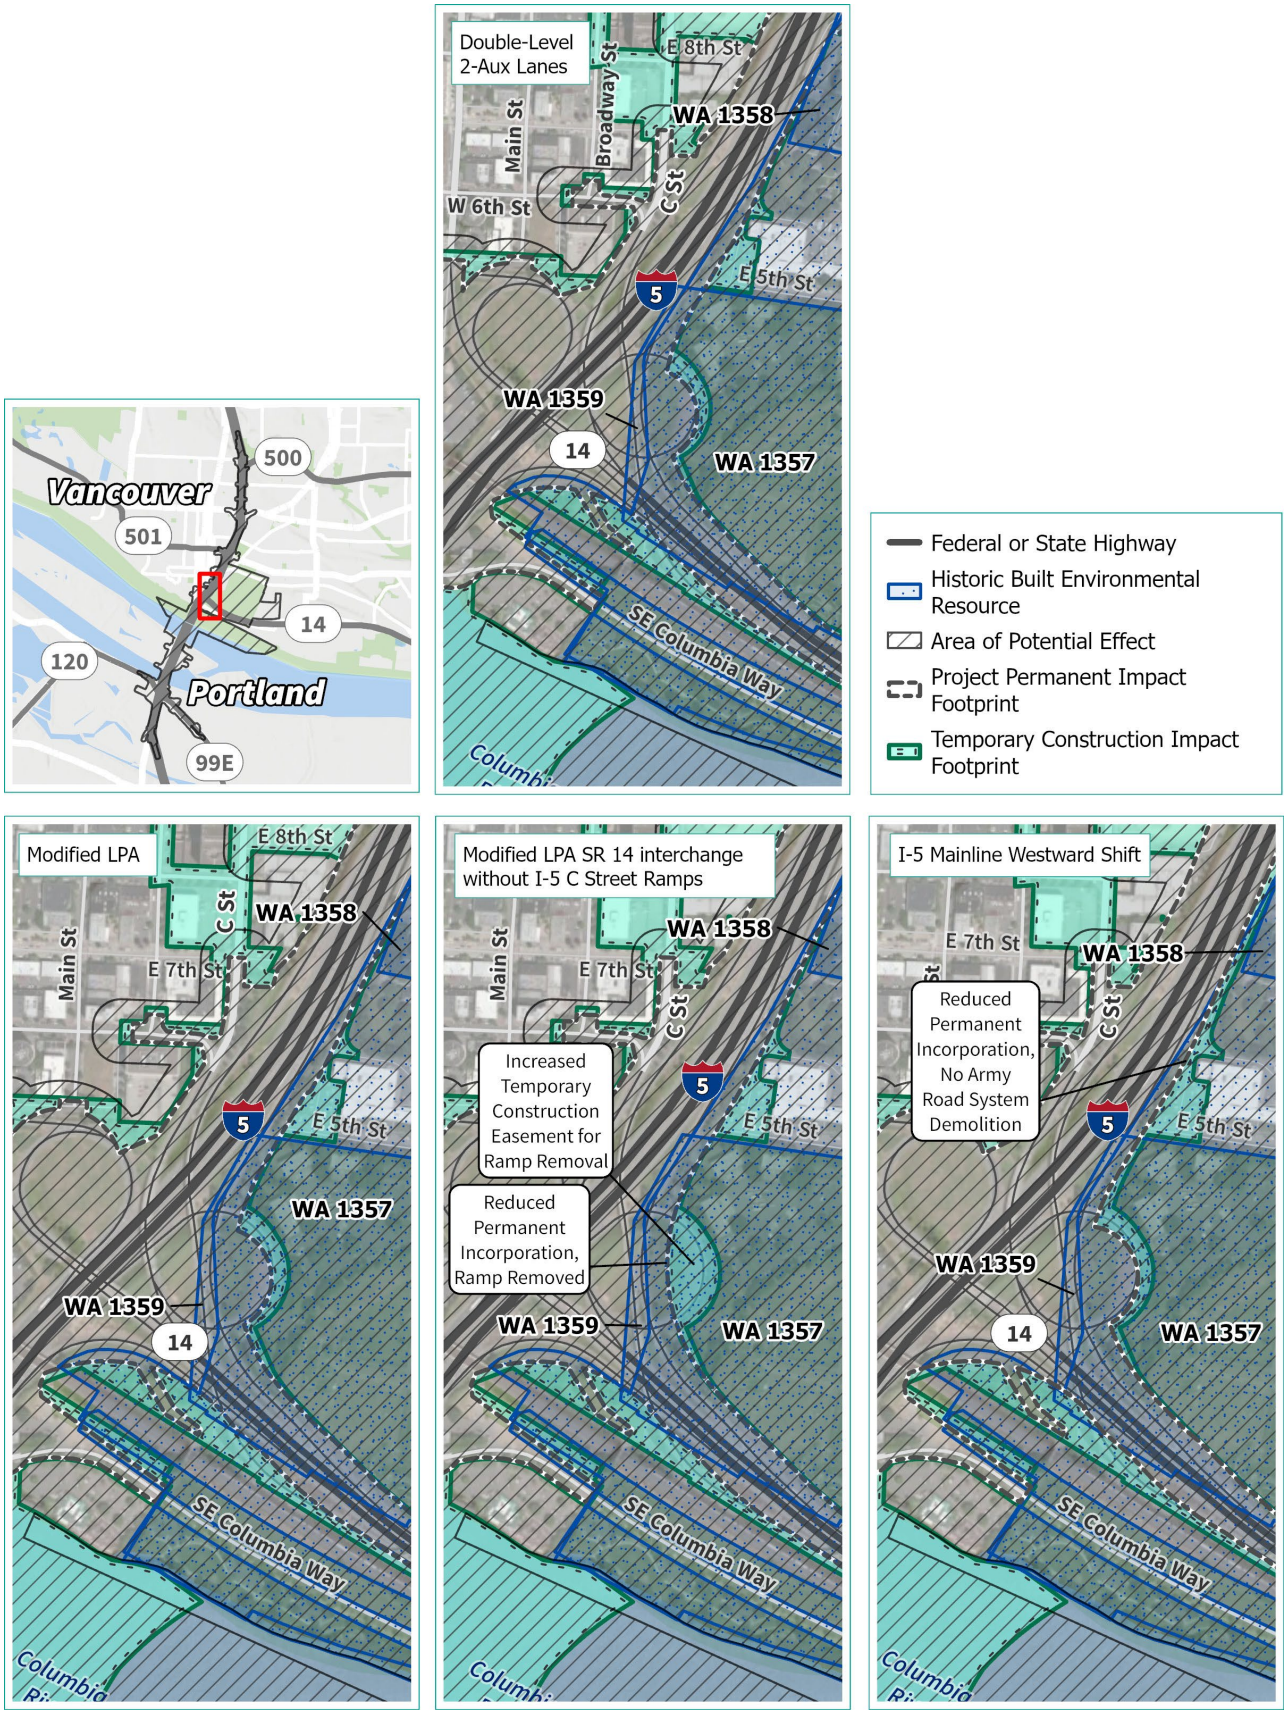

Figure 3.8-8. Design Options Comparison – Vancouver National Historic Reserve Historic District (WA 1357), North

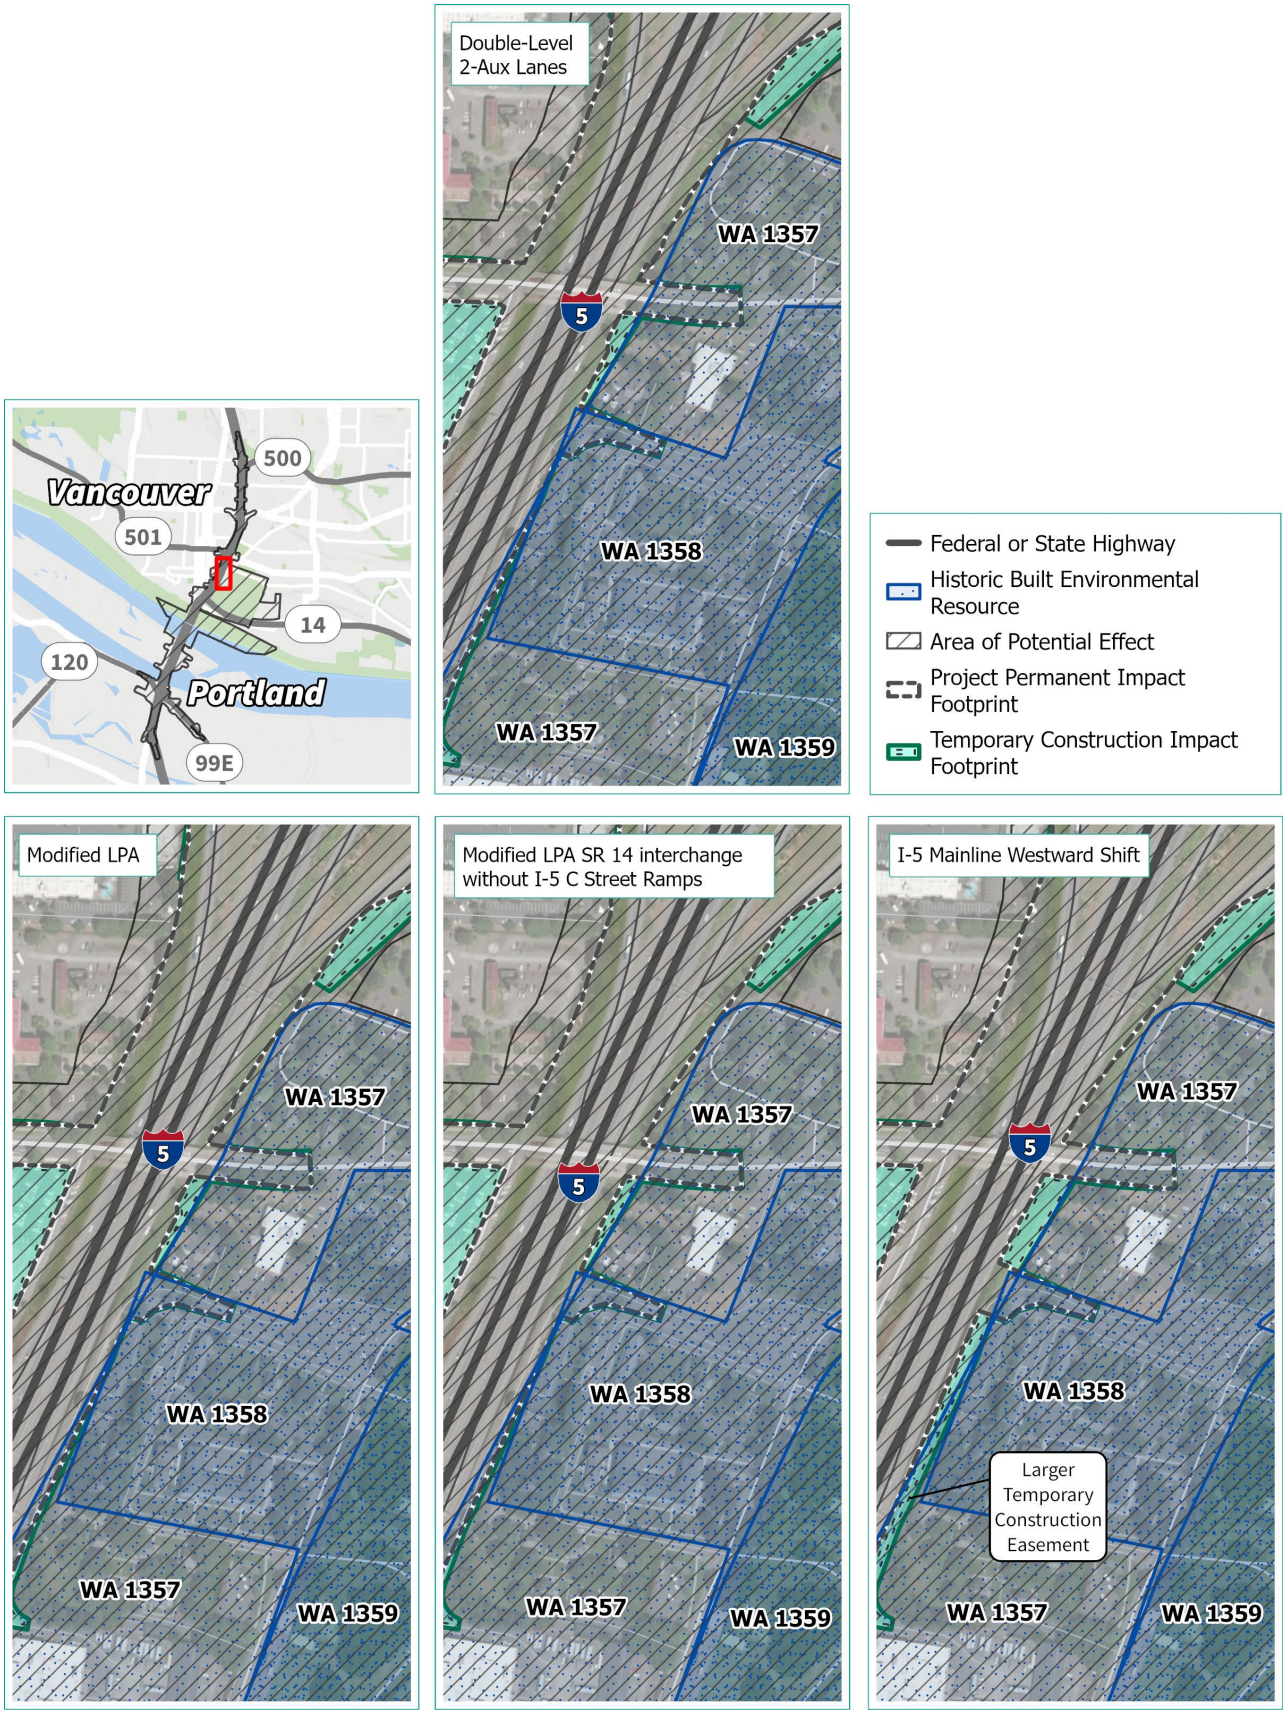

Table 3.8-7. Direct Effects of the Modified LPA on Oregon Historic Built Environment Resources

Map ID	Resource ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
OR 2	663154	Columbia Slough Drainage Districts Historic District	No Adverse Effect	• Permanent physical change would be relatively small compared to the overall extent of the historic district. Alterations to Mud Slough Drainage would be limited to a small portion of the structure at the east side of I-5; most of the structure would not be affected and would retain its existing features. • Temporary disturbances to vegetation and soil or temporary placement of fill would occur on approximately 2.56 acres. These areas represent only a small fraction of the overall historic district, which covers approximately 12,550 acres and includes a total of 27 linear miles of levees, fills, and cross levees. These temporary physical changes would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Columbia Slough Drainage Districts Historic District.
OR 155	N/A	East Vanport Commercial Center	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the East Vanport Commercial Center.
OR 56	50293	Portland Assembly Center	No Adverse Effect	• Construction activities, including construction of an expanded or new light-rail vehicle overnight facility, are more than 200 feet away from the existing complex of buildings and not expected to alter any of the Portland Assembly Center’s contributing components. • Permanent changes within the property’s setting would not alter characteristics that contribute to its historic significance. These changes would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Portland Assembly Center.

Map ID	Resource ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
OR 111	N/A	Jantzen Beach Moorage	Adverse Effect	• Physical destruction of part of the property that contributes to its historic significance. Construction of a new bridge and new light-rail transit bridge would require the removal of components that contribute to the NRHP eligibility of the Jantzen Beach Moorage, including a section of dock, at least two finger piers, and approximately 20 floating shelters. As such, the Modified LPA is considered to have an Adverse Effect on the Jantzen Beach Moorage.
OR 109	N/A	Jantzen Beach Water Tank	Adverse Effect	• Physical destruction of the property. Permanent right-of-way acquisition and construction of the new road that would join the existing North Jantzen Avenue alignment west of the subject property would require the demolition of all extant features of the property, including the water tank, pump house, and the associated backup diesel generator. As such, the Modified LPA is considered to have an Adverse Effect on the Jantzen Beach Water Tank.
OR 107	N/A	Harbor Shops	Adverse Effect	• Physical destruction of the property. Permanent right-of-way acquisition of the property to construct the proposed northbound and southbound Columbia River bridges would require demolition of extant features in the NRHP-eligible property, including the primary commercial building, surface parking lots and circulation, and planted medians. As such, the Modified LPA is considered to have an Adverse Effect on the Harbor Shops.
OR 120	N/A	Hayden Island Yacht Club Clubhouse	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the Hayden Island Yacht Club Clubhouse.

a All design options under the Modified LPA would have the same direct effects, unless specifically stated.

LPA = Locally Preferred Alternative; N/A = Not applicable; NEPA = National Environmental Policy Act; NRHP = National Register of Historical Places

Table 3.8-8. Direct Effects of the Modified LPA on Interstate Historic Built Environment Resources

Map ID	Resource ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
OR 50; WA 381a	OR 49361; WA N/A	Interstate Bridge (northbound)	Adverse Effect	• Physical destruction of the property. The Modified LPA would replace the existing northbound Interstate Bridge with a new northbound bridge. This would require removal of the existing northbound bridge. As such, the Modified LPA is considered to have an Adverse Effect on the Interstate Bridge (northbound).
OR 51; WA 381b	OR NA; WA 18781	Interstate Bridge (southbound)	Adverse Effect	• Physical destruction of the property. The Modified LPA would replace the existing southbound Interstate Bridge with a new bridge. This would require the removal of the existing southbound Interstate Bridge. As such, the Modified LPA is considered to have an Adverse Effect on the Interstate Bridge (southbound).
OR 165 and WA 1356	N/A	Lower Columbia River Federal Navigation Historic District	No Adverse Effect	• Physical change is relatively small in comparison to the overall extent of the historic district. The LCR FNC from Vancouver to Bonneville Lock and Dam is a nearly 40-mile-long structure, and construction of the two proposed bridges and their associated staging/work areas would be limited to its westernmost extent. The alignment of all three channels would be slightly revised, with the centerline of the northernmost channel route shifting slightly south and the centerline of the middle and southernmost channel routes shifting north to correspond with the pier locations of the proposed bridges. Additionally, the locations of the primary navigation channel route and the barge channel route would be switched. Although these changes would alter traffic along the LCR FNC, they would not alter its depth or design, the channel's character-defining features. Similarly, construction activities would be limited to the easternmost extent of the Upper Vancouver Turning Basin which would be shifted slightly west while maintaining its existing size. The easternmost pile dike within the Hayden Island Pile Dike System, the system's only pile dike located in the APE, would be avoided by construction and in-water staging activities. Each contributing structure would continue to be maintained by USACE and support ongoing safe navigation along the river. The Modified LPA would affect the NRHP-eligible LCR Federal Navigation Historic District, but that effect would not be adverse. • Temporary in-water staging or work areas approximately 1,000 feet east of the existing bridges and 1,000 feet west of the proposed bridges would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Lower Columbia River Federal Navigation Historic District.

a All design options under the Modified LPA would have the same direct effects, unless specifically stated.

LCR FNC = Lower Columbia River Federal Navigation Channel; LPA = Locally Preferred Alternative; NEPA = National Environmental Policy Act; USACE = U.S. Army Corps of Engineers

Table 3.8-9. Direct Effects of the Modified LPA on Washington Historic Built Environment Resources

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
WA 1138	731246	Who Song and Larry's	No Adverse Effect	• Construction impact area is within the Columbia River waterway to the east of Who Song and Larry's. The area would be used for staging and temporary construction activities, but these activities would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on Who Song and Larry's.
WA 1192	89097	Bridge Substation	Adverse Effect	• Physical destruction of the property. Permanent right-of-way acquisition and demolition of the bridge substation would be required to construct a proposed shared-use path and bridge. As such, the Modified LPA is considered to have an Adverse Effect on the Bridge Substation.
WA 7	33716	Fendrich's Furniture	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on Fendrich's Furniture.
WA 10	2124	Smith Tower	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on Smith Tower.
WA 21	20430	The Evergreen Hotel	No Adverse Effect	• The entrance in the south elevation may be rendered inaccessible during construction. However, the building's other entrance, in the east elevation, would continue to function as normal. The east elevation is larger and more highly ornamented than the south elevation, and it faces a more intact street grid; consequently, the entrance on this elevation may be considered more important to the Evergreen Hotel's ability to convey its significant development history. It is anticipated that the entrance on the south elevation would be returned to regular use following the conclusion of construction activities. As such, the Modified LPA temporary construction easement along the Evergreen Hotel's southern property boundary would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Evergreen Hotel.
WA 29	20436	U.S. National Bank Building	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the U.S. National Bank Building.

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
WA 149	89160	Normandy Apartments	Adverse Effect	• The Modified LPA with the centered I-5 mainline would not result in physical destruction or damage to the property or any part of the property that contributes to its historic significance. The Modified LPA would reconstruct and widen the I-5 corridor to the east of the property. Related activities would include the construction of a new elevated light-rail transit alignment and a ramp connecting I-5 to SR 14. A long, narrow permanent acquisition paralleling the eastern property boundary would be required. In addition, a subsurface easement extending under the southeast portion of the apartment building's east wing would be required to accommodate tie-back anchors for a retaining wall to be constructed immediately east of the building. • Under all Modified LPA design options, permanent changes within the property's setting would alter characteristics that contribute to its historic significance. New construction, including the elevated light-rail transit alignment, would be located within approximately 5 feet of the southeast corner of the apartment complex. This would reduce the current, approximately 33-foot-wide buffer between the building and the western edge of the pavement for the I-5 off-ramp connecting to SR 14. The large trees currently screening the east side of the building from I-5 would likely be removed for construction, eliminating the current visual barrier between the Normandy Apartments and the highway. The elevated light-rail transit alignment, which would rise to the approximate height of the apartment building, would introduce new and highly visible infrastructure that would undermine the property's setting. Additionally, the noise analysis indicates that the property would experience increased noise effects relative to the No-Build Alternative that exceed thresholds set for residential properties. As such, the Modified LPA is considered to have an Adverse Effect on the Normandy Apartments. • The Modified LPA with the westward shift of the I-5 mainline would result in physical destruction of the property. The Modified LPA with the westward shift of the I-5 mainline includes ramps up to 40 feet to the west between SR 14 and Mill Plain Boulevard. This design option would require permanent right-of-way acquisition of the Normandy Apartments property and the demolition of the apartment building and its associated landscaping. The Modified LPA with the westward shift of the I-5 mainline would result in a greater degree of permanent effects to this NRHP-eligible property.
WA 1357	674732	VNHR Historic District	Adverse Effect	• The Modified LPA with the centered I-5 mainline would result in physical destruction or damage to part of the property by demolishing a portion of the contributing Army Road System on East 5th Street where it terminates against I-5. In addition, vibration effects from construction are anticipated to affect contributing components of the historic district. As such, the Modified LPA is considered to have an Adverse Effect on the VNHR Historic District.

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
				• The Modified LPA with the westward shift of the I-5 mainline would not require demolition of a portion of the contributing Army Road System. However, vibration effects from construction are also anticipated to affect contributing components of the historic district under this design option and would also be considered to result in an Adverse Effect to the VNHR Historic District. • The Modified LPA would require the permanent acquisition of approximately 1.06 acres of new right of way including a narrow strip of land on the western edge of the VNHR along the main body of I-5, small segments of land on the southern edge of the VNHR along the main body of SR 14, and a 290-foot-long linear acquisition for a new pathway adjacent to the contributing Old Apple Tree and the SR 14 interchange. These permanent acquisitions would be required to widen I-5, upgrade the SR 14 interchange, and construct the new shared-use path near the Old Apple Tree. • The Modified LPA with the centered I-5 mainline would require a subsurface easement extending approximately 50 feet beneath the reserve's northwest corner to accommodate tieback anchors for a new retaining wall. These features are not anticipated to diminish the integrity of the property's significant historic features. The Modified LPA with the westward shift of the I-5 mainline would not require subsurface easements. • Under all Modified LPA design options, changes within the property's setting would alter characteristics that contribute to its historic significance. Construction of new bridge and ramp structures adjacent to the southwest corner of the historic district would introduce new visual elements into the viewshed of the Columbia River, which is an important element of the reconstructed Kanaka Village, Pearson Field, and an important interpretive view from the Mission 66 Visitor Center. Permanent introduction of visual elements would diminish the integrity of the property's significant historic features. Permanent introduction of audible elements would diminish the integrity of the property's significant historic features. The noise analysis indicates that the western and southwestern perimeter portions of the VNHR along I-5 and SR 14 would experience a noise impact, particularly to the westernmost buildings of the Officers Row area. These changes contribute to the Adverse Effect finding on the VNHR Historic District.

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
WA 918	N/A	Officers Row Historic District	Adverse Effect	• Introduction of audible elements would diminish the integrity of the property's significant historic features. While the NRHP documentation prepared in 1974 for this property does not explicitly identify a quiet setting as character defining for the property, the district was designed to minimize the passage of sound between buildings. Therefore, quiet is considered an important component of this property's setting. The noise analysis indicates that multiple contributing buildings along the west edge of the Officers Row Historic District would experience increased noise levels relative to the No-Build Alternative that are above the 67 dBA criterion for Section 4(f) sites.[b] This would diminish their integrity of setting and association sufficient to constitute an Adverse Effect on Officers Row Historic District.
WA 369	674448	Pearson Field Historic District	Adverse Effect	• Changes within the property's setting would alter characteristics that contribute to its historic significance. Under all design options, the Modified LPA would change the current setting of the Pearson Field Historic District by constructing infrastructure improvements approximately 2,880 feet west of the district's western NRHP boundary including the new Columbia River bridges, ramps associated with the SR 14 interchange, and improvements to the SR 14 alignment. Although the district's integrity of setting has been diminished since the end of its period of significance in 1941, principally by the construction of I-5 and SR 14, the property's view of the historic Interstate Bridge remains a vital component of its historic integrity and ability to convey its significance. Permanent introduction of visual elements would diminish the integrity of the property's significant historic features with the removal of the current bridge, and the property's view of the historic Interstate Bridge remains a vital component of its historic integrity and ability to convey its significance. As such, the Modified LPA is considered to have an Adverse Effect on Pearson Field Historic District.
WA 1358	674435	Vancouver Barracks Historic District	Adverse Effect	• The Modified LPA could result in physical destruction or damage to the property. Vibratory effects from the replacement of the highway retaining wall and upgrades to the roadbed are expected to impact the Post Hospital, which is a contributing component of this district. Physical damage from vibration is anticipated due to the building's unreinforced masonry construction and proximity to construction activities (as close as 6 feet). Although the severity of potential damage from construction-related vibration cannot be readily evaluated in advance, a worst-case scenario assumes the potential for structural damage to the Post Hospital. Such damage would render the building unusable or result in its partial or complete collapse. A new permanent acquisition of 0.34 acres along its northwest corner is not anticipated to alter the contributing elements of the property. While some roadways along the west edge and northwest corner of the district would be demolished, these do not contribute to the district's significance. Changes within the property's setting would alter characteristics that

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
				contribute to its historic significance. The district's historic view of the Columbia River waterfront and the historic Interstate Bridge would be altered by replacement of the bridge, as well as upgrades to the SR 14 interchange and approach. Permanent introduction of visual elements would diminish the integrity of the property's significant historic features. As such, the Modified LPA is considered to have an Adverse Effect on the Vancouver Barracks Historic District.
WA 1359	674436	Fort Vancouver National Historic Site	Adverse Effect	• No physical destruction or damage to the property or any part of the property that contributes to its historic significance. Permanent acquisition of approximately 0.2 acres of new right of way, including small segments of land on the southern edge of the Fort Vancouver National Historic Site along the main body of SR 14. In the same area, a new temporary construction easement of 0.46 acres would be required. The acquisitions would reduce the size of the overall site, and both the permanent acquisitions and temporary construction easements could result in removal of some vegetation buffer along its southwest edge, which helps shield the site's viewshed from some of the visual and auditory effects of the highways. • Permanent changes within the property's setting would alter characteristics that contribute to its historic significance. The Modified LPA would introduce new visual elements into the historic site's setting. These elements include replacement of the existing Interstate Bridge with a new structure which would be both on average taller and more substantial than the existing bridge, and associated upgrades to the SR 14 interchange to connect the new mid-level bridge span with ramps to the existing at grade alignment of I-5 and SR 14. Although the district's integrity of setting has been diminished since the end of its period of significance (1844–1846) in the mid-nineteenth century, these changes would further degrade the site's historic viewsheds of the Columbia River through the introduction of modern infrastructure on a greater size and scale than before. In addition, the temporary construction easement of 0.46 acres may result in the removal of some of the vegetation buffer along the southwest edge of the historic site. While this vegetation buffer would be replaced following implementation of the Program, the temporary physical changes would contribute to undermining the historic setting. Both these permanent and temporary changes within the property's setting would alter characteristics that contribute to historic significance. As such, the Modified LPA is considered to have an Adverse Effect on the Fort Vancouver National Historic Site.

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
WA 1148	731279	Washington State Patrol District Five Headquarters	No Adverse Effect	• The Modified LPA would require temporary construction easements (adjacent to permanent acquisitions of small areas from the southwest corner of the property, adjacent to Anderson Street, and from the northern boundary of the property, adjacent to E Evergreen Boulevard). However, these easements would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Washington State Patrol District Five Headquarters. • Infrastructure improvements proposed by the Modified LPA would alter the current setting of the Washington State Patrol District Five Headquarters property through the introduction of new visual, atmospheric, and audible elements. However, the degree of change from these new elements would be negligible. As such, the Modified LPA would have an effect on the NRHP-eligible Washington State Patrol District Five Headquarters, but that effect would not be adverse.
WA 150	18827	House of Providence	No Adverse Effect	• The Modified LPA would require a temporary construction easement along the southern property boundary at E Evergreen Boulevard. The easement would extend approximately 10 feet into the House of Providence's historic property boundary, overlapping character-defining landscape features such as gate posts, a low hedge, and concrete curb along the public sidewalk. However, the Modified LPA includes plans to restore to preconstruction conditions the character-defining features of the House of Providence located within the temporary construction easement along the southern property boundary at E Evergreen Boulevard. This includes preserving the gate posts and replacing in-kind the hedge and curb, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties. • A subsurface easement would extend approximately 100 feet into the property boundary but would remain more than 100 feet from the House of Providence contributing resources and would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the House of Providence. • Compared to the Modified LPA with the centered I-5 mainline, the Modified LPA with the westward shift of the I-5 mainline would expand the I-5 corridor into the eastern portion of the House of Providence's historic property boundary. The westernmost lanes of I-5, retaining wall, and noise wall would cross through the parcel containing the House of Providence, which would reduce the size of the area that historically contained the institution's grounds. The only

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
				character-defining features that would be altered by the Modified LPA with the westward shift of the I-5 mainline are the hedge and curb along the property's southern boundary, where a portion of these features would be removed. However, the loss of less than 50 feet of the hedge and curb represents a relatively small portion of these features, which currently run more than 350 feet along the southern property boundary; enough of the hedge and curb would remain unaltered at the center of the southern boundary to continue to convey the property's historic landscape qualities. Additionally, under this design option, the subsurface easement would extend farther west into the parcel than with the centered I-5 mainline, but the easement would remain more than 50 feet from the primary building and its associated landscape features. Therefore, the Modified LPA with the westward shift of the I-5 mainline would result in the same No Adverse Effect finding for the House of Providence as the Modified LPA with the centered I-5 mainline.
WA 1233	89149	Earls House	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the Earls House.
WA 1144	731267	Office Building, 1514 E Street	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the office building at 1514 E Street.
WA 1182b	731284	Rudy Luepke Senior Center	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the Rudy Luepke Senior Center.
WA 382	44853	Radio Transmission Building	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the Radio Transmission Building.
WA 1319	20317	Vancouver Barracks National Cemetery	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the Vancouver Barracks National Cemetery.
WA 1320	731277	St. James Acres Catholic Cemetery	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the St. James Acres Catholic Cemetery.

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
WA 1258	89483	Mickler House	No Adverse Effect	• Modified LPA improvements to E 29th Street would require a temporary construction easement from the extreme northern edge of the tax lot. Activities in this easement have the potential to disturb the northern edge of the concrete-paved walkway connecting the north (principal) elevation of the Mickler House to the sidewalk along E 29th Street; while this feature is considered contributing to the property's significance, disturbance or damage would be limited to its extreme northern edge and would not diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Mickler House.
WA 1168	731275 / 731276	Duplex Residences, 2901-03 and 2905-07 K Street	No Adverse Effect	• Temporary physical changes would damage or destroy characteristics that contribute to historic significance. The Modified LPA would include a temporary construction easement that extends into the property's southwest corner, which currently contains a portion of the property's grass lawn and one mature ornamental shrub. Construction activities may damage the lawn. However, the Modified LPA includes plans to restore the grass lawn. This includes replacing in-kind the lawn and preserving one mature ornamental shrub that would not be removed during construction, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties. As such, the Modified LPA is considered to have No Adverse Effect on the duplex residences at 2901-03 and 2905-07 K Street.
WA 61	89120	Porter House	No Adverse Effect	• The Modified LPA would construct additional interstate lanes to the west of the property and new intervening retaining and sound walls along the western edge of the alley separating the property from I-5. Construction of the retaining wall would require a permanent subsurface easement on the western portion of the Porter House property for the installation of subterranean tie-back anchors. The subsurface easement would extend into the yard to the rear of the dwelling's footprint. Surface-level construction activities are not anticipated to enter the tax lot, which is the NRHP eligibility boundary for the property. The Modified LPA would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Porter House.

Map ID	Property ID	Property Name	Section 106 Effects Finding	Modified LPA Direct Effects Analysis[a]
WA 62	25537	Hall House	No Adverse Effect	• The Modified LPA would construct additional interstate lanes to the east of the residence, on the opposite side of J Street, and new intervening retaining and sound walls along the eastern edge of J Street. Construction of the walls would require a permanent subsurface easement on the eastern portion of the property for the installation of subterranean tie-back anchors. The subsurface easement would extend into the side yard but not beneath the dwelling's footprint. Surface-level construction activities are not anticipated to enter the tax lot, which is the NRHP -eligibility boundary for the property. The Modified LPA would not alter any of the characteristics that qualify the property for inclusion in the NRHP in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. As such, the Modified LPA is considered to have No Adverse Effect on the Hall House.
WA 191	89189	Residence, 3405 K Street	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the residence at 3405 K Street.
WA 191	89189	Hood, William H. and Myrtle, Residence	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on the William H. and Myrtle Hood Residence.
WA 900	20458	Covington House	No Effect	• No alteration to the characteristics of the historic property that qualify it for inclusion in or eligibility for the NRHP. As such, the Modified LPA is considered to have No Effect on Covington House.

a All design options under the Modified LPA would have the same direct effects, unless specifically stated.
b Decibel thresholds applied for assessment of direct effects from noise as a result of construction and highway traffic are codified in 23 CFR 772 Table 1, Noise Abatement Criteria.
CFR = Code of Federal Regulations; IBR = Interstate Replacement Bridge; LPA = Locally Preferred Alternative; NEPA = National Environmental Policy Act; NRHP = National Register of Historic Places; VNHR = Vancouver National Historic Reserve

3.8.4 Indirect Effects

Indirect effects are those caused at a later time or farther away, but that are still reasonably foreseeable. The Modified LPA, including all design options, would include improved bicycle, pedestrian, highway, and transit access in Portland and Vancouver. This increased accessibility could make these areas more attractive for redevelopment or development of previously undeveloped areas. As described in Section 3.4, local and regional land use plans encourage growth and density in proposed areas near the stations proposed under the Modified LPA on Hayden Island and in downtown Vancouver, making these areas especially likely to redevelop.

Urban redevelopment frequently results in increased pressure to demolish or modify historic built environment resources in ways that are not compatible with their historic integrity, and new development in previously undeveloped areas can result in effects to significant settings of historic built environment resources. In addition, urban redevelopment or development of previously undeveloped areas can increase the potential for ground disturbance that could damage or destroy archaeological sites. While it is possible that implementation of the Modified LPA could result in access to new areas for future development or result in improved access to existing developed areas for redevelopment, there are currently no specific development or redevelopment projects that are contingent upon the Modified LPA planned. In addition, as discussed in Section 3.4, the Modified LPA is not expected to encourage urban sprawl-type growth in previously undeveloped areas. Therefore, no property-specific indirect effects have been identified for historic properties within the APE.

3.8.5 Program Planning to Avoid or Minimize Effects to Cultural Resources

Program planning has included identification of Modified LPA activities to avoid or minimize effects to historic properties. The "no adverse effect" findings for four historic built environment resources in the APE assumes implementation of the following activities:

- **House of Providence (WA 150).** Minimize effects by restoring to preconstruction conditions the character-defining features of the House of Providence located within the temporary construction easement along the southern property boundary at E Evergreen Boulevard. This includes preserving the gate posts, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties.
- **Duplex Residence at 2901 K Street (WA 1168a and WA 1168b).** Minimize effects by restoring the grass lawn within the temporary construction easement that extends into the property's southwest corner to its preconstruction state. This includes replacing in-kind the lawn and preserving one mature ornamental shrub that would not be removed during construction, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties.
- **Vancouver Barracks National Cemetery (WA 1319).** Avoid effects by preserving character-defining features along E Fourth Plain Boulevard within the temporary construction easement. This includes preservation of the perimeter fence, cobblestone wall with gates, perimeter road, and planting inside the boundary fence, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties.
- **Mickler House (WA 1258).** Reconstruct the fence, if necessary, following project completion. Minimize to the maximum extent possible the effects to the existing walkway and curb when implementing Americans with Disabilities Act design efforts.

Program planning also includes efforts to minimize effects to the Fort Vancouver National Historic Site. However, even with implementation of the following activity, the Modified LPA would result in an "adverse effect" finding for the Fort Vancouver National Historic Site:

- **Fort Vancouver National Historic Site (WA 1359).** Protect two historic trees in the allée, which are contributing components associated with the property, consistent with the Secretary of the Interior's Standards for the Treatment of Historic Properties. Replace the vegetation buffer removed within the temporary construction easement along the southwest edge of the property following Program implementation.

In addition, Program planning to avoid or minimize effects on cultural resources will include, for historic built properties within 500 feet of the construction activity, monitoring of construction activities where construction-related vibration would exceed 0.2 inches per second for transient vibrations and 0.1 inches per second for continuous vibrations.

3.8.6 Mitigation and Programmatic Agreement

Identification of the mitigation for adverse effects to historic properties assessed under NEPA will be completed through the NHPA Section 106 process. FHWA and FTA, in coordination with WSDOT and ODOT, and in consultation with Oregon SHPO, Washington DAHP, consulting tribes, and other consulting parties, have chosen to complete the Section 106 process and resolve adverse effects on historic properties through the development of a PA pursuant to 36 CFR 800.14(b). A Draft PA, with redactions for sensitive information as deemed appropriate by FHWA and FTA in consultation with consulting tribes and other consulting parties, is currently undergoing consultation and will be made available to the public prior to publication of the Final SEIS, as required by 36 CFR 800.14(b)(2)(ii). The Final PA will be executed prior to the issuance of the ROD and will be included as an appendix to the ROD.

A PA is used when effects on historic properties cannot be fully determined prior to approval for the undertaking, as allowed under 36 CFR 800.14(b)(1)(ii), and where other circumstances warrant a departure from the normal Section 106 process as allowed under 36 CFR 800.14(b)(1)(v). Given the complexities of the IBR Program and the anticipated mix of construction contract delivery methods, FHWA and FTA intend for the PA to include stipulations to govern the implementation of the Program post-PA execution. The PA will include stipulations that outline processes for continued consultation; APE amendment; post-PA execution phased identification of historic properties, assessment of effects, and resolution of adverse effects; training; inadvertent discovery; archaeological monitoring; treatment of historic built environment resources, archaeological resources, historic cemeteries, human remains; and other administrative stipulations.

FHWA and FTA, in coordination with WSDOT and ODOT, have initiated consultation on the development of the PA with Oregon SHPO, Washington DAHP, the federally recognized tribes, and other consulting parties. This initial consultation involved review of an outline of the PA and outlines of the attachments to the PA. Based on comments on the PA and attachment outlines, FHWA and FTA, in coordination with WSDOT and ODOT, will continue consultation with Oregon SHPO, Washington DAHP, the federally recognized tribes, and other consulting parties to prepare a draft of the PA and attachments. The draft will include the stipulations and legal language required by FHWA, FTA, and the Advisory Council on Historic Preservation for project and program-level PAs. The draft PA attachments will detail measures to resolve adverse effects on known historic properties and procedures for post-PA execution, cultural resource investigations, and consultation. Preparation of the draft is ongoing. The draft, once completed, will be made available to the public prior to publication of the Final SEIS.

3.9 Visual Quality

Highways and major transit facilities are highly visible elements of landscapes. They are noticeable to local residents, travelers using the facilities, and nearby motorists, bicyclists, pedestrians, and transit users. This section describes and evaluates changes to visual character from the alternatives and how that change in visual character would affect visual quality as perceived by viewers.

The information presented in this section is based on the Visual Quality Technical Report, which contains greater detail and analysis.

3.9.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with visual quality has been updated in this Draft SEIS to include:

- Updated FHWA methodology for evaluating visual quality in their Guidelines for the Visual Impact Assessment of Highway Projects (2015).
- Updated locations of some key viewpoints and landscape units (LUs) to reflect the Modified LPA.
- Changes in viewsheds, based on the location and extent of the Modified LPA.
- Modifications in the highway and structure form, scale, and materials.
- Changes to the project footprint necessitated by these changed conditions including adding bridge configuration options with varying heights with respect to proximity to viewsheds.

Differences in methodology make direct comparison difficult but Table 3.9-1 compares the general impacts and benefits of the CRC LPA to those of the Modified LPA as a result of the changes listed above. Based on the analysis described in this section, the effects of the Modified LPA would be similar to those of the CRC LPA.

Table 3.9-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Visual Quality LU	CRC LPA Effects as Identified in 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Columbia Slough LU	Visual effects in the LU and Scenic Corridor would be minor.	Some viewers would likely have negative visual quality impacts, but most would have neutral to beneficial. The overall impact to visual quality would be beneficial.	Differences between the CRC LPA and the Modified LPA would be minor in this LU. Visual quality would be similar.
Columbia River and Vancouver Downtown LUs	Views of bridge towers replaced with new bridges. Visual changes from higher bridges and the removal of bridge towers.	Some viewers would likely have negative visual quality impacts, but most would have neutral to beneficial. The overall impact to visual quality would be beneficial.	Similar change in the visual environment. The form, scale, and materials of the CRC LPA and the Modified LPA would be similar. Visual quality in the Vancouver Downtown LU would likely

Visual Quality LU	CRC LPA Effects as Identified in 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
			be more adverse because of the parking structures being moved from the Greater Central Park LU. The light-rail station would also move to the Vancouver Downtown LU but the extension of the light-rail guideway would be shorter and not located on downtown streets.
Greater Central Park LU	Visual impacts associated with the SR 14 structures and Clark Park and Ride. Other views improve with the Evergreen Community Connector.	Most viewers would likely have negative visual quality impacts, and the overall impact to visual quality would be adverse.	Compared to the CRC LPA, the Modified LPA moves the LRT station and park and ride structure to the Vancouver Downtown LU, which would reduce visual changes in the Greater Central Park LU. However, the Modified LPA's visual change from the prominence of the higher Columbia River bridges, C Street ramp, and SR 14 would have an overall adverse visual quality impact for sensitive recreational viewers compared to the CRC LPA.
Burnt Bridge Creek LU	Visual effects in the LU would be minor. (No Change in Visual Impact).	The visual environment would be similar to the existing conditions. The overall impact to visual quality would be neutral.	Visual differences between the CRC LPA and the Modified LPA would be minor in this LU. Visual quality would be similar.
Ruby Junction LU	Visual impacts are expected to be low because the added structures and uses are consistent with existing character and uses.	The visual environment would be similar to the existing conditions. The overall impact to visual quality would be neutral.	Differences between the CRC LPA and the Modified LPA would be minor in this LU. Visual quality would be similar.

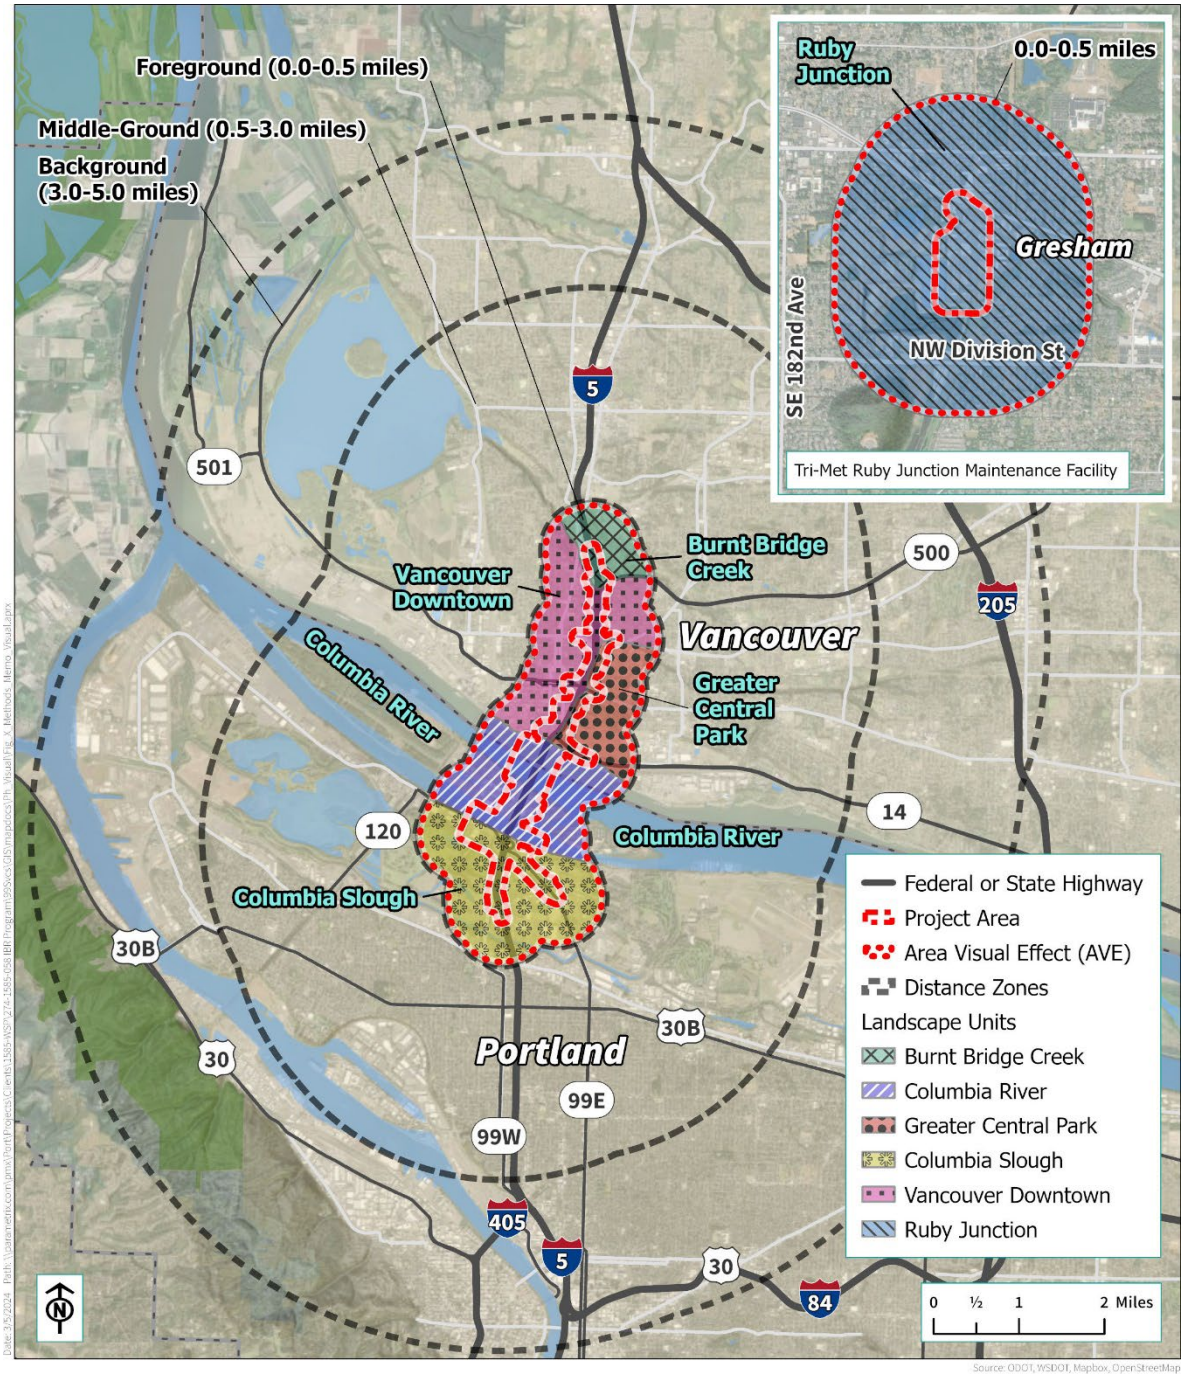
CRC = Columbia River Crossing; EIS = Environmental Impact Statement; LPA = Locally Preferred Alternative; LRT = light-rail transit; LU = Landscape unit;
SEIS = Supplemental Environmental Impact Statement; SR = State Route

3.9.2 Existing Conditions

FHWA's guidelines define the study area for visual quality analysis as the Area of Visual Effect (AVE) (FHWA 2015). The AVE is the area where views of the Modified LPA would be visible, determined by the physical constraints of the environment and the limits of human sight. Landforms (such as hills and mountains) and land cover (such as vegetation and buildings) limit views from large portions of the middle

and background distance zones (Figure 3.9-1). Therefore, the AVE for the Modified LPA, including the Ruby Junction Maintenance Facility, consists of areas within the foreground distance zone, which is 0 to 0.5 miles from the limits of ground disturbance. Along the I-5 corridor, background and middle ground distance zones were considered where they include scenic elements of views that could be altered or obstructed by the Modified LPA (i.e., bridges, ramps, etc.).

Figure 3.9-1. Area of Visual Effect and Landscape Units



Within the AVE, six defined LUs identify the existing visual character, viewer groups present, and current visual quality. Each LU is the geographic area used to assess changes to visual environments and character, sensitivity of viewers, and impact to visual quality. The six LUs are identified in Figure 3.9-1 and their existing resources and characteristics are described in Table 3.9-2.

It is not possible to assess every view within an LU, so key viewpoints (KVPs) were identified and used to define the existing visual character and visual quality and evaluate impacts to visual quality. The KVPs used in this analysis are shown in Figure 3.9-2. KVPs were selected because they represent a common or typical view from within an LU or because they are a view of a defining feature of the LU, such as a notable natural feature or important structure.

Table 3.9-2 Visual Character of Landscape Units

Landscape Unit	Visual Character
Columbia Slough	Views of North Portland Harbor and several sloughs, riparian areas, and large wetlands; level sports fields and recreational areas; large tracts of open space interrupted by large parking lots and industrial, retail, commercial, and transit and transportation development.
Columbia River	Riverine, industrial; flat landform; defined by near-continuous development along, and use of, the Columbia River. Open views upriver toward Mt. Hood.
Vancouver Downtown	Primarily developed residential, commercial, and retail areas. Smaller-scale urban core with higher density and taller structures, including mixed-use high-rise development along the waterfront.
Greater Central Park	Park-like campus and open fields crossed by several major roadways and elevated railroad tracks. Recreation- and education-oriented development.
Burnt Bridge Creek	Riparian valley between steep-sided slopes; residential development and open space.
Ruby Junction	Mix of industrial, commercial office, and retail development, including large-scale industrial uses such as sand and gravel mining and municipal transit maintenance and fleet services uses.

For each LU the visual analysis considers the sensitivity of the different viewer groups (people who would have views of or from the AVE) to changes in views and the visual character. The activities a viewer is engaged in, the visual context, and the values, expectations, and interests all affect viewer sensitivity. Although each viewer has individual preferences and sensitivities, there are three basic perceptions of the visual environments:

1. **Natural Harmony:** When viewing the natural environment, viewers evaluate the natural harmony of the existing scene, determining whether the composition is harmonious or inharmonious.
2. **Cultural Order:** When viewing the cultural environment, viewers evaluate cultural order, determining whether the composition is orderly or disorderly.
3. **Project Coherence:** When viewing a project environment, viewers evaluate how the visual character of all the elements of a project logically fit together and how the visual character of the project integrates with the visual character of the existing environment to form a complete whole. Viewers determine whether the project's composition is coherent (forms a logical whole) or incoherent (does not form a logical whole).

Table 3.9-3 summarizes the viewer groups present in each LU, their visual sensitivity and a qualitative rating of their perception of the existing elements of visual quality.

Figure 3.9-2. Key Viewpoints Used in the Visual Quality Analysis

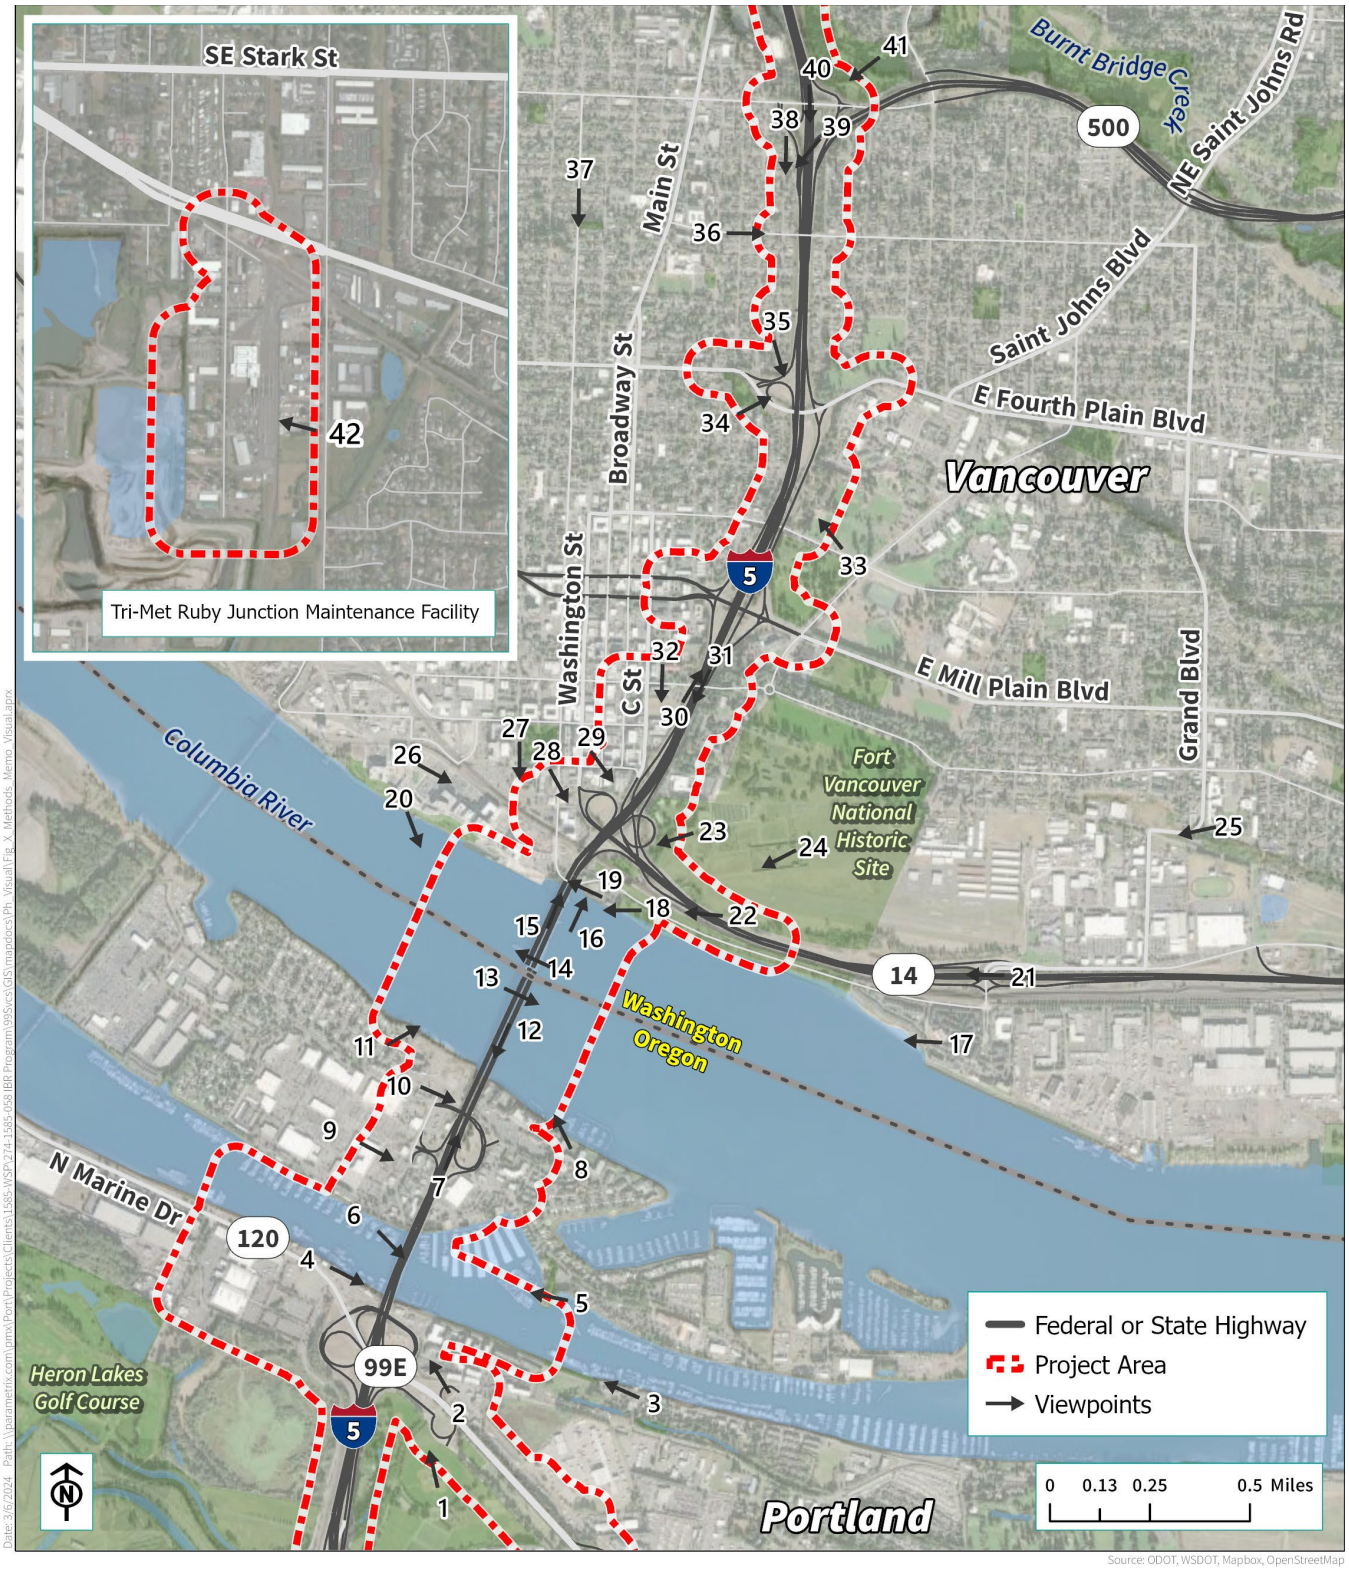


Table 3.9-3. Viewer Groups, Viewer Sensitivity, and Existing Visual Quality Ratings for Landscape Units

Landscape Unit	Viewer Groups	Viewer Sensitivity	Natural Harmony	Cultural Order	Project Coherence
Columbia Slough	Recreational, Residential, Motorist	Low (motorists) to High (recreational users)	Moderate	Low	Low
Columbia River	Recreational, Residential, Retail/Commercial, Motorist, Bicycle/Pedestrian	Low (motorists) to High (residential)	Moderate to High	Low	Low
Vancouver Downtown	Recreational, Residential, Retail/Commercial, Motorist, Bicycle/Pedestrian	Low (motorists) to High (residential)	Moderate	High	Low
Greater Central Park	Recreational, Motorist, Bicycle/Pedestrian	Low (motorists) to High (recreational users)	High	High	Low
Burnt Bridge Creek	Recreational, Residential, Motorist, Bicycle/Pedestrian	Low (all viewers)	High	Low	Moderate
Ruby Junction	Industrial, Commercial, Retail, Residential, Civic	Low (all viewers)	Low	Moderate to Low	Moderate to Low

3.9.3 Long-Term Benefits and Effects

"Long-term effects to visual quality" refers to how changes to visual resources affect the character of the physical, cultural, and project environments as perceived by viewers. The degree of impact to visual quality is determined by the compatibility of the visual change with the existing conditions and the sensitivity of viewers. The value of the effect to visual quality is identified as beneficial, adverse, or neutral.

Table 3.9-4 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on visual quality. Detailed analysis of the effects is provided in the following sections.

No-Build Alternative

Under the No-Build Alternative, the constructed elements of the project environment within the AVE would not change. Existing bridges, ramps, interchanges, roadways, and other structures would remain. With regular maintenance, such as painting, views containing the bridge structures are not expected to decline in visual quality, except in the event of a major earthquake, which could visibly damage the structures.

The No-Build Alternative assumes that all highway, roadway, and transit projects within the AVE planned to be built by 2045 would be constructed. Even with completion of those projects, traffic congestion and delays are forecasted to increase within the AVE. Additionally, periodic bridge lifts to allow Columbia River traffic to pass under the existing Interstate Bridge would continue to cause stopped traffic and congestion on I-5. Additional congestion reduces the coherence of the project environment, particularly as viewed by motorists, which could reduce visual quality. Visual changes from traffic congestion may adversely affect visual quality for some viewers in all LUs except for the Ruby Junction LU. However, these conditions would likely develop over time, allowing viewers to become accustomed to the changing visual environment. The overall long-term impact on visual quality would be neutral.

Table 3.9-4. Summary of No-Build Alternative and Modified LPA Effects on Visual Quality

No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift	Modified LPA with Single-Level Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, without C Street Ramps, Centered I-5	Modified LPA Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options
• Constructed elements within the Area of Visual Effect (AVE) would not change. Project environment coherence would be negatively affected by increased traffic and congestion, however, natural and cultural elements are expected to be compatible with the existing visual environment.	• Impacts would include new visual elements that could alter the visual character and quality in the AVE (e.g., new bridges across the Columbia River). LUs where the effect to visual quality are beneficial or neutral would have a natural, cultural, and project environment that is compatible with existing visual conditions. Adverse effects to visual quality would result from blocking views of the natural environment and changes in visual experience from elevated bridge structures, such as to viewers in the floating homes at the North Portland Harbor bridges.	• Additional width would contribute to a slightly increased visual mass for viewers in close proximity or beneath the structures in the Columbia River LU.	• Would include an improvement in perception of visual quality by shifting project elements slightly farther from sensitive viewers at Kanaka Village and other views from Fort Vancouver National Historic Site in the Greater Central Park LU.	• May become a beneficial feature from nearby views in the Columbia River LU depending on the chosen architectural design.	• In the closed position, the lower height of the bridge decks would be similar, or less visible, than the existing Interstate Bridge. Some components of a movable span could protrude higher into the skyline and be visible from Vancouver, Fort Vancouver, and Hayden Island areas. In an open position, which would be intermittent and limited, the increased visibility of the bridge deck may obstruct additional views and skylines, and likely intensify visual impacts, especially for sensitive recreational viewers. The overall bridge deck would be higher and more visible than the existing bridge deck.	• Would eliminate project environment elements associated with the C Street Ramps that would be visible for sensitive recreational viewers in the Greater Central Park LU.	• Potential changes in the cultural visual environment in the Vancouver Downtown LU.

AVE = area of visual effect; I-5 = Interstate 5; LPA = Locally Preferred Alternative; LU = landscape unit

Modified LPA

The primary elements of the Modified LPA that could alter visual character and quality are the new bridges across the Columbia River and North Portland Harbor; reconfiguration of roadways and interchanges; and construction of new light-rail transit facilities and park-and-ride sites. Within the AVE, the Modified LPA, with any of the design options, would have perceptible changes in scale, form, and materials from:

- The greater heights and widths of the new Columbia River bridges.
- Reconfiguration or modification of interchanges at N Marine Drive, Hayden Island, SR 14, Mill Plain Boulevard, Fourth Plain Boulevard, and SR 500.
- The introduction of light-rail transit guideway and stations.
- Removal of the existing Interstate Bridge.

For each LU, the following provides an assessment of the visual compatibility of, and viewer sensitivity to, the Modified LPA, including an assessment of the design options in the applicable LU, and its overall degree of impact on visual quality.

Columbia Slough Landscape Unit

Within the Columbia Slough LU, the Modified LPA includes changes to the Marine Drive and Victory Boulevard interchanges, the extension of light-rail transit from the existing terminus at the Expo Center, and a facility on the Expo Center property that would provide a small number of storage tracks, one small maintenance building for light maintenance, an operator break facility, and a parking lot for operators. This facility would necessitate reconstruction of the Expo Road entrance to the Expo Center and the parking lot gates and booths, but it would not alter the existing Expo Center buildings. As an example of changes to the visual environment within the Columbia Slough LU, Figure 3.9-3 shows the existing conditions from KVP 2 (along Marine Drive looking northwest toward pedestrian trails) and a photographic simulation of the Marine Drive Interchange with the Modified LPA.

While the Modified LPA would remove some existing trees and vegetation, the natural environment would continue to include views of distant shorelines, rolling hills, and mountain profiles from both northbound and southbound I-5. The cultural environment would generally remain unchanged, and the project environment of roadways and bridges would be compatible with the existing visual conditions.

The compatibility of the Modified LPA with the project environment would be the same with either the one or two auxiliary lane design option; there is not a change in the assessment of visual quality. In the Columbia Slough LU, there would be no change in the assessment of visual quality with the Modified LPA between the different bridge configurations (double-deck fixed-span, single-level fixed-span, or single-level movable-span). The Modified LPA with the single-level fixed-span configuration would provide more options for bridge architecture, such as the potential to use a finback or extradosed design. These bridge architecture designs would have additional associated visual mass and height above the bridge deck that may be visible from the Columbia Slough LU. They would also provide greater opportunity for a bridge design that meets the communities' design goals and could become a beneficial feature from nearby views.

Figure 3.9-3. Existing Conditions Photograph and Conceptual Photographic Simulation (N Marine Drive Looking Northwest at Pedestrian Trails)

Existing Conditions

Photographic simulation of Modified LPA

Note: The simulation illustrates the general layout and massing. Visual elements of the Modified LPA may change as the design progresses. Roadways, intersections, signage, markings, and other simulated elements reflect early conceptual design and are shown for illustration purposes only.

Four KVPs were identified to assess the visual quality in the Columbia Slough LU. For each KVP within the Columbia Slough LU, Table 3.9-5 provides a quantitative assessment of the existing visual quality, the visual quality with the Modified LPA, and the overall visual quality score for the LU. Natural harmony, cultural order, and project coherence were rated on a scale of 1 to 7, with 1 being very low, 4 being moderate, and 7 being very high. As shown in Table 3.9-5, the Modified LPA was found to have a neutral degree of impact on one KVP (KVP 3), an adverse degree of impact on one KVP (KVP 1), and a beneficial degree of impact on two KVPs (KVP 2 and 4). For the Columbia Slough LU overall, the change in visual quality from the Modified LPA would be expected to be beneficial.

Table 3.9-5. Columbia Slough Landscape Unit Degree of Impact on Visual Quality

KVP	Visual Quality – Existing [a]				Visual Quality – with Modified LPA [b]				Change	Degree of Impact on Visual Quality
	Natural Harmony	Cultural Order	Project Coherence	Overall	Natural Harmony	Cultural Order	Project Coherence	Overall		
1	5	3	3	3.7	3	3	3	3	-0.7	Adverse
2	3	2	2	2.3	3	2	3	2.7	0.4	Beneficial
3	5	3	3	3.7	5	3	3	3.7	0	Neutral
4	2	1	2	1.7	2	2	3	2.3	0.6	Beneficial
Overall Landscape Unit Change									0.3	Beneficial

Note: Visual quality score definitions: 1 = very low, 2 = low, 3 = moderately low, 4 = moderate, 5 = moderately high, 6 = high, 7 = very high

a The visual quality ratings for the No-Build Alternative are the same as the existing conditions.

b The visual quality ratings for the Modified LPA are the same for each design option.

KVP = key viewpoint; LPA = Locally Preferred Alternative; LRT = light-rail transit

Columbia River Landscape Unit

Within the Columbia River LU, the Modified LPA, with any of the design options, would include two new parallel Columbia River bridges North Portland Harbor bridges, the extension of LRT, including transit facilities on the Columbia River bridges, a new interchange on Hayden Island, , a modified SR 14 interchange, shared-use paths along the new bridge structures providing an active transportation connection across the Columbia River, and the removal of the existing Interstate Bridge.

Within the Columbia River LU trees, vegetation, shorelines (both on the Columbia River and North Portland Harbor), and other natural elements would be relatively unchanged. The bridge decks for all the Modified LPA's Columbia River bridge configurations would be higher than the existing bridge decks, which may increase a visual sense of openness along the Columbia River shoreline and increase natural harmony. The cultural environment would be altered with elevated lanes, ramps, and retaining walls, but land cover would block most direct views and the cultural environment overall would be orderly. The project environment would experience

Visual mass refers to the perceived weight or prominence of an object or element. Visual mass is not directly related to the actual physical weight of an object, but rather its visual appearance. It is determined by various factors such as size, shape, color, texture, contrast, and placement. Objects or elements that are larger, darker, more detailed, or placed in a prominent position tend to have more visual mass and attract greater attention from the viewer.

updated highway and active transportation facilities that meet current design standards and would improve movements and speeds, which would be beneficial to project coherence.

With the Modified LPA, the location and layout of the North Portland Harbor bridges and transit structure would involve relocating some of the floating homes on the Columbia Slough, resulting in the Columbia River bridges and transit structures being closer to the floating homes that remain. The scale of the North Portland Harbor bridge structures, ramps, and roadways would increase the existing footprint, modifying the visual environment from the floating home community. While the existing bridge over the North Portland Harbor provides a visual precedent, the expanded footprint of the North Portland Harbor bridge and new transit bridge under the Modified LPA would be new visual elements for adjacent residential viewers. These residential viewers would experience a high degree of visual change, and the new North Portland Harbor bridges would not be compatible with the existing visual conditions.

The new Columbia River bridge decks and ramps would be higher in elevation than the existing Interstate Bridge but would not be as high as the existing lift towers. These higher structures would be much more visible and would be likely to block views of neighbors in surrounding areas. As currently conceptualized, the Modified LPA with the double-deck fixed-span configuration would not have substantial structural elements extending above the bridge deck, which would maximize views of the surrounding landscape from the top bridge deck and improve views of the surrounding landscape from the Columbia River bridges for travelers.

For viewers at the water level of the Columbia River or from the shorelines, transit, pedestrian, and utility facilities on the lower decks would contribute to the visual height and mass of the Modified LPA's Columbia River bridges, but fewer piers and the higher deck height would allow greater view of the corridors between piers and under the bridge. Therefore, the scale and magnitude for on-water viewers and viewers at lower elevations would be similar to those of the existing Interstate Bridge.

Compared to the existing shared-use path on the existing Interstate Bridge, the shared-use path associated with the Modified LPA would be moved to the lower-level bridge deck. Views for pedestrians and bicyclists would be nearly enclosed and exposed to the underside of the bridge deck above. However, generously sized bicycle and pedestrian facilities with overlooks and rest points would replace the existing narrow pedestrian path adjacent to vehicular traffic, and views would be improved as viewers would be higher than the existing bridge. Features such as safety railing and bicycle lane striping would improve the project coherence for bicyclists and pedestrians. Safe facilities would allow more focus and attention on beneficial elements in the cultural and natural visual environment. The overall experience would be beneficial for bicyclists and pedestrians.

The design option to shift the I-5 mainline westward would have the same visual compatibility as the design option where the I-5 mainline remains centered. In addition, the design option at the SR 14 interchange to have or not have C Street Ramps would not change the visual environment for viewers within the Columbia River LU and the optional park-and-ride sites would either be not visible or barely visible from views.

The Modified LPA with the design option of two auxiliary lanes would expand the roadway width of I-5 by an additional 16 feet, which would be slightly closer to viewers and would contribute to a slightly increased visual mass. Motorists inside enclosed vehicles (including light-rail cars on the lower deck) would likely not discern the slight expansion associated with the second auxiliary lane. Similarly, the additional 16-foot width would likely have minimal visual change to viewers somewhat farther from the bridge.

In comparison to the Modified LPA with the double-deck fixed-span configuration, the Modified LPA with the single-level fixed-span configuration would be slightly wider and somewhat closer to nearby viewers. However, the single-level fixed-span configurations would have a slimmer vertical profile and would grant viewers in proximity or beneath the Columbia River bridges along the Vancouver waterfront with more expansive and unobstructed views below bridge decks and between piers. In addition, the Modified LPA with the single-level fixed-span configuration would provide more options for bridge architecture, such as the

potential to use a finback or extradosed design. While those architectural designs would have additional associated visual mass and height above the bridge deck, they would also provide greater opportunity for a bridge design that meets the communities' design goals and could become a beneficial feature from nearby views.

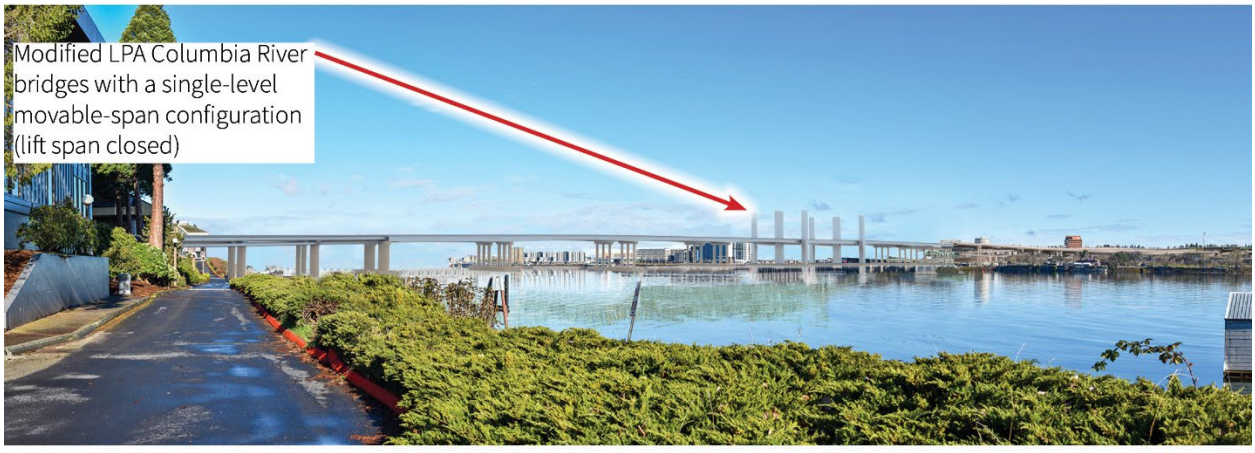
The Modified LPA with the single-level movable-span configuration would have bridge decks somewhat higher than the existing Interstate Bridge, which would slightly open up views from underneath. With the single-level movable-span configuration, the overall visual character and massing would be similar to the existing conditions or No-Build Alternative as there would be lift towers that would protrude higher into the skyline for areas in Vancouver, Fort Vancouver, and toward and from Hayden Island.

Overall, at the current level of design used in this analysis, the options for the bridge configurations would have a similar effect on visual quality. Figure 3.9-4 provides an existing condition photograph of the Interstate Bridge, a photographic simulation of the Modified LPA with the double-deck fixed-span configuration, and the Modified LPA with the single-level movable-span configuration. Figure 3.9-5 shows KVP 15 with an existing condition photograph of the Interstate Bridge, a photographic simulation of the Modified LPA with the double-deck fixed-span configuration, and a photographic simulation of the Modified LPA with the single-level movable-span configuration, both from the top deck looking north toward downtown Vancouver.

Figure 3.9-4. Existing Conditions Photograph and Conceptual Photographic Simulations (Columbia River Bridges)

Existing Condition

Photographic simulation of Modified LPA Columbia River bridges with a double-deck fixed-span configuration



Photographic simulation of Modified LPA with single-level movable-span configuration

Note: The simulations illustrate the general layout and massing of the Modified LPA double-deck fixed-span and single-level movable-span configurations. The movable-span configuration is shown in the closed position only because the open position would be intermittent and limited. Visual elements of the Modified LPA may change as the design progresses. Roadways, intersections, signage, markings, and other simulated elements reflect early conceptual design and are shown for illustration purposes only.

Figure 3.9-5. KVP 15: Existing Conditions Photograph and Conceptual Photographic Simulation (Columbia River Bridge northbound lane looking north to Vancouver)

Existing Conditions

Photographic Simulation of the Modified LPA with double-deck fixed-span bridge configuration

Photographic simulation of Modified LPA Columbia River bridge with single-level movable-span configuration

Note: The simulation illustrates the general layout and massing of the Modified LPA double-deck fixed-span and single-level movable-span configurations. Visual elements of the configurations may change as the design progresses. Conceptual photographic simulations are intended to illustrate general layout and massing of the Modified LPA. Roadways, intersections, signage, markings, and other simulated elements are conceptual and shown for illustration only. The early conceptual design may change as the design progresses.

Sixteen KVPs were identified to assess the visual quality in the Columbia River LU. For each KVP within the Columbia River LU, Table 3.9-6 provides a quantitative assessment of the existing visual quality and the visual quality with the Modified LPA. As shown in Table 3.9-6, five KVPs could have an adverse degree of impact to visual quality, six would have a neutral impact, and the remaining five would have a beneficial degree of impact. The overall LU change is a numeric average of the change of all KVPs combined. Based on this assessment, the Modified LPA would be expected to have a combined positive numeric change in the visual quality of KVPs and, therefore, an overall beneficial degree of impact to the visual quality of the Columbia River LU.

Table 3.9-6. Columbia River Landscape Unit Degree of Impact on Visual Quality

KVP	Visual Quality – Existing [a]				Visual Quality – with Modified LPA [b]				Change	Degree of Impact on Visual Quality
	Natural Harmony	Cultural Order	Project Coherence	Overall	Natural Harmony	Cultural Order	Project Coherence	Overall		
5	6	4	4	4.7	6	4	4	4.7	0.0	Neutral
6	6	3	2	3.7	4	2	1	2.3	-1.4	Adverse

20	6	5	3	4.7	6	5	2	4.3	-0.4	Adverse
Overall Landscape Unit Change									+4.4	Beneficial

Note: Visual quality score definitions: 1 = very low, 2 = low, 3 = moderately low, 4 = moderate, 5 = moderately high, 6 = high, 7 = very high
a The visual quality ratings for the No-Build Alternative are the same as the existing conditions.
b The visual quality ratings for the Modified LPA are the same for each design option.
KVP = key viewpoint; LPA = Locally Preferred Alternative

Vancouver Downtown Landscape Unit

In the Vancouver Downtown LU, views in the south include those toward the new Columbia River bridges. The Modified LPA also includes changes to the I-5 mainline, such as the design option for one or two auxiliary lanes, updates to interchanges, and the Evergreen Community Connector. In the Vancouver Downtown LU, the Modified LPA with either one or two auxiliary lanes would have similar visual changes as described in the Columbia River LU. In addition, the visual changes with the different options of bridge configurations would be the same as described in the Columbia River LU. Figure 3.9-6 provides an existing conditions photograph, a photographic simulation of the Modified LPA with the double-deck fixed-span configuration, and a photographic simulation of the Modified LPA with the single-level movable-span configuration, as seen from KVP 28 in downtown Vancouver.

While the changes to the I-5 roadway and interchanges may remove some vegetation that would change the natural environment, the Community Connector would provide opportunities to add natural elements and enhance natural harmony.

The Modified LPA, with any of the design options, would change the cultural environment. While the Modified LPA's visual changes would be similar with the design option of with or without the I-5 C Street ramps, the design option of the westward shift of the I-5 mainline would result in changes to existing buildings between C Street and the I-5 mainline. Building renovation or reconstruction as a result of the design option of the westward shift of I-5 would be expected to be compatible with the existing visual character.

The transit stations and park-and-ride site options also have the potential to change the cultural visual environment. While the architectural design of the transit stations and park-and-ride facilities would be determined as the design progresses; both stations and the park-and-ride facilities would be developed through public workshops and interested party group meetings and would use compatible massing, materials, and landscaping. Further, at any of the site options, the park-and-ride facilities would be developed in compliance with Vancouver regulations and guidelines, including building design and materials, lighting and signage, art elements, landscaping, and street trees, which would ensure the compatibility with the existing visual character. Other urban design elements such as plazas and light-rail stations may be considered enhancements to the visual environment.

Twelve KVPs were identified to assess visual quality in the Vancouver Downtown LU. For each KVP within the Vancouver Downtown LU, Table 3.9-7 provides a quantitative assessment of the existing visual quality and the visual quality with the Modified LPA. As shown in Table 3.9-7, six of the KVPs would have a neutral degree of impact to visual quality, two would have a beneficial degree of impact, and four would have an adverse degree of impact. Based on this assessment, the Modified LPA would be expected to have a combined positive numeric change in the visual quality of KVPs and, therefore, an overall slightly beneficial degree of impact on the visual quality of the Vancouver Downtown LU.

b The visual quality ratings for the Modified LPA are the same for each design option.

KVP = key viewpoint; LPA = Locally Preferred Alternative

Greater Central Park Landscape Unit

In the Greater Central Park LU, most views toward the Modified LPA would be blocked by existing vegetation and land cover. However, views in the southern part of the Greater Central Park LU would include the new Columbia River bridges and the modified SR 14 interchange. Other elements of the Modified LPA include changes to I-5 mainline, such as design options for one or two auxiliary lanes and the westward shift or centered mainline, updates to interchanges, and the Evergreen Community Connector. In the Greater Central Park LU, the Modified LPA with the design options for one auxiliary lane or two auxiliary lanes would have similar visual changes as described in the Columbia River LU.

In the natural environment, compared to the existing Interstate Bridge, the Modified LPA and all of the design options could block views of distant hills to the southwest from adjacent ground-level viewpoints to a slightly greater degree, but would not interfere with views from a greater distance or elevation, such as Grand Boulevard to the east (KVP 25). Compared to the existing Interstate Bridge, the Modified LPA and all of the design options would open views under the bridge as a result of the increased bridge height and the wider spacing between piers. The majority of natural visual elements would remain. For the cultural environment, while the bridge type and architecture are yet to be determined, a new bridge structure and the revised SR 14 interchange would noticeably change the visual experience as elevated structures such as piers, bridge decks, railings, and barriers would shift slightly closer to viewers.

The Modified LPA's design of the SR 14 interchange would result in a significantly different view from the Kanaka Village area (KVP 23). Figure 3.9-7 provides an existing condition photograph of KVP 23, a photographic simulation of the Modified LPA with double-deck fixed-span configuration without C Street Ramp, a photographic simulation of the Modified LPA with single-level movable-span configuration without C Street ramp, and a photographic simulation of the Modified LPA with single-level movable-span configuration in the open position with C Street Ramp. The Modified LPA with the design option that would eliminate the C Street ramps would eliminate project environment elements that would be visible for sensitive recreational viewers at Kanaka Village (KVP 23) and other views from the Fort Vancouver National Historic Site (see Figure 3.9-7). The Modified LPA with the design option that would shift the I-5 mainline west would shift project environment elements slightly farther from sensitive viewers. This shift would improve viewers' perception of the visual quality (see Figure 3.9-7 and Figure 3.9-8). For most viewers within the Greater Central Park LU, the park-and-ride options would be behind or under the I-5 mainline or Columbia River bridges and would not be visible.

The Modified LPA with the single-level movable-span configuration would have bridge decks somewhat higher than the existing Interstate Bridge. However, compared to the double-deck fixed-span and single-level fixed-span configurations, the deck height would be lower, resulting in less visibility from the Greater Central Park LU. The single-level movable-span bridge configuration would have a slimmer profile than the double-deck fixed-span bridge configuration, but the increased height of the lift towers would add to its visual weight, meaning the size, color, and shape would draw more attention to this configuration. In the normal (closed) condition, the lower bridge deck and higher towers would likely balance the visual effects compared to the double-deck fixed-span configuration; however, impacts would change when the bridge is open. The bridge deck between the lift towers would be higher and more visible when in an open configuration. This increased visibility of the bridge deck may obstruct additional views and skylines, and likely intensify visual impacts, especially for sensitive recreational viewers. The overall bridge deck would be higher and more visible than the existing bridge deck. Because bridge lifts would not be lengthy or frequent, the exposure of these visual effects to sensitive and non-sensitive viewers would be limited.

Visual changes associated with the different bridge configuration options would be the same as described in the Columbia River LU. For KVP 23, Figure 3.9-8 shows the existing conditions photograph, a photographic simulation of the Modified LPA with the double-deck fixed-span configuration with C Street ramp, the Modified LPA with the single-level movable-span configuration with C Street ramp, and a photographic simulation of Modified LPA with single-level movable-span configuration in the open position with C Street ramp. With both of these configurations, I-5 and the Columbia River bridges would likely still be at least partially visible beyond existing vegetation.

Photographic simulation of Modified LPA with single-level movable-span open configuration with C Street ramp

Note: The simulation illustrates the general layout and massing of the Modified LPA double-deck fixed-span and single-level movable-span configurations. Visual elements of the configurations may change as the design progresses. Roadways, intersections, signage, markings, and other simulated elements reflect early conceptual design and are shown for illustration purposes only.

Six KVPs were identified to assess visual quality in the Greater Central Park LU. For each KVP within the Greater Central Park LU, Table 3.9-8 provides a quantitative assessment of the existing visual quality and the visual quality with the Modified LPA. As shown in Table 3.9-8, four of the KVPs would have a neutral degree of impact to visual quality and two would have an adverse degree of impact. Based on this assessment, the overall degree of impact of the Modified LPA on the visual quality of the Greater Central Park LU would be expected to be adverse.

Table 3.9-8. Greater Central Park Landscape Unit Degree of Impact on Visual Quality

KVP	Visual Quality – Existing [a]				Visual Quality – with Modified LPA [b]				Change	Degree of Impact to Visual Quality
	Natural Harmony	Cultural Order	Project Coherence	Overall	Natural Harmony	Cultural Order	Project Coherence	Overall		
21	4	3	4	3.7	4	3	4	3.7	0.0	Neutral
22	5	5	3	4.3	5	5	3	4.3	0.0	Neutral
23	6	6	2	4.7	3	6	2	3.7	-1.0	Adverse
24	6	6	2	4.7	6	6	2	4.7	0.0	Neutral
25	4	3	3	3.3	4	3	3	3.3	0.0	Neutral
33	6	4	4	4.7	5	4	4	4.3	-0.4	Adverse
Overall Landscape Unit Change									-1.4	Adverse

Note: Visual quality score definitions: 1 = very low, 2 = low, 3 = moderately low, 4 = moderate, 5 = moderately high, 6 = high; 7 = very high.
[1] The visual quality ratings for the No-Build Alternative are the same as the existing conditions.
[2] The visual quality ratings for the Modified LPA are the same for each design option.
KVP = key viewpoint; LPA = Locally Preferred Alternative Burnt Bridge Creek Landscape Unit

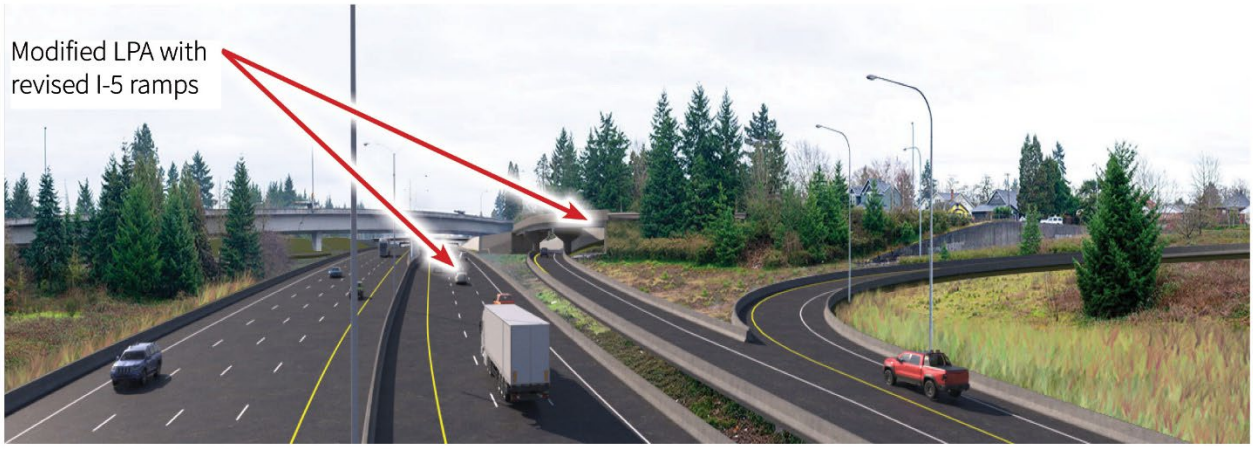
Burnt Bridge Creek Landscape Unit

In the Burnt Bridge Creek LU, the elements of the Modified LPA would be similar to and compatible with the existing visual character. Figure 3.9-9 shows a photograph of the existing conditions from KVP 40 and a photographic simulation of the Modified LPA. There would be no change in visual character from the Modified LPA with one auxiliary lane or two auxiliary lanes. In addition, the Columbia River bridges would not be visible from most locations in the Burnt Bridge Creek LU; therefore, the different bridge configuration options do not result in changes in visual character or quality.

While the Modified LPA may result in the removal of some trees and vegetation, it is not expected to change the character of the natural environment, which is that of a suburban greenway. The overall cultural environment would be orderly and compatible with the existing environment and would be a neutral visual impact. Minor changes, cohesive with the existing environment, would be made to the project environment.

Figure 3.9-9. Existing Conditions and Conceptual Photographic Simulation (39th Street Overpass Looking South)

Existing Conditions



Photographic simulation of Modified LPA

Note: The simulation illustrates the general layout and massing of the Modified LPA. Visual elements of the Modified LPA may change as the design progresses. Roadways, intersections, signage, markings, and other simulated elements reflect early conceptual design and are shown for illustration purposes only.

Three KVPs were identified to assess the degree of impact on viewers and the overall visual quality in the Burnt Bridge Creek LU. For each KVP within the Burnt Bridge Creek LU, Table 3.9-9 provides a quantitative assessment of the existing visual quality of the Burnt Bridge Creek LU and the visual quality with the Modified LPA. The overall visual quality score would remain the same under the Modified LPA; therefore, the degree of visual quality impact for the Burnt Bridge Creek LU would be neutral.

Table 3.9-9. Burnt Bridge Creek Landscape Unit Degree of Impact on Visual Quality

KVP	Visual Quality – Existing [a]				Visual Quality – with Modified LPA [b]				Change	Degree of Impact on Visual Quality
	Natural Harmony	Cultural Order	Project Coherence	Overall	Natural Harmony	Cultural Order	Project Coherence	Overall		
39	5	4	4	4.3	5	4	4	4.3	0.0	Neutral
40	4	3	4	3.7	3	3	5	3.7	0.0	Neutral
41	6	5	3	4.7	6	5	3	4.7	0.0	Neutral
Overall Landscape Unit Change									0.0	Neutral

Note: Visual quality score definitions: 1 = very low, 2 = low, 3 = moderately low, 4 = moderate, 5 = moderately high, 6 = high, 7 = very high. Scores are based on the visual simulations prepared for the project.
a The visual quality ratings for the No-Build Alternative are the same as the existing conditions.
b The visual quality ratings for the Modified LPA are the same for each design option.
LPA = Locally Preferred Alternative; KVP = key viewpoint

Ruby Junction Landscape Unit

The Ruby Junction Maintenance Facility would be expanded to accommodate the additional light-rail vehicles associated with the extension of light-rail with the Modified LPA. The expansion would include several parcels and existing buildings, structures, vegetation, and other elements on the purchased properties would be removed. However, the expansion of the Ruby Junction Maintenance Facility would be visually compatible with the existing facility and would not change the natural, cultural and project visual character in the Ruby Junction LU.

Table 3.9-10 provides a quantitative assessment of the existing visual quality and the visual quality with the Modified LPA from KVP 42 in the Ruby Junction LU. As shown in Table 3.9-10, the Modified LPA was determined to have a neutral degree of impact to the visual quality at KVP 42. Based on this assessment, the overall impact of the Modified LPA on the visual quality of the Ruby Junction LU would be expected to be neutral.

Table 3.9-10. Ruby Junction Landscape Unit Degree of Impact on Visual Quality

KVP	Visual Quality – Existing [a]				Visual Quality - with Modified LPA [b]				Change	Degree of Impact on Visual Quality
	Natural Harmony	Cultural Order	Project Coherence	Overall	Natural Harmony	Cultural Order	Project Coherence	Overall		
42	3	2	3	2.7	3	2	3	2.7	0.0	Neutral
Overall Landscape Unit Change									0.0	Neutral

Note: Visual quality score definitions: 1 = very low, 2 = low, 3 = moderately low, 4 = moderate, 5 = moderately high, 6 = high, 7 = very high.
a The visual quality ratings for the No-Build Alternative are the same as the existing conditions.
b The visual quality ratings for the Modified LPA are the same for each design option.
KVP = key viewpoint; LPA = Locally Preferred Alternative

3.9.4 Temporary Effects

Temporary visual effects would be related to the construction of the Modified LPA, which includes the construction of the new bridges and the removal of the existing bridge. Visible construction elements would be removed upon completion of construction work.

No-Build Alternative

The No-Build Alternative includes planned transportation projects in the AVE through 2045. Construction of these projects, as well as ongoing repair and maintenance activities for I-5 in the AVE (e.g., painting, repaving, and repairing pavement), would take place under the No-Build Alternative. Ongoing maintenance, repair, and construction would result in repeated temporary visual impacts introducing visual clutter that would have a slight adverse degree of impact to visual quality.

Although difficult to predict, if a future seismic event were to occur under the No-Build Alternative, it could result in cracks, damaged surfaces and finishes, structural deformations, or collapses of structures and the Interstate Bridge, depending on severity. Bridge closures could affect regional vehicular and river traffic for extended periods of time. Viewers may be exposed to heavy traffic on detour routes for long durations and visual clutter from construction activities to repair or replace bridge and roadway elements. The degree of impact to visual quality would be major and adverse.

Modified LPA

During construction of the Modified LPA, the quality of views to and from the construction area would be temporarily altered. Construction-related signage and heavy equipment would be visible in the vicinity of construction sites. Vegetation may be removed from some areas to accommodate the construction of the bridges, new ramps, and the light-rail transit guideway. This would degrade or partially obstruct views or vistas. Nighttime construction would be necessary to minimize disruption to daytime traffic. Temporary lighting may be necessary for nighttime construction of certain project elements. This temporary lighting would affect residential areas by exposing residents to glare from unshielded light sources and by increasing ambient nighttime light levels.

Staging of equipment and materials would occur in areas of the AVE throughout the construction period, generally within existing or newly purchased right of way or on nearby vacant parcels. At least one large site would be required for construction offices, to stage the larger equipment such as cranes, and to store materials such as rebar and aggregate. Work in staging areas would entail vegetation removal, construction vehicle movement, fencing, material storage, bright colors, flashing lights, nighttime lighting, dust, and other visual elements.

Construction activities would be visible to both neighbors and travelers in the AVE, primarily within the visual context of the existing roadway. Lighting, human-made structures and materials, bright colors, and vehicle movement would be visible within the AVE. While these visual changes are typical of construction activities, they would contribute to a perception of a disorderly cultural environment and incoherent project environment. Therefore, during construction, both neighbors and travelers would perceive a temporary degradation and adverse degree of impact to visual quality. In particular, residential neighbors (who prefer maintaining natural harmony and cultural order) adjacent to construction activities would perceive construction activities as degrading the existing visual quality.

Temporary visual effects from the Modified LPA with the single-level movable-span configuration would be similar in character to those described above; however, taller cranes would be needed to construct the lift towers. In addition, construction of the Modified LPA and the temporary visual effects could last up to two additional years. For all other bridge configurations, tall cranes would be required for a shorter duration during the demolition of the existing lift towers.

Visual impacts due to construction activities are, by nature, temporary, and visible detractions related to construction would be removed upon completion. Therefore, the Modified LPA would have a high degree of adverse impact on the visual quality of the AVE but would be limited by the duration of the construction of each item, and impacts would be temporary.

3.9.5 Indirect Effects

The Modified LPA would have indirect effects on visual character and visual quality. These effects could result from potential changes in land use within the AVE that may occur over time as a result of the Modified LPA and are anticipated to occur primarily in the Columbia River LU and the Vancouver Downtown LU.

Columbia Slough Landscape Unit

This LU is already a highly developed urban area, but improved vehicular access and reduced congestion may support denser development in areas currently planned for such development (see Section 3.4.4). Development would occur in compliance with the City of Portland land use plans and regulations. This would likely have a positive effect on the visual character, depending on the quality of design and materials used, compared with what is being replaced (primarily existing buildings and parking lots). Indirect impacts to visual quality as a result of the Modified LPA for this LU are not anticipated.

Columbia River Landscape Unit

Under the Modified LPA, potential indirect land use changes in this LU would primarily involve redevelopment around the proposed transit station on Hayden Island. These areas are already highly developed and new development would occur in compliance with the City of Portland's land use plans and regulations. Views for boaters, air passengers, and pedestrians are unlikely to change significantly because views of new development are likely to be blocked by existing structures or would be in character with existing development. In some instances, existing views of the Columbia River, distant hills, and Mount Hood may be obstructed by new development. However, as most transit-oriented development is anticipated to occur west of I-5, the impacts on views of Mount Hood from I-5 should be relatively minor. Therefore, the indirect effect to visual quality from the Modified LPA for this LU is anticipated to be neutral.

Vancouver Downtown Landscape Unit

The Modified LPA may have an indirect effect of encouraging redevelopment in the more urban areas of this LU, particularly in areas near new LRT stations consistent with Vancouver's plans to accommodate growth by increasing land use density in areas served by high-capacity transit. Such development would be in compliance with the City of Vancouver's land use plans and regulations. New development could obstruct views of the project environment, as well as the Columbia River, distant hills in Portland, and Mount Hood. Indirect land use changes may occur primarily around the proposed transit stations in downtown Vancouver and near Evergreen Boulevard (including the Community Connector), as new areas are opened or removed due to the SR 14 interchange and adjustments to the Mill Plain intersection. Because these areas are already highly developed, potential new transit-oriented development is anticipated to have either no effect or a positive effect on the visual character, depending on the quality of design and materials used compared to the structures being replaced. The visual quality experienced by neighbors on local streets is unlikely to be noticeably changed, as new buildings would become part of the existing urban view. Travelers on I-5 are also unlikely to experience changes in views as views are largely limited to highway infrastructure. Therefore, the indirect effect on visual quality from the Modified LPA is anticipated to be neutral.

Greater Central Park Landscape Unit

The Greater Central Park LU includes the Fort Vancouver National Historic Site, Clark College, Officers Row, Pearson Field, Marshall Park, and Hudson's Bay High School. Most areas within the LU are either protected or developed. Therefore, indirect impacts to visual quality as a result of changed land use or substantially increased development density are not anticipated for this LU. Potential changes in the visual setting of historic properties are discussed in Section 3.8, Historic and Archaeological Resources.

Burnt Bridge Creek Landscape Unit

Riparian areas and steep slopes that define the visual character in this LU would not change, and improving local and regional traffic congestion is not likely to change land uses. Therefore, indirect impacts to visual quality from the Modified LPA are not anticipated for this LU.

Ruby Junction Landscape Unit

Indirect impacts to visual quality as a result of changed land use or substantially increased development density are not anticipated for this LU.

3.9.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

The following section identifies potential mitigation measures to address the long-term effects of the Modified LPA to visual quality.

Regulatory Requirements

- Meet the design standards of the Cities of Vancouver and Portland and the Tri-County Metropolitan Transportation District and the Clark County Public Transit Benefit Area Authority for visual quality, including street furniture and transit stations.
- Restore impacted roadsides in interchange and corridor areas in accordance with applicable vegetation and tree mitigation requirements.

Program-Specific Mitigation

The following Program-specific mitigation is recommended for the Modified LPA, as feasible.

Mitigation Common to All Landscape Units

- For local streets and transit stations, restore damaged landscapes, replant street trees, and provide enhanced landscapes to integrate the facilities into the community.
- Shield station and facility lighting.
- Minimize structural bulk, such as for ramps and columns.
- Design architectural features to blend with the surrounding community.
- Design gateways in coordination with applicable local plans including designs for landscaping, wall treatments, and other Program improvements.

Mitigation for Transit Stops and Stations

- Design transit structural and architectural elements to be context-sensitive, and system-related signage and transit patron cues to be consistent with other transit system elements within respective systems.

- Design the signal pole color, location, and style in accordance with the lighting district standards of the jurisdiction where the poles will be located (Portland or Vancouver).
- Integrate transit facilities into the design of the Community Connector.

Place-Specific Mitigation

Transit Stations and Park and Rides

- Conduct public design charrettes during the final design phases to refine the plans for each station area and park and ride.

Columbia River Landscape Unit

North Portland Harbor Crossings

- Preserve views of Mount Hood, to the extent practicable, for all users.

Hayden Island

- Integrate transit stations with the ground level, such as with landscaping.
- Evaluate surrounding views from the transit platform.
- Consult with the federally recognized tribes in the design process and provide opportunities to include cultural features such as public art, historic education, plazas, or indigenous canoe watercraft landing and taking off locations.

Hayden Island Bridgehead

- Separate structures to admit daylight, if feasible. Maintain the separation between bridge structures across the island to ensure daylight and viable landscape at ground level, if feasible.
- Explore the incorporation of preserved bridgehead character into final design.
- Consult with the federally recognized tribes in the design process and provide opportunities to include public art, historic education, plazas, water access, or other cultural features.
- Explore public art opportunities on Hayden Island to announce arrival in Oregon, including pylons, piers, and other structures.

Columbia River Spans

- Design the active transportation on the Columbia River bridges for as low-stress an environment as possible.
- Use art and landscaping to build anticipation of the river crossing in those approaching the main span, as feasible.
- Include lighting that would give expression to the architecture after dark, as feasible.

North Bank

- Incorporate a destination public open space under the bridge area, as feasible.
- Consult with the federally recognized tribes in the design process and provide opportunities to include cultural features such as public art, historic education, plazas, or water access.
- Encourage creating or enhancing spaces, events, or initiatives that activate open spaces and urban environments along the Main Street extension to the river. Enhancements may include public art, street furniture, bike and pedestrian facilities, popup markets and public events, or other measures.
- Activate open spaces and screen structures with landscaping.

- Use architecture or public art to mark entry and departure from each bridge.

Vancouver Downtown Landscape Unit

Transit Structure "Landing" in Vancouver

- Provide landscaping, public art, or other façade treatments for the walls of the light-rail landing structure, as feasible.
- Coordinate and design transit structures and facilities in conjunction with the Community Connector.

Park-and-Ride Facilities

- Incorporate design guidelines and consider input from Central Park and downtown interested parties and the general public.
- Buffer the park and ride from adjacent uses, mainly with landscaping but potentially with public art, fencing, or other elements, as feasible.
- Comply with City of Vancouver Design Standards and have plans reviewed by the Vancouver Design Review Committee.
- To the extent feasible, eliminate potential glare from the park-and-ride structure components.
- Incorporate public art reflective of the unique context at each park-and-ride facility.

McLoughlin Boulevard Crossing

- Coordinate lighting under structures with city and I-5 lighting.
- Keep the spaces beneath freeway structures clear of unauthorized uses to the extent possible.

Greater Central Park Landscape Unit

SR 14 Interchange

- Maintain existing vegetation wherever possible, particularly between the Kanaka Village and SR 14 ramps. Landscape plans should include plantings as visual screens. Replacement trees should be as large caliper trees as practical to replace screening value as quickly as possible.
- Provide visual and physical connections between under-bridge structures. Connect the Vancouver Land Bridge and Old Apple Tree Park with downtown Vancouver by combining improved sight lines, improved access, and integrated landscape design.
- Use Vancouver Land Bridge landscaping in new landscaped areas as feasible.
- Activate open spaces and screen structures with landscaping. Use landscape to organize the diversity and extent of open spaces associated with the interchanges and to screen the railroad berm.

Burnt Bridge Creek Landscape Unit

- Ensure compatibility of overpass approaches with neighborhoods with input from the neighborhood facing each end of the bridges, as feasible.
- Identify a local design theme for overpasses.

Ruby Junction Landscape Unit

No mitigation for construction impacts would be warranted in the Ruby Junction LU.

Mitigation for Temporary Effects

Regulatory Requirements

There are no regulatory requirements for temporary effects to visual quality, specifically. The Program would meet federal, state, and local design standards for light and glare.

Program-Specific Mitigation

- Follow standard construction specifications regarding the reduction of light and glare.
- Shield construction site lighting to reduce spillover light onto nearby residences and businesses, as feasible.
- Minimize visual obtrusiveness by locating construction equipment and stockpiling materials in less visually sensitive areas, when feasible, and in areas not visible from the road or to residents and businesses.
- Provide, as feasible, public areas to observe the construction and demolition processes, using them as an opportunity for public education.

3.10 Air Quality

Many natural and human activities generate air pollutants that can affect human and environmental health. Air quality is closely tied to transportation (including motor vehicles, trucks, and buses), which is a major contributor of air pollutants in the Portland-Vancouver area. This section evaluates the long-term and temporary effects of the No-Build Alternative and the network improvements of the Modified LPA for two types of air pollutants:

- Mobile source air toxics (MSAT). The Clean Air Act identifies 188 air toxics, of which MSAT are a subset of nine pollutants emitted by vehicles. These nine pollutants are also included in the Oregon Department of Environmental Quality's (DEQ) Toxic Air Contaminant Priority List.
- Criteria pollutants. These pollutants have federally established limits based on human health and environmental criteria.

Information presented in this section is based on the Air Quality Technical Report, including details of the emissions analyses for MSAT and criteria pollutants. Greenhouse gas emissions are discussed in Section 3.12, Energy, and Section 3.19, Climate Change.

3.10.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CPA LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with air quality has been updated in this Draft SEIS to include:

- Updated analysis to address National Ambient Air Quality Standards (NAAQS) and other recent federal guidance, such as FHWA's Updated Interim Guidance on Mobile Source Air Toxic Analysis in NEPA Documents (FHWA 2023a) and FHWA's Frequently Asked Questions for Conducting Quantitative MSAT Analysis for FHWA NEPA Documents (FHWA 2023b).
- Revised methodology based on the updated ODOT Air Quality Manual and WSDOT Guidance on Addressing Air Quality, Greenhouse Gas Emissions, and Energy for WSDOT projects.
- Removed an assessment for localized carbon monoxide at congested intersections, as the region's 20-year carbon monoxide maintenance period ended in 2017. Therefore, transportation projects in the region are no longer required to demonstrate conformity.
- Updated the analysis based on updated transportation modeling data.
- Calculated criteria pollutants using the U.S. Environmental Protection Agency's (EPA's) Motor Vehicle Emissions Simulator Model (MOVES) (version 3.1.0)[1], which is the version used in current regional modeling analyses in Oregon and Washington. CRC emissions estimates were developed using EPA's MOBILE6.2 model, which MOVES replaced.
- Deleted reference to the Portland Air Toxics Solution study, as it only projected emissions to 2017.
- Added a summary of Oregon State Toxic Air Contaminant Program, which was most recently amended in November 2021.

[1] As of August 2023, MOVES 4 is now the EPA's regulatory emissions modeling system. The EPA has provided a two-year grace period, meaning that MOVES 3 is still an acceptable and appropriate model for regional emissions analyses.

- Changes to the project footprint, as necessitated by changed conditions, and changes in existing land uses resulting in changes to proximity to sensitive receptors.

Table 3.10-1 compares the impacts and benefits of the CRC LPA to those of the Modified LPA as a result of the changes listed above, which include many updates in the analysis methodology and traffic modeling data. Based on the analysis described in this section, the effects of the Modified LPA would be similar to those of the CRC LPA. Overall, the Modified LPA would reduce the emissions of air quality pollutants compared to existing conditions.

Table 3.10-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Change in VMT used to calculate air pollutant emissions – Difference from Existing (2005 in CRC LPA and 2015 in Modified LPA).	• 40% (2030)	• 62% (2045)	• Variations in methodology such as the base year of analysis and MSAT study area.
MSAT Emissions (2030 in CRC LPA and 2045 in Modified LPA) – Difference from Existing (2005 in CRC LPA and 2015 in Modified LPA). [a]	• 1,3-Butadiene: -53% • Acetaldehyde: N/A • Acrolein: -52% • Benzene: -57% • Diesel Particulate Matter: -93% • Ethylbenzene: N/A • Formaldehyde: -48% • Naphthalene: -37% • Polycyclic Organic Matter: N/A	• 1,3-Butadiene: -100% • Acetaldehyde: -85% • Acrolein: -90% • Benzene: -70% • Diesel Particulate Matter: -88% • Ethylbenzene: -29% • Formaldehyde: -88% • Naphthalene: -94% • Polycyclic Organic Matter: -96%	• CRC LPA MSAT emissions are in units of pounds per summer day and Modified LPA MSAT emissions are in tons per year. • Additional differences include analysis years, updates to future volume projections, updates to federal air emissions standards, and updates to EPA's emission factor model.
Regional Criteria Pollutant Emissions (2030 in CRC LPA and 2045 in Modified LPA) – Difference from Existing (2005 in CRC LPA and 2015 in Modified LPA). [b]	• Carbon Monoxide (winter): -26% • Nitrogen Dioxide: -74% • Sulfur Dioxide: N/A • Volatile Organic Compounds: -56% • Total PM_{10}: -92% • Total $PM_{2.5}$: -91%	• Carbon Monoxide: -63% • Nitrogen Dioxide: -79% • Sulfur Dioxide: 9% • Volatile Organic Compounds: 25% • Total PM_{10}: 21% • Total $PM_{2.5}$: -48%	• CRC LPA Regional Criteria Pollutant Emissions are in tons per day and Modified LPA Regional Criteria Pollutant Emissions are in tons per year.

Source: CRC 2011

Note: 2019 is the baseline year for most existing conditions data. The exception is for outputs that rely on the Metro/RTC regional travel demand model, which has not yet updated its base year model from 2015. As a result, all Metro/RTC regional travel demand model outputs summarize 2015 data based on 2015 land use, population, and employment data.

a MSAT Emissions for CRC are in pounds per day and for Modified LPA are in tons per year.

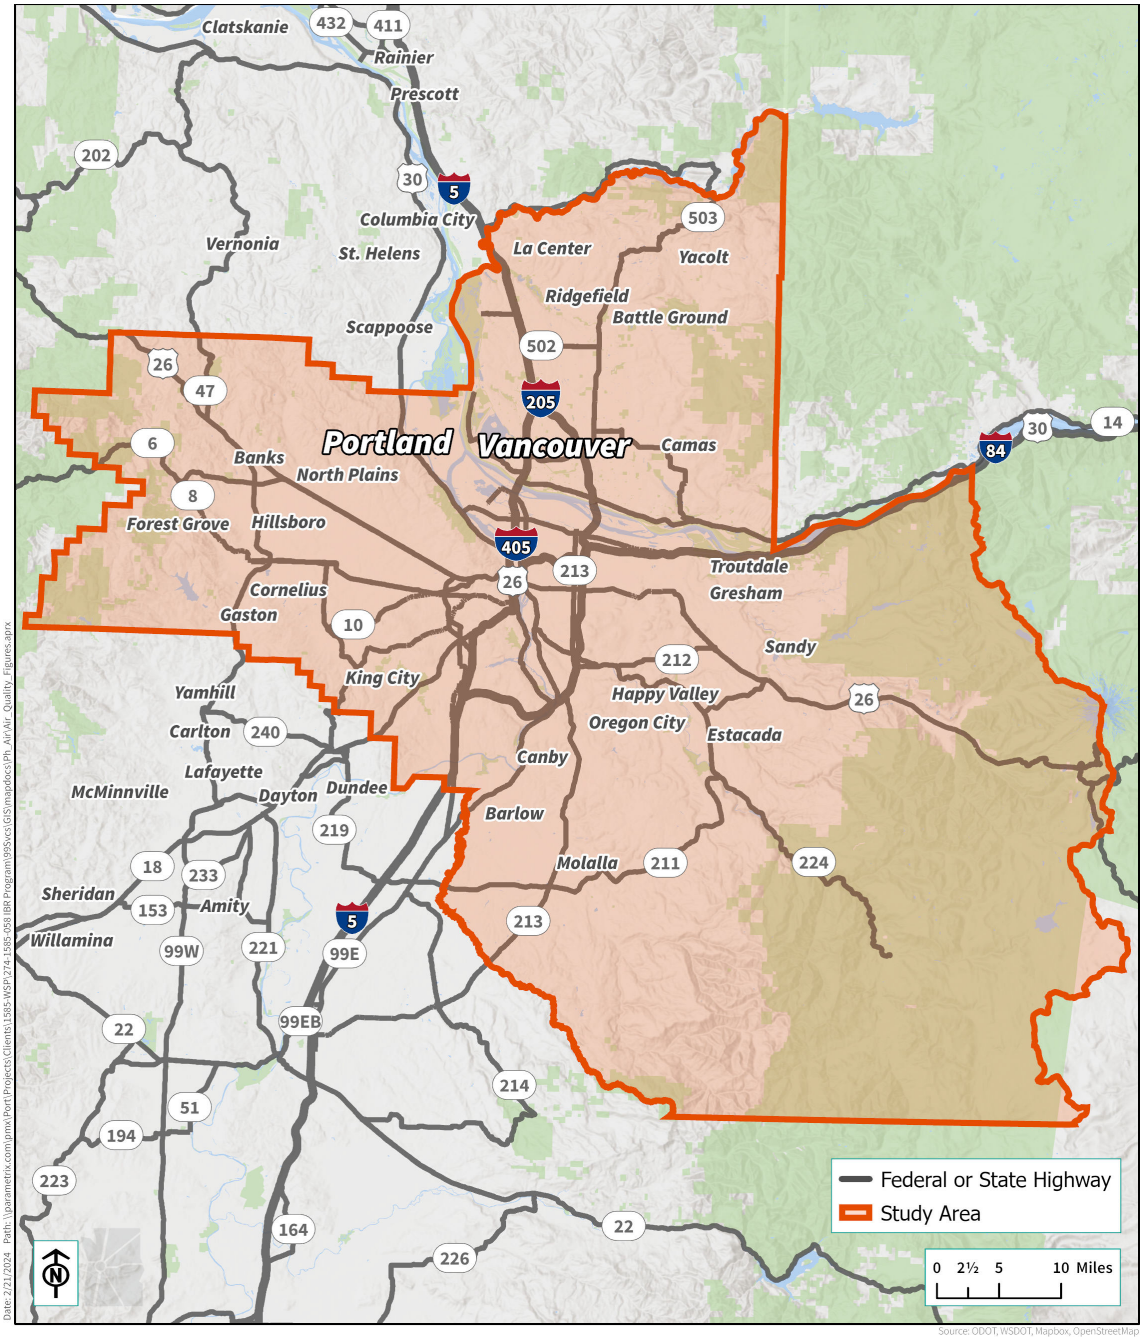
b Regional Criteria Pollutant Emissions for CRC are in tons per day and for Modified LPA are in tons per year.

CRC = Columbia River Crossing; EIS = Environmental Impact Statement; EPA = Environmental Protection Agency; LPA = Locally Preferred Alternative; MSAT = Mobile Source Air Toxics; N/A = not applicable; VMT = vehicle miles traveled

3.10.2 Existing Conditions

The study area is shown in Figure 3.10-1. The Oregon DEQ measures air pollutant levels with a network of air monitoring and sampling equipment at more than 40 sites throughout the state, including the study area. The Washington State Department of Ecology (Ecology) does not operate many monitors in the Vancouver area because the monitors operated by DEQ fulfill the federal monitoring requirements for the metropolitan area. Over the last 10 years, pollutant concentrations have been trending mostly downward for most locations, with most exceptions corresponding to wildfire smoke events. DEQ implements several programs that regulate emissions of air toxics and monitors ambient levels present at various locations across Oregon. DEQ uses this concentration data to develop strategies to reduce ambient levels of air toxics in the state. The Air Quality Technical Report includes tables of recent monitoring data for criteria pollutants and air toxics.

Figure 3.10-1. Air Quality Study Area



Air Quality Pollutants and Standards

Mobile Source Air Toxics

MSAT emissions are the subset of air toxics emitted by mobile sources. The priority MSAT pollutants include benzene, 1,3-butadiene, naphthalene, polycyclic organic matter, formaldehyde, acrolein, ethylbenzene, acetaldehyde, and diesel particulates. Exposure to these pollutants over time can affect human health. Unlike criteria pollutants, MSAT pollutants do not have regulatory standards.

The EPA's MOVES 3.1.0 model was used to estimate the MSAT emissions (in tons per year) for existing conditions, the No-Build Alternative and the Modified LPA. The analysis was performed according to FHWA guidance that recommends estimating emissions for roadway segments that are expected to have a change in volume of more than 5% compared to the No-Build Alternative. The roadway network used for the emissions analysis is shown by the roadway segments highlighted in Figure 3.10-2.

The MOVES model estimates emissions from this MSAT network based on details from regional travel demand modeling (traffic volumes, speeds, and vehicle mix) and region-specific MOVES inputs that describe the climate, fuel supply, and vehicle registration. DEQ and Ecology provided data files to run two MOVES models to determine the emissions on Oregon and Washington roadway segments, using regional conditions for each state. The Air Quality Technical Report presents details of the travel demand modeling assumptions, including the consideration of potential trip diversion.

Criteria Pollutants

The EPA has developed NAAQS for six major air pollutants. Areas previously designated nonattainment areas that are now in compliance with air quality standards are classified as "attainment" areas or "maintenance areas." A table of the current NAAQS is found in the Air Quality Technical Report.

The study area spans four counties in the Portland and Vancouver metropolitan areas; the EPA has designated both metropolitan areas as in attainment for all criteria pollutants. The area was previously designated as nonattainment for carbon monoxide and 1-hour ozone. As of October 2, 2017, the 20-year transportation conformity planning period associated with the Carbon Monoxide Maintenance Plan was completed. All measures and requirements contained in the Carbon Monoxide Maintenance Plan must be complied with until the EPA approves a revision to the state plan; however, transportation projects are no longer required to demonstrate NAAQS compliance with the transportation conformity requirements of 40 Code of Federal Regulations Part 93 subpart A.

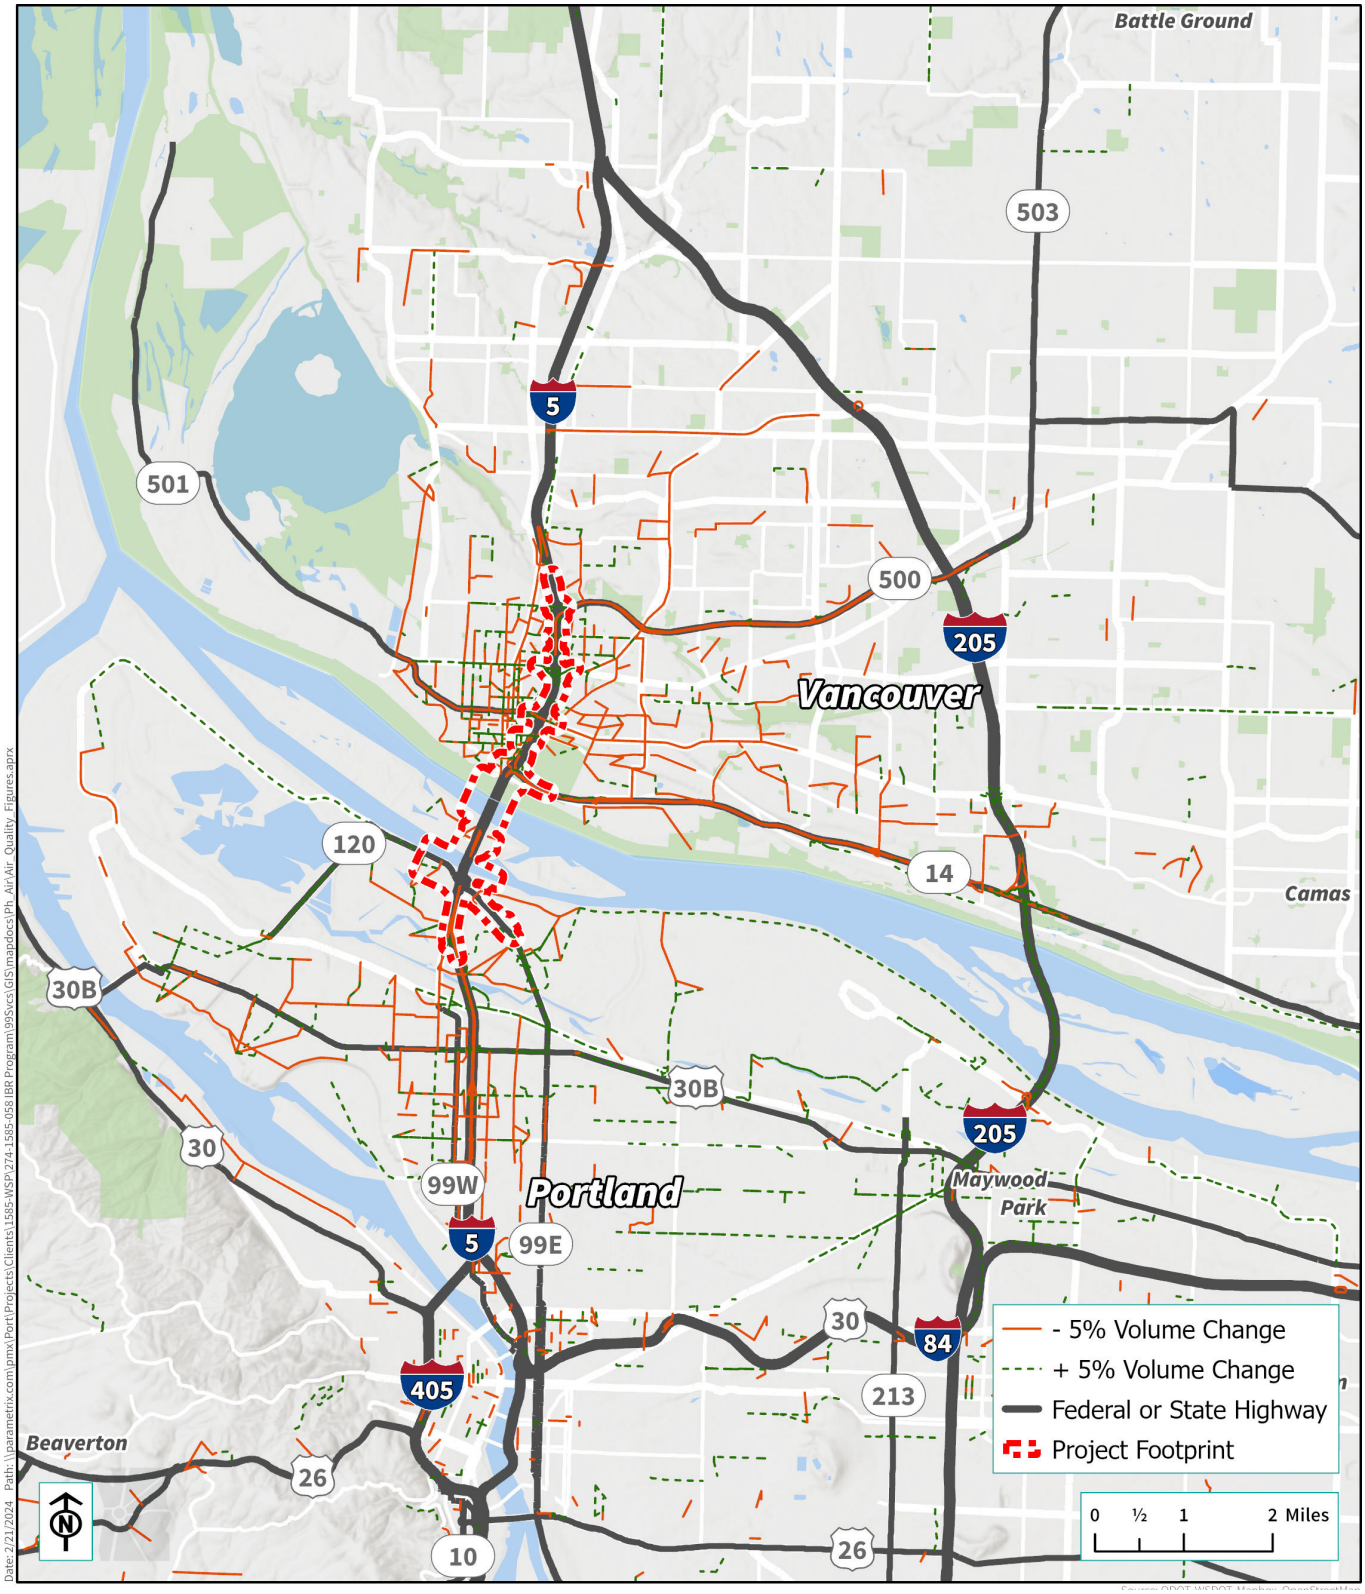
In 2005, EPA revoked the 1-hour ozone standard. At the time, the Portland-Vancouver region was subject to an ozone maintenance plan. The maintenance plan, including regional commitments for transportation strategies to address ozone, is still in effect.

The criteria pollutant emissions analysis followed the same methodology described for the MSAT analysis to provide a comparison of emissions between existing and future conditions.

As part of Oregon's State Implementation Plan for carbon monoxide, Transportation Control Measures (TCMs) were identified to reduce emissions by reducing vehicle use (DEQ 2004). Although transportation conformity is no longer required after the 20-year maintenance period, the following TCMs were applicable between the years of 2006 and 2017 and are examples of strategies that have been used to reduce emissions:

- Transit Service Increase: Regional transit service revenue hours (weighted by capacity) are increased 1% per year. The increase is assessed on the basis of a five-year rolling average of actual hours for assessments conducted between 2006 and 2017.

Figure 3.10-2. Roadway Emissions Analysis Network



- Bicycle Paths : Jurisdictions and government agencies must program a minimum total of 28 miles of bicycle paths or trails within the Portland metropolitan area between the years 2006 and 2017. Bicycle paths must be consistent with state and regional bikeway standards. A cumulative average of 5 miles of bikeways or trails per biennium must be funded from all sources in each Metropolitan Transportation Improvement Program. Facilities subject to this TCM must be in addition to those required for expansion or reconstruction projects under Oregon Revised Statutes 366.514.
- Pedestrian Paths : Jurisdictions and government agencies must program at least 9 miles of pedestrian paths in mixed-use centers between the years 2006 and 2017, including the funding of a cumulative average of 1.5 miles in each biennium from all sources in each Metropolitan Transportation Improvement Program. Facilities subject to this TCM must be in addition to those required for expansion or reconstruction projects under Oregon Revised Statutes 366.514, except where such expansion or reconstruction is located within a mixed-use center.

Sensitive Receptors

While air quality effects on all members of the population are evaluated, potential effects on sensitive receptors are of particular concern. Sensitive receptors are facilities that house or attract children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants. Hospitals, schools, and assisted living facilities are examples of sensitive receptors. Table 3.10-2 lists the hospitals, schools, and assisted living facilities located near the Program footprint. Many of these facilities are located in downtown Vancouver, west of the Program footprint.

3.10.3 Long-Term Effects

Table 3.10-3 summarizes the effects on air quality of the No-Build Alternative and the Modified LPA with the double-deck fixed-span, single-level fixed-span, and single-level movable-span configurations. Detailed analysis of the effects is provided in the following sections.

No-Build Alternative

Air pollutant emissions from the regional transportation system would continue, including from idling vehicles during bridge openings under the No-Build Alternative (Table 3.10-4 and Table 3.10-5). Although vehicle miles traveled (VMT) would increase substantially between now and 2045, emissions of most MSAT and criteria pollutants would go down because of more stringent regulation of fuels and emissions.

Modified LPA

The Modified LPA would not cause long-term adverse air quality impacts. Emissions reductions vary by pollutant. Decreases range from 29% to 100%, with minor differences between the Modified LPA and the No-Build Alternative (Table 3.10-4 and Table 3.10-5). Changes in criteria pollutant emissions compared to existing conditions range from reductions of up to 79% to increases of up to 25%, depending on the pollutant.

Air pollutant emissions are expected to be substantially lower in the future than under existing conditions for all pollutants evaluated, except SO_2, VOC, and total PM_{10}. The predicted emissions reduction would be almost entirely due to EPA regulations, fuel and engine standard improvements. Emissions reduction associated SO_2, VOC, and total PM_{10} would not outpace emissions increases caused by VMT growth.

Future 2045 emissions for the Modified LPA are less than 2045 No-Build Alternative for all pollutants. The emissions shown for the roadway segments are meant to present the difference between the No-Build Alternative and the Modified LPA—the MOVES model results do not represent the total emissions for the entire regional study area.

Compared to the No-Build Alternative, travel demand modeling that includes projected transit ridership and potential trip diversion to avoid tolls, showed the Modified LPA would lower emissions of MSAT and criteria pollutants by improving traffic flow and reducing VMT within the study area. Compared to the Modified LPA with the double-deck fixed-span configuration, the Modified LPA with the single-level fixed-span (any bridge type option) or the single-level movable-span configuration may slightly reduce operational vehicle emissions because of the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.

Table 3.10-3. Summary of Air Quality Effects of the No-Build Alternative and the Modified LPA as Compared to Existing Conditions

1	2	3	4	5
Effect	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One or Two Auxiliary Lanes, with or without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Single-Level Fixed-Span Configuration, a One or Two Auxiliary Lanes, with or without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One or Two Auxiliary Lanes, with or without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options
VMT in MSAT study area	• 3,537,900 VMT in 2045 (66% increase compared to existing conditions).	• 3,455,400 VMT in 2045 (62% increase compared to existing conditions).	• Same as effects listed in Column 3.	• Same as effects listed in Column 3.
Changes in air pollutant emissions	• Future regional emissions would be substantially lower than existing emissions for all MSAT, CO, NO_X, and $PM_{2.5}$. Future regional emissions of SO_2, VOC would be up to 25% higher than existing conditions due to increased VMT.	• Similar to No-Build Alternative (slightly lower emissions than No-Build Alternative due to reduced VMT).	• Similar to effects listed in Column 3, but may slightly reduce operational emissions due to the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.	• Similar to effects in Column 4, except for a minor increase in air quality pollutants due to vehicles idling during bridge openings. There would be fewer bridge openings than with the No-Build Alternative.
Changes in MSATs emissions (2045)	• 1,3-Butadiene: 100% reduction • Acetaldehyde: 82% reduction • Acrolein: 89% reduction • Benzene: 69% reduction • Diesel Particulate Matter: 86% reduction • Ethylbenzene: 29% reduction • Formaldehyde: 86% reduction • Naphthalene: 93% reduction • Polycyclic Organic Matter: 93% reduction	• 1,3-Butadiene: 100% reduction • Acetaldehyde: 85% reduction • Acrolein: 90% reduction • Benzene: 70% reduction • Diesel Particulate Matter: 88% reduction • Ethylbenzene: 29% reduction • Formaldehyde: 88% reduction • Naphthalene: 94% reduction • Polycyclic Organic Matter: 96% reduction	• Similar to effects listed in Column 3, but may slightly reduce operational emissions due to the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.	• Similar to effects in Column 4, except for a minor increase in air pollutants due to vehicles idling during bridge openings. There would be fewer bridge openings than with the No-Build Alternative.

1	2	3	4	5
Changes in regional criteria pollutant emissions	• Carbon Monoxide: 61% reduction • Nitrogen Dioxide: 75% reduction • Sulfur Dioxide: 16% increase • Volatile Organic Compounds: 26% increase • Total PM_{10}[a]: 46% increase • Total $PM_{2.5}$[b]: 39% reduction	• Carbon Monoxide: 63% reduction • Nitrogen Dioxide: 79% reduction • Sulfur Dioxide: 9% increase • Volatile Organic Compounds: 25% increase • Total PM_{10}[a]: 21% increase • Total $PM_{2.5}$[b]: 48% reduction	• Similar to effects in Column 3, but may slightly reduce operational emissions due to the lower profile grade, which would reduce acceleration and braking of vehicles crossing the bridges.	• Similar to effects in Column 4, except for a minor increase in air quality pollutants due to vehicles idling during bridge openings. There would be fewer bridge openings than with the No-Build Alternative.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.
LPA = Locally Preferred Alternative; MSAT = Mobile Source Air Toxics; $PM_{2.5}$ = particulate matter less than or equal to 2.5 microns in diameter; PM_{10} = particulate matter less than or equal to 10 microns in diameter; VMT = vehicle miles traveled

Table 3.10-4. Mobile Source Air Toxics Emissions (Tons per Year)

Pollutant	Existing (2015)	No-Build Alternative (2045)	Modified LPA (2045)[a]	Modified LPA Difference from Existing	Modified LPA Difference from No-Build Alternative
MSAT Study Area Daily VMT	2,128,200	3,537,900	3,455,400	62%	-2%
1,3-Butadiene	0.7	0.0	0.0	-100%	0%
Acetaldehyde	2.4	0.4	0.4	-85%	-14%

Benzene	14.2	4.3	4.3	-70%	-1%
Diesel Particulate Matter	10.8	1.6	1.3	-88%	-14%
Ethylbenzene	19.0	13.5	13.4	-29%	-1%
Formaldehyde	3.61	0.51	0.45	-88%	-12%
Naphthalene	0.47	0.03	0.03	-94%	-7%
Polycyclic Organic Matter	0.19	0.01	0.01	-96%	-42%

Note: Percentage differences calculated prior to rounding.
a The data for the Modified LPA applies to all design options except the two auxiliary lane option.
LPA = Locally Preferred Alternative; MSAT = Mobile Source Air Toxics; VMT = vehicle miles traveled

Table 3.10-5. Criteria Pollutant Emissions (Tons per Year)

Pollutant	Existing (2015)	No-Build Alternative (2045)	Modified LPA (2045)[a]	Modified LPA Difference from Existing	Modified LPA Difference from No-Build Alternative
MSAT Study Area Daily VMT	2,128,200	3,537,900	3,455,400	62%	-2.3%
Carbon Monoxide	4,355	1,687	1,597	-63%	-5.3%
Nitrogen Dioxide	897	226	184	-79%	-18.5%
Sulfur Dioxide	2.4	2.8	2.6	9%	-5.7%
Volatile Organic Compounds	662	830	826	25%	-0.6%
Total PM_{10}[b]	46.0	67.1	55.9	21%	-16.6%
Total $PM_{2.5}$[c]	18.5	11.3	9.6	-48%	-14.5%

Note: Percentage differences calculated prior to rounding.
a The data for the Modified LPA applies to all design options except the two auxiliary lane option.
b Total PM_{10} emissions are the sum of PM_{10} exhaust, PM_{10} brake wear, and PM_{10} tire wear.
c Total $PM_{2.5}$ emissions are the sum of $PM_{2.5}$ exhaust, $PM_{2.5}$ brake wear, and $PM_{2.5}$ tire wear.
LPA = Locally Preferred Alternative; MSAT = Mobile Source Air Toxics; $PM_{2.5}$ = particulate matter less than or equal to 2.5 microns in diameter; PM_{10} = particulate matter less than or equal to 10 microns in diameter; VMT = vehicle miles traveled

The Modified LPA with the double-deck fixed-span configuration and the single-level fixed-span configuration (any bridge type option) would eliminate emissions from idling during a bridge opening. The Modified LPA with the single-level movable-span configuration would still result in idling and emissions due to bridge openings; however, because it would have a higher vertical navigation clearance than the existing bridge, it could result in fewer bridge openings and reduced idling compared to the No-Build Alternative. Because the different bridge configurations would not result in meaningfully different regional VMT and speed, there was no change to the regional travel demand model output, and no additional air quality modeling was warranted. The emissions are considered to be the same as discussed above for the Modified LPA.

As discussed in the Navigation Technical Report, the configuration ultimately selected would affect navigation patterns. However, emissions from marine vessels were not evaluated because it is anticipated there would be no change in vessel idling emissions. Currently, bridge openings are scheduled as needed so vessels can pass with limited need for idling. The Modified LPA incorporating any of the configuration or bridge type options would result in either the same or less emissions from idling vessels. It is possible that marine traffic could increase if the need for bridge openings is eliminated; while the potential increase in marine traffic is beyond the scope of this project to predict it would be anticipated that the increased marine traffic would not require a bridge opening and therefore not result in marine idling.

Compared to the Modified LPA with one auxiliary lane, the analysis of the long-term effects of the Modified LPA with two auxiliary lanes using the regional travel demand model shows no statistical difference in pollutant emissions (Table 3.10-6 and Table 3.10-7); pollutant emissions are within a 1.5% difference.

As in the case of the configuration and bridge type options described above, the long-term effect on air quality of the Modified LPA would be the same for any of the design options except the two auxiliary lane options (i.e., with or without the I-5 C Street ramps at the SR 14 interchange, with the centered I-5 mainline or the westward shift, and with each of the park-and-ride site options). Because design options other than the two auxiliary lane option would not result in meaningfully different regional VMT and speed, no additional air quality modeling was conducted.

Table 3.10-6. Mobile Source Air Toxics Emissions for the Modified LPA with One or Two Auxiliary Lanes (Tons per Year)[a]

Pollutant	Modified LPA with One Auxiliary Lane (2045)	Modified LPA with Two Auxiliary Lanes (2045)	Difference Between Modified LPA with One and Two Auxiliary Lanes
MSAT Study Area Daily VMT	3,455,400	3,462,400	0.2%
1,3-Butadiene	0.00	0.00	0.0%
Acetaldehyde	0.4	0.4	-0.9%
Acrolein	0.02	0.02	-0.6%
Benzene	4.3	4.3	0.0%
Diesel Particulate Matter	1.3	1.3	-0.9%
Ethylbenzene	13.4	13.4	0.0%
Formaldehyde	0.45	0.45	-0.7%
Naphthalene	0.03	0.03	-0.2%

Pollutant	Modified LPA with One Auxiliary Lane (2045)	Modified LPA with Two Auxiliary Lanes (2045)	Difference Between Modified LPA with One and Two Auxiliary Lanes
Polycyclic Organic Matter	0.01	0.01	0.0%

a Data in this table apply to all design options, unless otherwise indicated.
LPA = Locally Preferred Alternative; MSAT = Mobile Source Air Toxics; VMT = vehicle miles traveled

Table 3.10-7. Criteria Pollutant Emissions for the Modified LPA with One or Two Auxiliary Lanes (Tons per Year)[a]

Pollutant	Modified LPA with One Auxiliary Lane (2045)	Modified LPA with Two Auxiliary Lanes (2045)	Difference Between Modified LPA with One and Two Auxiliary Lanes
MSAT Study Area Daily VMT	3,455,400	3,462,400	0.2%
Carbon Monoxide	1,597	1,596.1	0.0%
Nitrogen Dioxide	184	181.6	-1.4%
Sulfur Dioxide	2.6	2.6	0.0%
Volatile Organic Compounds	826	825.5	0.0%
Total PM_{10}[b]	55.9	55.3	-1.2%
Total $PM_{2.5}$[c]	9.6	9.5	-1.0%

a Data in this table apply to all design options, unless otherwise indicated.
b Total PM_{10} emissions are the sum of PM_{10} exhaust, PM_{10} brake wear, and PM_{10} tire wear.
c Total $PM_{2.5}$ emissions are the sum of $PM_{2.5}$ exhaust, $PM_{2.5}$ brake wear, and $PM_{2.5}$ tire wear.

MSAT Health Effects

Within the study area, there may be localized areas where ambient concentrations of MSAT with the Modified LPA could be different from the No-Build Alternative. The magnitude and duration of potential localized concentration increases cannot be reliably quantified because of uncertainty in future emissions, weather patterns, exposure pathways, and causation of effects.

In FHWA's view, the information needed to credibly predict Program-specific health impacts due to changes in MSAT emissions is incomplete or unavailable. The outcome of such an assessment, adverse or not, would be influenced more by the uncertainty introduced into the process through assumption and speculation than by any genuine insight into the actual health impacts directly attributable to MSAT exposure associated with a proposed action.

Sensitive Receptors

Some occupants of hospitals, schools, assisted living facilities and other sensitive receptors are more susceptible to the adverse effects of air pollutants than the general public. All of the design options would have the same air quality effect on sensitive receptors in the area (as listed in Table 3.10-2), except the Modified LPA with I-5 mainline westward shift would shift traffic closer to the sensitive receptors, which are located west of the Program footprint and could change localized pollutant emissions. Because the Portland

and Vancouver metropolitan areas are in attainment for NAAQS, no further analysis is necessary to confirm that the Modified LPA would not result in pollutant concentrations in excess of the NAAQS.

3.10.4 Temporary Effects

No-Build Alternative

The No-Build Alternative would not involve construction and therefore would not result in construction-related air quality effects.

Modified LPA

Construction of the Modified LPA under any of the design options includes construction of the new bridges and removal of the existing Interstate Bridge. Construction-related activities would result in temporary air emissions, which could include increases in particulate matter in the form of fugitive dust (from demolition, ground clearing and preparation, grading, stockpiling of materials, on-site movement of equipment, and transportation of construction materials) and exhaust emissions from material delivery trucks, construction equipment, and workers' private vehicles. Dust emissions increase during dry weather, construction activities, or high wind conditions. Temporary impacts to air quality from construction activities would occur during the 9- to 15-year Program-wide construction period, which is expected to last from 2 to 10 years in specific locations. Although this construction duration is longer than the 5 years usually considered as temporary under transportation conformity rules (40 CFR 93.123), these rules do not apply to areas like Portland, which are in attainment for all NAAQS. Locations of elevated emissions would likely occur directly next to the construction activities, staging areas, and material hauling routes. All design options of the Modified LPA are expected to have similar temporary construction effects.

At this design stage, the Program has not developed detailed construction sequencing plans, which depend on funding, permitting, and other future considerations. Once these plans are developed, some areas located near concentrations of construction activity may be exposed to elevated levels of emissions. To better understand the potential for increased air emissions near construction sites, particularly for construction activities near sensitive receptors, the IBR Program team reviewed the example of the Dan Ryan Expressway, which had similar scope to the IBR Program. During construction of the Dan Ryan Expressway, air monitoring was conducted at 27 sites—at schools, parks, public housing, and public facilities—where the population was expected to be more sensitive to air contaminants. The monitored pollutants included total dust, respirable silica, lead, asbestos, polycyclic aromatic hydrocarbons (as diesel components), PM_{10}, and $PM_{2.5}$. Air monitoring was conducted during the construction period (from January 2005 until October 2007) and federal air quality standards were not exceeded. The results from the Dan Ryan Expressway project indicate that the construction activities for the Modified LPA should not result in violations of air quality standards and should not pose an undue health risk to the neighboring communities, including sensitive populations. More information on the Dan Ryan Expressway project can be found in the Air Quality Technical Report.

3.10.5 Indirect Effects

Indirect effects are those caused at a later time or farther away, but that are still reasonably foreseeable. The Modified LPA, under any of the design options, may indirectly encourage development, particularly in light-rail station areas, due to improved bicycle, pedestrian, highway, and transit access in Portland and Vancouver. Such development could generate additional traffic, which would increase air emissions; however, because the Modified LPA would provide additional transportation options such as transit and nonmotorized facilities, any increase in emissions is expected to be minor. As described Section 3.4, Land Use and Economic Activity, the magnitude and location of development facilitated by the Modified LPA would be consistent with all local and regional land use plans, and the IBR Program is not expected to result in urban sprawl, which

tends to increase air emissions. No additional indirect effects would occur under the Modified LPA. All design options of the Modified LPA are expected to have similar indirect effects.

3.10.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

The requirements of the Oregon and Washington State Implementation Plans would continue to be implemented by the states; there are no regulatory requirements that would be directly implemented by the IBR Program.

Program-Specific Mitigation

Long-term air quality impacts are not expected to occur because of the Modified LPA, and Program-specific mitigation for long-term impacts is not proposed.

Temporary Effects

There are no thresholds associated with the temporary effects to air quality. Although there is no mitigation required to meet applicable emissions thresholds, measures would be required to protect and minimize temporary effects on air quality during construction. ODOT, WSDOT, and all project contractors would comply with standard and regulatory mitigation measures. As construction phasing plans and mitigation measures are further developed, potential air quality impacts to sensitive receptors will be considered, particularly those due to prolonged construction emissions and/or simultaneous or sequential construction activities. Best management practices, including strategies to reduce fugitive dust and reduce vehicle idling, would be implemented to reduce and mitigate air quality emissions during construction.

Regulatory Requirements

To protect and minimize temporary effects on air quality during construction, standard and regulatory mitigation measures such as best management practices would be implemented.

Construction contractors would be required to comply with the following standard and regulatory air quality measures in Oregon:

- Division 208 of OAR 340.
- ODOT Standard Specifications Section 290.
- The Clean Diesel Construction Standard (OAR-731-005-0800).
- Oregon House Bill 2007, known as the “Clean Diesel Bill.”
- The City of Portland Clean Air Construction Program to reduce diesel emissions by implementing a standard set of idle reduction and diesel equipment requirements on job sites.

Standard and regulatory mitigation measures for air quality in Washington include:

- WSDOT Standard Specifications for Road, Bridge, and Municipal Construction, Section 1.07.5(4).
- Fugitive dust control best management practices set forth in the Associated General Contractors of Washington Education Foundation and Fugitive Dust Task Force pamphlet, “Guide to Handling Fugitive Dust From Construction Projects.”

Program-Specific Mitigation

- Through contract specifications, encourage all contractors to minimize impacts to surrounding communities such as using newer low-emitting construction equipment and electric equipment, and avoiding haul routes through residential areas.

3.11 Noise and Vibration

This section summarizes the guidelines and standards for evaluating noise and vibration impacts, existing noise levels, the long-term and temporary noise and vibration levels from the No-Build Alternative and the Modified Locally Preferred Alternative (LPA), and mitigation measures for noise and vibration impacts. The information presented in this section is based on the Noise and Vibration Technical Report. Section 3.16, Ecosystems, provides information about noise-related effects on fish and wildlife within the study area's environment.

How do decibels relate to sound levels?

The human ear generally cannot detect very slight changes in noise levels. The smallest change in noise level that a human ear can perceive is about 3 decibels, while increases of 5 decibels or more are clearly noticeable. For most people, a 10-decibel increase in noise levels is perceived as a doubling of sound level.

3.11.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC LPA. Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with noise and vibration has been updated in this Draft SEIS to include:

- Updated existing noise measurements for traffic noise modeling and transit noise assessment.
- Updated all peak-hour and peak-truck-hour traffic data for traffic noise assessment.
- Updated all transit operation assumptions for transit noise and vibration assessment.
- Updated the locations of sensitive noise receptors based on changes in land use.
- New FHWA, WSDOT, and ODOT traffic noise assessment guidance and FTA noise and vibration guidance.
- Developed new traffic noise model and transit noise and vibration assessment models.
- Changes to the project footprint, as necessitated by changed conditions, and in existing land uses resulting in changes to proximity to sensitive receptors.

Table 3.11-1 compares the impacts and benefits between the CRC LPA and the Modified LPA as a result of the changes listed above. Based on the analysis described in this section, the Modified LPA would have fewer residences, and other noise-sensitive land uses, that would have an increase in highway or transit noise levels or ground-borne vibrations that would meet FHWA's or FTA's threshold to be considered an impact. Key modifications that led to this decrease in highway noise, transit noise, and vibration impacts include reductions to the highway footprint at the I-5/SR 500/39th Street interchange and the realignment of light-rail from downtown Vancouver to along the I-5 corridor.

Table 3.11-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS (without Mitigation)	Modified LPA Effects as Identified in this Section (without Mitigation)	CRC LPA Effects as Identified in the 2011 Final EIS (with Mitigation)	Modified LPA Effects as Identified in this Section (with Mitigation)	Explanation of Differences
Number of receptors that exceed highway noise thresholds	325	198	110	121	Reduced highway footprint at the I-5/SR 500/39th St Interchange.
Number of receptors with moderate transit noise impact levels	31	12	0	0	Moved transit alignment from downtown Vancouver to along I-5.
Number of receptors with severe transit noise impact levels	0	0	0	0	No change.
Number of receptors with transit vibration impacts	15	13	0	13	Impacts associated with the Modified LPA are in proximity to the direct fixation trackway in downtown Vancouver.

3.11.2 Existing Conditions

Understanding Sound

How Sound Levels Are Measured

Two aspects of sound that partially determine its impacts are loudness and frequency. The loudness of sound is a result of its energy, which is measured in decibels (dB); an A-weighted decibel (dBA) measures noise as perceived by the human ear.

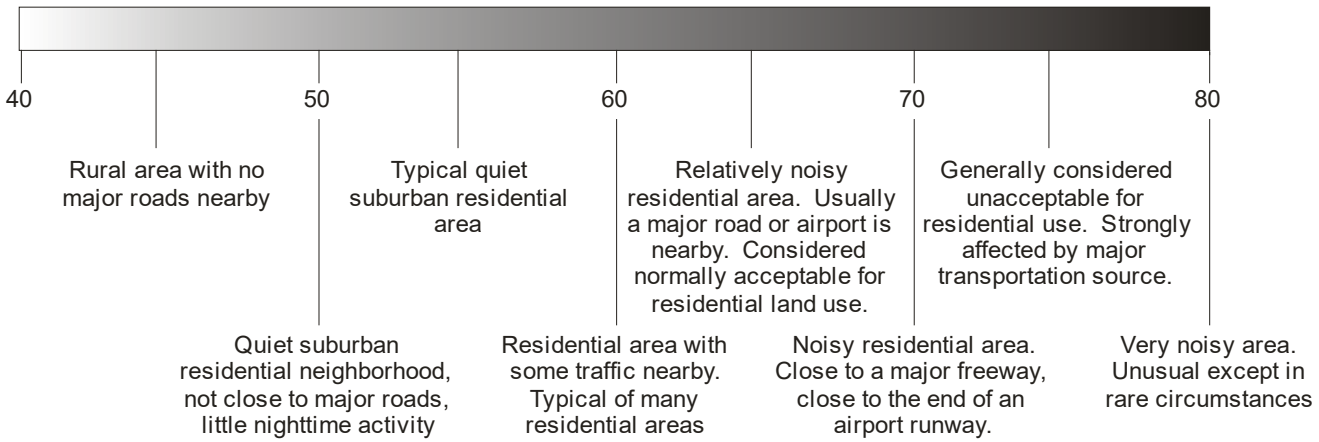
Most noise levels at a given location vary over time. To account for this variation, a commonly used noise measurement is the equivalent sound pressure level (L_{eq}). This noise analysis uses L_{eq} to describe traffic and transit noise at schools, libraries, and other noise-sensitive institutional uses. Consistent with FTA noise regulations, this analysis also gives more weight to noise that occurs at night (from 10:00 p.m. to 7 a.m.). This method produces the *day-night equivalent sound level*, which is abbreviated as L_{dn}.

The Noise and Vibration Technical Report (Chapter 2.4) provides detailed methods for sound level monitoring and noise model development.

Typical Noise Levels

Figure 3.11-1 shows typical community noise levels. Figure 3.11-2 shows how some common noise sources are perceived by the human ear.

Figure 3.11-1. Typical Community Noise Levels (in L_{dn})



Source: FTA 1995

L_{dn} = day-night equivalent sound level Noise Criteria and Analysis Methods

Highway Traffic Noise Criteria

Federal, state, and local governments regulate and provide guidance for acceptable noise and vibration levels to ensure the public's health and wellbeing. For highways and transit systems, FHWA, FTA, ODOT, and WSDOT have developed guidance for assessing noise and vibration impacts. This assessment also considers applicable regulations from the City of Portland and City of Vancouver.

Table 3.11-2 summarizes FHWA's traffic noise abatement criteria. ODOT is responsible for implementing the FHWA regulations in Oregon, and WSDOT administers the FHWA regulations in Washington. Under ODOT policy, a traffic noise impact occurs if predicted noise levels approach within 2 dBA or exceed the FHWA criteria; the criteria apply to the peak noise impact hour. Under WSDOT policy, a traffic noise impact occurs if predicted noise levels approach within 1 dBA of or exceed the FHWA criteria. Both agencies consider an increase of 10 dBA or more to be a substantial impact.

Figure 3.11-2. Typical Noise Source and Human Perception of Sound Levels

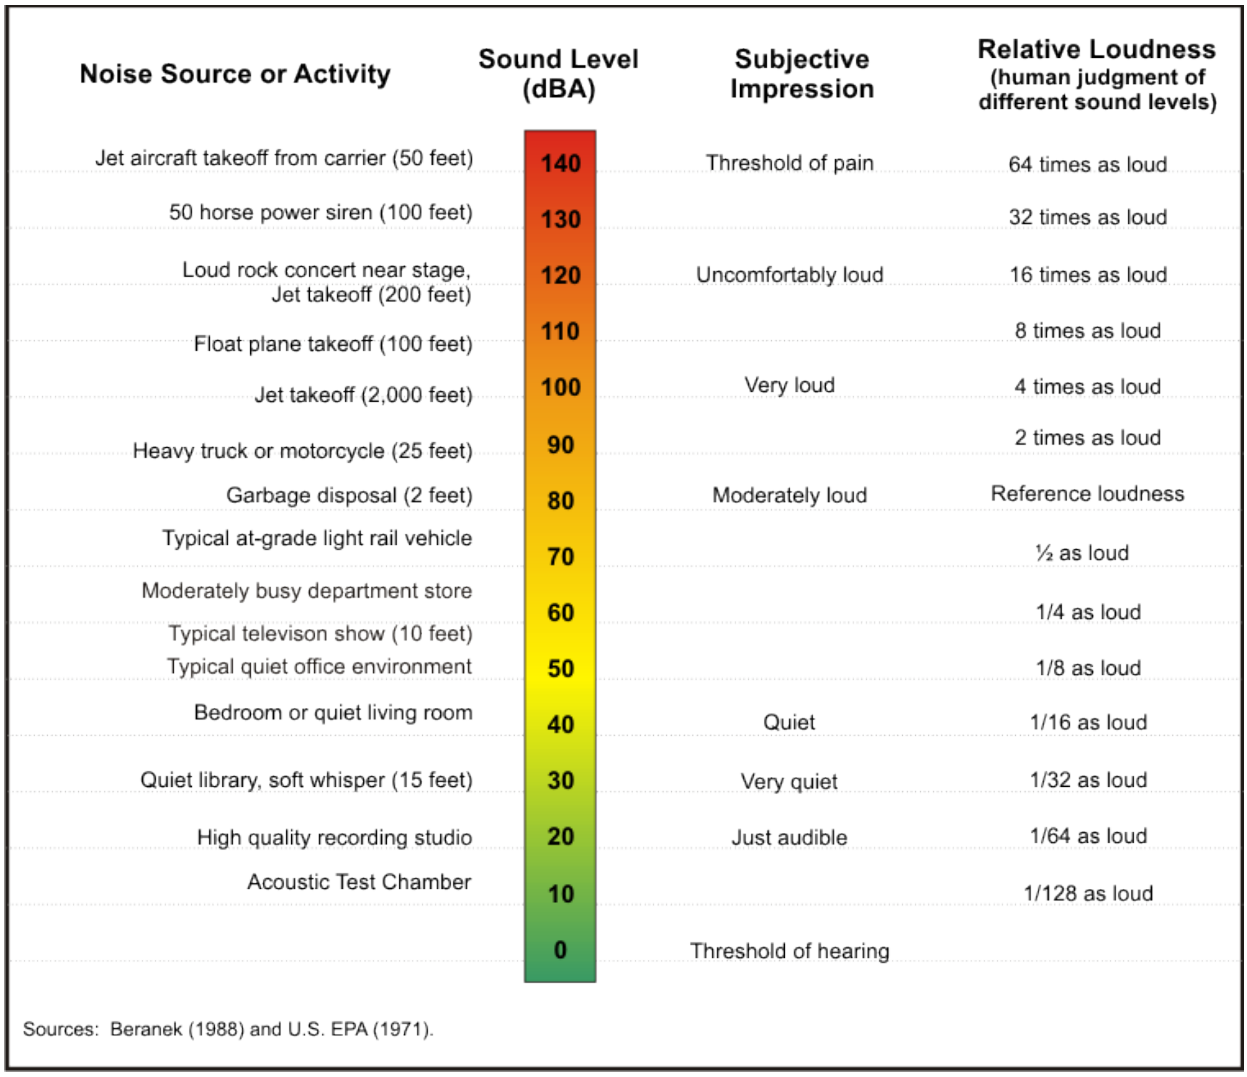


Table 3.11-2. FHWA Traffic Noise Abatement Criteria by Land Use Category

Activity Category	Hourly $L_{eq}(h)$ (dBA)	Description of Activity
A	57 (exterior)	Lands on which serenity and quiet are of extraordinary significance and serve an important public need and where the preservation of those qualities is essential if the area is to continue to serve its intended purpose.
B	67 (exterior)	Residential (single and multifamily units).
C	67 (exterior)	Active sports areas, amphitheaters, auditoriums, campgrounds, cemeteries, day care centers, hospitals, libraries, medical facilities, parks, picnic areas, places of worship, playgrounds, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, recreation areas, Section 4(f) sites, schools, television studios, trails, and trail crossings.
D	52 (interior)	Auditoriums, day care centers, hospitals, libraries, medical facilities, places of worship, public meeting rooms, public or nonprofit institutional structures, radio studios, recording studios, schools, and television studios.

Activity Category	Hourly $L_{eq}(h)$ (dBA)	Description of Activity
E	72 (exterior)	Hotels, motels, offices, restaurants/bars, and other developed lands, properties or activities not included in A–D or F. Includes undeveloped land permitted for these activities.
F	N/A	Agriculture, airports, bus yards, emergency services, industrial logging, maintenance facilities, manufacturing, mining, rail yards, retail facilities, shipyards, utilities (water resources, water treatment, electrical), and warehousing
G	N/A	Undeveloped lands that are not permitted

Note: The noise abatement criteria for Categories B, C, and E also apply to undeveloped land with building permits.
Leq(h) = A-weighted (dBA) hourly equivalent steady state sound levels used for impact determination and are not design standards for abatement; N/A = not applicable

Construction Noise Criteria

In Washington, daytime construction noise is exempt from regulations in the Washington Administrative Code (WAC). Table 3.11-3 presents the WAC maximum allowable nighttime noise levels, above which the governing jurisdiction would require obtaining a noise variance. WAC noise control regulations apply to park-and-ride lots and transit stations (Table 3.11-3 and Table 3.11-4).

Table 3.11-3. Washington State Noise Control Regulation

Source of Noise	Receiver of Noise:[a] Residential	Receiver of Noise:[a] Commercial	Receiver of Noise:[a] Industrial
Residential	45	57	60
Commercial	47	60	65
Industrial	50	65	70

a Maximum allowable nighttime sound level in dBA. Sound level limits are based on measurements taken at the property lines of receiving properties.
dBA = A-weighted decibels

In addition to the noise standards listed in Table 3.11-3, there are exemptions for short-term noise exceedances, including those outlined in Table 3.11-4, based on the minutes per hour that the noise limit is exceeded.

Table 3.11-4. Washington State Exemptions for Short-Term Noise Exceedances

Statistical Descriptor [a]	Minutes Exceeded Per Hour	Adjustment to Maximum Sound Level
L_{25}	15 (25% of 1 hour)	+5 dBA
$L_{8.3}$	5 (8.3% of 1 hour)	+10 dBA
$L_{2.5}$	1.5 (2.5% of 1 hour)	+15 dBA

a L_{25}, $L_{8.3}$, and $L_{2.5}$ are the noise levels that are exceeded 25%, 8.3%, and 2.5% of the time (1 hour, in this case).
dBA = A-weighted decibels

Section 00292.32 of the ODOT Standard Specifications (Section 00292.32) includes construction noise abatement measures that apply to highway construction activities within Oregon. These abatement measures are considered mitigation and are discussed in Section 3.11.7.

Federal Transit Administration Noise Criteria

The FTA Transit Noise and Vibration Impact Assessment Manual provides FTA transit noise impact criteria applicable to noise generated by light-rail transit (FTA 2018). The FTA noise impact criteria identify the following noise-sensitive land use categories:

- **Category 1:** Buildings or parks where quiet is an essential element of their purpose.
- **Category 2:** Residences and buildings where people normally sleep. This includes residences, hospitals, and hotels where nighttime sensitivity is assumed to be of utmost importance.
- **Category 3:** Institutional land uses with primarily daytime and evening use. This category includes schools, libraries, churches, office buildings, and other commercial and industrial land uses.

Under these criteria, the degree to which transit operations are allowed to change the overall noise environment is reduced with increasing levels of existing noise. FTA's criteria include two impact levels, shown in Figure 3.11-3 and summarized below:

- **Severe Impact:** Project-generated noise in this range is likely to cause a high level of community annoyance. With severe impacts, alternative project alignments should be considered in an effort to avoid severe impacts.
- **Moderate Impact:** In this range, other project-specific factors must be considered to determine the magnitude of the impact and the need for mitigation. These other factors can include the predicted increase over existing noise levels, the types and number of noise-sensitive land uses affected, existing outdoor-indoor sound insulation, and the cost-effectiveness of mitigating noise to more acceptable levels.

No impact occurs when noise levels remain below the noise thresholds, which are dependent on land uses and existing noise levels.

Typically, state regulations are more stringent than FTA criteria, and in such cases, state regulations are used to estimate impacts from stationary noise sources. For example, the Oregon Department of Environmental Quality regulations were used to estimate impacts from the proposed expansion of the Ruby Junction Maintenance Facility and Hayden Island light-rail station (shown in Table 3.11-5). However, FTA criteria still apply and are used to determine noise impacts from stationary sources where there are no state or local noise regulations or where FTA criteria are more stringent.

Figure 3.11-3. Federal Transit Administration Transit Noise Impact Criteria

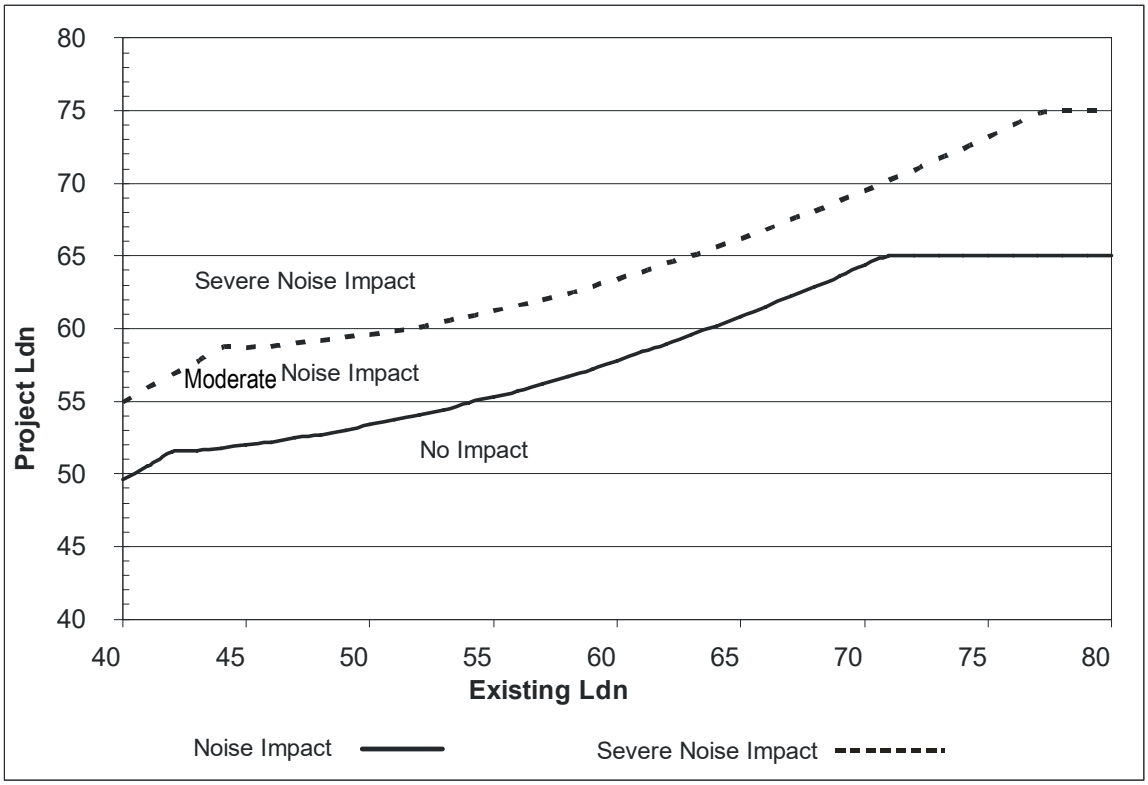

Table 3.11-5. Oregon Department of Environmental Quality Industrial and Commercial Noise Source Standards

Statistical Descriptor	Existing Noise Source (dBA): 7 a.m. to 10 p.m.	Existing Noise Source (dBA) 10 p.m. to 7 a.m.	New Noise Source (dBA): 7 a.m. to 10 p.m.	New Noise Source (dBA) 10 p.m. to 7 a.m.	New Source in Quiet Area (dBA) 7 a.m. to 10 p.m.	New Source in Quiet Area (dBA) 10 p.m. to 7 a.m.
L_1	75	60	75	60	60	55
L_{10}	60	55	60	55	55	50
L_{50}	55	50	55	50	50	45

Source: Oregon Administrative Rules 340-35-035, Tables 7, 8, and 9
a L_1, L_{10}, and L_{50} are the noise levels that are exceeded 1%, 10%, and 50% of the time (1 hour, in this case).
dBA = A-weighted decibels

City Noise Standards

In Portland, daytime construction noise up to 85 dBA is exempt, with additional exemptions for impact tools. From 7:00 p.m. to 7:00 a.m., and all day on Sundays, the City of Portland has restrictive noise regulations that apply to construction (City of Portland Municipal Code, Title 18, Noise Control). Under the noise control ordinance, virtually all major construction projects require a noise variance if work is planned during nighttime hours or on Sundays. Large projects typically require coordination with the City of Portland's Noise Review Board, which often imposes additional restrictions on construction.

The City of Vancouver has incorporated WAC noise regulations (Table 3.11-3 and Table 3.11-4) into the Vancouver Municipal Code (VMC). The City of Gresham has incorporated Oregon Department of Environmental Quality noise regulations (Table 3.11-5) into the Gresham Noise Control Code (Gresham Revised Code Article 7.20).

Understanding Vibration

How Vibration Levels Are Measured

Ground-borne vibration is a form of energy that travels from a source through the ground to another location. Two types of vibration were analyzed—vibration from the operation of the proposed light-rail extension and vibration from construction.

The severity of impact caused by vibration is related to its velocity and is discussed in terms of both inches per second and decibels, as appropriate. Velocity of vibration in decibels is noted as "VdB."

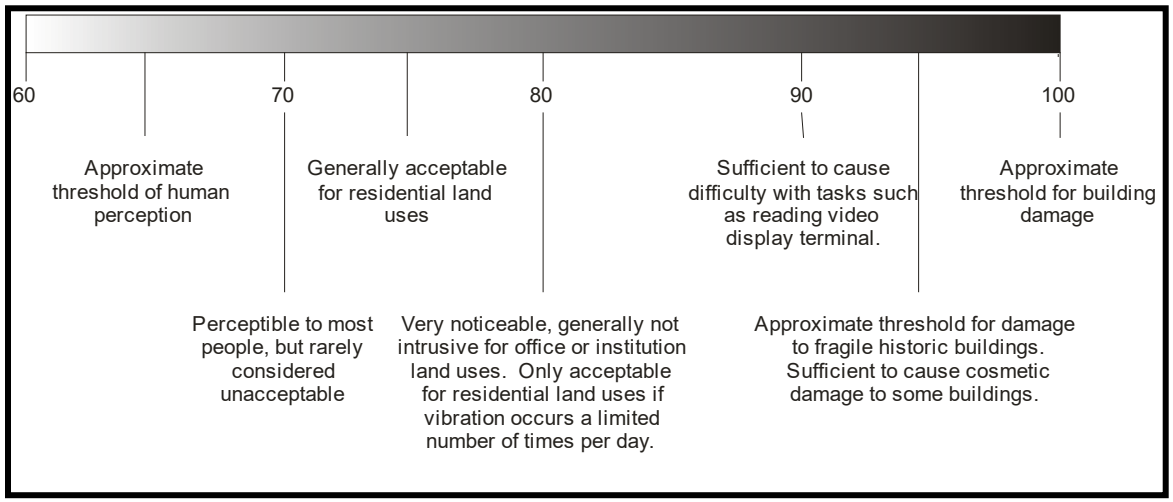
Ground-Borne Vibration vs. Ground-Borne Noise

The effects of ground-borne vibration include perceived movement of building floors, rattling of windows, or shaking of items on shelves. When ground-borne vibration creates a rumbling noise inside buildings, it is called ground-borne noise.

Typical Vibration Levels

Figure 3.11-4 gives a general idea of the effects of different levels of vibration on humans and buildings. Existing levels of building vibration from traffic and other local sources are usually in the range of 40 to 50 VdB, which is well below the range of human perception.

Figure 3.11-4. Human and Building Response to Ground-Borne Vibration Levels



Source: FTA 1995

Vibration Criteria and Analysis Methods

Vibration Criteria

FTA has developed impact criteria for acceptable levels of both ground-borne vibration and ground-borne noise that apply to light-rail transit.

Table 3.11-6 summarizes FTA's impact criteria for most buildings. Some buildings, such as concert halls, TV and recording studios, and theaters, can be very sensitive to ground-borne vibration and ground-borne noise but do not fit into the three categories shown in Table 3.11-6. Because of the sensitivity of these buildings, the

FTA has developed ground-borne vibration and ground-borne noise criteria for "special buildings," shown in Table 3.11-7.

Table 3.11-6. FTA Ground-Borne Vibration and Noise Impact Criteria

Land Use Category	Ground-Borne Vibration Impact Levels Frequent [a] Events	Ground-Borne Vibration Impact Levels Occasional Events	Ground-Borne Vibration Impact Levels Infrequent [b] Events	Ground-Borne Noise Impact Levels Frequent [a] Events	Ground-Borne Noise Impact Levels Occasional Events	Ground-Borne Noise Impact Levels Infrequent [b] Events
Category 1: Buildings where low ambient vibration is essential for interior operations.	65 VdB [c]	65 VdB [c]	65 VdB [c]	N/A [d]	N/A [d]	N/A [d]
Category 2: Residences and buildings where people normally sleep.	72 VdB	75 VdB	80 VdB	35 dBA	38 dBA	43 dBA
Category 3: Institutional land uses with primarily daytime use.	75 VdB	78 VdB	83 VdB	40 dBA	43 dBA	48 dBA

a "Frequent Events" is defined as more than 70 vibration events per day. Most rapid transit projects fall into this category.
b "Infrequent Events" is defined as fewer than 70 vibration events per day. This category includes most commuter-rail systems.
c This criterion limit is based on levels that are acceptable for most moderately sensitive equipment such as optical microscopes. Vibration-sensitive manufacturing or research equipment would require detailed evaluation to define the acceptable vibration levels. Ensuring lower vibration levels in a building often requires special design of the heating, ventilation, and air-conditioning system and stiffened floors.
d Vibration-sensitive equipment is generally not sensitive to ground-borne noise.
dBA = A-weighted decibels; N/A = not applicable; VdB = vibration in decibels

Table 3.11-7. Ground-Borne Vibration and Noise Impact Levels for Special Buildings

Type of Building or Room	Ground-Borne Vibration Impact Levels Frequent [a] Events	Ground-Borne Vibration Impact Levels: Occasional or Infrequent [b] Events	Ground-Borne Noise Impact Levels: Frequent [a] Events	Ground-Borne Vibration Impact Levels: Occasional or Infrequent [b] Events
Concert Halls	65 VdB	65 VdB	25 dBA	25 dBA
TV Studios	65 VdB	65 VdB	25 dBA	25 dBA
Recording Studios	65 VdB	65 VdB	25 dBA	25 dBA

Type of Building or Room	Ground-Borne Vibration Impact Levels Frequent [a] Events	Ground-Borne Vibration Impact Levels: Occasional or Infrequent [b] Events	Ground-Borne Noise Impact Levels: Frequent [a] Events	Ground-Borne Vibration Impact Levels: Occasional or Infrequent [b] Events
Auditoriums	72 VdB	80 VdB	30 dBA	38 dBA
Theaters	72 VdB	80 VdB	35 dBA	43 dBA

Note: If the building will rarely be occupied when the trains are operating, there is no need to consider impacts. As an example, consider locating a commuter-rail line next to a concert hall. If no commuter trains will operate after 7 p.m., the trains would rarely interfere with the use of the hall.

a "Frequent Events" is defined as more than 70 vibration events per day. Most rapid transit projects fall into this category.

b "Infrequent Events" is defined as fewer than 70 vibration events per day. This category includes most commuter-rail systems.

dBA = A-weighted decibels; VdB = vibration in decibels

City Vibration Standards

The City of Portland (Chapter 33.262, Off-Site Impacts) restricts continuous, frequent, or repetitive vibrations that exceed a 0.002 gravitational constant peak. Vibrations from temporary construction and vehicles that leave the site (such as trucks, trains, airplanes, and helicopters) are exempt. Vibrations lasting less than 5 minutes per day are also exempt. Vibrations from primarily on-site vehicles and equipment are not exempt.

The City of Gresham does not regulate vibration.

The City of Vancouver has incorporated vibration regulations into the VMC, including prohibiting off-site vibration impacts that are discernible without instruments at the property line. This prohibition would apply to all nighttime construction activities and the operation of light-rail stations and park-and-ride lots. Construction activity between the hours of 7 a.m. and 8 p.m. is exempt from these vibration regulations. The operations of public streets and sidewalks, rail maintenance yards, and essential public facilities, such as the interstate highway system, are exempt from these regulations 24 hours a day.

Existing Noise Levels in the Study Area

Traffic noise levels were modeled at 875 locations representing approximately 1,204 noise-sensitive land uses within the study area. For the light-rail transit analysis, noise levels were modeled at 16 locations representing 52 noise-sensitive land uses. Some of the modeling locations used for the traffic noise analysis were also used for the transit analysis. Each of these locations has one or more noise receptors that constitute sensitive land uses, such as a residence, historic buildings, hotel, motel, or park (see sidebar). Existing outdoor noise levels range from 49 to 75 dBA L_{eq}, with 24-hour L_{dn} noise levels ranging from 53 to 75 dBA.

Overall, noise levels in the study area are dominated by traffic on I-5. The year 2019 was used for existing conditions because it aligns with the traffic study completed for the IBR Program. Under existing conditions (2019), an estimated 160 noise-sensitive land uses approach or exceed the applicable traffic noise criteria in the study area. This includes single-family and multifamily residences, along with several hotels, parks, schools, and a cemetery. Of the existing noise-sensitive land uses that exceed applicable noise criteria levels, 50 are in Portland and 110 are in Vancouver. The Noise and Vibration Technical Report provides the existing modeled locations and noise levels for each subarea summarized below.

What are noise-sensitive receptors and residential equivalents?

A noise-sensitive receptor is a property where frequent exterior human use occurs and where a lower noise level would be beneficial. The nuisance level for traffic noise is perceived differently by people depending on the situation. For instance, roadway noise may not bother people walking to a commercial establishment but may disturb people at a backyard pool or while they are sleeping. Residential equivalency is a measurement of the amount of use at special sites such as schools, parks, churches, and hospitals.

Portland Existing Modeled Traffic Noise Levels

Current noise levels approach or exceed the ODOT Noise Abatement Approach Criteria (NAAC) at 50 locations adjacent to I-5, including approximately 19 floating homes, with noise levels of 65 to 69 dBA L_{eq}. Existing noise levels at multilevel apartment units located along N Marine Drive also approach or exceed the ODOT NAAC. These apartment units have private outdoor patios facing N Marine Drive, with noise levels ranging from 65 to 71 dBA L_{eq}.

Downtown Vancouver Existing Modeled Traffic Noise Levels

The analysis of noise levels in downtown Vancouver focuses on I-5, SR 14, and associated ramps. The traffic noise model also includes local streets that influence noise in the study area. Currently, 37 noise-sensitive sites approach or exceed the WSDOT noise abatement criteria (NAC), primarily due to I-5 traffic noise. Locations that would undergo noise impacts are mostly clustered at apartment buildings located just southwest of the I-5/E Mill Plain Boulevard interchange, C Street and E 7th Street, and a newly constructed building along Washington Street between West 4th and West 5th Streets.

Fort Vancouver Existing Modeled Traffic Noise Levels

At the Vancouver National Historic Reserve (VNHR), including the Fort Vancouver National Historic Site and nearby areas, noise levels currently range from 52 to 75 dBA L_{eq}, with the highest levels at unshielded areas along I-5 and SR 14. Currently, six modeled locations along the Fort Vancouver Park Trail and Confluence Land Bridge Trail within the Fort Vancouver Historic District, and three modeled locations along the Waterfront Renaissance Trail approach or exceed the WSDOT NAC.

Vancouver East Existing Modeled Traffic Noise Levels

East of I-5 and north of E Mill Plain Boulevard, noise levels currently range from 49 to 73 dBA L_{eq}, with the highest levels at residences not located behind existing noise walls north of E Fourth Plain Boulevard. Currently, 16 modeled locations at residences and one modeled location at Marshall Park approach or exceed the WSDOT NAC.

Vancouver West Existing Modeled Traffic Noise Levels

West of I-5 and north of E Mill Plain Boulevard, current noise levels range from 49 to 75 dBA L_{eq}, with the highest levels at residences located close to I-5 both north and south of E 39th Street. Currently, noise levels at 42 residences, Kiggins Bowl, Discovery Middle School, and two offices approach or exceed the WSDOT NAC.

Existing Noise Levels for Light-Rail Transit Analysis

Existing noise level data for the light-rail analysis were taken from on-site measurements and following methods in the FTA Transit Noise and Vibration Manual. Locations in the transit corridor that were used for the traffic noise analysis were also used for the light-rail analysis. The noise levels provided represent primarily residential uses, with some uses such as hotels that include overnight sleeping. Existing noise levels ranged from 69 to 77 L_{eq} and 77 to 83 L_{dn} in downtown Vancouver; from 58 to 73 L_{eq} and 66 to 81 L_{dn} at sites in north Portland; and from 69 to 71 L_{eq} and 67 to 70 L_{dn} in the area around the Ruby Junction Maintenance Facility.

3.11.3 Long-Term Effects

No-Build Alternative

Under existing conditions (2019), there are approximately 160 traffic noise impacts to noise-sensitive land uses; that number would rise to 215 under the No-Build Alternative (2045). Background traffic growth would cause an increase in traffic noise levels throughout the study area. Under the No-Build Alternative, routine maintenance of the existing noise walls in Vancouver would occur, but no new noise walls would be constructed. Under the No-Build Alternative), none of transit improvements associated with the IBR Program would occur, so there would be no new transit noise or vibration impacts from the Program.

This analysis does not address vibration levels associated with the No-Build Alternative because no new source of vibration is anticipated under the No-Build Alternative.

Portland Modeled Traffic Noise Levels

Forty-nine of the 50 receptors where existing noise levels approach or exceed the ODOT NAAC are predicted to continue to approach or exceed the ODOT traffic noise criteria under the No-Build Alternative (2045). In addition to these 49 receptors, it is predicted that traffic noise levels at 15 more locations near I-5 and N Marine Drive will approach or exceed the ODOT traffic noise criteria under the No-Build Alternative. Noise levels under the No-Build Alternative would range from 45 to 70 dBA L_{eq} with a 1 to 2 dBA increase over existing conditions at most locations due to an increase in traffic volumes.

Under the No-Build Alternative, noise levels at the estimated 19 floating homes that currently experience noise impacts, and an additional 10 floating homes, are predicted to approach or exceed the ODOT NAAC with noise levels of 65 to 69 dBA $L_{eq.}$ At most locations, noise levels would increase by 1 to 2 dBA due to an increase in traffic volumes in 2045. Most of the remaining traffic noise levels above the ODOT NAAC are located at the apartment complexes along N Marine Drive. Under the No-Build Alternative noise levels are predicted to exceed the ODOT NAAC at the same 30 apartments under the existing conditions and an additional four apartments within the Newport Apartment complex (Noise and Vibration Technical Report, Table 4-1), with

levels ranging from 49 to 70 dBA L_{eq}. Most locations are predicted to experience an increase of 1 to 2 dBA over existing noise levels. Traffic noise levels under the No-Build Alternative also approach or exceed the ODOT NAAC at one commercial property.

Downtown Vancouver Modeled Traffic Noise Levels

Under the No-Build Alternative, traffic noise levels in downtown Vancouver are predicted to approach or exceed the WSDOT traffic noise criteria at the same 37 multifamily residences and trail as under the existing conditions, and at five additional residential units and one additional trail use (see the Noise and Vibration Technical Report, Table 4-3). No-Build Alternative noise levels would range from 51 to 73 dBA L_{eq}. Compared to existing conditions, noise levels would increase 1 to 7 dBA, with most modeled locations showing an increase of 1 to 2 dBA. Increases in noise levels would result from an increase in traffic volumes from existing conditions to the year 2045. The highest predicted noise level under the No-Build Alternative would be 73 dBA L_{eq} at the apartments under construction at 400 Washington Street.

Fort Vancouver Modeled Traffic Noise Levels

Noise levels at the VNHR under the No-Build Alternative are projected to range from 53 to 76 dBA L_{eq}, with the highest levels at unshielded areas along I-5 and SR 14. In general, noise levels are predicted to increase by 1 to 2 dBA over existing conditions within the VNHR due to an increase in traffic volumes. Currently, noise levels within the Fort Vancouver Historic District along the Fort Vancouver Trail and Confluence Land Bridge Trail, and along the Waterfront Renaissance Trail located outside the Fort Vancouver Historic District, approach or exceed the WSDOT NAC. Under the No-Build Alternative, the same sites would continue to approach or exceed the WSDOT NAC, with two additional trail use locations in the Fort Vancouver Historic District and one Historic District/office location exceeding the WSDOT NAC (see the Noise and Vibration Technical Report, Table 4-5).

North Vancouver, East of I-5 Modeled Traffic Noise Levels

Future noise levels under the No-Build Alternative at the modeling locations in this area of north Vancouver east of I-5 and north of E Mill Plain Boulevard ranged from 50 to 74 dBA L_{eq}, an increase of 1 to 3 dBA over existing noise levels. These increases are due to an increase in traffic volumes from existing conditions to the year 2045. Currently, 17 locations approach or exceed the WSDOT NAC. Under the No-Build Alternative, 30 locations approach or exceed the WSDOT NAC (Noise and Vibration Technical Report, Table 4-7). Noise levels do not approach or exceed the WSDOT NAC at the hospital, church, or cemeteries located in this subarea, but they do exceed the criteria at 25 residences and at athletic fields and other outdoor-use areas at Marshall Park.

North Vancouver, West of I-5 Modeled Traffic Noise Levels

Future No-Build Alternative noise levels at the modeling locations in this subarea north of Mill Plain Boulevard to Discovery Middle school range from 50 to 76 dBA L_{eq}, an increase of 1 to 3 dBA over existing noise levels. These increases are due to an increase in traffic volumes from existing conditions to the year 2045. Under the No-Build Alternative, the number of residences with noise levels that would approach or exceed the WSDOT NAC is predicted to increase from the current 47 locations to 65. The same locations predicted to reach the WSDOT NAC under existing conditions would also exceed the WSDOT NAC under the No-Build Alternative, along with 18 additional residences and two additional use areas at the Kiggins Bowl, one outdoor use at Discovery Middle School, and two offices (see the Noise and Vibration Technical Report, Table 4-9).

Modified LPA

Without mitigation, traffic noise impacts under the Modified LPA are expected to increase compared to existing conditions due to an increase in future traffic volumes and shift in roadway alignments. Compared to the No-Build Alternative, the Modified LPA without mitigation would be expected to have fewer traffic noise

impacts due to program acquisitions near the new Columbia River bridge alignment. Program acquisitions for the future Columbia River bridge alignment include houseboats located between Hayden Island and the Oregon mainland. Without mitigation, traffic noise impacts under the Modified LPA would occur at 198 residential equivalents. The Modified LPA, with mitigation, would replace existing noise walls in Vancouver with new noise walls as necessary for project construction. All existing noise walls that would be replaced in-kind (i.e., no changes to wall length or height) are evaluated as part of this analysis (see the Noise and Vibration Technical Report, Section 7).

Figure 3.11-5 through Figure 3.11-11 show the modeled noise impacts of the Modified LPA at locations within the study area. Potential changes in noise and vibration levels and effects for the design options were evaluated qualitatively by reviewing design changes in relation to the Modified LPA. Results from the noise analysis conducted for individual historic properties are discussed in Section 3.8, Cultural Resources.

Table 3.11-8 summarizes the major differences in impacts and benefits across the Modified LPA's bridge configurations, the one-auxiliary-lane and two-auxiliary-lane options, and the No-Build Alternative. The design options are discussed qualitatively for comparative purposes.

Table 3.11-8. Noise and Vibration Impacts and Benefits for the Modified LPA Bridge Configurations and Auxiliary Lane Options and No-Build Alternative

Modified LPA Bridge Configuration and Auxiliary Lane Design Option and No-Build Alternative	Noise and Vibration Impacts
Modified LPA with Double-Deck Fixed-Span Configuration and One Auxiliary Lane	• Without mitigation, the number of traffic noise impacts would be lower (198) in 2045 than under the No-Build Alternative due to the Program's acquisitions of houseboats located near the Columbia River bridge alignments. • With mitigation, existing noise walls in Vancouver would be replaced as necessary for project construction, which would reduce the number of traffic noise impacts to 121. • Transit vibration impacts would occur at 13 receptors in downtown Vancouver, including a 12-unit apartment complex located at E 7th Street and E C Street and a movie theater located at E 8th Street and E C Street.
Modified LPA with Single-Level Fixed-Span Configuration and One Auxiliary Lane	Similar noise and vibration impacts to the Modified LPA with the double-deck fixed-span bridge configuration, except: • Minor increases in highway noise (0 to 4 dBA at the closest noise-sensitive uses) and highway noise impacts east and west of the bridges as a result of the wider bridge spans (99 feet wider) and lower roadway deck (29 feet lower). • Users on the shared-use path across the Columbia River bridges would have less shielding and more exposure to noise from highway vehicles. • Transit vibration levels would increase for houseboats at Jantzen Beach and in downtown Vancouver due to the westward shift of the light-rail alignment from the increased width of the bridges over the Columbia River.
Modified LPA with Single-Level Movable-Span Configuration and One Auxiliary Lane	• Similar noise and vibration impacts to the single-level fixed-span configuration due to the similarity in noise source locations and distance to noise-sensitive receptors.

Modified LPA Bridge Configuration and Auxiliary Lane Design Option and No-Build Alternative	Noise and Vibration Impacts
Modified LPA with Double-Deck Fixed-Span Configuration and Two Auxiliary Lanes	Transit vibration impacts would be the same as for Modified LPA with one auxiliary lane. Traffic noise impacts before and after mitigation would be similar to the Modified LPA with one auxiliary lane, except: • Slight differences in noise levels (0 to 2 dBA at the noise-sensitive uses closest to the bridges: Sites PD-036, PD-037, DT-030 to DT-032, FV-048 to FV-052, and FV-071) are anticipated because the second auxiliary lane would bring traffic approximately 16 feet closer to noise-sensitive land uses located east and west of I-5.
No-Build Alternative	• 215 receptors would exceed highway noise thresholds. • No receptors would have moderate or severe transit noise impact levels. • No vibration impacts without the extension of light-rail.

dBA = A-weighted decibels; LPA = Locally Preferred Alternative

Figure 3.11-11. Modified LPA with Double-Deck Fixed-Span Configuration and One Auxiliary Lane – 2045 Traffic Noise Impacts – E 39th Street to Terminus

Portland/Hayden Island - Modified LPA Modeled Traffic Noise Levels

Under the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane, noise levels at modeled locations in Portland would range from 49 to 71 dBA L_{eq}. Most locations would experience an increase of 2 to 4 dBA over existing conditions, with increases of up to 11 dBA at one location, site PD-007, which represents one mobile home in the Jantzen Beach recreational vehicle (RV) park on Hayden Island. Noise levels would be 2 dBA above to 2 dBA below noise levels under the No-Build Alternative, at most locations.

The greatest increase in noise levels under the Modified LPA, with any of the design options, is predicted at the Jantzen Beach RV park, located at the north end of Hayden Island and west of I-5. Noise levels in this area are predicted to increase 4 to 11 dBA over existing conditions and 4 to 10 dBA above No-Build Alternative noise levels; this is because the Modified LPA, with any of the design options, would shift the alignment of I-5 closer to homes at the RV park. While noise levels would increase at all of the RV homes, as shown in Figure 3.11-6 the modeling showed that three of the RV homes may experience a substantial noise increase (defined as an increase of 10 dBA or greater). An existing block wall at the RV park and a nearby hotel building provides some shielding against noise, as modeled. Noise levels under the Modified LPA, with any of the design options would not approach or exceed ODOT's NAAC impact criteria at the RV park; however, the increase in noise levels would meet the threshold of 10 dBA over existing noise levels, making this a substantial increase.

Other areas that are predicted to undergo ODOT NAAC impacts include the floating homes in North Portland Harbor (sites PD-077 to PD-082, PD-084 to PD-095), the apartments located closest to N Marine Drive (PD-157 to PD-161A-C, PD-163A-C, PD-167A-C, PD-168A-C to PD-172A-C, and PD-172A-C), and one soccer field (PD-192) at Delta Park. In the area between Hayden Island and the Oregon mainline, the IBR Program would acquire 34 floating homes to allow for the new Columbia River bridge alignment. Due to this acquisition, the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would result in fewer sites predicted to undergo an increase in noise than under the No-Build Alternative. Displaced homes are represented by modeled sites PD-096 to PD-127, and PD-129. As shown in Figure 3.11-6, the floating homes at the end of the dock (represented by modeled sites PD-076 and PD-083) experience additional noise shielding from the existing terrain and would not be subject to an NAAC impact. In addition to the floating home displacements, modeled sites PD-038, PD-039, PD-040, PD-042, PD-043, PD-046, PD-048, PD-050 to PD-055, PD-128, PD-131, and PD-132, which represent several commercial businesses and restaurants on N Center Avenue, would be displaced.

The Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would approach or exceed the ODOT NAAC at 62 locations. A substantial increase impact of 10 dBA over existing noise levels is predicted at three residences located at the Jantzen Beach RV park. Figure 3.11-5 and Figure 3.11-6 show the location of each traffic noise impact under the Modified LPA in Portland.

Downtown Vancouver - Modified LPA Modeled Traffic Noise Levels

In downtown Vancouver, traffic noise levels under the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would approach or exceed the WSDOT NAC at the same 37 multifamily residences as existing conditions and at an additional four residences—one fewer than the No-Build Alternative. Traffic noise levels would approach or exceed the NAC at one office and one outdoor-use area at the Vancouver Community Library. Noise levels would range from 51 to 74 dBA L_{eq}, with noise levels within 1 dBA of existing conditions at most locations, and within a range of -1 to 6 dBA compared to existing noise levels where roadway alignment shifts closer to or further from noise receptor locations. At one undeveloped property along Columbia Street (DT-049), noise levels would be 12 dBA higher than existing conditions.

Noise levels resulting from the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would be within 3 dBA of No-Build Alternative noise levels at most locations. Where roadways

would be closer to or further from noise receptor locations, the change in traffic noise levels would range from -8 to 8 dBA compared to the No-Build Alternative. The highest noise levels under Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would be 74 dBA L_{eq}, predicted to occur outside a building used as office and commercial space (DT-019) located north of E Evergreen Boulevard. In downtown Vancouver, no substantial noise level increases would occur. Figure 3.11-7 and Figure 3.11-8 show the location of each traffic noise impact under the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane in downtown Vancouver.

Compared to the Modified LPA with the double-deck fixed-span bridge configuration, one auxiliary lane and with the C Street ramps, the elimination of C Street ramps at the SR 14 interchange would result in a minor change in traffic noise levels below the common threshold of human hearing (0 to 2 dBA). This difference is due to the removal of these roadways, which would shift traffic to other roadways in the area. Compared to the Modified LPA with the double-deck fixed-span bridge configuration, one auxiliary lane, and centered I-5 mainline, the westward shift of the I-5 mainline would also shift traffic noise to the west but would result in a barely perceptible increase (2 to 3 dBA) in traffic noise levels west of I-5 near the southbound mainline and ramps. The I-5 mainline westward shift would require two additional acquisitions located east of C Street between E 7th Street and E 8th Street. One of these buildings houses commercial businesses, including a restaurant (DT-025), a theater, and a salon, and the other is an apartment building (DT-027). The design option of a centered I-5 mainline would result in traffic noise levels above the impact criteria at the apartment building, while the design option to shift the I-5 mainline west would acquire this noise-sensitive land use and thus exclude it from the total number of noise impacts.

Fort Vancouver - Modified LPA Modeled Traffic Noise Levels

The Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would result in the same WSDOT NAC exceedances as the No-Build Alternative at Fort Vancouver trails, one Fort Vancouver Historic Village site, and one of four offices. In the VNHR, noise levels would be above the WSDOT NAC at two residences and four total offices, with outdoor noise levels at one of the two offices predicted to experience a substantial increase of 10 dBA over existing conditions. Noise levels would range from 54 to 75 dBA L_{eq}, with a decrease of 2 dBA below existing conditions at Old Apple Tree Park and nearby trail and an increase of up to 10 dBA over existing conditions at one Fort Vancouver office, represented by site FV-004. Compared to the No-Build Alternative, traffic noise levels under the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane are expected to increase throughout much of the Fort Vancouver area, with an increase of 10 dBA at one site—site FV-004—and decrease by as much as 4 dBA at Old Apple Tree Park, represented by site FV-039. Figure 3.11-7 and Figure 3.11-8 show the location of each traffic noise impact in Fort Vancouver.

North Vancouver, East of I-5 - Modified LPA Modeled Traffic Noise Levels

In north Vancouver east of I-5, the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would exceed the WSDOT NAC at 26 locations near the future I-5 alignment. The 26 locations include 26 of the 31 WSDOT NAC exceedances predicted under the No-Build Alternative (including 21 of the 25 exceedances at residences and five of the six outdoor-use locations at Marshall Park). No substantial increase impacts are predicted under the Modified LPA.

Noise levels would range from 49 to 73 dBA L_{eq} and would fall within 1 to 3 dBA of existing conditions at most locations. Compared to existing conditions, noise levels would range from a decrease of 5 dBA below existing conditions to an increase of 3 dBA above existing conditions. Compared to the No-Build Alternative, traffic noise levels are expected to be within 1 dBA throughout much of this subarea, with only slight increases of 0 to 2 dBA at most locations. Noise reductions of up to 6 dBA are predicted at outdoor-use areas south of the Department of Veterans Affairs (VA) Hospital from the shift in the northbound I-5 off-ramp to Fourth Plain

Boulevard. Figure 3.11-9, Figure 3.11-10, and Figure 3.11-11show the location of each traffic noise impact in north Vancouver east of I-5.

North Vancouver, West of I-5 - Modified LPA Modeled Traffic Noise Levels

In north Vancouver, west of I-5, noise levels under the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would exceed the WSDOT NAC at 54 locations, which is seven more NAC impacts than existing conditions and 12 fewer NAC impacts than the No-Build Alternative. The 54 exceedance locations with the Modified LPA include the sites with an exceedance under existing conditions and the No-Build Alternative, which include residences, Kiggins Bowl, and one outdoor location at Discovery Middle School. No NAC impacts are predicted with the Modified LPA at the two offices that experience NAC impacts under existing conditions or under the No-Build Alternative.

Noise levels at this location would range from 49 to 76 dBA L_{eq}. Increases in noise levels over existing conditions would range from 2 to 12 dBA at residences between E 33rd Street and E 39th Street, where the I-5 southbound on-ramps would be shifted west (closer to residences). In this area, seven single-family homes would be displaced between E 35th Street and E 37th Street. Displaced residences are represented by modeled sites VW-056, VW-059, VW-062, VW-065, VW-068, VW-071, and VW-077. In this area, the Modified LPA with the double-deck fixed-span bridge configuration and one auxiliary lane would result in fewer sites predicted to experience increases in noise than the No-Build Alternative due to the seven displaced residences.

A 2 to 4 dBA increase in noise levels over existing conditions is predicted at most locations in this area. Compared to the No-Build Alternative, noise levels would be within 1 dBA at most locations and would have similar increases of up to 10 dBA at residences near the ramp improvements between E 33rd Street and E 39th Street. Six residences located between E 33rd Street and E 35th Street are predicted to undergo substantial noise impacts. The six residences are represented by five modeled sites: VW-080, VW-082, VW-084, VW-094, and VW-098. Figure 3.11-9, Figure 3.11-10, and Figure 3.11-11 show the location of each traffic noise impact in north Vancouver west of I-5.

Portland Light-Rail Noise

The only noise-sensitive land use between the existing light-rail alignment at the Expo Center and the Portland and Oregon boundary is several rows of floating homes in North Portland Harbor. The Modified LPA, with any of the design options, would require relocation of the first row of homes and one home on the second dock; therefore, those homes were not analyzed for noise impacts. Light-rail noise was analyzed at the nearest remaining homes based on the distance between the proposed tracks and the homes. In all, 36 homes on the west side of the proposed North Portland Harbor and Columbia River bridges were evaluated for light-rail noise. The existing L_{dn} for the homes was extrapolated from measured data and on-site inspections.

The analysis predicted noise levels below the FTA noise impact criteria under the Modified LPA, including at the nearest remaining floating homes in North Portland Harbor. At all other noise-sensitive properties in the Portland portion of the project area, noise from light-rail operations would be well below the traffic noise levels, including the manufactured home residential area along the Columbia River. The cumulative effects at receptor LRT-3 would be less than 1 dB because the train noise would be more than 10 dB lower than the existing ambient levels. Results at the floating homes in North Portland Harbor are shown in Table 3.11-9 under site LRT-3.

Portland Transit Station Noise

The analysis reviewed the noise-sensitive receptors located nearest to the station improvements under the Modified LPA, following the FTA's guidance for noise-screening distances. These included the Hayden Island Station, Expo Center Station, and Expo Center Overnight Station. The nearest noise-sensitive receptors were

located beyond the FTA noise-screening distance at each of the Portland Transit Stations. Therefore, no noise impacts are predicted at these locations.

Ruby Junction Maintenance Facility

The planned expansion of the Ruby Junction Maintenance Facility is 350 feet from the nearest homes on SE 202nd Avenue, which is located within the FTA noise-screening distance. Modeled noise levels at the nearest home that would result from overall maintenance yard improvements are predicted to be below the FTA moderate and severe impact criteria. Results are shown in Table 3.11-9 under site "OMF-1."

The other noise-sensitive land uses located closest to improvements at Ruby Junction Maintenance Facility are single-family residences at SE 196th Avenue and residences at the Mobile Park Plaza at 19776 SE Stark Street. Both noise-sensitive use areas were reviewed with the FTA noise-screening distances and are located beyond the screening distance from the planned improvements. Therefore, no noise impacts are predicted at either location.

Downtown Vancouver - Modified LPA Modeled Transit Noise and Vibration Effects

Downtown Vancouver Light-Rail Noise

The Modified LPA would have moderate noise impacts at one location between the southern Columbia River bridge landing and W 6th Street—modeled site LRT-1 (the Normandy Apartments located at 316 E 7th Street). These impacts would result from special track work (i.e. turnouts, crossovers, switches). Noise levels with light-rail operations at this location are predicted to be 67 dBA L_{dn}. The criterion for moderate impacts at site LRT-1 is 66 dBA L_{dn}. Therefore, moderate noise impacts are predicted at this location.

Downtown Vancouver Transit Station Noise

The FTA noise-screening distances were used to review the nearest noise-sensitive receptors to station improvements included in the Modified LPA: Evergreen Station, and Waterfront Station. These receptors were located beyond the FTA noise-screening distance at each of the Vancouver Transit Stations; therefore, no noise impacts are predicted.

Downtown Vancouver Park-and-Ride Noise

Two planned park-and-ride facilities with multiple options in downtown Vancouver were reviewed against the FTA noise-screening distances. Park-and-ride lots 1a and 1c, located near the planned Waterfront Station, and park-and-ride lot 2a, located near the planned Evergreen Station, were located beyond FTA noise-screening distances. Therefore, no noise impacts are predicted.

Downtown Vancouver park-and-ride lot 1b, at W 4th Street and Columbia Street, is located within the FTA noise-screening distance from the new apartments under construction at 400 Washington Street (shown as "PNR-1" on Table 3.11-9). Modeled noise levels that would result from park-and-ride lot 1b are predicted to be below the FTA moderate and severe impact criteria. Therefore, no noise impacts are predicted at 400 Washington Street. The park-and-ride lot 2b at C Street and E 7th Street is located within the FTA noise-screening distance from the Normandy Apartments located at 316 E 7th Street and the Econo Lodge located at 601 Broadway Street. Modeled noise levels that would result from park-and-ride lot 2a are predicted to be below the FTA moderate and severe impact criteria; therefore, no noise impacts are predicted at either location. Results are shown in Table 3.11-9.

Downtown Vancouver Total Transit Noise

Total transit noise was evaluated to identify any additional impact locations that weren't identified when evaluating individual noise sources. Impacts and calculated noise levels presented in Table 3.11-9 include

noise from all Modified LPA transit improvements. Calculated noise levels are unchanged from individual noise levels due to the distance from stationary noise sources from sites located near the light-rail alignment. However, all noise levels are influenced by highway noise, which is included in the evaluation of mitigation measures presented in Section 3.11.6.

Downtown Vancouver Combined Highway and Transit Noise

LRT-1 is the one location where highway noise and transit noise impacts result from the Modified LPA. Since traffic noise approaches the transit noise of 69 dBA the noise level from both sources could be 1 to 2 dB higher during the peak traffic hour of the day at this location. See Section 7.8.1 of the Noise and Vibration Technical Report for additional information.

Portland Light-Rail Vibration

Sites sensitive to vibration were reviewed, along with the location of transit improvements, to identify potential vibration impacts. In this area, the proposed extension of light-rail is on a structure in most areas and is not near vibration-sensitive buildings. The one area that includes sites sensitive to vibration near transit improvements is the area of floating homes located near the proposed light-rail bridge from the Portland mainland to Hayden Island. Because these homes are located on water, minimal transmission of vibration is expected, and no impacts are predicted. The other transit facilities included in the Modified LPA located in and around Portland are Hayden Island Station, Expo Center Station, Expo Center Overnight Station, and the Ruby Junction Maintenance Facility, located in Gresham. As no vibration-sensitive sites are located in close proximity to these sites, no impacts are predicted. Therefore, no transit-related vibration impacts are predicted in the Portland area.

Downtown Vancouver Light-Rail Vibration

Vibration levels at the Normandy Apartments located at 316 E 7th Street (LRV-1) and the mixed-use building at 801 C Street that includes the Regal City Center Cinema (LRV-2) are predicted to exceed the FTA vibration criteria due to the close proximity of special trackwork to each building. Maximum vibration levels at these sites could reach 77 to 81 VdB as shown in Table 3.11-10. The ground-borne vibration levels are due to the special trackwork near the receptors and not the vibration generated by the train passbys. Vibration levels at the Econo Lodge hotel at 601 Broadway (LRV-4) are predicted to be below the FTA vibration impact criteria. Figure 3.11-12, at the end of this section, provides an aerial view of this area and identifies the grouping of the homes and location of the proposed light-rail alignment. The Modified LPA with the I-5 mainline westward shift design option would result in higher vibration levels in downtown Vancouver due to the westward shift of the light-rail alignment; however, no additional vibration impacts are anticipated due to the distance to sensitive receptors.

Table 3.11-9. Modified LPA L_{eq} and L_{dn} for Transit Operations

Receptor [a]	Area Description [b]	Land Use	Number of Units [c]	Existing Noise [d] (dBA)	Modified LPA Primary Transit Noise Source	Modified LPA Noise Contribution [e] (dBA)	FTA Impact Criteria: Moderate (dBA)	FTA Impact Criteria: Severe (dBA)	Units with Moderate Impacts:	Units with Severe Impacts:

b General description of the area of analysis.
c FTA vibration impact criteria.
d Predicted vibration level.
e Amount the predicted level exceeds the criteria.
f Number of individual structures affected.
g Because these SF residences are on water, minimal transmission of ground vibration occurs.
FTA = Federal Transit Administration; MF = multifamily; SF = single family; VdB = vibration decibels; "-" = no impact

No transit-related vibration impacts are predicted in the Portland area. In Vancouver, vibration impacts would affect 12 multifamily residences at the Normandy Apartments at 316 E 7th Street (LRV-1) and a multi-use building at 801 C Street that includes a cinema and commercial businesses (LRV-2) shown in Figure 3.11-12.

3.11.4 Temporary Effects

No-Build Alternative

Under the No-Build Alternative, there would be no construction of replacement bridges, no removal of existing bridge, and none of the other proposed roadway, transit, or stormwater improvements associated under the Modified LPA. Because no program improvements are included in the No-Build Alternative, short-term effects would be limited to noise-sensitive land uses near ongoing maintenance activities.

Modified LPA

Construction Activities

Construction of the new Columbia River bridges, removal of the existing Interstate Bridge, and improvements to interchanges, local roads, and various transit facilities would require equipment and machinery common to roadway, transit, bridge, and structural projects. Table 3.11-11 provides a list of the typical types of equipment used for this kind of construction, the corresponding activities, and the maximum noise levels as measured at 50 feet from the noise source under normal use.

Figure 3.11-12. Downtown Vancouver Transit Noise and Vibration Analysis and Impacts

Table 3.11-11. Typical Construction Equipment, Use, and Reference Maximum Noise Level

Equipment	Typical Expected Project Use [a]	L_{max} [b]	Source [c]
Air Compressors	Used for pneumatic tools and general maintenance - all phases	70–76	a, b, c
Backhoe	General construction and yard work	78–82	b, c
Backhoe	General construction and yard work	78–82	b, c
Concrete Pump	Pumping concrete	78–82	b, c
Concrete Saws	Concrete removal, utilities access	75–80	b, c
Crane	Materials handling, removal, and replacement	78–84	b, c
Excavator	General construction and materials handling	82–88	b, c
Forklifts	Staging area work and hauling materials	72	a, b, c
Haul Trucks	Materials handling, general hauling	86	b, c
Jackhammers	Pavement removal	74–82	b, c
Loader	General construction and materials handling	86	b, c
Pavers	Roadway paving	88	b

Equipment	Typical Expected Project Use [a]	L_{max} [b]	Source [c]
Pile Drivers	Support for structure and hillside	99–105	b, c
Power Plants	General construction use, nighttime work	72	b, c
Pumps	General construction use, water removal	62	b, c
Pneumatic Tools	Miscellaneous construction work	78–86	c
Service Trucks	Repair and maintenance of equipment	72	b, c
Tractor Trailers	Material removal and delivery	86	c
Utility Trucks	General project work	72	b
Vibratory equipment	Shore up hillside to prevent slides and soil compacting	82–88	b, c
Welders	General project work	76	b, c

a Typical maximum noise level under normal operation as measured at 50 feet from the noise source.

b Maximum noise level as measured at a distance of 50 feet under normal operation.

c Sources of noise levels presented:

Portland, Oregon Area Projects: Light-rail, I-5 Preservation, and Hawthorne Bridge construction projects and other measured data.

U.S. Department of Transportation construction noise documentation and other construction noise sources.

Construction Noise

The Modified LPA would be completed in the following four typical construction phases.

Preparation

Major noise-producing equipment used during the preparation stage could include concrete pumps, cranes, excavators, haul trucks, loaders, and tractor trailers. During this phase, maximum noise levels could reach 82 to 94 dBA at the nearest residences (50 to 100 feet) for normal construction activities.

Other major noise sources that may be required include the use of vibratory and impact equipment to install piles or sheet piles. Other equipment expected during this phase includes backhoes, air compressors, forklifts, pumps, power plants, service trucks, and utility trucks.

Construction

Construction impacts would persist at the construction site, and temporary noise impacts would occur at various times throughout construction and demolition over approximately a 9- to 15-year construction period. The loudest noise sources during construction of the new bridges would be pile drivers, cement mixers, concrete pumps, pavers, haul trucks, and tractor trailers. Drilled shafts would be used to reduce the number of piles driven. The cement mixers and concrete pumps would be required for construction of the superstructure. Maximum noise levels would range from 82 to 94 dBA at the closest receiver locations.

Approximately 3,311 temporary piles would be installed and removed during the multiyear construction of the Columbia River and North Portland Harbor bridges. These piles would be staged throughout the in-water construction and demolition periods. Between 100 and 400 temporary piles could be in the water at a given time.

An average of six temporary, load-bearing piles could be installed per day using one or two impact drivers. Some amount of impact pile driving in the Columbia River or North Portland Harbor would occur on approximately 735 days spread over the estimated six in-water work windows that would be required for the construction of the Columbia River bridges.

Three hundred impact strikes could be required to finish driving or proofing a given pile. This number of strikes would require approximately 30 to 45 minutes of impact hammer activity. Between two and three piles per day could be installed or proofed with an impact hammer, with an estimated total maximum number of 900 impact strikes per day if a single impact pile driver is in operation, or up to 1,800 impact strikes per day if two pile-driving rigs are operated concurrently. Actual pile production rates vary, and a typical day would likely have fewer strikes.

A bubble curtain or similarly effective noise attenuation device would be implemented during all impact pile driving, and a hydroacoustic monitoring plan would be implemented during impact pile driving to confirm the level of attenuation provided. This monitoring program would require unattenuated pile strikes in order to confirm the amount of attenuation provided by the system. Up to 75 unattenuated strikes could be required to accomplish this testing. Testing would occur up to approximately 40 days total over the course of construction. On each day of testing, unattenuated pile strikes would occur over a period of less than 10 minutes.

During construction, up to two impact pile drivers could operate simultaneously near one another. In addition, the contractor could elect to have both a vibratory and impact pile-driving rig in operation simultaneously. Operation of two pile-driving rigs simultaneously is not expected to produce greater decibel levels. Pile strikes from both drivers would need to be synchronous (within 0.0 and approximately 0.1 seconds apart) to produce higher noise levels than a single pile driver operating alone. Because this level of synchronicity is highly unlikely, the analysis assumes that pile drivers would not generate noise levels greater than that of a single pile driver. Refer to Section 3.16, Ecosystems, for additional information regarding construction noise impacts to underwater species.

The Modified LPA with any of the design options would result in temporary impacts to noise levels associated with construction of the Columbia River bridges and associated roadway and interchange improvements. The extent and nature of these impacts would be minimized and avoided to the extent possible through the implementation of best management practices (BMPs), such as implementing a bubble curtain (or similarly effective noise attenuation device) during all in-water impact pile driving.

Miscellaneous Activities

General construction activities would occur after completion of the heavy construction and would include installation of bridge railings, signage, lighting, roadway striping, and others. As shown in Table 3.11-12, many of these activities are expected to produce noise levels above 80 dBA at 50 feet for extended periods of time.

Demolition

Demolition of the existing structures would require heavy equipment such as concrete saws, cranes, excavators, hoe-rams, haul trucks, jackhammers, loaders, and tractor trailers. Maximum noise levels could reach 82 to 93 dBA at the nearest receptors.

Table 3.11-12 provides the noise levels for each of the four typical construction phases as measured at 50 feet from the construction activity. The noise levels shown in Table 3.11-12 are the typical maximums and would only occur periodically during the heaviest periods of construction. Actual hourly noise levels could be substantially lower than those stated, depending on the level of activity at that time and the distance from the work site to the noise-sensitive properties.

Table 3.11-12. Noise Levels for Typical Construction Scenarios at 50 Feet from Work Site

Scenario [a]	Equipment [b]	L_{max} [c] (dBA)	L_{eq} [d] (dBA)
Preparing for construction of new structures.	Air compressor, backhoe, concrete pump, crane, excavator, forklift, haul truck, loader, water pump, power plant, service truck, tractor trailer, utility truck, and vibratory equipment	94	87
Constructing new structures and paving roadways.	Air compressor, backhoe, cement mixer, concrete pump, crane, forklift, haul truck, loader, paver, pump, power plant, service truck, tractor trailer, utility truck, vibratory equipment, and welder	94	88
Conducting miscellaneous activities, including striping, lighting, and providing signs.	Air compressor, backhoe, crane, forklift, haul truck, loader, pump, service truck, tractor trailer, utility truck, and welder	91	83
Demolishing existing structures.	Air compressor, backhoe, concrete saw, crane, excavator, forklift, haul truck, jackhammer, loader, power plant, pneumatic tools, water pump, service truck, and utility truck	93	88

Note: Combined worst-case noise levels for all equipment 50 feet from work site.
a Operational conditions under which the noise levels are projected.
b Normal equipment in operation under the given scenario.
c L_{max} (dBA) is an average maximum noise emission for the construction equipment under the given scenario.
d L_{eq} (dBA) is an energy average noise emission level for construction equipment operating under the given scenario. For this type of equipment, the L_{eq} is approximately equal to the L_{50} (that is, noise level that is exceeded 50 percent of the time).
dBA = A-weighted decibels

The construction noise study assumed worst-case noise levels during each of the four general construction phases for periods of maximum construction activity. Actual noise levels experienced during construction would generally be lower than those described below. The information in Table 3.11-12 was used to predict construction noise levels for several distances from the project work area. Figure 3.11-13 is a graph of the construction noise level versus distance for the phases of project construction listed in Table 3.11-12.

Construction Vibration

Major vibration-producing activities would occur primarily during preparation for the new bridges and demolition of the existing bridge. Activities that have the potential to produce high levels of vibration would include pile driving, vibratory shoring, soil compacting, and some hauling and demolition activities. Vibration effects from pile driving or vibratory sheet installations could occur within 50 to 100 feet of sensitive receivers. It is unlikely that vibration levels would exceed 0.5 inches per second (approximate threshold for building damage) at distances greater than 100 feet from the construction sites. Although analysis indicates that buildings in the study area would not experience adverse vibration-related impacts from construction, owners of two historic structures (Barracks Post Hospital and Clark County Museum) have expressed concerns. See Section 3.8, Historic and Archaeological Resources, for further discussion of efforts to measure, monitor, and, if necessary, mitigate vibration impacts to these historic structures.

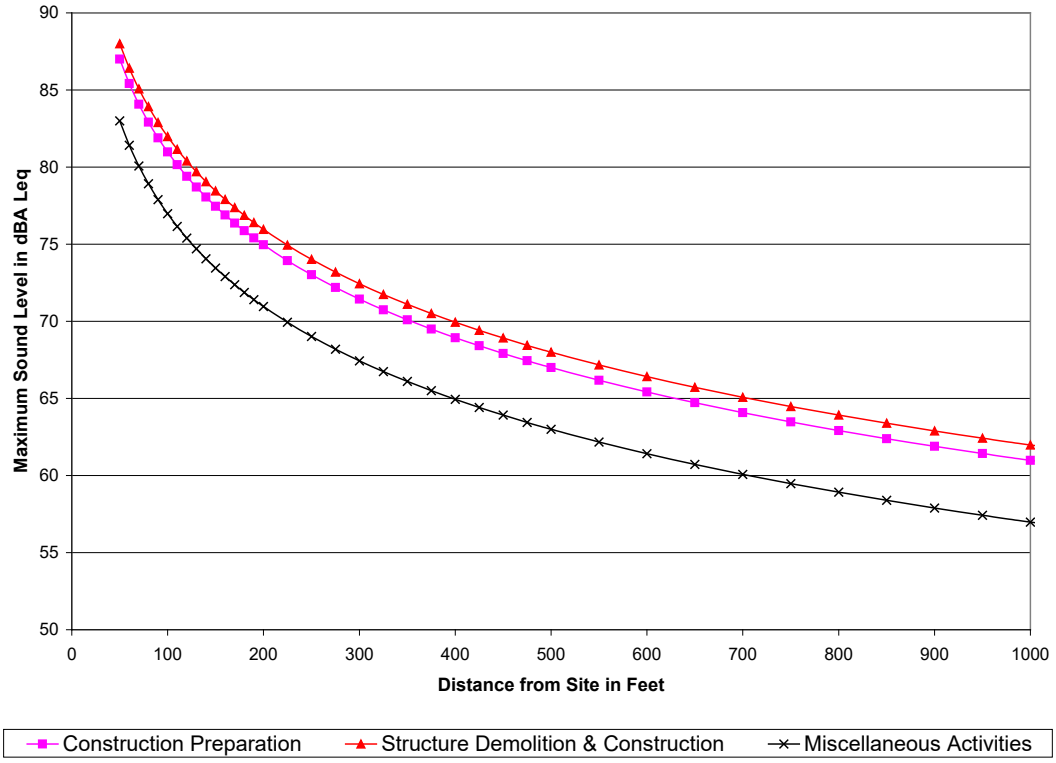
The mitigation measures intended to protect marine life from pile-driving hydroacoustic impacts, as described in Section 3.16, Ecosystems, would also reduce the potential for noise and vibration impacts to nearby noise-sensitive land uses.

3.11.5 Indirect Effects

An indirect effect of the Modified LPA on population and employment distribution and land use patterns is the promotion of more transit-oriented development around the new transit stations and support of minor

redistribution in future population and employment growth from outlying areas to the I-5 corridor, consistent with local land use plans. This increase in density and activity would likely result in further minor increases in ambient noise and vibration in the study area, and additional residents, including sensitive receptors, would be exposed to the urban noise levels in the study area. Because this new residential and commercial development is expected to occur in areas that already experience a fairly high level of background noise and vibration, and because new residents moving into that sound environment would do so by choice, indirect noise and vibration effects are anticipated to be minor.

Figure 3.11-13. Noise Level vs. Distance for Typical Construction Phases



Source: Noise and Vibration Technical Report

3.11.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Highway Traffic Noise Mitigation

Mitigation related to highway traffic noise, including mitigation (abatement) measures that meet ODOT's and WSDOT's feasibility and reasonableness criteria, may be recommended for inclusion in the Modified LPA. Feasibility primarily deals with engineering considerations such as whether substantial noise level reductions can be achieved or whether there would be a negative effect on property access resulting from the placement of noise walls (WSDOT 2020). Reasonableness comprises three factors: (1) if abatement is cost-effective; (2) if abatement can achieve the design goal; (3) and if the abatement is desired by benefiting receptors (WSDOT 2020). The complete evaluation of potential traffic noise abatement measures can be found in Section 7 of the Noise and Vibration Technical Report, including discussion of isolated noise receptors where mitigation would not be reasonable.

Under ODOT and WSDOT policies, the following noise abatement measures must be considered:

- Traffic management measures (for example, traffic control devices and signing for prohibition of certain vehicle types, time-use restrictions for certain vehicle types, modified speed limits, and exclusive land designations).
- Highway design measures (for example, alteration of horizontal/vertical alignments).
- Acquisition of property rights (either in fee or lesser interest) for construction of noise barriers.
- Acquisition of real property or interests therein (predominantly unimproved property) to serve as a buffer zone to preempt development that would be adversely affected by traffic noise.
- Sound insulation of all Activity Category D land uses, including public use or nonprofit institutional structures.
- Construction of sound barriers (including landscaping for aesthetic purposes), whether within or outside the highway right of way. Interstate construction funds may not participate in landscaping. The use of landscaping for noise abatement requires a minimum of 65 feet of densely planted, mature vegetation to provide a noticeable noise abatement up to 6 dB (NCHRP 2021).

Noise mitigation was evaluated at all locations where traffic noise impacts were predicted. Noise walls were evaluated to mitigate noise impacts at 16 locations in Washington and three in Oregon. Fourteen of the 16 noise walls in Washington (Noise Walls 1 through 9 and Noise Walls 11, 11A, 12, 14, and 15) were found to meet WSDOT criteria for the placement of a feasible noise wall. However, only 10 locations—Noise Walls 1 through 8, Noise Wall 11A, and Noise Wall 12—met WSDOT criteria for the placement of both a feasible and reasonable noise barrier. Included in the 10 recommended noise walls, Noise Walls 2 through 8 would replace existing noise walls.

Two of the three noise walls evaluated in Oregon (Noise Walls 16 and 17) did not meet ODOT criteria for the placement of a feasible noise wall. The third noise wall evaluated in Oregon (Noise Wall 18) met ODOT criteria for the placement of both a feasible and reasonable noise barrier.

Noise mitigation results would be the same for the Modified LPA with all bridge configurations, one or two auxiliary lanes, and the SR 14 Interchange without C Street ramps. The only difference in highway traffic noise mitigation between the Modified LPA design options is that under the I-5 mainline shifted west design option, Noise Wall 12 would not be recommended because the noise-affected property would be acquired.

The 11 feasible and reasonable noise walls are listed below and described in Section 7.2.1.1 of the Noise and Vibration Technical Report. The general location of each feasible and reasonable noise wall is described below and shown on Figure 3.11-14 to Figure 3.11-20. Table 3.11-13 summarizes each noise wall evaluation.

- Noise Wall 1: west side of I-5 from the southbound on-ramp from Main Street to E 39th Street.
- Noise Wall 2: west side of I-5 between E 39th Street and E 33rd Street.
- Noise Wall 3: east side of I-5 between E 33rd Street and SR 500.
- Noise Wall 4: west side of I-5 between E 33rd Street and E 29th Street.
- Noise Wall 5: east side of I-5 between E 33rd Street and E 29th Street.
- Noise Wall 6: west side of I-5 between E 29th Street and E 26th Street/E Fourth Plain Boulevard.
- Noise Wall 7: east side of I-5 between E 29th Street and E Fourth Plain Boulevard.
- Noise Wall 8: west side of I-5 between E 4th Plain Boulevard and E McLoughlin Boulevard.
- Noise Wall 11A: east side of I-5 between E Evergreen Boulevard and Officers Row.
- Noise Wall 12: west side of I-5 between E 7th Street and E 8th Street.
- Noise Wall 18: north side of N Marine Drive and east of I-5.

Note: N/A = not applicable for walls that do not meet feasibility. Details of all wall evaluations are presented in the Noise and Vibration Technical Report.

a Impacts based on WSDOT NAC, ODOT NAAC, and Substantial Increase thresholds with 2045 Modified LPA.

b Impacts benefited based on reduction from 2045 Modified LPA with existing noise walls in place.

c Total benefits based on reduction from 2045 Modified LPA without existing noise in place.

d Planning level cost calculated from WSDOT's planning level cost of $51.61 per square foot and ODOT's planning level cost of $30 per square foot for wall heights up to 16 feet and $37.50 per square feet for wall heights from 17 to 25 feet.

e WSDOT Cost allowance and ODOT wall cost per benefited receiver.

f Cost reasonableness based on WSDOT Noise Policy Reasonableness guidelines and ODOT's Noise Manual Cost Effectiveness Criteria.

LPA = Locally Preferred Alternative; NAAC = Noise Abatement Approach Criteria; NAC = Noise Abatement Criteria; ODOT = Oregon Department of Transportation; WSDOT = Washington State Department of Transportation

Statement of Likelihood

Based on the findings of this analysis, ODOT and WSDOT will further evaluate traffic noise abatement measures in the form of noise walls during the final design of the Modified LPA. The 11 noise wall locations (10 in Washington and 1 in Oregon) determined to be feasible and reasonable (Noise Walls 1, 2, 3, 4, 5, 6, 7, 8, 11A, 12, and 18) will be re-assessed in detail during final design.

The 11 noise walls would mitigate impacts at 76 residences or residential equivalent receiver locations and would benefit an additional 125 residences or residential equivalents. The combined preliminary cost for the 11 recommended noise walls totals approximately $6,823,000. If conditions change substantially during final design of the Modified LPA, the mitigation measure may no longer be feasible and reasonable and, therefore, would not be constructed as part of the Program. A final decision will be made upon the completion of the final design, a cost-estimating process, and the public involvement process, which includes balloting of benefitted receptors.

The IBR Program Team will also continue to evaluate installation of a tall safety barrier or sound barrier along the elevated light-rail transit structure between E 6th Street and E 8th Street in downtown Vancouver to mitigate transit noise impacts at site LRT-1. LRT-1 represents the Normandy Apartments at 316 E 7th Street in downtown Vancouver. A 3- to 4-foot acoustically absorbent wall or 6-foot reflective wall would be effective at reducing transit noise levels at this location by 7 to 10 dBA.

As described in Section 7.8.1 of the Noise and Vibration Technical Report, there is one location (the Normandy Apartments at 316 E 7th Street in downtown Vancouver) where the Modified LPA would have highway noise impacts and transit noise impacts. Additional information is presented in Section 7.8.1 of the Noise and Vibration Technical Report to support the recommendation to include both the highway traffic noise barrier (Noise Wall 12) and a sound barrier along the elevated structure (at site LRT-1).

Light-Rail Noise and Vibration Mitigation

Light-Rail Noise Mitigation

Table 3.11-14 summarizes the single transit noise impact location, mitigation measures, and future light-rail noise levels after mitigation. Aerial photos of the analysis areas and mitigation are shown in Figure 3.11-21.

Portland Light-Rail Noise Mitigation

No transit noise impacts are predicted in Portland; therefore, no mitigation is needed.

Vancouver Light-Rail Noise Mitigation

- Install tall safety barriers or sound barriers along the elevated structure to mitigate the noise impacts at site LRT-1, which represents the Normandy Apartments located at E 7th Street and E C Street in downtown Vancouver. A 3- to 4-foot acoustically absorbent wall or 6-foot reflective wall would reduce noise levels at this location by 7 to 10 dBA.
- Equip all light-rail track curves with a radius of less than 300 feet with wayside lubricators. After construction of the alignment, during the initial testing, if additional curves are identified with wheel squeal, install wayside track lubricators, as necessary.

e Noise from operation of the light-rail only. This is the noise level used to determine impacts under the FTA criteria.
f Exterior noise level with mitigation.
g FTA impact criteria.
h Number of units adversely affected by project noise.
i Mitigation measures.
dBA = A-weighted decibel; FTA = Federal Transit Administration; SF = single family

Figure 3.11-21. Light-Rail Noise and Vibration Impacts Post-Mitigation

Light-Rail Vibration Mitigation

Portland Vibration Mitigation

No vibration impacts are predicted in Portland; therefore, no mitigation is needed.

Vancouver Vibration Mitigation

- Use resilient rail fasteners to mitigate vibration impacts along direct fixation track way. Resilient rail fasteners typically reduce vibration levels by 5 VdB, which would not reduce all the predicted vibration levels below the FTA 72 VdB criteria for residential land uses. Receivers LRV-1 and LRV-2, with predicted levels of 77 VdB and 81 VdB, respectively, would be the only locations where there is still a potential for vibration impact following mitigation.
- Perform additional testing to ensure that the vibration levels at LRV-1 and LRV-2 would be below the 72 VdB criteria (Figure 3.11-9).

Table 3.11-15 summarizes the vibration levels with and without mitigation. Figure 3.11-21 shows the vibration impacts and proposed mitigation in downtown Vancouver.

Table 3.11-15. Modified LPA Vibration Mitigation Analysis

Location	Receptor	Area Description [b]	Land Use	FTA Vibration Criteria [c] (VdB)	Vibration Level [d] (VdB)	Vibration Level with Mitigation [e] (VdB)	Number of Potential Impacts with Mitigation [f]
Vancouver	LRV-1	E 7th Street/E C Street	MF	72	77	72	12
	LRV-2	E 8th Street/E C Street	Theater	72	81	76	1 - Theater

e Predicted vibration level with mitigation.
f Number of individual structures affected.
FTA = Federal Transit Administration; MF = multifamily; SF = single family; VdB = vibration decibels

Table 3.11-16 summarizes the long-term noise and vibration impacts that would result from the Modified LPA with the double-deck bridge configuration and one auxiliary lane. The Noise and Vibration Technical Report documents that, aside from the differences discussed above for the I-5 mainline westward shift design option, noise levels would be similar for the other design options. Table 3.11-8 summarizes the major differences in impacts and benefits across the Modified LPA's bridge configurations, the one-auxiliary-lane and two-auxiliary-lane options, and the No-Build Alternative. As detailed in Table 3.11-8, the difference in noise levels between design options result from the distance between the nearest noise-sensitive land uses and the design options, minimal change in traffic noise shielding from roadway alignments to noise-sensitive land uses, and no large change in peak hour traffic between design options.

Table 3.11-16. Comparison of Effects of the Modified LPA with the Double-Deck Bridge Configuration and One Auxiliary Lane without and with Mitigation

Technical Considerations	Modified LPA without Mitigation	Modified LPA with Mitigation
Number of receptors that exceed highway noise thresholds	198	121
Number of receptors with moderate transit noise impact levels	12	0
Number of receptors with severe transit noise impact levels	0	0
Number of receptors with transit vibration impacts	13	13

Noise/Vibration Mitigation Summary

Table 3.11-17 summarizes IBR Program mitigation related to noise and vibration during operation and construction.

Table 3.11-17. Noise/Vibration Mitigation Summary

IBR Program Area	Noise/Vibration Mitigation during IBR Program Operation	Noise/Vibration Mitigation during IBR Program Construction
Portland Mainland	Highway: Noise Wall 18 Light-Rail: Equip all light-rail track curves with a radius of less than 300 feet with wayside lubricators. After construction of the alignment, during the initial testing, if additional curves are identified with wheel squeal, install wayside track lubricators, as necessary.	• Comply with ODOT construction noise abatement measures (§ 00290.32 Noise Control) at the time of construction. • If a specific noise impact complaint occurs during the construction of the Modified LPA, implement noise mitigation measures outlined in this section as directed by the engineer. • In addition to § 00290.32, ODOT would also implement additional noise abatement methods, including: • Limit activities that produce the highest noise levels (such as hauling, loading spoils, jack hammering, and using other demolition equipment) from 7:00 a.m. to 7:00 p.m. Maximum noise levels associated with pile driving could reach 105 dBA at distances of 50 feet. Mitigation of the noise associated with pile driving would, when possible, include drilled shafts or auguring rather than driving piles (however, using an auger is not likely to be feasible or practical for all locations) or limiting the times the activity could take place. Other less effective methods of reducing noise from pile driving include coating the piles, using pile pads, or using piston mufflers. In the event that pile driving exceeds the limits set forth in Table 3.11-4, a noise variance would be requested from the local jurisdiction. • Keep a construction log for each of the construction staging areas. The log would contain general construction information such as the time an activity took place, type of equipment used, and other information that might help with potential noise effects. • Establish a complaint hotline to investigate noise complaints and compare them to the construction

IBR Program Area	Noise/Vibration Mitigation during IBR Program Operation	Noise/Vibration Mitigation during IBR Program Construction
		logs. A construction monitoring and complaint program would help to ensure that all equipment meets state, local, and any manufacturer's specifications for noise emissions. Equipment not meeting the standards would be removed from service until proper repairs were made and the equipment retested for compliance. This procedure would apply to all haul trucks, loaders, excavators, and other equipment that would be used extensively at the construction sites and that would contribute to potential noise effects. • Use equipment complying with pertinent equipment noise standards of the EPA. • Monitor all activities that might produce vibration levels at or above 0.5 inches per second if structures are near the construction activity, in compliance with WSDOT and ODOT requirements. This would include pile driving, vibratory sheet installation, soil compacting, and other construction activities with the potential to cause high levels of vibration. • For historic built properties within 500 feet of construction, monitor construction activities where construction-related vibration would exceed 0.2 inches per second for transient vibrations and 0.1 inches per second for continuous vibrations.
Portland/Hayden Island	Highway: None. Light-Rail: Equip all light-rail track curves with a radius of less than 300 feet with wayside lubricators. After construction of the alignment, during the initial testing, if additional curves are identified with wheel squeal, install wayside track lubricators, as necessary.	Same as Portland Mainland.
I-5/SR 14 Interchange	Highway: Noise Wall 11A, Noise Wall 12	Same as Portland Mainland with the following clarification for WSDOT:

IBR Program Area	Noise/Vibration Mitigation during IBR Program Operation	Noise/Vibration Mitigation during IBR Program Construction
	Light-Rail: Install tall traffic safety barriers or sound barriers along the elevated structure to mitigate the noise impacts at site LRT-1, which represents the Normandy Apartments. A 3- to 4-foot acoustical absorbent wall or 6-foot reflective wall would be effective at reducing noise levels at this location by 7 to 10 dBA. Equip all light-rail track curves with a radius of less than 300 feet with wayside lubricators. After construction of the alignment, during the initial testing, if additional curves are identified with wheel squeal, install wayside track lubricators, as necessary. Use resilient rail fasteners to mitigate for vibration impacts located along direct fixation track way. Resilient rail fasteners typically reduce vibration levels by 5 VdB, which would bring all the predicted vibration levels to, or below, the FTA 72 VdB criteria for residential land uses. Receivers LRV-1 and LRV-2, with predicted levels of 77 VdB and 81 VdB, respectively, would be the only locations where there is still a potential for vibration impact. Perform additional testing to ensure that the vibration levels at LRV-1 and LRV-2 would be below the 72 VdB criteria	Although WSDOT does not have noise control provisions, WSDOT would voluntarily comply with ODOT Standard Specification for Construction, § 00290.32 Noise Control (2015) for work completed in Washington.
E 8th Street to McLoughlin Boulevard	Highway: None Light-Rail: Equip all light-rail track curves with a radius of less than 300 feet with wayside lubricators. After construction of the alignment, during the initial testing, if additional curves are identified with wheel squeal, install wayside track lubricators, as necessary.	Same as I-5/SR 14 Interchange.
McLoughlin Boulevard to E 30th Street	Highway: Noise Wall 6, Noise Wall 7, Noise Wall 8 Light-Rail: None.	Same as I-5/SR 14 Interchange.
E 30th Street to E 39th Street	Highway: Noise Wall 2, Noise Wall 3, Noise Wall 4, Noise Wall 5 Light-Rail: None.	Same as I-5/SR 14 Interchange.

IBR Program Area	Noise/Vibration Mitigation during IBR Program Operation	Noise/Vibration Mitigation during IBR Program Construction
E 39th Street to Terminus	Highway: Noise Wall 1 Light-Rail: None.	Same as I-5/SR 14 Interchange.

Notes:
A final decision will be made upon the completion of the final design, a cost-estimating process, and the public involvement process. Additional vibration mitigation measures intended to protect marine life are described in Section 3.16, Ecosystems. Additional mitigation measures related to built historic resources are described in Section 3.8, Cultural Resources.

Temporary Effects

Construction noise and vibration BMPs applicable to the Modified LPA with any design option are discussed below.

Construction Noise

Regulatory Requirements

- Comply with ODOT construction noise abatement measures (§ 00290.32 Noise Control) at the time of construction.
- If a specific noise impact complaint occurs during the construction of the Modified LPA, implement noise mitigation measures outlined in this section as directed by the engineer.

Although WSDOT does not have noise control provisions, WSDOT would voluntarily comply with § 00290.32 for work completed in Washington.

Program-Specific Mitigation

In addition to § 00290.32, ODOT and WSDOT would also implement additional noise abatement methods, including:

- Limit activities that produce the highest noise levels (such as hauling, loading spoils, jack hammering, and using other demolition equipment) to 7:00 a.m. to 7:00 p.m. Maximum noise levels associated with pile driving could reach 105 dBA at distances of 50 feet. Mitigation of the noise associated with pile driving would, when possible, include drilled shafts or auguring rather than driving piles (however, using an auger is not likely to be feasible or practical for all locations) or limiting the times the activity could take place. Other less effective methods of reducing noise from pile driving include coating the piles, using pile pads, or using piston mufflers. In the event that pile driving exceeds the limits set forth in Table 3.11-4, a noise variance would be requested from the local jurisdiction.
- Keep a construction log for each of the construction staging areas. The log would contain general construction information such as the time an activity took place, type of equipment used, and other information that might help with potential noise effects.
- Establish a complaint hotline to investigate noise complaints and compare them to the construction logs. A construction monitoring and complaint program would help to ensure that all equipment meets state, local, and any manufacturer's specifications for noise emissions. Equipment not meeting the standards would be removed from service until proper repairs were made and the equipment retested for compliance. This procedure would apply to all haul trucks, loaders, excavators, and other equipment that would be used extensively at the construction sites and that would contribute to potential noise effects.
- Use equipment complying with pertinent equipment noise standards of the U.S. Environmental Protection Agency.

Construction Vibration

Regulatory Requirements

- Monitor all activities that might produce vibration levels at or above 0.5 inches per second if structures are near the construction activity, in compliance with WSDOT and ODOT requirements. This would include pile driving, vibratory sheet installation, soil compacting, and other construction activities with the potential to cause high levels of vibration.
- For historic built properties within 500 feet of construction, monitor construction activities where construction-related vibration would exceed 0.2 inches per second for transient vibrations and 0.1 inches per second for continuous vibrations.

Additional vibration mitigation measures intended to protect marine life are described in Section 3.16, Ecosystems. Additional mitigation measures related to built historic resources are described in Section 3.8, Cultural Resources.

Program-Specific Mitigation

No program-specific mitigation measures are proposed for vibration levels during construction.

3.12 Energy

Federal, state, and local policies (as discussed in the Energy Technical Report) support energy conservation. Transportation energy efficiency is primarily regulated through vehicle efficiency requirements. There are no regulatory standards for transportation facility energy efficiency. Operational energy consumption was evaluated using Oregon Metro's regional travel demand model. The information presented in this section is based on the Energy Technical Report.

3.12.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with energy has been updated in this Draft SEIS to include:

- Revised methodology based on ODOT's updated Air Quality Manual and WSDOT's Guidance on Addressing Air Quality, Greenhouse Gas Emissions, and Energy for WSDOT projects.
- Updated data and models, such as the FHWA Infrastructure Carbon Estimator and the FTA Greenhouse Gas (GHG) Estimator to measure emissions and energy consumption from the construction and maintenance of transportation projects, and the U.S. Environmental Protection Agency's (EPA) latest version of MOtor Vehicle Emission Simulator (MOVES) that estimates emissions and energy consumption from on-road vehicles.
- Updated scenarios for electric vehicle assumptions.
- Change in transportation modeling and analysis.
- Changes to the project footprint, as necessitated by changed conditions, and in existing land uses resulting in changes to proximity to sensitive receptors.

Table 3.12-1. compares the impacts and benefits of the CRC LPA to those of the Modified LPA as a result of the changes listed above. Based on the analysis described in this section, the effects of the Modified LPA would be similar to those of the CRC LPA. Although the methodologies and units used to report energy use have changed since the CRC Final EIS, both the CRC LPA and Modified LPA would reduce energy consumption and GHG emissions.

Table 3.12-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Annual energy use during operations	Approximately 324,940 BTU of regional transportation energy consumption (mmBtu/day) [a]	Approximately 271,187 BTU of regional transportation energy consumption (mmBtu/day)	• Updates to the MOVES modeling tool, which includes fuel economy and fuel efficiency standards that have been adopted since 2011. • Changes in underlying assumptions about energy consumption from

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
			transit agencies. Values used for the CRC LPA were system-wide whereas values used for the Modified LPA are based on attributable changes.
Total GHG emissions during operations	Approximately 24, 746 metric tons/day (2030)	Approximately 26,325 metric tons/day (2045)	• Same as annual energy use during operations (above).
Vehicle Miles Traveled	Approximately 36.4 million (2030 9-hour regional VMT)	Approximately 58.9 million (2045 daily regional VMT)	• VMT for the CRC LPA was reported for a 9-hour period, whereas VMT for the Modified LPA is reported for a daily (24-hour) period. • Variations in methodology, such as the base year of analysis.
Construction impacts to energy consumption and GHG emissions	Approximately 11,447,104 mmBTU and 871,265 $MTCO_2e$	Approximately 2,601,017 mmBTU and a range of 412,627 to 469,444 $MTCO_2e$	• Updates to methodology and availability of FHWA Infrastructure Carbon Estimator

a CRC estimates on energy use are based on a different underlying assumption about energy consumption. CRC values are system-wide energy values based on data from transit agencies. IBR values are based only on changes due to the Program.

CRC = Columbia River Crossing; BTU = British thermal units; FHWA = Federal Highway Administration; GHG = greenhouse gas; IBR = Interstate Bridge Replacement; mmBTU = one million British thermal units; MOVES = MOtor Vehicle Emission Simulator; MTCO2e = metric tons of carbon dioxide equivalent; VMT = vehicle miles traveled

3.12.2 Existing Conditions

The energy analysis considered effects within the "traffic assignment area," which is the area where the Modified LPA would affect vehicle traffic. The study area and traffic assignment area are shown in Figure 3.12-1.

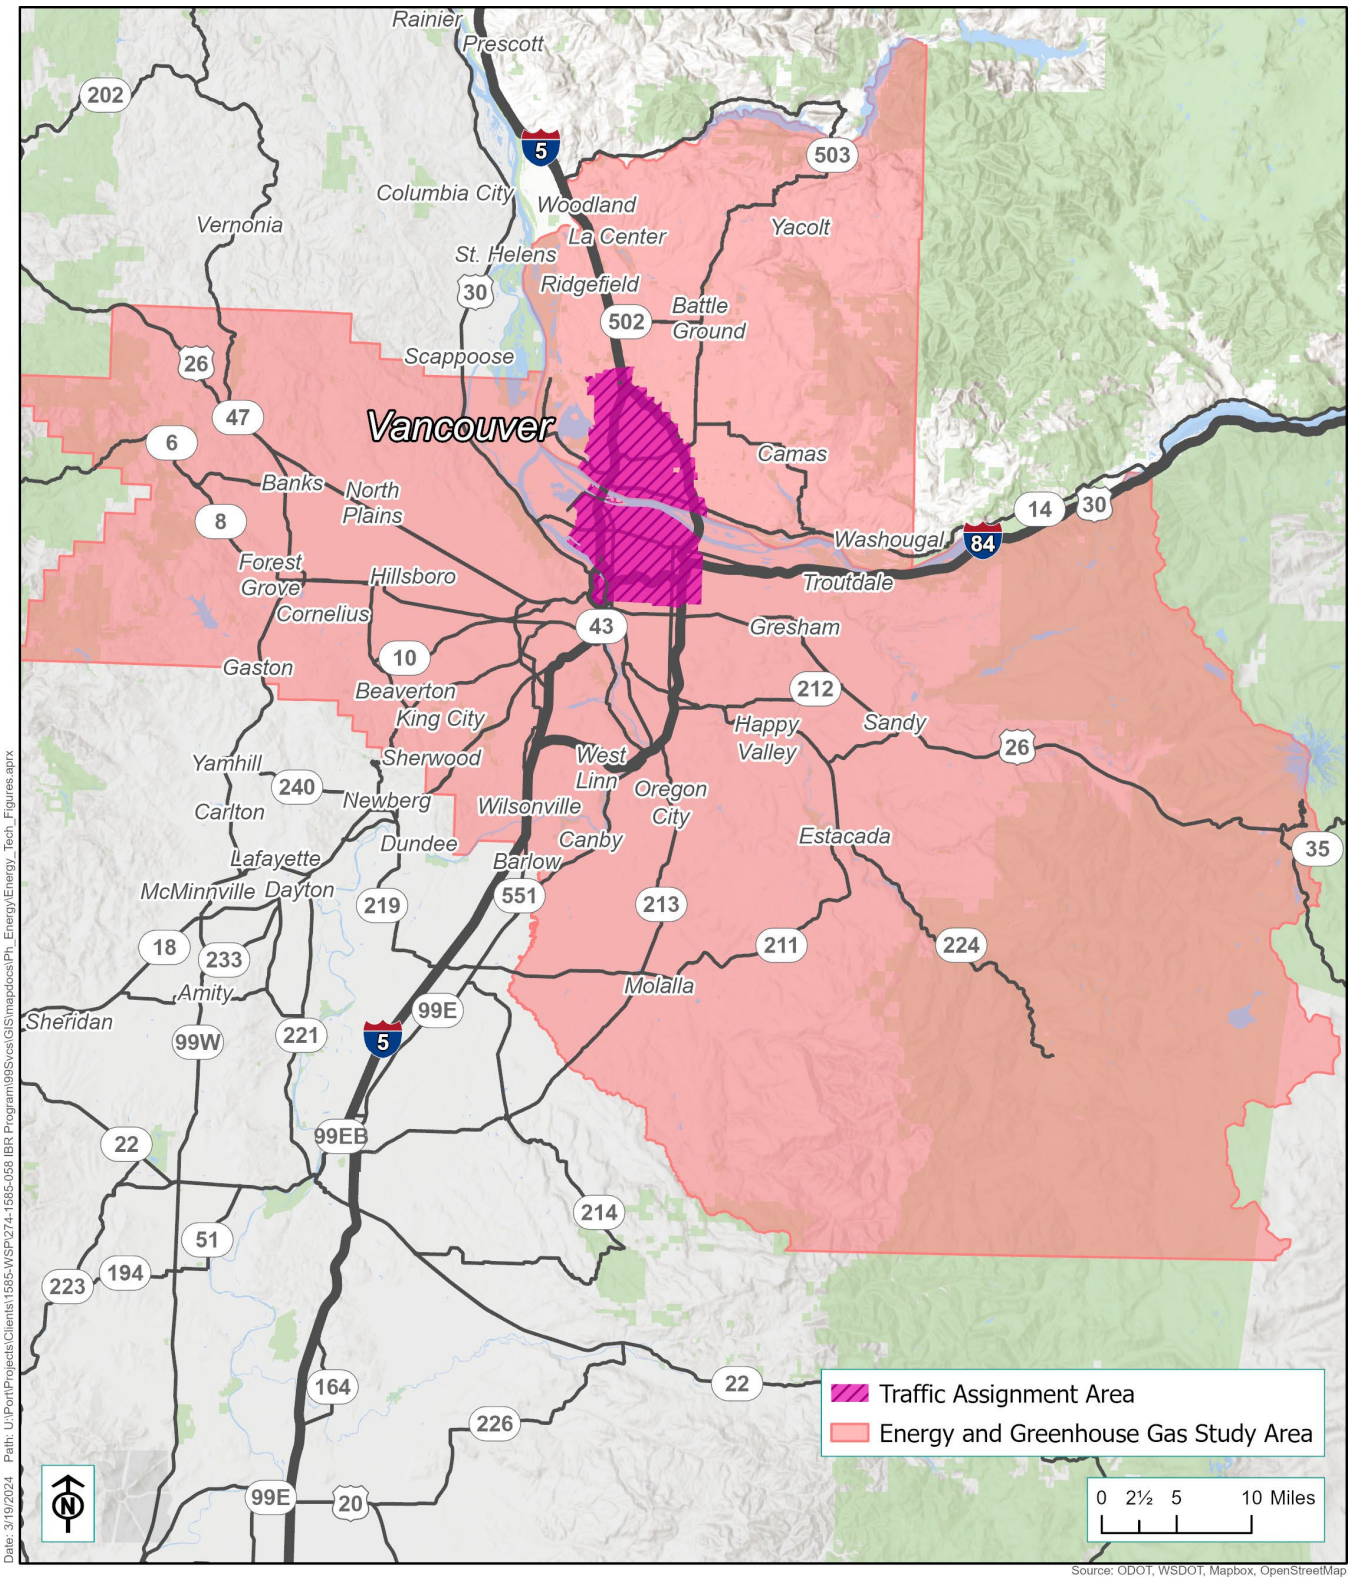
To represent existing conditions, energy consumption was estimated for the analysis year 2015; 2015 corresponds to the base year of the regional travel demand model that serves as the basis for the regional emissions analysis. More recent regional data was not available. The EPA MOVES model, version 3.1.0, was used to estimate energy consumption from the roadway links in the study area. Long-term effects to energy consumption from roadway maintenance, transit maintenance, and transit operations are demonstrated as an increase or decrease to a baseline condition; therefore, the energy consumption from existing roadway maintenance, transit maintenance, and transit operations in the study area were not quantified. The analysis for transit operations focused on new transit operations and stations that would be implemented as part of the Modified LPA.

National Energy Demand Projections

The U.S. Energy Information Administration projects that energy consumption in the transportation sector will remain lower than 2019 levels through 2050 because travel significantly decreased in 2020 as a result of

COVID-19 lockdowns and because improvements in fuel economy and a shift to electrification will offset projected resumed travel growth. As a result, energy consumption by light-duty and heavy-duty vehicles is projected to remain lower than 2019 levels through 2045.

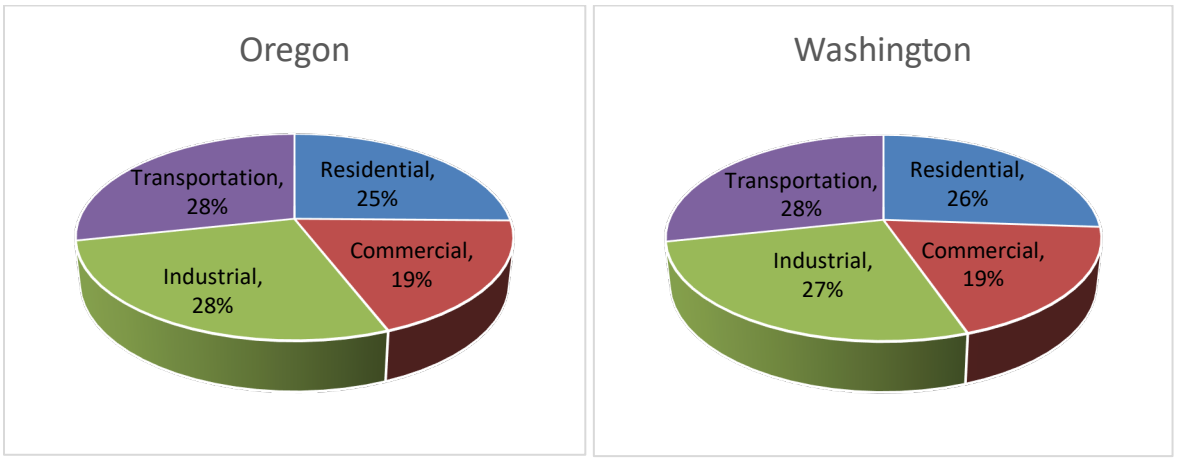
Figure 3.12-1. Energy Study Area and Traffic Assignment Area



Washington and Oregon Energy Trends

Transportation accounts for a substantial portion of the energy consumed in Oregon and Washington—approximately 28% for both states (Figure 3.12-2). Petroleum (e.g., gasoline, diesel, and jet fuel) was the predominant source of transportation-related energy consumption in Oregon and Washington in 2020, at approximately 98% for each state. Natural gas and electric vehicles accounted for the remaining 2% of transportation energy consumption.

Figure 3.12-2. State Energy Consumption by End-Use Sector, 2020



Source: EIA 2022

In 2020, Oregon ranked 29th out of the 50 states for transportation energy consumption, with 279 trillion British thermal units (Btu) of transportation energy consumed, and 35th in transportation energy consumption per capita, at approximately 65.8 million Btu (EIA 2022). Washington ranked 18th in transportation energy consumption, with 505 trillion Btu of transportation energy consumed, and 38th in transportation energy consumption per capita, with about 65.4 million Btu consumed per capita in 2020.

3.12.3 Long-Term Benefits and Effects

This analysis compares the Modified LPA's potential adverse and beneficial effects to those of the No-Build Alternative, including the type and amount of energy consumed in construction and operation.

Table 3.12-2 summarizes the effects of the Modified LPA, design options, and No-Build Alternative on energy. Additional information is provided in the sections that follow.

Table 3.12-2. Summary of Energy Effects from the Modified LPA, the Design Options, and the No-Build Alternative

1	2	3	4	5	6	7
Effect	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 or I-5 Westward Shift, All Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5, All Park-and-Ride Site Options	Modified LPA with Single-Level Fixed-Span Configuration, [a] One Auxiliary Lane, C Street Ramps, Centered I-5, All Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, All Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5, All Park-and-Ride Site Options
Total Regional Transportation Energy Consumption (mmBtu/day)	• 271,933 in 2045 without electric vehicles. • 190,771 in 2045 with electric vehicles.	• 271,187 in 2045 without electric vehicles (-0.27% compared to No-Build Alternative). • 190,302 in 2045 with electric vehicles (-0.25% compared to No-Build Alternative).	• Similar to the effects listed in Column 3. Modeling results estimate a non-statistically significant difference of less than 0.1%.	• Similar to effects listed in Column 3, but would slightly reduce operational emissions due to the reduced profile grade of the new Columbia River bridges.	• Similar to effects listed in Column 5, except it would increase energy consumption due to the electricity required to raise and lower the bridge and as a result of idling that would be anticipated by a portion of the queued vehicles on the freeway during bridge closures.	• Similar to effects listed in Column 3, but would create additional congestion on local streets due to the removal of the C Street ramps, which would decrease vehicle efficiency, resulting in increased energy consumption.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge type options.

Energy consumption for the Modified LPA and the No-Build Alternative was estimated for 2045 using the travel demand model results, which includes consideration of shifts from vehicles to transit (Table 3.12-3). Carbon dioxide equivalent (CO_2e) was estimated as part of this analysis, and the results are presented in Section 3.19, Climate Change.

The EPA MOVES model, version 3.1.0, was used to estimate energy consumption and emissions of CO_2e from the study area roadway links. The MOVES model does not include assumptions about future electric vehicle use beyond what is included in federal fuel economy standards. However, by 2045 WSDOT and ODOT expect that the use of electric vehicles in Oregon and Washington will have increased substantially. To reflect the anticipated future use of electric vehicles, the Oregon Department of Environmental Quality provided MOVES input files and a post-processing methodology to create two scenarios comparing the No-Build Alternative and the Modified LPA: one with MOVES defaults for electric vehicles and one with assumptions about the region's transition to electric vehicles. The electric vehicle scenario assumes that by 2045, 52% of all passenger vehicles would be electric and thus would have zero tailpipe emissions of CO_2e. Increased adoption of electric medium-duty and heavy-duty trucks were also included. Emissions of CO_2e from electric vehicles were calculated based on estimates of the carbon intensity of the local power supply and estimates of the electricity needed to power an electric vehicle.

No-Build Alternative

Roadway and Transit Operations and Maintenance

Due to federal fuel and engine regulations, the energy efficiency of motor vehicles is expected to increase substantially over the next two decades. As a result, the energy consumed by roadway operations under the No-Build Alternative in 2045 would be lower than existing energy consumption (Table 3.12-3), despite an increase in annual VMT in the study area over this same period.

Table 3.12-3. Daily Energy Consumption in the Study Area and Traffic Assignment Area

Parameter	Existing (2015)	No-Build (2045) without Electric Vehicles	Modified LPA (2045) without Electric Vehicles	Modified LPA Difference from No-Build without Electric Vehicles	No-Build Alternative with Electric Vehicles (2045)	Modified LPA with Electric Vehicles (2045)	Modified LPA Difference from No-Build with Electric Vehicles
Daily Regional VMT [a]	43,017,600	59,042,000	58,950,700	-0.15%	59,042,000	58,950,700	-0.15%
Total Regional Transportation Energy Consumption (mmBtu/day)	290,732	271,933	271,187	-0.27%	190,771	190,302	-0.25%
Daily Traffic Assignment Area VMT	11,267,300	14,349,500	14,270,500	-0.55%	14,349,500	14,270,500	-0.55%

Parameter	Existing (2015)	No-Build (2045) without Electric Vehicles	Modified LPA (2045) without Electric Vehicles	Modified LPA Difference from No-Build without Electric Vehicles	No-Build Alternative with Electric Vehicles (2045)	Modified LPA with Electric Vehicles (2045)	Modified LPA Difference from No-Build with Electric Vehicles
Total Traffic Assignment Area Energy Consumption (mmBtu/day)	76,557	67,466	66,704	-1.13%	47,863	47,380	-1.01%

Note: Results from this table were generated using the MOVES model.

a Daily VMT represents regional link-level data provided by the IBR Program transportation analysts for the MOVES analysis. The VMT used for the MOVES analysis could be slightly different from the Regional VMT reported in the Transportation Technical Report due to differences in how VMT is allocated to specific roadway segments. Note that this daily VMT differs from the analysis for air quality, which evaluates a specific roadway network.

LPA = Locally Preferred Alternative; mmBtu = million British thermal units; VMT = vehicle miles traveled

The No-Build Alternative would not modify the energy consumption necessary for transit operations, roadway maintenance, or transit maintenance.

Modified LPA

Roadway Operations

Similar to the No-Build Alternative, compared to the existing condition VMT is expected to increase approximately 37% by 2045 under the Modified LPA; however, vehicle efficiency would lower estimated energy consumption within the region and within the traffic assignment area (Table 3.12-2).

Looking only at the traffic assignment area, 2045 energy consumption under the Modified LPA is estimated to decrease by approximately 1.01% compared to the No-Build Alternative. This is the same for the Modified LPA with the double-deck fixed-span configuration and the single-level fixed-span configuration (all bridge type options). The single-level movable-span configuration could increase energy consumption as a result of idling by queued vehicles on the roadways during bridge closures and potentially the energy required to raise and lower the bridge opening.

Compared to the Modified LPA with one auxiliary lane, the regional modeling results estimate a slight decrease in energy consumption with the Modified LPA with two auxiliary lanes. However, the decrease is not statistically significant (less than 0.03%). An additional analysis using an operational model output for changes in speed and congestion on the I-5 corridor show that energy consumption with the Modified LPA with two auxiliary lanes could decrease 0.5% compared to the Modified LPA with one auxiliary lane.

The Modified LPA without the C Street ramps at the I-5 and SR 14 interchange would result in additional congestion on local streets and increased energy consumption. Because this analysis is based on the regional travel demand model, this potential increase is not quantified. The Modified LPA with the centered I-5 mainline or mainline shifted west would have the same long-term energy consumption. All of the park and ride site options could equally encourage transit use, which was accounted for in the regional travel demand model and reflected in the energy consumption modeling results for the Modified LPA.

Energy consumption is different between the scenarios with and without electric vehicles because electric vehicles also require energy, but they shift the demand from petroleum to the electrical grid. The extension of Tri-County Metropolitan Transportation District (TriMet) and Clark County Public Transit Benefit Area

Authority (C-TRAN) service, the tolling of the river crossing, and active transportation would reduce overall VMT increases that would otherwise be anticipated from the added capacity associated with the Modified LPA.

Transit Operations

Energy consumption from transit operations would increase under the Modified LPA due to the increase in electricity needs for new transit vehicles, stations and park and ride facilities (Table 3.12-4). The additional energy needs for new transit vehicles and new transit facilities are less than 8% of the energy consumption from on-road vehicles. Energy consumption estimates in Table 3.12-4 reflect the new, additional energy needs for transit operations.

Table 3.12-4. Modified LPA Transit Operations Energy Consumption

Transit Element	Energy Consumption (mmBtu/year)
Light-Rail Vehicles	2,638
Transit Stations	1,146

Source: FTA Greenhouse Gas Emissions Estimator output model 2023 (available in the Energy Technical Report Appendix B)
mmBtu = million British thermal units

Roadway and Transit Maintenance

The annual energy consumption estimate for additional routine roadway maintenance (sweeping, restriping, and landscaping), transit vehicle maintenance, and light-rail track maintenance under the Modified LPA is approximately 11,000 million British thermal units (mmBtu) per year.

Collisions

The Modified LPA would meet current design standards and would decrease the level of traffic congestion, which would reduce collision frequency. During traffic incidents, new shoulders would be used for maintenance and emergencies, which would reduce congestion in the general purpose lanes. Reducing the congestion caused by collisions would in turn reduce energy consumption compared to the No-Build Alternative because of the reduction in idling traffic. This reduction in energy consumption was not quantified due to methodology constraints, which are described in more detail in the Energy Technical Report.

Bridge Openings

While there is no standard methodology to estimate how many drivers turn off their engines during a bridge opening, it is expected that at least a portion of drivers on the highway leave their vehicles idling during a bridge opening. Therefore, the Modified LPA with the double-deck fixed-span configuration and the single-level fixed-span configuration would be expected to reduce energy consumed by idling traffic during bridge openings. The Modified LPA with the single-level fixed-span configuration (all bridge type options) would further slightly reduce energy consumption due to the lower profile grade of the new Columbia River bridges (approximately 29 feet lower than the Modified LPA's double-deck fixed-span bridge configuration). The Modified LPA with the single-level movable-span configuration would also reduce energy consumption with a lower profile grade; however, compared to the Modified LPA with the fixed-span configurations, the Modified LPA with the single-level movable-span configuration may include additional energy consumption from the electricity required to raise and lower the vertical lift, and the energy consumption from idling vehicles would be similar to the No-Build Alternative.

3.12.4 Temporary Effects

No-Build Alternative

The No-Build Alternative does not propose construction of new transportation facilities. Accordingly, no definable construction energy consumption is associated with the No-Build Alternative.

Modified LPA

Construction of the Modified LPA would include construction of the new bridges and removal of the existing Interstate Bridge. Using FHWA's Infrastructure Carbon Estimator (ICE) modeling tool, Table 3.12-5 presents estimated construction energy consumption for the Modified LPA over the construction period. The Modified LPA with two auxiliary lanes would have a wider I-5 roadway (approximately 4% larger total pavement area), resulting in an increase in energy consumption during construction compared to the Modified LPA with one auxiliary lane. However, the ICE modeling tool is a planning-level tool that cannot capture the quantity of this increase for this analysis.

Table 3.12-5. Modified LPA Energy Consumption from Construction Activities

Project Element	Total Energy Consumption (mmBtu)
Materials	2,244,692
Transportation	107,794
Construction	248,531
Total	**2,601,017**

Source: FHWA Infrastructure Carbon Estimator (ICE) model output 2023 (available in the Energy Technical Report Appendix A)
a Values calculated from the ICE model
mmBtu = million British thermal units

Design data are not available at a level of detail required to estimate the potential construction-related energy consumption among design options. Design options that require a greater volume of materials (e.g. the single-level movable-span configuration) would require a greater amount of energy to power additional construction equipment; however, design data to needed determine the material volumes and associated equipment use would not be available until final design.

3.12.5 Indirect Effects

The energy analysis of the Modified LPA is based on travel demand modeling that includes expected growth and planned projects in the region, including growth facilitated by the Modified LPA consistent with local and regional land use plans (see Section 3.4.4). The Modified LPA is not expected to create other effects that would cause indirect impacts to energy use and GHG emissions. Energy consumption could be affected by induced changes in patterns of land use, population density, or population growth rate. Land use changes would be expected to occur in compliance with local land use plans. Section 3.4, Land Use and Economics, evaluates the potential for induced land use growth associated with the Modified LPA.

3.12.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

State-level legislation and policy in Oregon and Washington support reducing emissions from transportation to minimize contributions to climate change; however, there are no specific requirements for mitigation in federal, state, or local regulations. The Program supports state, regional, and local goals to reduce GHG emissions. To help facilitate a shift from single-occupancy vehicles, the Program would improve multimodal transportation options, including:

- Extended light-rail
- Expanded active transportation facilities
- Demand management (e.g., variable-rate tolling)
- Operation and maintenance efficiencies

Program-Specific Mitigation

- Use energy-efficient electrical systems for transit stations and other electrical needs to decrease energy consumption.

Temporary Effects

Regulatory Requirements

- In Oregon, comply with ODOT Standard Specifications Section 290.
- In Washington, company with WSDOT Standard Specifications Division 1-07.

Program-Specific Mitigation

- All work in Washington and Oregon will follow the WSDOT Environmental Manual, Chapter 425: Air Quality, Energy, and Greenhouse Bases, including:
  - Minimize delays to traffic during peak travel times.
  - Minimize unnecessary idling of on-site diesel construction equipment.
  - Educate vehicle operators to shut off equipment when not in active use to reduce emissions from idling.
  - Prepare a traffic control plan with detours and strategic construction timing (e.g., night work) to move traffic through the area and reduce backups and delays to the traveling public to the extent practicable.
- Continue to consider advances in energy-reducing and/or energy-saving materials and methods.

3.13 Electric and Magnetic Fields

This section assesses whether electric and magnetic fields (EMF) generated by light-rail transit (LRT) facilities, which use an overhead electrical supply, would cause adverse effects. The information in this section is based on the Electromagnetic Fields Technical Report.

3.13.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with EMF has been updated in this Draft SEIS to include:

- Updates to methodology for evaluating EMF.
- Changes in the project footprint necessitated by changed conditions resulting in shifting the light-rail transit alignment and locations of substations and a new overnight facility.

Based on the analysis in this section, the effects of the Modified LPA would be similar to those of the CRC LPA. The Modified LPA and the CRC LPA would both result in an increase in EMF exposure near the light-rail alignment, including at substations and within light-rail vehicles. Exposure levels in both cases would remain below applicable exposure guidelines. However, there would be changes between the CRC LPA and the Modified LPA in sensitive land uses exposed to EMF, as described in Table 3.13-1.

Table 3.13-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in This Section	Explanation of Differences
Sensitive Land Uses	• Northernmost electrical substation would be located between 17th Street and McLoughlin Boulevard in Vancouver, land currently in residential use. The five residential parcels closest to the substation would be acquired. • New transit-oriented development activities and sensitive uses would be located a considerable distance from proposed substation locations.	• Proposed Evergreen substation would be located approximately 100 feet south of a multifamily residential complex. EMF levels from the station would be below the public exposure guidelines. • The other three proposed substations are not near residential buildings or other EMF-sensitive land uses.	Differences are due to the change in the LRT alignment in downtown Vancouver (shifted from downtown streets to along I-5) and the change in the northern LRT terminus.

CRC = Columbia River Crossing; EIS = Environmental Impact Statement; LPA = Locally Preferred Alternative; LRT = light-rail transit

3.13.2 Existing Conditions

Current Guidelines and Regulations

Federal regulations set limits for EMF exposure in the workplace and in public areas that apply to AM and FM radio, television, and wireless sources (47 Code of Federal Regulations 1.1307(b)). Schools, daycare facilities, hospitals, senior living facilities, research facilities, and universities are considered sensitive receptors to EMF. The FTA has adopted guidance on approaches to preventing and reducing community environmental, health, and safety impacts from transit-generated EMF and electromagnetic radiation, including best management practices for light-rail systems.

The International Commission on Non-Ionizing Radiation Protection (ICNIRP), in association with the World Health Organization and the American Conference of Governmental Industrial Hygienists, has developed voluntary occupational guidelines for EMF exposure, shown in Table 3.13-2.

Table 3.13-2. Exposure Guidelines for Power Frequency (60 Hz) Electromagnetic Fields

Exposure at 60 Hz	Electrical Field (kV/m)	Magnetic Field (mG)
International Commission on Non-Ionizing Radiation Protection		
Occupational	8.3	10,000
General Public	4.2	2,000
American Conference of Governmental Industrial Hygienists		
Occupational Exposure Should Not Exceed this Level	25	10,000
Prudence Dictates Use of Protective Clothing Above this Level	15	–
Exposure of Workers with Cardiac Pacemakers Should Not Exceed this Level	1	1,000

Sources: ICNIRP 2010; ACGIH 2015
Hz = hertz; kV/m = kilovolts per meter; mG = milligauss

EMF Generation and the Existing TriMet Light-Rail System

The main sources of EMF associated with LRT are the traction power system elements for the TriMet MAX LRT system. Table 3.13-3 shows the strength of the magnetic field at distances of 30, 65, and 100 feet from the light-rail tracks. As shown in Table 3.13, the magnetic field strength weakens rapidly as distance from the tracks increases. The highest measured value (167 milligauss [mG]) is well below the ICNIRP standard of 2,000 mG for public exposure to magnetic fields.

Units for Electric and Magnetic Fields

Voltage is similar to “electrical pressure” in an electrical line. This pressure produces an electrical field that extends out from the line and is measured in volts per meter (V/m). Current, in an active electrical line, also produces a magnetic field around the line. Magnetic fields are measured in units of gauss (G). Since most magnetic fields are weak, these fields are typically measured in milligauss (mG or 1/1,000th of a gauss).

Electrical systems can be either direct current (DC) or alternating current (AC). The electricity in wall sockets and power lines is alternating current. Direct current powers the MAX light-rail system in Portland. The frequency of alternating current is measured in hertz (Hz).

Table 3.13-3. Magnetic Field Strength at Distance from TriMet's Light-Rail Tracks (mG)

Direction	30 Feet	65 Feet	100 Feet
Horizontal	167.0	44.6	13.3
Vertical	17.8	8.2	3.4

Source: Edelson and Holmstrom 1998
mG = milligauss

Direct current magnetic fields measured in 2008 at TriMet's light-rail substations ranged from 107 to 601 mG at the perimeter of the buildings and from 47 to 551 mG at light-rail stations. Magnetic field measurements taken inside light-rail cars fluctuated between approximately 0.38 and 8.13 mG at approximately seat height (CRC 2011), indicating that EMF emissions are extremely low within the light-rail vehicles used in the existing light-rail system. All the field intensities measured in TriMet's system are below the public exposure guidelines.

The analysis in this section includes a review of the EMF measurements reported in the CRC EMF technical report (CRC 2011), updated with similar and more recent rail systems approved and in operation since 2011. Because the proposed light rail extension with the Modified LPA would include system elements consistent with the existing TriMet MAX light rail system (such as power levels, substation ratings, and facility and system design), EMF levels along the light rail extension would be identical to those produced along the current TriMet MAX light rail system in Portland. Therefore, the data from the CRC EMF technical report is sufficient to assess potential EMF exposure levels for the Modified LPA.

3.13.3 Long-Term Benefits and Effects

Table 3.13-4 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on EMF. Detailed analysis of the effects is provided in the following sections.

Table 3.13-4. Summary of No-Build Alternative and Modified LPA Effects on Electric and Magnetic Fields

No Build Alternative	Modified LPA (all design options)
No change.	EMF emissions would increase slightly at certain locations along the light rail extension but would remain well below exposure guidelines.

No-Build Alternative

Existing EMF levels in the study area are a function of global background magnetic fields and EMF generated by nearby sources (e.g., utility power cables, office equipment, internal building wiring, and any other electrical apparatus). EMF levels fluctuate over time, depending on the operation of these nearby sources. Under the No-Build Alternative, there would be no change in existing EMF levels.

Modified LPA

There would be no changes to existing EMF sources or levels related to the highway components of the Modified LPA, including the one or two auxiliary lane options, the option with or without the C Street ramps, the option to shift the I-5 mainline to the west, the single-level fixed-span configuration option (all bridge types), or the single-level movable-span configuration option.

The light-rail trains would be powered by electricity, creating EMF fluctuations each time a train passes by. In the study area overall, EMF levels under the Modified LPA would be similar to those under the No-Build

Alternative. Within and near the new light-rail right of way, near new substations, and within the light-rail vehicles, EMF emissions would increase slightly compared to the No-Build Alternative but would remain well below exposure guidelines. The Modified LPA with the single-level fixed-span configuration and the single-level movable-span option would shift the LRT alignment across the Columbia River slightly west of the double-deck fixed-span configuration but EMF levels would remain well below exposure guidelines.

Figure 3.13-1 illustrates the locations of the light-rail substations proposed under the Modified LPA and the adjacent land uses. The proposed Evergreen substation would be located approximately 100 feet south of a multifamily residential complex in downtown Vancouver. Based on measurements taken at similar traction power substations, EMF levels from the Evergreen substation would be below the general public exposure guidelines shown in Table 3.13-1. The other three proposed substations are not near residential buildings or other EMF-sensitive land uses.

The Modified LPA would produce EMF from LRT, which is powered by electricity. However, the EMF intensities would be below exposure guidelines for risks to human health.

3.13.4 Temporary Effects

Construction of the Modified LPA, including construction of the Columbia River bridges and removal of the Interstate Bridge, would require electrical power (i.e., through the use of generators) for certain activities (e.g., to operate certain tools and lighting equipment) but is not expected to result in appreciable changes to EMF levels in the study area. Magnetic fields from generators and associated cables at accessible distances would be well under the maximum short-term exposure limits (ICNIRP 2008, 2020).

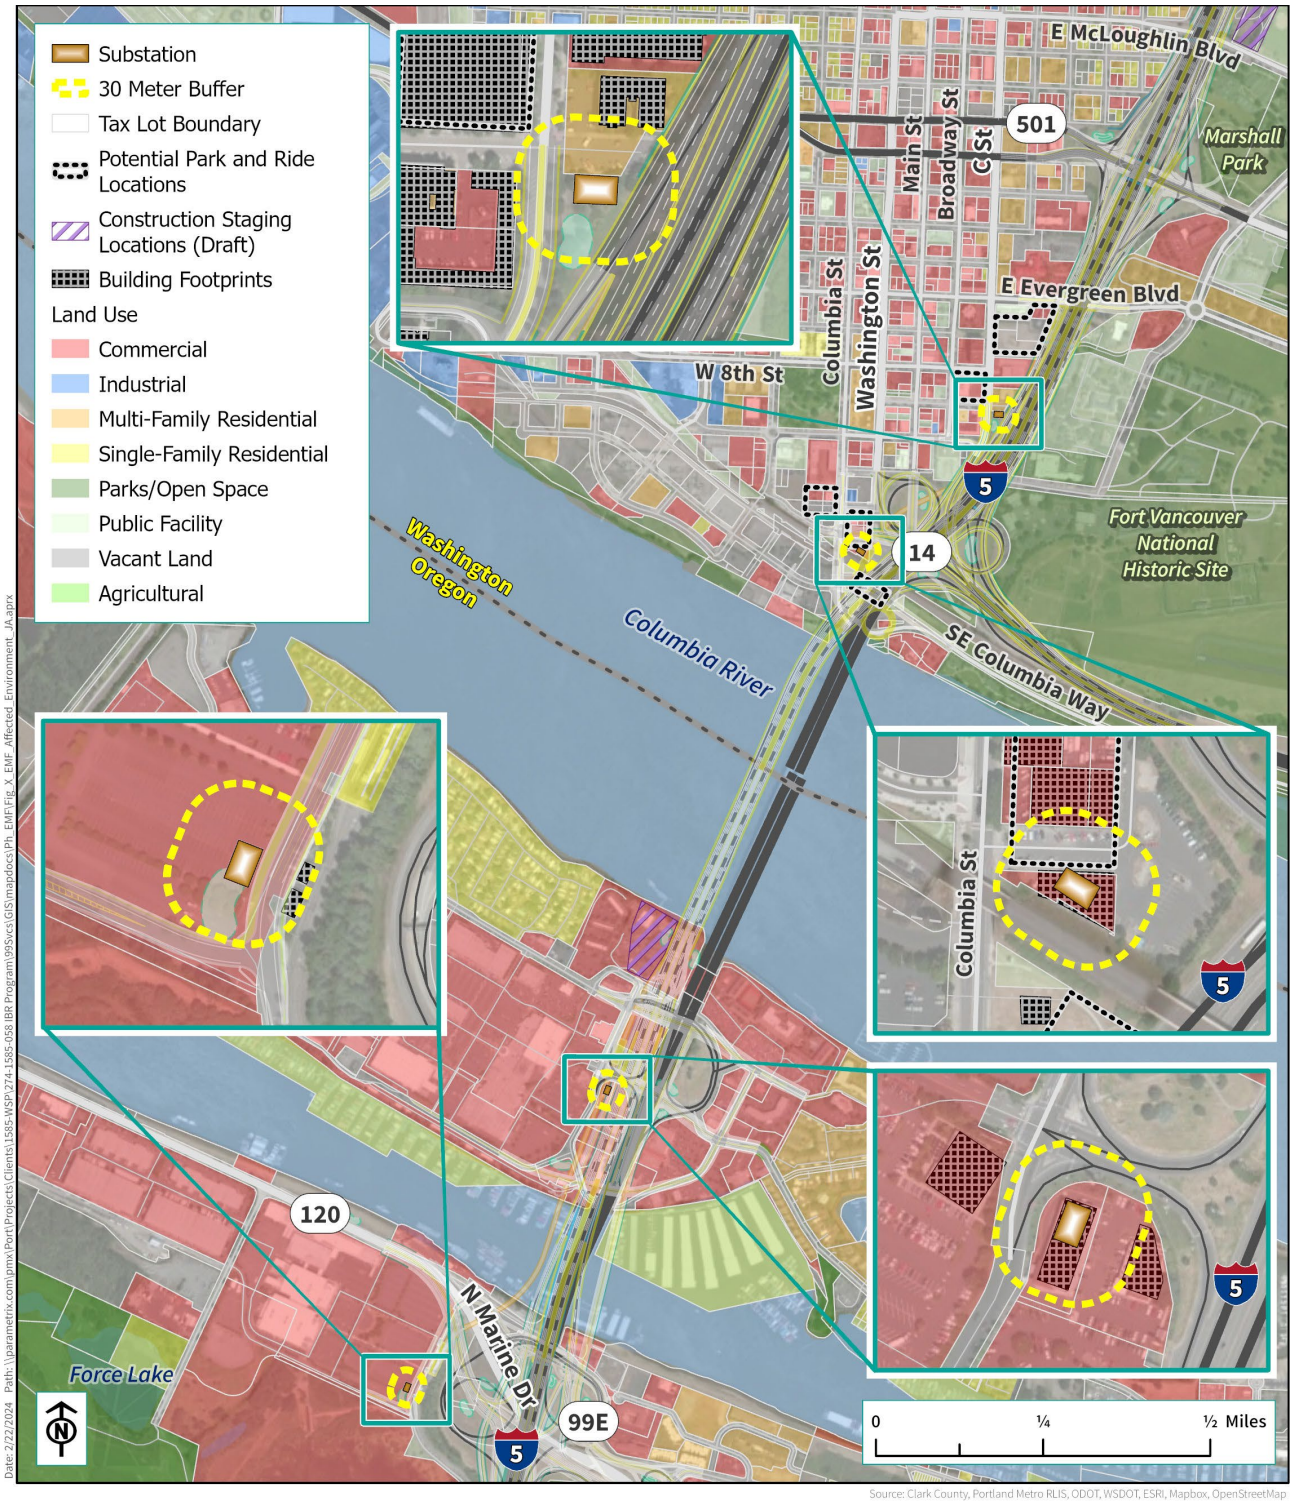
3.13.5 Indirect Effects

After decades of study and human exposure a direct link between EMF levels and adverse health impacts has not been firmly established (ICNIRP 2010). Consequently, no indirect effects from EMF are anticipated from the Modified LPA or the No-Build Alternative.

3.13.6 Potential Avoidance, Minimization, and Mitigation Measures

The levels of EMF anticipated to result from the Modified LPA are less than the exposure standards for both the workplace and the public; therefore, mitigation would not be necessary. The IBR Program would follow FTA guidance on best management practices for avoiding and minimizing EMF levels from light-rail systems.

Figure 3.13-1. Modified LPA Proposed Light-Rail Substations and Existing Land Uses



3.14 Water Quality and Hydrology

In urban areas, pollutants that wash off roadways during storms, such as automotive fluids, heavy metals, and small particles, degrade water quality in rivers and streams. The design and placement of roadways and stormwater systems can affect the quality and flow of water discharged from these features and the hydrology of the surrounding area. Placing structures such as bridge piers or roadways on a levee, in a waterway or its floodplain could affect the severity of floods during storm events. For this reason, modification to a levee or construction in waterways and their floodplains is strictly regulated and must consider the incremental contribution toward flood conditions.

What is the difference between water quality and hydrology?

In this analysis, water quality refers to the characteristics of the water—its temperature and oxygen levels, how clear it is, and whether it contains pollutants. Hydrology refers to the flow of water—its volume, where it drains, and how quickly the flow rate changes in a storm.

The information presented in this section is based on the Water Quality and Hydrology Technical Report. Additional detail on the impact of water quality to fish is in Section 3.16, Ecosystems. Additional detail on groundwater resources can be found in Section 3.17, Geology and Groundwater. Additional detail on potential changes in precipitation patterns as a result of climate change is in Section 3.19, Climate Change.

3.14.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with water quality and hydrology has been updated in this Draft SEIS to include:

- Changes to federal, state, and local regulations and permits.
- Changes in permitting processes, most notably for the Clean Water Act (CWA) Section 401 Water Quality Certification and Section 402 National Pollutant Discharge Elimination System (NPDES).
- Updates to Section 303(d)-listed impaired waters.
- Changes to climate predictions and modeling tools.
- Changes to constituents of emerging concern, including 6PPD-quinone.
- Addition, removal, and updating of data sources as appropriate.
- Expansion of the Ruby Junction Maintenance Facility in 2014.
- Changes in the project footprint necessitated by changed conditions.

Table 3.14-1 compares the impacts and benefits of the CRC LPA to those of the Modified LPA as a result of the changes listed above. Based on the analysis described in this section, water quality, hydrology, and stormwater management effects of the Modified LPA would be similar to those of the CRC LPA.

Table 3.14-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Water Quality	Beneficial effect on receiving water quality, as the design of the proposed facilities would include BMPs to remove pollutants in runoff from all roadway surfaces within the project footprint.	Beneficial effect on receiving water quality, as the design of the proposed facilities would include BMPs to remove pollutants in runoff from all roadway surfaces within the project footprint.	Negligible
Hydrology	Potential to cause long-term hydrologic effects to waterbodies due to an increase in impervious surfaces.	Potential to cause long-term hydrologic effects to waterbodies due to an increase in impervious surfaces.	Negligible
Stormwater management	• Could cause changes in peak flows and runoff volumes in local receiving waters because of the increased impervious surfaces in the study area. • Would improve treatment of existing impervious surfaces.	• Could cause changes in peak flows and runoff volumes in local receiving waters because of the increased impervious surfaces in the study area. • Would improve treatment of existing impervious surfaces.	Negligible
New and Rebuilt Impervious Surfaces (acres)[a]	267 acres (PGIS)	207 acres (CIA)	The design footprint of the Modified LPA has been reduced.
Total Suspended Solids Discharged from Impervious Surfaces (lbs/year)	19,579 lbs/year	16,694 lbs/year	The design footprint of the Modified LPA has been reduced. Pollutant loads are a function of treated and untreated areas. Both the CRC LPA and the Modified LPA would manage and treat all stormwater runoff from existing, new, or rebuilt impervious surfaces.

Note: Data are approximate and rounded.

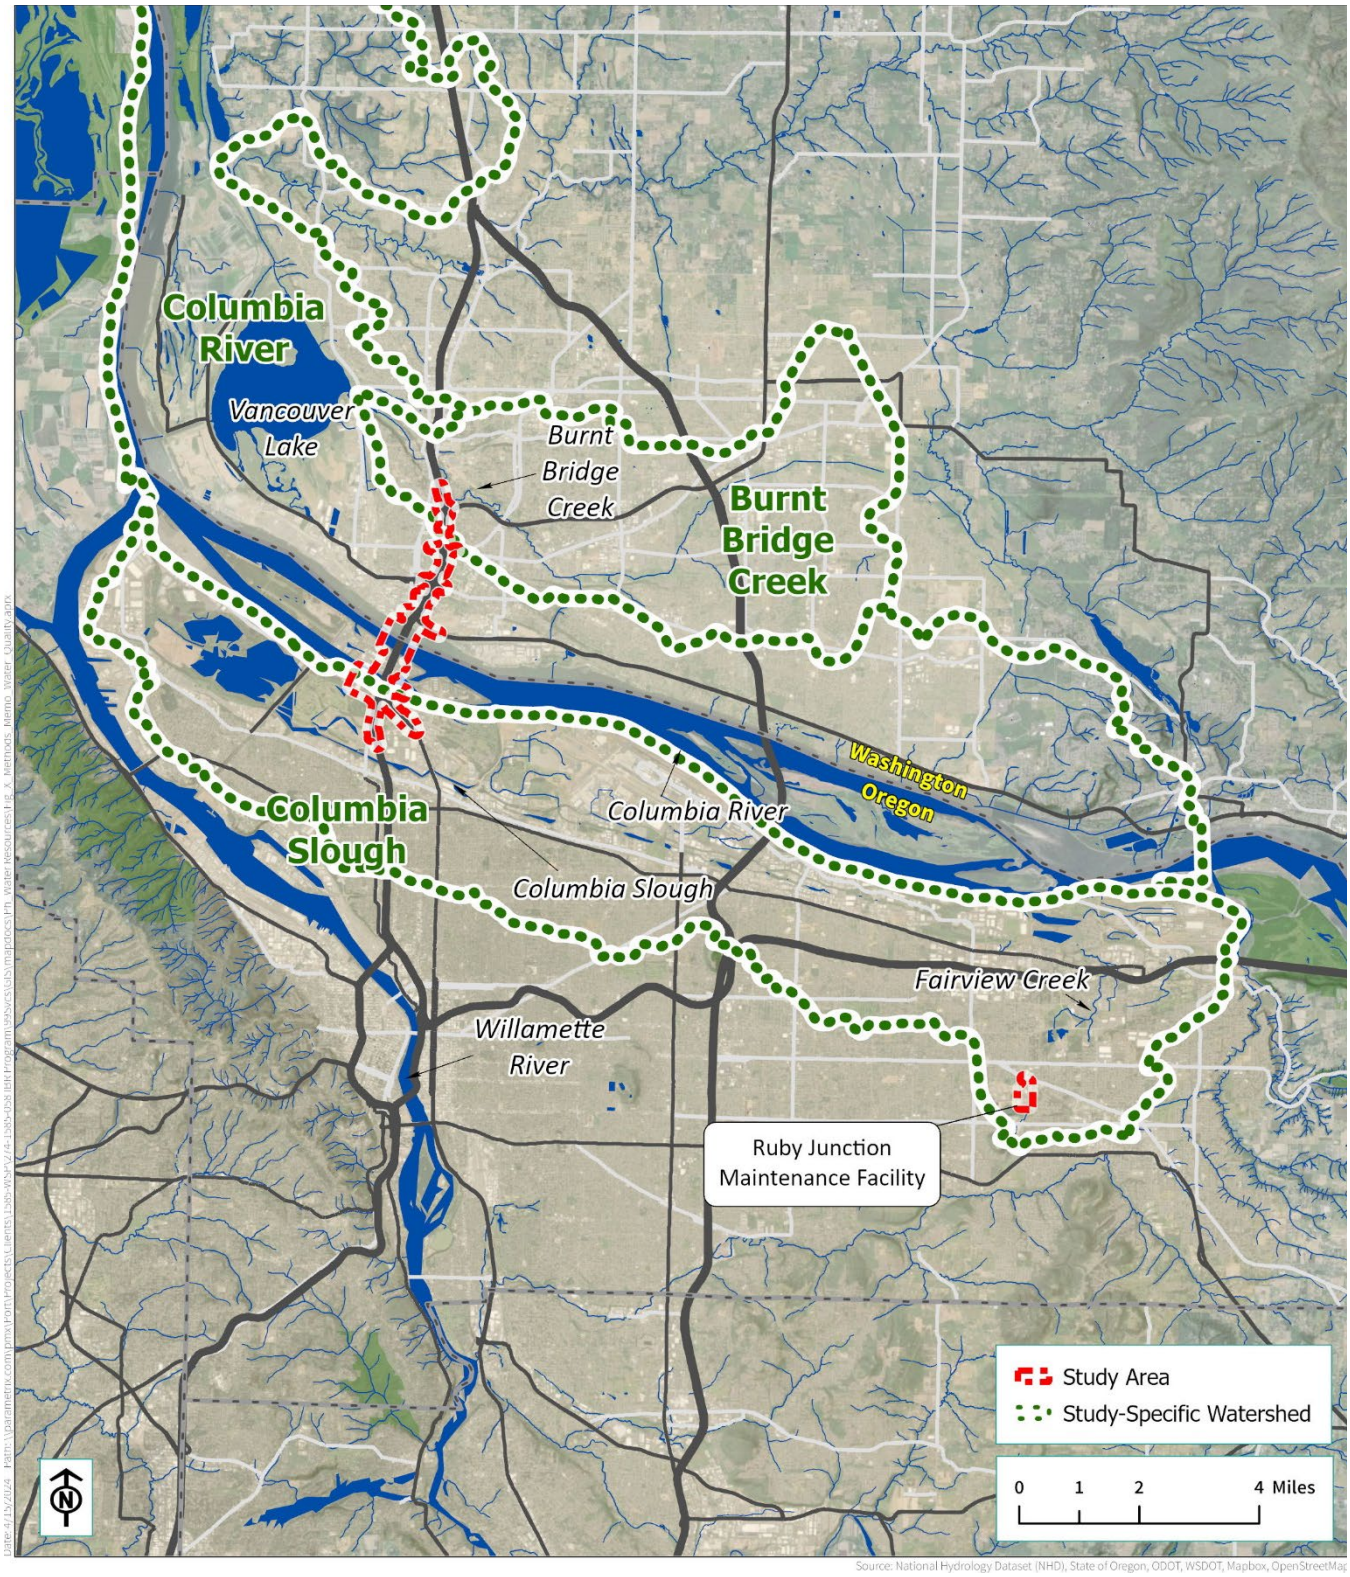
a Terminology and methodology was updated between the CRC project and IBR Program to be consistent with current regional stormwater management guidance. CIA encompasses both PGIS and non-PGIS.

BMP = best management practice; CIA = contributing impervious area; CRC = Columbia River Crossing; EIS = Environmental Impact Statement; lbs = pounds; LPA = Locally Preferred Alternative; N/A = not applicable; PGIS = Pollution Generating Impervious Surfaces

3.14.2 Existing Conditions

For this analysis, waterbodies and their contributing watersheds have been delineated based on their hydrologic connectivity to the study area. Watersheds into which runoff is, or could be, discharged are referred to as "receiving waters." Figure 3.14-1 shows the study area and watersheds.

Figure 3.14-1. Water Quality and Hydrology Study Area and Study-Specific Watersheds



Hydrology

The study area lies within the main Columbia River valley, except for a small area north of the SR 500 interchange that is located in the Burnt Bridge Creek watershed. Burnt Bridge Creek flows into Vancouver Lake before discharging to the Columbia River. The Columbia River and North Portland Harbor (a branch of the Columbia River south of Hayden Island) both cross under I-5 within the study area, while the Columbia Slough and Burnt Bridge Creek cross I-5 south and north of the study area, respectively. As a result of the Portland Metro Levee System, runoff from the Delta Park area between North Portland Harbor and the lower Columbia Slough, which was formerly part of the Columbia River floodplain, is now discharged to the lower Columbia Slough via pump stations. The Columbia Slough, which parallels the Columbia River floodplain, discharges near the confluence of the lower Willamette River and Columbia River.

What is a watershed?

A watershed is an area of land from which all precipitation and surface water drains to the same place and, generally, the same waterbody. Watersheds vary in shape and size, as determined by topography and geology, and can cross county, state, and national boundaries.

The study area around the Ruby Junction Maintenance Facility in Gresham, Oregon lies within the 100-year floodplain of Fairview Creek (Figure 3.14-2). Fairview Creek discharges into the upper Columbia Slough downstream of the maintenance facility.

In the study area, floodplains designated by the Federal Emergency Management Agency (FEMA) include those adjacent to the Columbia Slough, the Columbia River, and Burnt Bridge Creek (Figure 3.14-2). These floodplains are confined to the immediate vicinity of the streams by levees or, in the case of Burnt Bridge Creek, by steep slopes. For reference, the FEMA-modeled water surface elevation of the 100-year floodplain at the existing Interstate Bridge crossing of the Columbia River is approximately 32 feet referenced to the North American Vertical Datum of 1988.

Local Climate

The climate within the study area is characterized by short, dry, warm summers, with a typically cool and wet spring, fall, and winter. The Coast Range to the west of the study area offers limited shielding from Pacific Ocean storms, while the Cascade Mountains to the east provide an orographic lift of moisture-laden westerly winds, resulting in moderate rainfall. See Section 3.19, Climate Change, for a discussion of potential climate change trends.

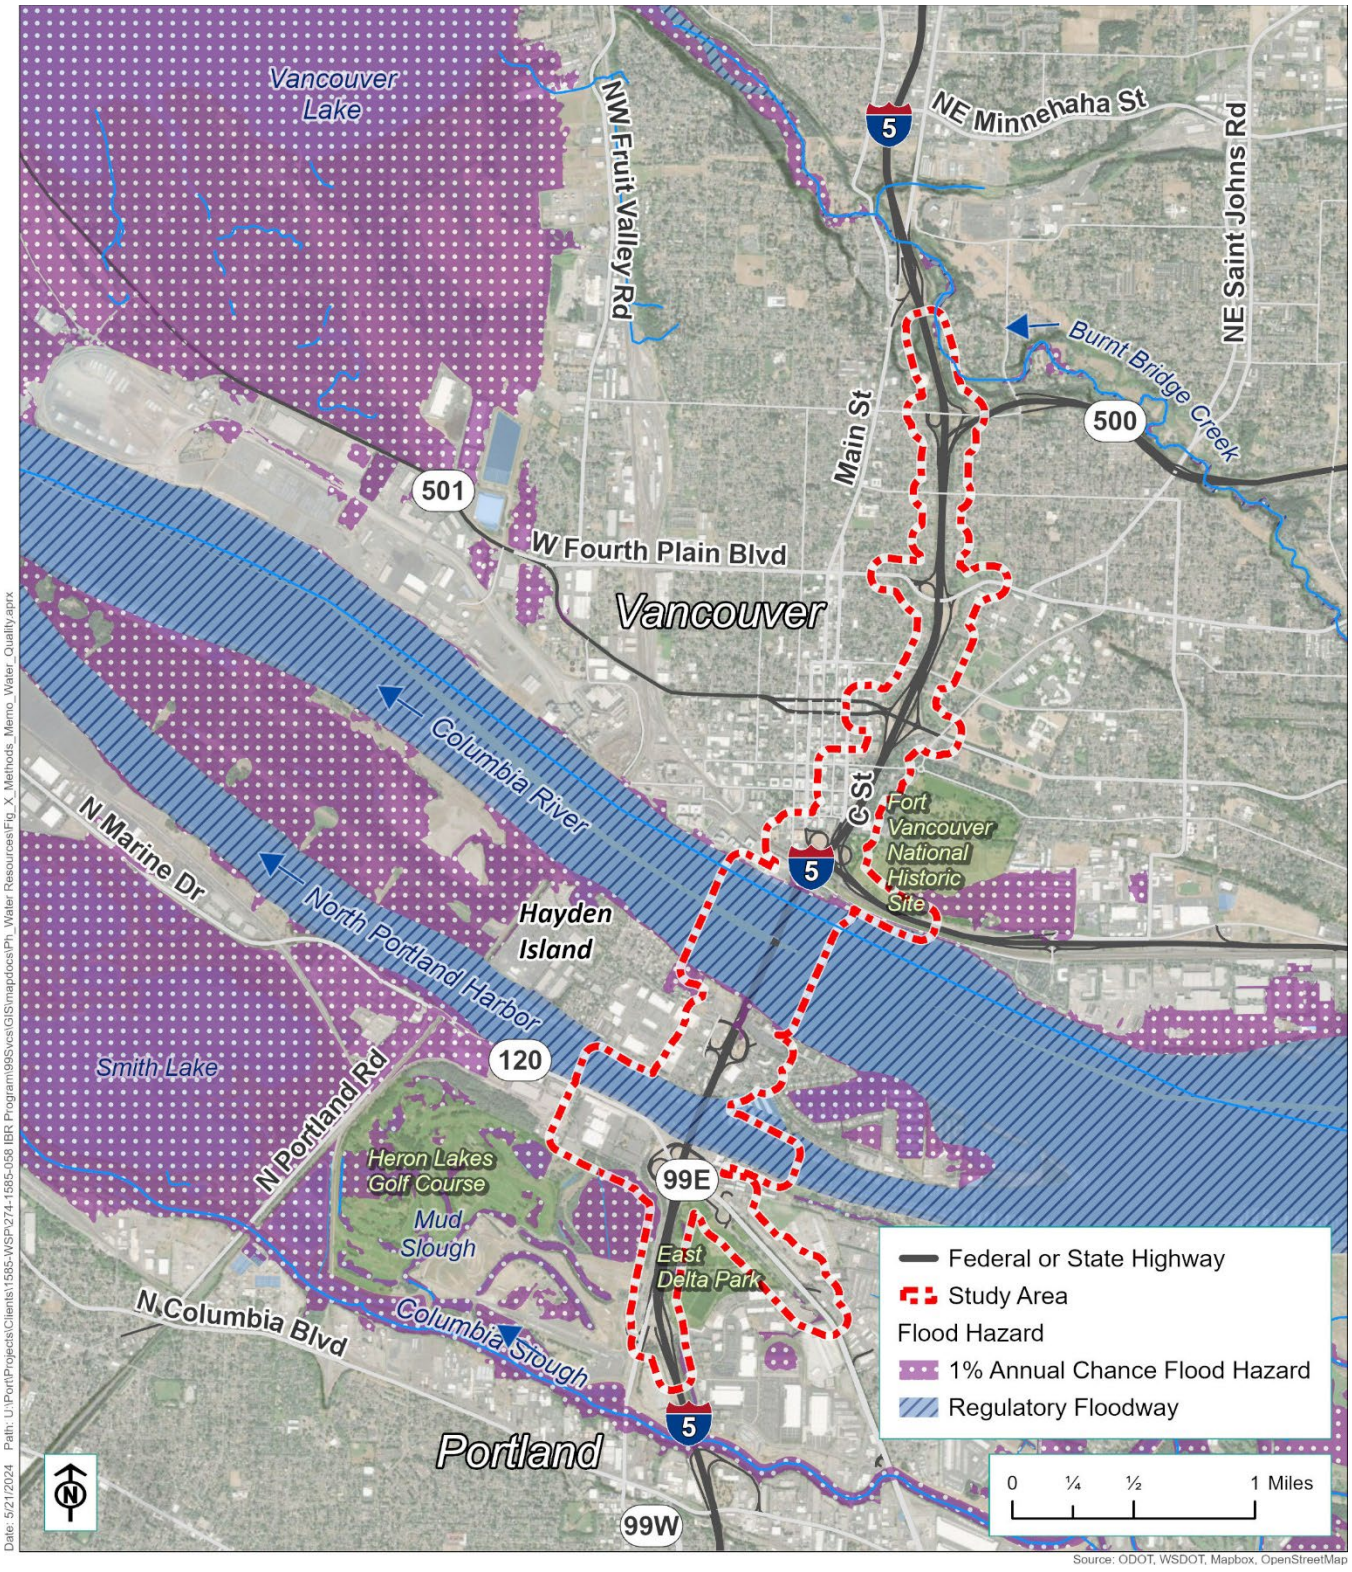
Receiving Waters

Columbia Slough

The Columbia Slough is a slow-moving, low-gradient drainage channel running nearly 19 miles from Fairview Lake in the east to the Willamette River in the west. The slough is a remnant of the historical system of lakes, wetlands, and channels that once dominated the south floodplain of the Columbia River. Its watershed drains approximately 32,700 acres of land in portions of Troutdale, Fairview, Gresham, Maywood Park, Wood Village, and unincorporated Multnomah County. The slough and areas to its north are currently intensively managed to provide drainage and flood control with pumps, weirs, and levees.

The slough is divided into upper, middle, and lower reaches. The upper and middle reaches receive water from Fairview Lake, Fairview Creek, and Wilkes Creek, as well as groundwater, natural springs, and overland flow and stormwater outfalls from industrial, commercial, and residential land uses in the surrounding area. The lower reach is tidally influenced while flows in the middle and upper reaches are controlled by pumping and gravity gates.

Figure 3.14-2. Federal Emergency Management Agency Floodplain Boundaries in the Study Area



Columbia River and North Portland Harbor

Within the study area, the Columbia River and North Portland Harbor are a constrained and highly managed waterway primarily influenced by upstream dams. Development of the hydropower system on the Columbia River has significantly influenced peak seasonal flows in the river, as well as their velocity and timing. Annual spring flows to the Columbia River estuary have been reduced on average by 50% to 55% from historical levels, while winter flows between October and March have increased by 35% compared to historical rates. The Columbia River is tidally influenced in its lower reaches below the Bonneville Dam, including the study area. Flows and water surface elevations in this area are influenced by tidal fluctuations, resulting in minimal streamflow at times and daily elevation changes.

The study area in the vicinity of the Columbia River is highly urbanized with a complex system of roadways (including I-5, state highways, local access roads, and residential streets), parking lots, and other impervious surfaces. Over the past 150 years, historical off-channel areas have been filled, rechanneled, diverted, and otherwise developed for agricultural and urban use. The channelization of the watershed has combined with the development of the hydropower system to dramatically alter the historical hydrologic regime.

For the stormwater analysis, the Columbia River watershed has been divided into the south and north sides of the river. The Columbia River South watershed includes the portion of the study area that discharges to North Portland Harbor and to the Columbia River south of the Oregon-Washington state line, including the Hayden Island area. The Columbia River North watershed includes the study area from the Oregon-Washington state line north to the SR 500 interchange.

Burnt Bridge Creek

Burnt Bridge Creek is a small tributary to the lower Columbia River. It originates east of Vancouver and flows west to its outlet at Vancouver Lake, then drains into the Columbia River via Lake River. Within the study area, the creek meanders through Leverich Park, northeast of the I-5/SR 500 interchange, before turning north to parallel I-5. Within the study area, development in the vicinity of Burnt Bridge Creek is similar to the vicinity of Columbia River.

Historically, Burnt Bridge Creek has been prone to flooding. Development of the study area has increased peak flows, reduced base flows, and altered the timing of flows compared to historical conditions. Several actions have been taken to reduce or relieve flooding, including channel modification, installation or upsizing of culverts, installation of storm lines, and construction of drainage systems. Additional flow control elements, along with stormwater treatment facilities and habitat enhancements, were added as part of the Burnt Bridge Creek Greenway Improvement Project.

Fairview Creek

Fairview Creek is a 5-mile-long urban stream that originates in a wetland near Grant Butte in Gresham and drains to Fairview Lake, approximately 11 miles east of the study area. Fairview Creek is a tributary to the eastern portion of the Columbia Slough. Historically, Fairview Creek had been a tributary of the Columbia River, but water from the wetlands where it originates was diverted into an artificial channel that drains into the Columbia Slough, which is a tributary of the Willamette River. In 1960, water managers built a dam along Fairview Creek to create Fairview Lake for water storage and recreation. The creek's 6.5-square-mile watershed receives stormwater runoff from the cities of Gresham, Wood Village, and Fairview.

Water Quality

States are required to monitor and regulate water quality in their rivers and streams under Section 303(d) of the CWA. Waterbodies that fail to meet the water quality standards for one or more pollutants are referred to as being "303(d)-listed." Under Section 303(d), states also must develop action plans to address water quality concerns, including setting Total Maximum Daily Loads (TMDLs) for particular pollutants in a waterway.

Table 3.14-2 presents the 303(d)-listed waterways in the study area and water quality standards they do not currently meet. Table 3.14-2 also shows the pollutants for which TMDLs have been established.

Table 3.14-2. Water Quality-Limited Waterways within the Study Area

Waterway	303(d) Listing Factors	Established TMDLs
Columbia Slough	• Toxics (iron) • Biocriteria [a] • Aquatic weeds	• Toxics (lead, PCBs, DDE/DDT, dieldrin, dioxin) • Eutrophication (pH, dissolved oxygen, phosphorus, and chlorophyll a) • Bacteria • Temperature
Columbia River (includes North Portland Harbor)	• In Oregon: – Toxics (PCBs, PAHs, DDT metabolites [4,4'-DDE]) • In Washington: – Vinyl chloride	• Dioxin • Total dissolved gas • Temperature
Burnt Bridge Creek	• Eutrophication (dissolved oxygen, pH) • Fecal coliform bacteria • Temperature	• None
Fairview Creek	• Biocriteria [a]	• Bacteria • Temperature

a Biological criteria (biocriteria) are a way of describing the qualities that must be present to support a desired condition in a waterbody. Biocriteria are based on the numbers and kinds of organisms present and are regulatory-based biological measurements. Oregon Department of Environmental Quality defines biocriteria as the measure by which "Waters of the State must be of sufficient quality to support aquatic species without detrimental changes in the resident biological communities" (Oregon Administrative Rule 340-041-0011).

4,4'-DDE = dichlorodiphenyldichloroethylene; DDT = dichlorodiphenyltrichloroethane; PAH = polycyclic aromatic hydrocarbon; PCB = polychlorinated biphenyl; TMDL = Total Maximum Daily Load

Stormwater

The purpose of stormwater management strategies is to reduce stormwater runoff peak flows and pollutants discharged into receiving waters from impervious surfaces. Measures (e.g., installing perimeter protection/silt fences, inspecting equipment, implementing spill containment, restricting work during rain or wet weather) used to achieve these reductions are referred to as best management practices (BMPs), and are established in regulatory permits and guidance (see Section 3.14.6, Potential Avoidance, Minimization, and Compensatory Mitigation Measures, for more detail). Current regulations require BMPs when roadways are reconstructed or when new impervious surface is added. BMPs have been shown to effectively reduce sediment, metals, and other pollutants from runoff. Their effectiveness in removing polycyclic aromatic hydrocarbons (PAHs), microplastics, and

What is stormwater infiltration?

Stormwater infiltration is the process by which stormwater sinks into the soil, becoming groundwater that, in turn, feeds rivers and lakes. Stormwater infiltration can occur naturally, where soil conditions and geography allow, or in artificially created stormwater infiltration facilities.

constituents of emerging concern, including 6PPD-quinone (a byproduct of tire dust that is toxic to salmonids), are less well known.

Within the study area, surface water runoff from I-5 is generally confined to the paved roadway by continuous curbs and concrete barriers. Closed (pipe) drainage systems convey flows to surface water outfalls. Runoff from the bridges across North Portland Harbor and the Columbia River drains through scuppers to the water surface below. Most stormwater from I-5, including interchange areas, currently flows directly into receiving waters without treatment to remove roadway pollutants. There are several minor exceptions:

- The Burnt Bridge Creek watershed includes a treatment and infiltration pond that reduces sediment, metals, and other pollutants from runoff. Overflows from this pond are discharged to an existing wet pond in the vicinity that provides infiltration.
- A 3-acre area within the Columbia Slough watershed infiltrates in adjacent pervious area and does not discharge to existing outfalls.
- About 3 acres of runoff from SR 14 is dispersed to adjacent areas, where it infiltrates or evaporates.
- Runoff from the existing Ruby Junction Maintenance Facility partially drains to Fairview Creek through a proprietary stormwater filtration system and partially is infiltrated using dry wells contributing to groundwater within the Columbia Slough watershed.

Table 3.14-3 shows the existing impervious area and treated and untreated stormwater areas for each receiving waterbody in the study area. The contributing impervious area (CIA) represents the acreage of impervious surface within the study area that drains to each waterbody. Of the 177.6 total acres of CIA within the study area, approximately 21.2 acres are infiltrated. The remaining 156.4 acres discharge to receiving waters without treatment.

Table 3.14-3. Existing Impervious Area and Treated and Untreated Stormwater (acres)

Receiving Waterbody	Total Contributing Impervious Area	Infiltrated Impervious Area	Treated Impervious Area Draining to Outfall(s)	Untreated Impervious Area Draining to Outfall(s)
Columbia Slough	38.5	3.0	0.0	35.5
Columbia River South (Oregon)	45.8	0.0	0.0	45.8
Columbia River North (Washington)	76.4	3.0	0.0	73.4
Burnt Bridge Creek	9.6	7.9	0.0	1.7
Fairview Creek	7.3	7.3	0.0	0.0
Total	**177.6**	**21.2**	**0.0**	**156.4**

3.14.3 Long-Term Benefits and Effects

Table 3.14-4 summarizes the water quality and hydrology effects of the Modified LPA, including design options, and No-Build Alternative followed by a discussion of the effects.

Table 3.14-4. Summary of Water Quality and Hydrology Effects from the Modified LPA Design Options and No-Build Alternative

Water Quality and Hydrology Consideration	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, with or without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5, all Park-and Ride Site Options	Modified LPA with Single-Level Fixed-Span Configuration[a], One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options
Water Quality and Stormwater Management	• No change, (area would remain untreated until stormwater treatment could be addressed according to state prioritization and available funding).	• Beneficial effect on receiving water quality (due to BMPs to remove pollutants). • Could cause changes in peak flows and stormwater runoff volumes.	• Beneficial effect on receiving water quality (due to BMPs to remove pollutants) with slight increase to pollutant loads. • Could cause changes in peak flows and stormwater runoff volumes.	• Beneficial effect on receiving water quality (due to BMPs to remove pollutants). • Could cause changes in peak flows and stormwater runoff volumes.	• Potential for additional and accidental minor spills of materials and pollutants used for maintenance and operation of the movable-span configuration.
Contributing Impervious Area	178 acres total: • 0 acres treated. • 21 acres infiltrated. • 157 acres untreated.	207 acres total: • 190 acres treated. • 17 acres infiltrated. • 0 acres untreated.	211 acres total: • 194 acres treated. • 17 acres infiltrated. • 0 acres untreated.	211 acres total: • 193 acres treated. • 18 acres infiltrated. • 0 acres untreated.	214 acres total: • 197 acres treated. • 17 acres infiltrated. • 0 acres untreated.
Total Suspended Solids	• 120,272 lbs/year.	• 16,694 lbs/year.	• 17,037 lbs/year.	• 16,984 lbs/year.	• 17,336 lbs/year.
Hydrology	• No change (continued release of stormwater with degraded quality into receiving waters).	• Potential to cause long-term hydrologic effects due to an increase of 30 acres of contributing impervious area.	• Potential to cause long-term hydrologic effects due to an increase of 34 acres of contributing impervious area.	• Potential to cause long-term hydrologic effects due to an increase of 33 acres of contributing impervious area.	• Potential to cause long-term hydrologic effects due to an increase of 37 acres of contributing impervious area.

a The long-term effects associated with the single-level fixed-span configuration would be approximately the same for all bridge type options.
BMP = best management practice; lbs = pounds

No-Build Alternative

Under the No-Build Alternative, most of the existing impervious surface area along roadways in the study area would remain untreated, which would allow for the continued release of stormwater with degraded quality into the study area's receiving waters. However, with no way to quantify future emissions or other pollutants, such as 6PPD-quinone and for the purposes of the present analysis, it is assumed that the No-Build Alternative would maintain existing water quality conditions and would not result in long-term changes (either increased or decreased impacts). Therefore, in this section, the No-Build Alternative is discussed only in comparison to the Modified LPA.

Modified LPA

The Modified LPA includes a stormwater conveyance and detention system that would comply with all federal, state, and local water quantity and quality standards at the time of construction. The proposed design for the Modified LPA includes inlets, catch basins, and gravity pipe drainage systems that would collect and convey runoff from the new bridges, transit guideway, and road improvements to stormwater treatment facilities. The treatment facilities would reduce total suspended solids, particulates, and dissolved metals to the maximum extent practicable before runoff reaches surface waters or is infiltrated.

The Modified LPA would also cross the Portland Metro Levee System with the extension of light-rail north from Expo Center, with modifications to the I-5 mainline north of North Victory Boulevard, with the North Portland Harbor bridges, and with local road revisions of N Marine Drive and N Expo Road. Such modifications may include activities to restore temporarily disturbed portions of the levees, or permanent modifications where proposed infrastructure would intersect with the existing levees or where access to the levees would change as a result of reconfiguration of the roadways. Modifications may also include improvements to existing levee function, if such improvements are requested or required. Modifications or improvements would be coordinated with the USACE and the Urban Flood Safety and Water Quality District for consistency with the planned future condition of the levees. The assessment presented below of long-term effects to water quality and hydrology associated with the Modified LPA includes effects associated with potential modifications to the federal levee system.

The Modified LPA would manage flow control and runoff in the Burnt Bridge Creek watershed and at the Ruby Junction Maintenance Facility via detention and infiltration. In the North Portland Harbor area runoff from some existing impervious surfaces, and a few sections of new or modified roadway with the Modified LPA, would be conveyed, treated, and discharged to the Columbia Slough. All other runoff generated by the Modified LPA, regardless of bridge configuration, would be conveyed, treated, and discharged within the watershed in which it is generated.

The Modified LPA would increase contributing impervious surface compared to existing conditions. Table 3.14-5 shows how the Columbia River bridge configurations would change the amount of CIA by acre. The Modified LPA with the I-5 mainline westward shift, SR 14 interchange without C Street ramp, and the different park-and-ride site options would not increase the amount of CIA compared to the Modified LPA alone, and therefore would have the same hydrology, water quality, and stormwater effects as the Modified LPA with one auxiliary lane and the double-deck fixed-span configuration.

The long-term hydrological effects resulting from changes in impervious area would be a small percentage of the study area watersheds, ranging from an increase of 0.007% in the Columbia Slough watershed to a decrease of -0.011% in the Fairview Creek watershed. The Modified LPA with two auxiliary lanes would result in a slight increase in the CIA compared to the Modified LPA with one auxiliary lane because of the additional pavement. Compared to the Modified LPA with the double-deck fixed-span configuration, the single-level fixed-span and movable-span configurations would have a greater amount CIA from the wider dimensions of the bridges and interchanges.

Table 3.14-5. Contributing Impervious Area by Bridge Configuration

Bridge Configuration	Columbia Slough (acres)	Columbia River South (acres)	Columbia River North (acres)	Burnt Bridge Creek (acres)	Fairview Creek (acres)	Total Project (acres)
No-Build Alternative (Existing Conditions)	38.5	45.8	76.4	9.6	7.3	177.6
Modified LPA with One Auxiliary Lane and Double-Deck Fixed-Span Configuration	40.7	51.6	97.4	10.7	6.8	207.2
Modified LPA with Two Auxiliary Lanes and Double-Deck Fixed-Span Configuration	41.1	52.3	100.2	10.7	6.8	211.1
Modified LPA with Single-Level Configuration[a] and One Auxiliary Lane	40.4	52.4	100.2	10.7	6.8	210.5

a The single-level fixed-span and single-level movable-span configurations (any bridge type options) would result in the same amount of CIA.

Hydrology

The addition of impervious surface, such as new roadway, within a watershed generates additional stormwater runoff and reduces stormwater infiltration into groundwater. These changes have the potential to increase flooding, alter peak flows, increase runoff volumes to local receiving waters, and decrease water infiltration and groundwater recharge. The magnitude of the effects depends on a variety of factors, including the degree of increase in CIA and the characteristics of the receiving water. The Modified LPA would comply with the stormwater design requirements in place at the time of construction, including requirements that may be updated to reflect climate-induced changes to rainfall patterns.

The change in flow volume fluctuation, peak flows, and runoff quantities in these waterbodies would be minimal for any of the Modified LPA bridge configurations compared to the No-Build Alternative. These impacts would be further minimized using flow controls (engineered measures to control the amount and velocity of stormwater discharging into a receiving water) for discharges to Fairview Creek and Burnt Bridge Creek. Flow control would not be required for the Columbia River or Columbia Slough, because they are considered large waterbodies that are exempt from flow control requirements (BES 2020).

In 2024, the City of Portland updated its building code and zoning code for development within floodplains. The updates are intended, in part, to comply with the recommendations of the 2016 Federal Emergency Management Agency (FEMA) National Flood Insurance Program Biological Opinion (BO) that was issued by NOAA Fisheries in 2016. For the FEMA-designated floodways in the study area—in compliance with Executive Order 11988 for Floodplain Management—a location hydraulic study would be conducted for the Modified LPA and the analysis would be included in the Final SEIS. Based on a preliminary hydraulic assessment, there may be a small net rise to the base flood elevation of the Columbia River and North Portland Harbor. During the final design phase, this preliminary assessment would be confirmed with the hydraulic analysis once design concepts progress to a sufficient level of detail. If the hydraulic analysis shows a resulting rise in the base flood elevation, mitigation would be explored. Mitigation measures could include alternative pier cap shapes to improve hydraulic efficiency and cutting of soils to compensate for reduced flood storage capacity. Currently, the potential areas of cut are anticipated to be entirely within the footprint of the Modified LPA. The

results of hydraulic analysis and coordination with the City of Portland would determine whether the needed cut volume would require the acquisition of additional property. If mitigation measures cannot reduce base flood elevation change from the IBR Program to zero net rise, the change would be documented in a floodplain evaluation report and a public notice that would include the reasons for this finding and alternatives considered. Prior to construction, a floodplain permit from the City of Portland would be required. If the Modified LPA results in a net rise of base flood elevations, a Conditional Letter of Map Revision would be required from FEMA prior to issuing the floodplain permit.

No new or expanded roads or facilities are proposed for the Burnt Bridge Creek floodway. A small area within the study area at the Ruby Junction Maintenance Facility is mapped within the 100-year floodplain of Fairview Creek. The new or expanded roads or facilities with the Modified LPA would not encroach upon the Special Flood Hazard Area for Fairview Creek and, therefore, no increase in 100-year flood elevations is expected.

Water Quality

Runoff from transportation facilities is typically associated with a number of pollutants, including suspended sediments, nutrients, PAHs, oils and grease, antifreeze from leaks, cadmium and zinc from mechanical and tire wear, 6PPD-quinone from tire wear and road dust, and copper from wear and tear of brake pads, bearings, metal plating, and engine parts. The Modified LPA includes the extension of light-rail into downtown Vancouver and other transportation systems management and travel demand management measures, which could reduce the number of vehicles, and therefore tires (i.e., the source of 6PPD-quinone), on study area roads compared to the No-Build Alternative. The Modified LPA would have a substantial beneficial effect on water quality because it would include stormwater treatment facilities to remove pollutants in runoff from all roadway surfaces within the project footprint. Methods proposed for mitigation and treatment of runoff are detailed in Section 3.14.6.

All design options would have similar impacts to water quality. The Modified LPA with two auxiliary lanes would have a greater increase in impervious surface and result in slightly increased pollutant loads, as compared to the Modified LPA with one auxiliary lane. The Modified LPA with the single-level movable-span configuration could have the potential for additional pollutants and minor long-term water quality impacts; it is difficult to collect stormwater from the movable portion of the bridge structure when lifting, lifted, and lowering, as well as accidental spills that could flow directly into the waterbody during over-water maintenance of the movable span. No matter which design option is selected, the Modified LPA would include stormwater treatment facilities that would treat runoff from all roadway surfaces within the project footprint.

For various pollutants, Table 3.14-6 shows the levels of reduction predicted under the Modified LPA with one auxiliary lane and double-deck fixed-span configuration compared to the No-Build Alternative. The greatest reduction would be in suspended solids, which would be reduced by approximately 86% compared to the No-Build Alternative.

Table 3.14-6. Contributing Impervious Area and Annual Pollutant Load Estimates for the Modified LPA

Environmental Metric	No-Build Alternative	Modified LPA with One Auxiliary Lane, Double-Deck Fixed-Span
Treated CIA (acres)	0.0	189.7
Infiltrated CIA (acres)	21.2	17.5
Untreated CIA (acres)	156.4	0.0
Total CIA (acres)	177.6	207.2

Environmental Metric	No-Build Alternative	Modified LPA with One Auxiliary Lane, Double-Deck Fixed-Span
Total Suspended Solids (lbs/year)	120,272	16,694
Total copper (lbs/year)	25.0	7.6
Dissolved copper (lbs/year)	6.3	5.7
Total zinc (lbs/year)	153.3	39.8
Dissolved zinc (lbs/year)	48.5	26.6

CIA = contributing impervious area; lbs = pounds

As shown in Table 3.14-4, the Modified LPA with one auxiliary lane and a double-deck fixed-span configuration would increase the CIA within the study area by 29.6 acres to 207.2 acres, as compared to the No-Build Alternative. The Modified LPA with the two auxiliary lanes and double-deck fixed-span configuration would increase the CIA within the study area by 33.5 acres, as compared to the No-Build Alternative, and the Modified LPA with the one auxiliary lane and single-level fixed-span or movable-span configuration would increase CIA by 32.9 acres.

Contributing impervious area (CIA)

For the Modified LPA, the CIA is defined as all new, rebuilt, or replaced impervious surface areas and contiguous existing impervious area that contribute stormwater runoff. The CIA does not include runoff from impervious surface area outside the Modified LPA footprint that flows through outfalls that would not be modified.

Of the total CIA, the Modified LPA would treat stormwater runoff from 189.7 acres and runoff from 17.5 acres would be infiltrated. This accounts for all the stormwater runoff from existing, new, or reconstructed impervious surface area within the project footprint, including runoff from bridges over the Columbia River. While infiltrated areas would not receive treatment, runoff would be naturally filtered through ground percolation before entering receiving waters through groundwater.

As discussed in Section 3.1, Transportation, daily traffic volume models show that the Modified LPA would slightly decrease vehicle miles traveled within the study area. Decreasing vehicle miles traveled would reduce idling and brake pad wear, which may reduce the amount of copper and other traffic-related pollutants currently carried by corridor runoff. The Modified LPA with a fixed-span bridge configuration would further reduce idling and brake pad wear compared to the Modified LPA with a movable-span bridge configuration, where traffic on I-5 would be stopped during a bridge lift.

Routine winter maintenance activities over a larger roadway area could also affect water quality under the Modified LPA. Highway sanding can result in large quantities of gravels and particulates making their way into adjacent waterbodies. Similarly, chemical anti-icing and de-icing agents can result in contaminants making their way into adjacent waterbodies. However, impacts from winter maintenance activities are expected to be minimal because the frequency of use is relatively low (approximately 30 days a year), and runoff from the roadways would be treated to reduce potential pollutant loads from these activities.

Stormwater

As described, the Modified LPA could cause changes in peak flows and runoff volumes in local receiving waters because of the increased CIA in the study area. The amount of flow control (detention or retention) provided, in combination with the stormwater treatment facilities, would be evaluated per regulatory guidance as the Modified LPA design progresses; the updated analysis would be provided in the Final SEIS. As

noted in the discussion of hydrology above, the Modified LPA would comply with the stormwater design requirements in place at the time of construction, including requirements that may be updated to reflect climate-induced changes to rainfall patterns.

Within the Columbia Slough and the Columbia River watersheds, Oregon and Washington regulations do not require flow control for stormwater runoff. These large waterbodies are exempt from flow control requirements for direct discharges unless the stormwater conveyance systems carrying the flows have capacity limitations. Therefore, there are no flow control facilities proposed for the Modified LPA in these watersheds.

Within the Burnt Bridge Creek watershed, stormwater flow (volume) control is required by the Washington State Department of Ecology. Runoff from the Modified LPA would continue to discharge to an existing infiltration pond in the Burnt Bridge Creek watershed; overflow from this infiltration pond during extreme runoff events is discharged to Burnt Bridge Creek via a spillway and open channel. Although the Modified LPA design would increase the total CIA within the Burnt Bridge Creek watershed, it would reduce the total impervious surface area draining to this existing infiltration pond through the replacement of other existing water quality facilities with enhanced stormwater treatment. The Modified LPA would thereby reduce the overall volume of stormwater to the infiltration pond, reducing the frequency of discharges to Burnt Bridge Creek during extreme flow events. Therefore, no negative long-term effects on stormwater are likely for this watershed as a result of the Modified LPA.

For the Fairview Creek watershed, the Modified LPA would adhere to the City of Gresham's stormwater management requirements by infiltrating the stormwater. Thus, the Modified LPA would not have long-term effects on stormwater quantity for the watershed.

3.14.4 Temporary Effects

No-Build Alternative

The No-Build Alternative would not result in construction activities and would not have temporary effects on water quality and hydrology.

Modified LPA

The Modified LPA with any of the bridge configuration and bridge type options and with one or two auxiliary lanes and potential levee modifications would have similar temporary effects on hydrology, water quality, and stormwater as described below.

Hydrology

Construction of the Modified LPA, including construction of the new bridges and removal of the existing bridge would place temporary obstructions in the Columbia River and North Portland Harbor. Large temporary structures may be present in these areas for several years to assist with the construction of the Columbia River and North Portland Harbor bridges and the demolition of the existing bridge structures. The Modified LPA would also use cofferdams at some pier complexes to isolate the work area from active flow in the Columbia River and contain waste material and sediments. Given the scale of the Columbia River, its width, volume, and flow rates and the regulation of river flows by upstream dams, the hydraulic effect of these temporary

What are cofferdams?

A cofferdam is a temporary, watertight enclosure used to isolate work areas from surrounding waters. The Modified LPA could require cofferdams to isolate work areas in the Columbia River where new bridge pier foundations are constructed near the shore or where existing piers are removed.

structures is expected to be minor. Construction of the Modified LPA would require a floodplain permit from local jurisdictions and a hydraulic analysis to ensure there are no temporary adverse effects on the Columbia River's hydrologic regime.

Construction of depressed roadway sections (i.e., sections below the surrounding ground level) can have effects on groundwater. Construction below grade and near or beneath the water table may require groundwater pumping for dewatering. Pumping may affect groundwater flows to nearby waterways, as well as groundwater quality and stormwater quantity. However, since pumping would likely occur when the water table and river stages are high (e.g., during winter flows), this is not likely to have a substantial effect on the hydrology of affected waterways.

No temporary effects on the hydrology of Fairview Creek are anticipated for the expansion of the Ruby Junction Maintenance Facility since the required stormwater treatment facilities, which include infiltration for the entire expansion area, would be constructed ahead of and in preparation for construction of the expanded facilities.

Water Quality

Although there are numerous sources of chemical pollutants, there is a low risk that chemicals would actually enter the receiving waters. All reasonable precautions would be taken to avoid and minimize water quality impacts during construction activities including staging, construction of the new bridges, removal of the existing bridge, and modifications to levees. The measures are outlined in Section and would be developed in more detail once site--specific environmental analyses are conducted. The measures would ensure that water quality impacts during construction are minimized through the use of BMPs specified in the temporary erosion and sediment control plans (TESCPs) and spill prevention, control, and countermeasures (SPCC) plans developed for all necessary NPDES permits. Temporary effects on the quality of receiving waters within the study area may still be possible and may include the following:

- Increased turbidity due to ground disturbance around waterways associated with construction or staging.
- Discharge of pollutants to surface waters due to equipment leaks or spills in the vicinity of waterways.
- Groundwater contamination due to upland ground improvement activities including deep soil mixing with cementitious material and/or aggregate.
- Sediment and contaminant migration into groundwater or surface water from equipment pressure or steam cleaning operations following construction periods.
- Discharge of pollutants to surface waters due to the use of fertilizers, pesticides, or herbicides during restoration or revegetation activities.
- Contamination of groundwater due to direct infiltration of toxic contaminants during groundwater pumping from locations of known existing groundwater contamination.
- Infiltration of polluted surface water into groundwater.
- Increased turbidity due to riverbed disturbance during in-water work.
- Release of pollutants due to spills or leaks of cement during pier footing and column construction.
- Construction material or other objects falling into the Columbia River and North Portland Harbor during the construction of the new bridges and demolition of the old bridge.
- Release of existing contaminated sediments due to disturbance of riverbed sediments containing hazardous materials during in-water work. Sampling and analyzing potentially hazardous sediments prior to construction is addressed in the IBR Hazardous Materials Technical Report.

Throughout the study area, construction improvements would disturb the ground, which may expose soil to erosion from wind, rain, and runoff. Waterbodies in the study area could receive sediment-laden runoff by way of stormwater inlets, ditches, or other forms of conveyance, which could result in increased turbidity and excessive sediment deposits. Construction equipment operating on land could release pollutants (e.g., petroleum-based fuel or other fluids) or construction materials that could enter waterbodies by way of stormwater inlets, ditches, or other forms of conveyance.

Dewatering during construction may create a cone of depression and the potential for the movement of contaminated groundwater from nearby hazardous materials sites. A hazardous materials analysis indicated that there are potential high-risk sources of contamination near proposed depressed road sections.

Staging area activities also have the potential to increase stormwater runoff and pollutant loading. Staging areas would meet all applicable permit and stormwater requirements during and following their use. As with all construction activities, impacts to water quality would be minimized through the use of BMPs specified in the TESCPs and SPCC plans developed for all necessary NPDES permits.

Following construction, the use of fertilizers, pesticides, or herbicides during restoration and revegetation activities may affect the water quality of receiving waters. Their use, however, would be minimized, especially near receiving waters. The Modified LPA would adhere to requirements described in ODOT Standard Specifications 01040.00 to 01040.90 and/or WSDOT Standard Specification 8-02 “Roadside Restoration.”

Stormwater

Construction activities related to the Modified LPA would increase stormwater runoff within the study area and create temporary effects related to hydrology and water quality. In general, potential temporary effects could result from increased stormwater runoff due to ground disturbance, increased potential for pollutants in runoff in and around construction and staging sites and equipment, and increased construction-generated stormwater runoff due to groundwater pumping during depressed roadway construction.

The Columbia River and North Portland Harbor would experience an increase in stormwater volumes due to the impervious surfaces of nearby staging areas, barges, temporary work bridges, and other structures related to overwater construction. Temporary construction effects are not anticipated to affect Fairview Creek because stormwater is currently treated or infiltrated on-site at the creek, and this would continue during and after construction. Therefore, additional measures to treat stormwater are not needed. Stormwater conveyed off-site would require prescribed treatment to ensure that runoff was not turbid or contaminated.

3.14.5 Indirect Effects

Population growth and land use development are anticipated to occur under both the Modified LPA and the No-Build Alternative. Development can affect water quality and hydrology by increasing the amount of impervious area (for example, by adding rooftops and parking lots); this, in turn, increases stormwater runoff quantities and pollutant loads, resulting in potential impacts to receiving waters and floodplains. As described in Section 3.4, Land Use and Economic Activity, the Modified LPA is expected to facilitate higher-density development—such as transit-oriented development around light-rail stations—in already urbanized areas, consistent with local land use plans. Concentrating growth can help conserve natural resources from the potentially adverse effects of development on the urban periphery, such as habitat loss and contamination from stormwater runoff. Conversely, the No-Build Alternative, because it would not provide new high-capacity transit, would be less likely to result in dense growth and hence would be less protective of natural resources.

Any new development or redevelopment facilitated by the Modified LPA would have to comply with the relevant laws, regulations, policies, and codes in force at the time. These requirements, which include restrictions on tree removal, stormwater treatment and floodplain regulations, and environmental zone and

critical areas protections, would limit negative impacts from development and redevelopment. These regulations require avoidance or minimization of impacts on environmentally sensitive resources, including those that address water quality and hydrology and floodplains. In light of these protections, indirect effects from the Modified LPA and potential future development are expected to be minimal.

3.14.6 Potential Avoidance, Minimization, and Compensatory Mitigation Measures

Long-Term Effects

Regulatory Requirements

- As design progresses, conduct a detailed hydraulic analysis of the affected floodplains. If a rise in the base flood elevation is predicted, assess mitigation through floodplain excavation (cut/fill balance) activities within the footprint of the Modified LPA and determine whether additional land may be required to accomplish the required mitigation. Conduct a location hydraulic study to document the impacts, mitigation measures, evaluation of alternatives, and findings in accordance with the provisions of 23 CFR 650A.
- Work with the City of Portland to ensure flood storage compensation does not jeopardize threatened and endangered species and their habitat (revised Floodplain Development Code Chapter 24.50 Flood Hazard Areas).
- Comply with ODOT and WSDOT stormwater management requirements and the Cities of Portland and Vancouver regulations for the portions of the Modified LPA along City-managed roads during construction and for the long-term treatment of stormwater runoff prior to discharge into receiving waters.
- Select and design water quality BMPs to ensure compliance with all federal, state, and local regulatory requirements, including construction and municipal stormwater permit requirements issued through CWA Section 401, to reduce suspended solids, particulates, and dissolved metals; to reflect the latest climate models; and to treat newly identified pollutants like 6PPD-quinone.
- Construct flow control facilities to infiltrate or reduce the flow rates of all study area runoff, pursuant to local regulatory requirements. Mitigation for increased runoff to the Columbia Slough or the Columbia River would not be required because these water bodies are exempt from stormwater quantity management. However, the effects of increased runoff would be reduced using stormwater infiltration. This would allow groundwater recharge to continue and minimize the increase in runoff volumes and peak discharges.

Program-Specific Mitigation

Hydrology

- Offset potential rise in the base flood elevation through floodplain excavation (cut/fill balance) activities as determined through a location hydraulic study.
- In the Burnt Bridge Creek watershed, construct infiltration facilities to provide complete infiltration of all Program-related runoff, such as providing underground injection control requirements, to the extent practicable, for the wellhead protection zone present in the watershed to manage stormwater volumes. As design progresses, select site-specific BMP facilities**.**

- Prepare stormwater monitoring plan(s) to evaluate the long-term performance and effectiveness of the updated stormwater conveyance and treatment systems. Based on the findings, complete modifications or enhancements to the system(s) to meet discharge performance criteria.
- Compensate for additional fill in floodplains to achieve a no net loss of floodplain as a result of removal of materials within the City of Portland Floodplain Hazard Areas.

Water Quality

Where applicable in the project area, the following proposed water quality treatment facilities would be used to treat stormwater runoff and mitigate the increase in contributing impervious surfaces. Definitions of these treatment facility types are presented in Section 7.2.2 of the Water Quality and Hydrology Technical Report.

- Treat stormwater runoff through bioretention ponds/planters, biofiltration swales, bioslopes (Oregon), and/or media filter drains (Washington) that provide water quality treatment via infiltration through a phosphorus-free, compost-amended soil medium and/or vegetation. Vegetation also provides uptake of some water.
- Water quality treatment facilities that have demonstrated effectiveness for advanced treatment will be designed according to each jurisdiction's specifications, such as the Washington State Department of Ecology's Technology Assessment Protocol program (Washington), the 2020 Stormwater Management Manual (Portland), and Vancouver's Surface Water Management Program.

Temporary Effects

Regulatory Requirements

Regulatory requirements for temporary effects of stormwater runoff during construction would include compliance with ODOT, WSDOT, Portland, and Vancouver's regulations including the preparation of an SPCC plan and pollution control plan (PCP), and TESCP. In addition, all federal, state, and local permits related to water quality and hydrology would be obtained. See Section 8 in the Water Quality and Hydrology Technical Report for a complete list of required federal, state, and local permits.

Spill Prevention/Pollution Control Measures

- Require the contractor to prepare an SPCC plan and PCP prior to beginning construction. These plans would be provided to the National Oceanic and Atmospheric Administration Marine Fisheries Service (NOAA Fisheries) for review and approval. The SPCC plan and PCP would identify the appropriate spill containment materials, as well as the means and methods of implementation, response, and reporting, in the event of a spill. All elements of the SPCC plan and PCP would be available at the project site at all times. For additional details, consult ODOT Standard Specification 00290.00 to 00290.90 and WSDOT Standard Specification 1-07.15.

Site Erosion/Sediment Control Measures

- Require the contractor to prepare and implement a TESCP to minimize impacts associated with clearing, vegetation removal, grading, filling, compaction, or excavation. The BMPs identified in the TESCP would be used to control sediments in areas impacted by vegetation removal or ground-disturbing activities. Additional temporary control measures may be required beyond those described in the TESCP if it appears pollution or erosion may result from weather, the nature of the materials, or progress on construction. For additional details, consult ODOT Standard Specifications 00280.00 to 00280.90 and WSDOT Temporary Erosion and Sediment Control Manual M3109.02.

- Stabilize all exposed soils as directed in measures prescribed in the TESCP. Hydro-seed all bare soil areas following grading activities and revegetate all temporarily disturbed areas with native vegetation indigenous to the location. For additional details, consult ODOT Standard Specifications 01030.00 to 01030.90 and WSDOT Temporary Erosion and Sediment Control Manual M3109.02.
- Where site conditions support vegetative growth, plant native vegetation indigenous to the location in areas temporarily disturbed by construction activities. Revegetation of construction easements and other areas would occur after the project is completed. Trees would be planted when consistent with highway safety standards. Riparian vegetation would be replanted with species native to geographic region. Planted vegetation would be maintained and monitored to meet regulatory permit requirements. For additional details, consult ODOT Standard Specifications 01040.00 to 01040.90 and WSDOT Temporary Erosion and Sediment Control Manual M3109.02.

Program-Specific Mitigation

Hydrology

- Minimize changes to groundwater hydrology by limiting groundwater pumping to areas where it cannot be avoided.

Water Quality

- Study, test, and remediate sites with existing soil or groundwater contamination near construction areas before any construction. See Section 3.18, Hazardous Materials for specific mitigation actions.
- Conduct in-water work during approved periods for the Columbia River as approved by the Washington Department of Fish and Wildlife, Oregon Department of Fish and Wildlife, NOAA Fisheries, and the U.S. Fish and Wildlife Service. See Section 3.16, Ecosystems, for specific mitigation measures.
- Stage construction equipment used for in-water work activities above the ordinary high-water mark. Only the operational portion of construction equipment would enter the active stream channel (below the ordinary high-water mark).
- If in-water dredging is required outside of a cofferdam, use a clamshell bucket within the established in-water work windows. Dredging, handling, and disposal of dredged materials shall be conducted consistent with the requirements and conditions of the regulatory permits issued for the Modified LPA.
- If required, monitor turbidity and provide a rest period to allow turbidity, if any, to dissipate between in-water work activities.

3.15 Wetlands and Other Waters

Wetlands and other waters perform valuable functions for fish, wildlife, environmental quality, and surrounding human communities. The federal Clean Water Act (CWA) gives environmental oversight for waters and wetlands to the U.S. Army Corps of Engineers (USACE). The CWA also gives the U.S. Environmental Protection Agency (EPA) and USACE jurisdictional oversight for "traditional navigable waters" of the U. S. State governments generally share the regulatory control with the USACE.

Wetlands and other waters regulated by the CWA are called jurisdictional wetlands and other waters. Federal and state laws require projects that could impact wetlands and other waters to first avoid and minimize impacts where possible. Impacts to jurisdictional waters, such as adding or removing bridge piers or other structures in a river, or filling, excavating, or building in a wetland, require joint federal, state, and local permitting. If impacts are unavoidable, the project must compensate for these impacts by restoring or creating new wetlands or other waters to ensure that the overall environmental functions they provide are not diminished. Some jurisdictions also restrict activities in areas within a certain distance of wetlands, known as buffer zones.

The information presented in this section is based on the Wetlands and Other Waters Technical Report. In addition, Section 3.14, Water Quality and Hydrology, and Section 3.16, Ecosystems, provide more information about the relationship between wetlands, fish and wildlife habitat, and water quality.

Are all wetlands, rivers, and streams "jurisdictional"?

Complex regulations determine which wetlands and other waters are jurisdictional. All wetlands and other waters that are potentially jurisdictional were considered in this analysis, and this section refers to them all as simply wetlands or other waterways. Final determinations of the boundaries and legal status of each would be made by the appropriate agencies during the permit process after the NEPA process is complete.

3.15.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with wetlands and other waters has been updated in this Draft SEIS to include:

- Updated determination of waters of the U.S. based on recent decisions from the U.S. Supreme Court and the subsequent updated conforming rule issued by EPA and USACE.
- Updates to methodology for wetland evaluations and updated plant species lists developed by EPA and USACE.
- Updates to existing conditions based on fieldwork to identify and confirm wetland boundaries within the study area.
- Changes in the project footprint necessitated by changed conditions. Updates to proposed mitigation or compensation for wetland and wetland buffer effects to reflect current guidance.

Table 3.15-1 compares the impacts and benefits of the CRC LPA to the Modified LPA as a result of the changes listed above. Based on the analysis in this section, the effects of the Modified LPA, including design options, would be similar to those of the CRC LPA.

Table 3.15-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA [a] Effects as Identified in This Section	Explanation of Differences
Wetland Fill	0 acres	0.58 acres	• Additional wetlands were identified on mainland Oregon between N Martin Luther King Jr. Boulevard and N Union Court. The design change that altered local access to N Union Court would alter additional wetland impacts.
Wetland Buffer Fill	0.41 acres	7.39 acres	• Additional wetlands were identified on mainland Oregon between N Martin Luther King Jr. Boulevard and N Union Court. The design change that altered local access to N Union Court would result in additional wetland impacts. • The City of Portland expanded Environmental Overlay Zone areas, and the regulations that accompany them increased the acreage of wetland buffer impacts.
Other Waters (Fill/Restoration)	0.76 acres (net fill)	- 0.13 acres (net restoration)	• New techniques in pile cap installation would reduce the amount of benthic habitat impacts, coupled with the removal of the existing bridge footings, would result in a net restoration of fill in other waters.

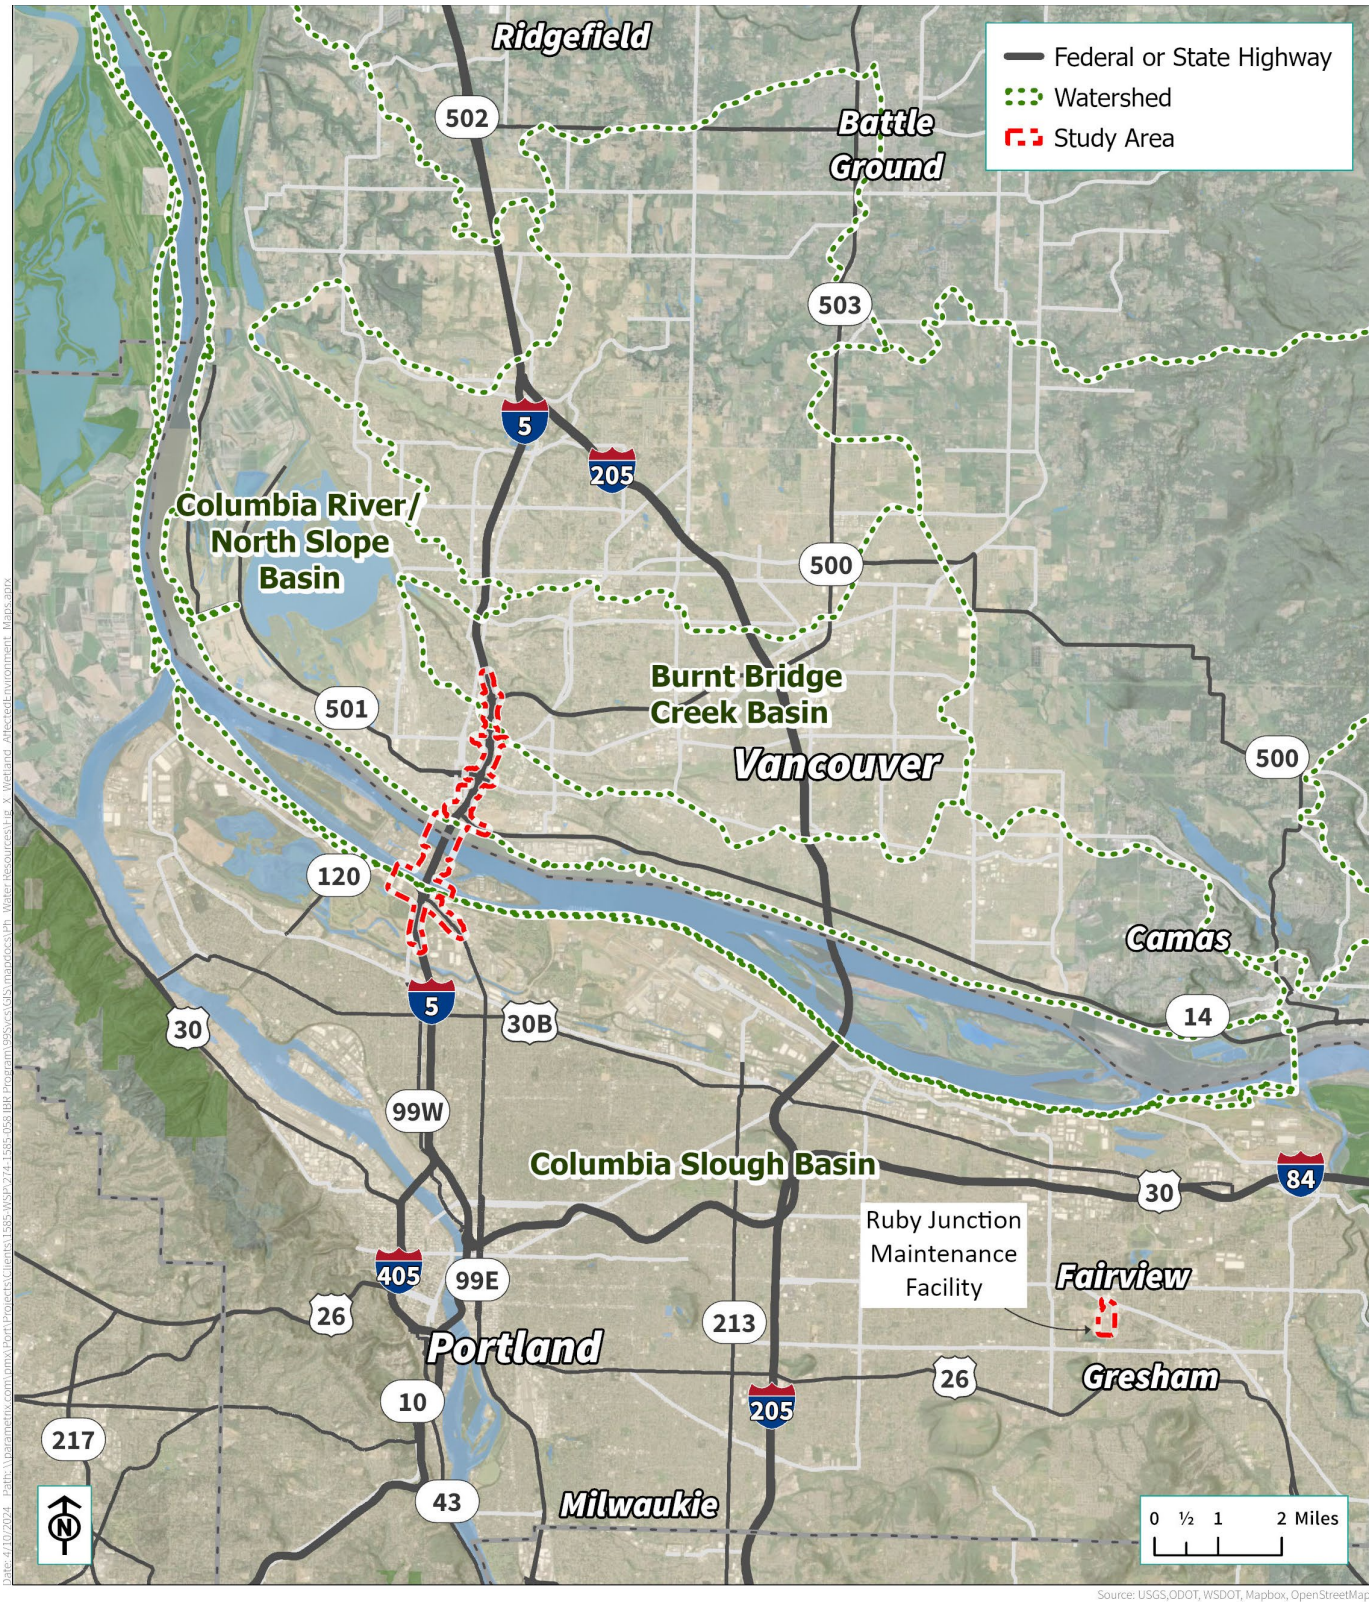
Note: Data are approximate and have been rounded.
a The Modified LPA effects are based on the double-deck-fixed-span configuration with one auxiliary lane.

3.15.2 Existing Conditions

The existing conditions for wetlands and other waters includes information on resources that were initially delineated in 2008 as part of the CRC project, updated with new information from the City of Portland's Wetland Inventory Project and field-identified wetland boundaries in 2022 and 2023. A preliminary wetland and other waters delineation report will be published once field delineations have been completed. Field delineations should be completed in 2024 and results from the field delineations will be included in the final environmental impact statement.

The study area for the wetlands and other waters analysis is shown in Figure 3.15-1. The study area is the area that could experience direct impacts from the construction and operation of the Modified LPA, including the expansion of the Ruby Junction Maintenance Facility in Gresham, Oregon.

Figure 3.15-1. Wetlands and Other Waters Study Area



Wetlands in Oregon

There are large wetland systems to the east and west of the study area in Oregon that are remnants of the extensive wetland system that existed on the floodplain of the Columbia River before development. These

wetland systems were changed by the construction of dikes and levees, which drained land and added fill material to low spots, first for agricultural purposes and then for urban development. In addition, constructed wetlands were established to manage stormwater runoff near the roadway in the study area. Despite the reduction in area, the remaining wetlands in the study area perform important functions and have high value due to their rarity and wildlife value.

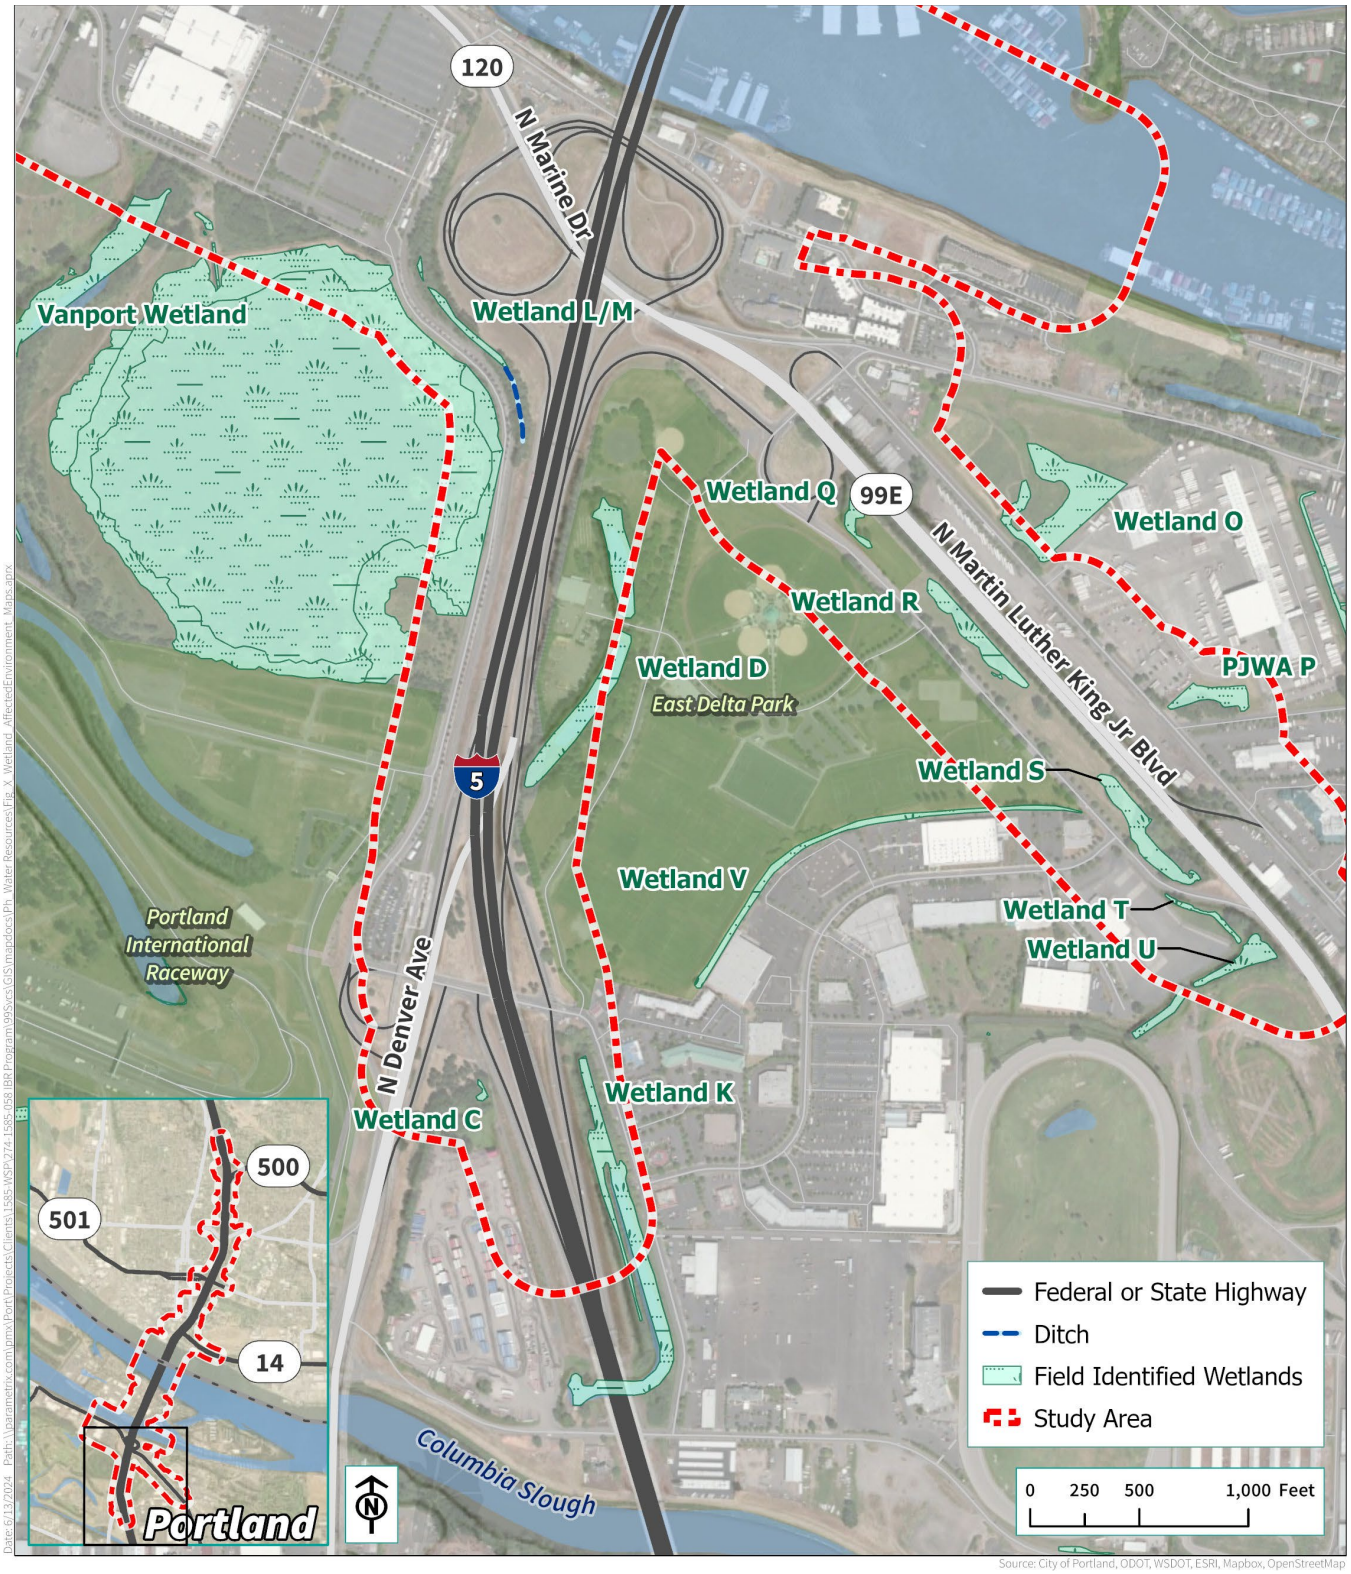
The study area in Oregon includes a complex of small wetland systems, some of which are connected by culverts, near the I-5 roadway. These wetlands are remnants of the former slough system that have been modified to increase drainage and convey stormwater from the surrounding area to the Columbia Slough. Within the Columbia Slough watershed, there are 13 identified wetlands and, potentially, a jurisdictional ditch that intersects the study area, shown in Figure 3.15-2. The wetlands are identified alphabetically, in the order they were identified in the field or by off-site databases, in Table 3.15-2. No wetlands were identified in the Ruby Junction Maintenance Facility area.

Table 3.15-2. Wetlands Identified within the Study Area in Oregon

Wetland ID	Wetland Type	Size (acres)
Wetland C	PEM	0.07
Wetland D	PFO/SS/EMHx	2.67
Wetland K	PUBHh	3.0
Wetlands L/M	PFOC	0.34
Wetland O	PEM	2.63
Potentially Jurisdictional Wetland/Water Area P (PJWA P)	PEM	0.61
Wetland Q	PEM	0.30
Wetland R	PEM	0.97
Wetland S	PEM	1.10
Wetland T	PEM	0.18
Wetland U	PEM	0.55
Wetland V	PEM	1.18
Vanport Wetland	PFO/SS/EMHx	66.6

Note: No wetlands were identified at the Ruby Junction Maintenance Facility.
Key: PEM = palustrine emergent; PFOC = palustrine, forested, seasonally flooded; PFO/SS/EM = palustrine forested/scrub-shrub/emergent; PFO/SS/EMHx= palustrine, forested/scrub-shrub/emergent, permanently flooded, excavated; PUBHh = palustrine, unconsolidated bottom, permanently flooded, excavated.

Figure 3.15-2. Field-Identified Wetlands and Other Waters - Oregon



Source: CRC Wetland Data (2011); City of Portland (2023)

Wetlands in Washington

Within the study area in Washington, there are two delineated wetland systems within the Burnt Bridge Creek watershed, shown in Figure 3.15-3 and listed in Table 3.15-3. No wetlands were identified in the Columbia River/Columbia Slope watershed. Figure 3.15-3 also shows Wetland B and the WSDOT Burnt Bridge wetland complex, which were identified during the CRC project analysis. These wetland systems are shown for additional context; however, they are outside of the current study area.

Table 3.15-3. Wetlands Identified within the Study Area in Washington

Wetland ID	Wetland Type	Size (acres)
Wetland H	PEMA	0.12
PJWA I (Kiggins Bowl wetlands)	PFO	1.00

N/A= Not available; PEMA= palustrine emergent, temporarily flooded; PJWA = Potential Jurisdictional Water/Wetland Area; PFO = palustrine forested

Other Waters

The study area contains two regulated waters of the state and U.S.—the Columbia River and Burnt Bridge Creek—and one potentially regulated water (ditch) of the state and U.S. The Columbia River (including North Portland Harbor, which is also known as the Oregon Slough) between the Oregon mainland and Hayden Island) is also classified as a "traditional navigable water" of the U.S. EPA and USACE have jurisdictional oversight for "[a]ll waters which are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to ebb and flow of the tide" (33 CFR Section 328.3(a)(1); 40 CFR Section 120.2(a)(1)). "Traditional navigable water" includes all the navigable waters of the U.S., as defined in 33 CFR Part 329. Table 3.15-4 provides a description of jurisdictional waters in the study area.

Modified LPA

The subsections below describe the long-term impacts that would occur with the Modified LPA. Anticipated filling or reduction of wetlands and other waters, and their buffers, as a result of the Modified LPA are mapped in Figure 3.15-4 and Figure 3.15-5. The acreage of fill or reduction to individual wetlands and their buffers is shown in Table 3.15-5.

As described in Chapter 2, activities associated with the Modified LPA would likely require both temporary and permanent modifications to portions of the Portland Metro Levee System, which is a system of federal flood control levees along the south bank of the Columbia River/North Portland Harbor. Modifications may include activities to restore temporarily disturbed portions of the levees, permanent modifications where proposed infrastructure would intersect with the existing levees, or where access to the levees would change as a result of reconfigured roadways. Modifications may also include improvements to existing levee function, if such improvements are requested or required. Modifications or improvements would be coordinated with USACE and Urban Flood Safety and Water Quality District for consistency with the planned future condition of the levees. The assessment of long-term effects to wetlands and other waters presented below includes those associated with potential modifications to the federal levee system.

Source: CRC Wetland Data (2011)

Table 3.15-4. Other Jurisdictional and Potential Jurisdictional Waters within the Study Area

Waters	Description	Designation Type
Potential Jurisdictional Ditch (No name/ID given) (Oregon)	A stormwater ditch, adjacent to Wetland System L/M, within the city of Portland. The ditch enters the wetland system and flows to the Vanport wetland through two culverts. The ditch is located at the toe of a roadway prism and receives stormwater runoff from the roadway prism slope and TriMet light-rail tracks. This ditch was not considered a jurisdictional resource by DSL in 2008.	• Jurisdictional waterway status will be evaluated during permitting process.
Columbia River/North Portland Harbor (Oregon Slough) (Oregon and Washington)	At RM 106, this traditional navigable waterway is highly managed and confined by levees. It is relatively free flowing compared to upstream reaches. Stream flow and stage height are affected by: • Bonneville Dam management and other upstream dams. • Tidal shifts in the Pacific Ocean. • Heavy barge traffic. Shorelines within the cities of Portland and Vancouver.	• Traditional navigable waters of the U.S. regulated by USACE. • Regulated waterway of the state and U.S. • Local designations: - City of Portland Environmental Overlay Zone. - Critical Area and Shoreline of the state designations by the City of Vancouver/State of Washington.
Burnt Bridge Creek (Washington)	Perennial stream located in Burnt Bridge Creek watershed within the city of Vancouver.	• Regulated waterway of the state and U.S. • Critical Area and Shoreline of the state designations by the City of Vancouver/State of Washington.

DSL = Oregon Department of State Lands; RM = river mile; TriMet = Tri-County Metropolitan Transportation District of Oregon; USACE = U.S. Army Corps of Engineers

LPA = Locally Preferred Alternative; PJWA = Potentially Jurisdictional Water Area

3.15.3 Long-Term Benefits and Effects

Long-term impacts occur when an alternative results in removal or fill within jurisdictional wetlands, regulated wetland buffers, or other waters of the state or U.S. The following process has been used to determine long-term impacts on wetlands and other waters:

- Map project components relative to wetlands and other waters, and their buffers, identified in Section 3.15.2.
- Evaluate impacts to the functions of wetlands and other waters.
- Quantify the area of wetlands, other waters, and designated buffers affected.

No-Build Alternative

No filling or reduction of wetlands or wetland buffers would result from the No-Build Alternative. Untreated stormwater would continue to be discharged into wetlands and other waters in the study area. Development would continue to occur along roadways in the study area, which would increase impervious surfaces that would discharge into wetlands and other waters.

Wetlands and Buffers

The Modified LPA, including each of the design options, would permanently excavate or fill approximately 0.58 acres of wetlands, all of which would be in Oregon. The wetlands that would experience the largest impacts are Wetland Q, with 0.3 acres of fill, and Wetland R, with 0.21 acres of fill. This fill and reduction in wetland size would result in a loss of wetland functions.

The Modified LPA, including each of the design options, would also permanently excavate or fill a total of approximately 7.39 acres of wetland buffer. Almost all of this impact would be in Oregon, with the buffers of the Vanport wetland, Wetland Q, and Wetland R experiencing the largest impacts. In Washington, 0.06 acres of wetland buffer would be impacted at Wetland H, which is associated with Burnt Bridge Creek.

Other Waters

The Modified LPA would construct new in-water permanent bridge piers in the Columbia River and North Portland Harbor for the Columbia River bridges and the bridges over North Portland Harbor. The Modified LPA with the double-deck fixed-span configuration would result in 0.91 acres of filled river bottom. Demolition of the foundations for the existing Interstate Bridge in the Columbia River and North Portland Harbor would restore 1.04 acres of river bottom. Therefore, construction of the Modified LPA with the double-deck fixed-span configuration would result in a net restoration of approximately 0.13 acres of waterway.

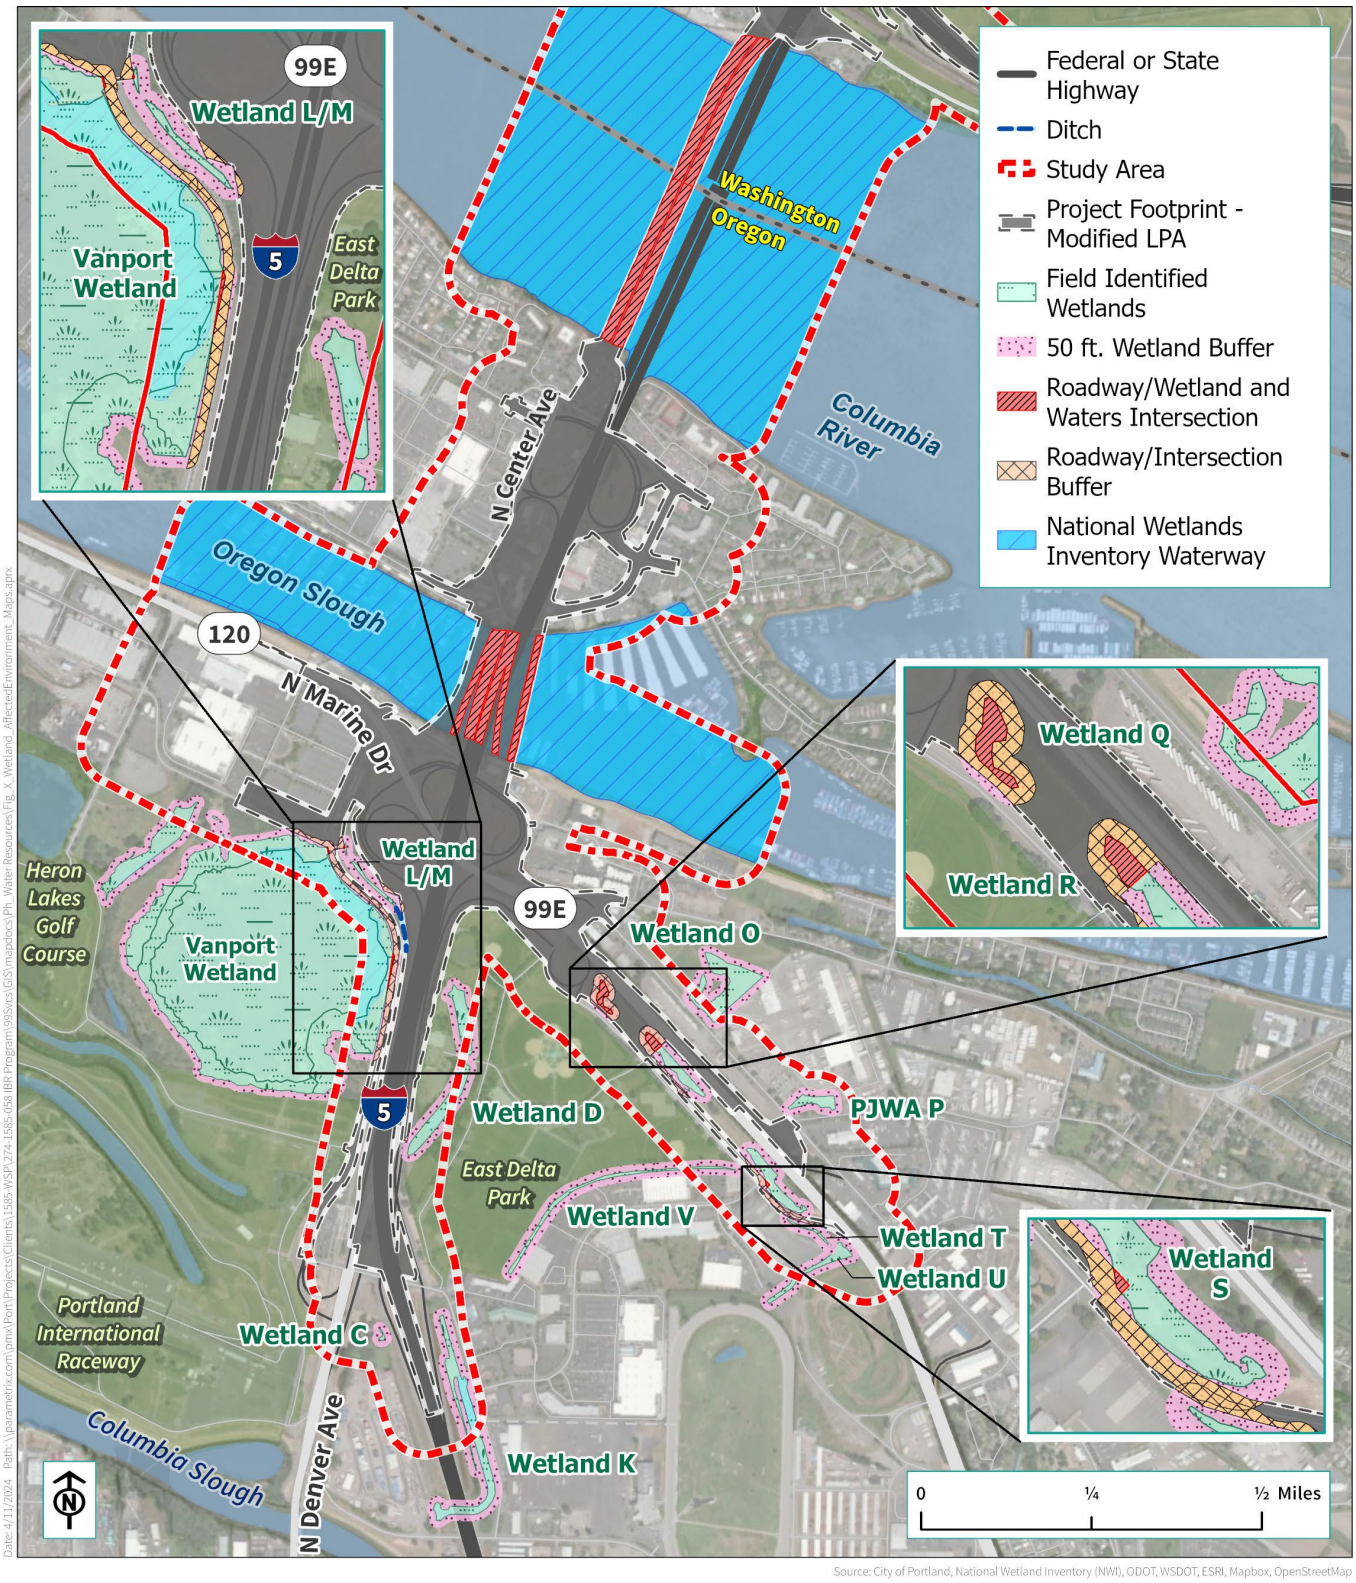
The Modified LPA with single-level fixed-span configuration would have a slightly larger permanent width than the double-deck fixed-span configuration. The Modified LPA with single-level fixed-span configuration would fill approximately 1.07 acres of waterway for new bridge foundations and would restore approximately 1.04 acres by removing the existing bridge foundations, resulting in a net loss of approximately 0.03 acres of in-water area.

The Modified LPA with single-level movable-span configuration would have a slightly larger in-water footprint than the fixed-span configurations. The Modified LPA with the single-level movable-span configuration would fill approximately 1.11 acres of waterway and would restore approximately 1.04 acres by removing the existing bridge foundations. This would result in a net loss of approximately 0.07 acres of in-water area. The Modified LPA with the single-level movable-span configuration would also have the potential for minor water quality impacts associated with the maintenance and operation of the lift span, including the potential accidental discharge of cleaning, painting, and maintenance chemicals.

Comparison of Bridge Configurations and Design Options

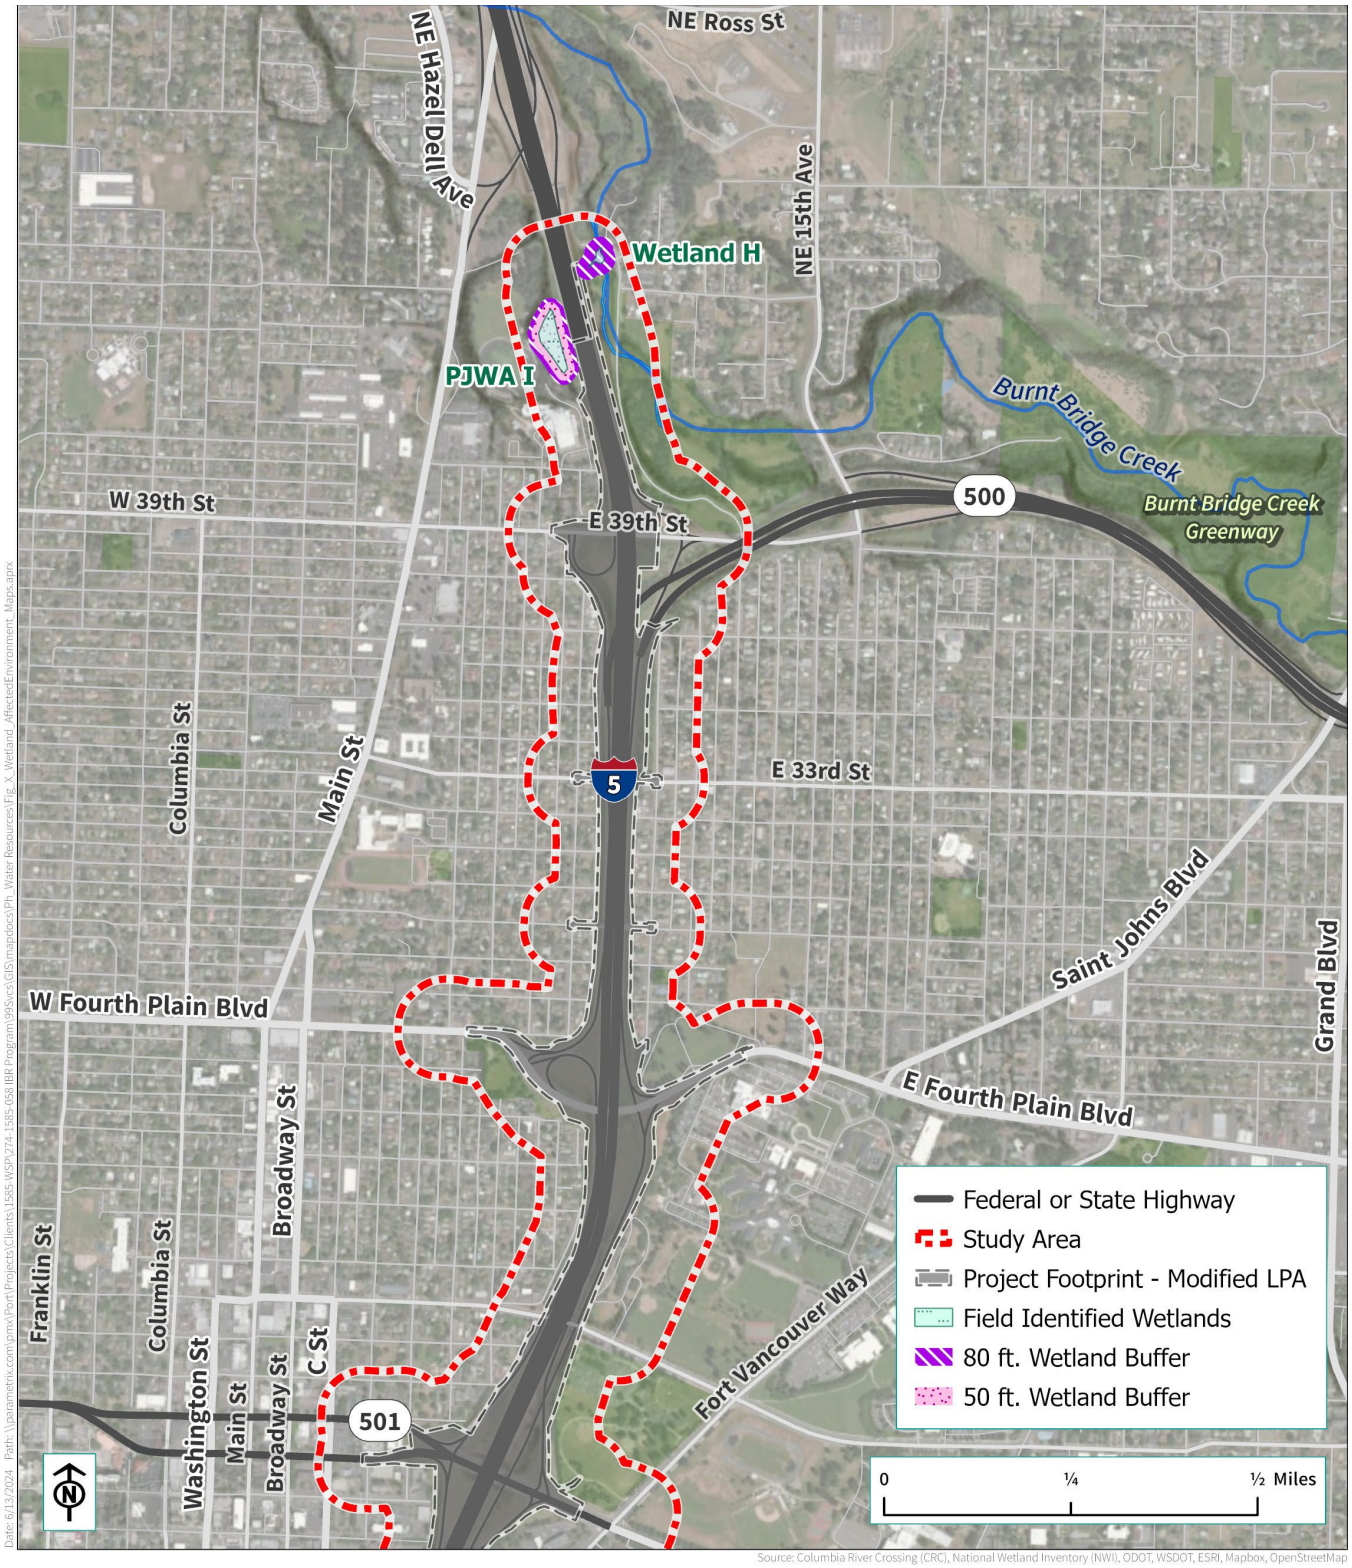
When comparing the No-Build Alternative and the Modified LPA with the double-deck fixed-span configuration, the Modified LPA has more wetland and wetland buffer impacts but less net fill within other waters (Table 3.15-6). The design options of a centered I-5 mainline or westward shift, with or without the SR 14 C Street ramps, and the park-and-ride site options would not result in different effects to wetlands and other waters. All of the Modified LPA bridge configurations would have the same amounts of direct, temporary, or indirect wetland and wetland buffer impacts. However, the bridge configurations would have differing amounts of fill to other waters, as discussed above and shown in Table 3.15-6.

Figure 3.15-4. Modified LPA Filling or Reduction of Wetlands and Other Waters – Oregon



Source: CRC Wetland Data (2011); City of Portland (2023)

Figure 3.15-5. Modified LPA Filling or Reduction of Wetlands and Other Waters – Washington



Source: CRC Wetland Data (2011)

Table 3.15-6. Long-Term Effects Comparison of Alternatives and Bridge Configurations

Alternative and Bridge Configuration	Wetlands (acres)	Wetland Buffers (acres)	Other Waters (acres)	Other Waters - Net Change (acres)
No-Build Alternative	0	0	0	0
Modified LPA with Double-Deck Fixed-Span Configuration [a]	0.58	7.39	0.91 (fill) - 1.04 (removal)	-0.13 (restoration)
Modified LPA with Single-level Fixed-Span Configuration [a, b]	0.58	7.39	1.07 (fill) -1.04 (removal)	0.03 (loss)
Modified LPA with Single-level Movable-Span Configuration [a]	0.58	7.39	1.11 (fill) -1.04 (removal)	0.07 (loss)

Data are approximate and have been rounded.

a Effects would be the same with one or two auxiliary lanes.

b Effects would be the same for all single-level fixed-span bridge type options

3.15.4 Temporary Effects

Construction of the Modified LPA would include construction of the new bridges and removal of the existing Interstate Bridge. The temporary effects analysis includes areas where construction activities would occur outside of the permanent project footprint. Temporarily affected areas were assumed to be restored following construction, with functions returning to pre-construction performance after a period of time. The time to be considered at pre-construction performance varies by agency and can be as long as two years or as short as six months depending on the individual agency's guidance.

No-Build Alternative

The No-Build Alternative would not result in temporary effects on wetlands or other waters.

Modified LPA

Wetlands

In Oregon, approximately 2.56 acres of wetlands (Wetland L/M, Wetland R, Wetland S, Wetland T, and Wetland U) and 7.11 acres of wetland buffer would have a temporary disturbance to wetland vegetation due to construction activities.

In Washington's Burnt Bridge Creek watershed, approximately 1.19 acres of wetland buffer at Wetland H and PJWA I would have a temporary disturbance to wetland vegetation due to construction activities.

Other Waters

Temporary effects on the North Portland Harbor and the Columbia River would vary depending on the specific in-water construction methods used to construct the new bridge structures and deconstruct the existing bridge structures. Temporary effects could include fill for temporary piles to support construction platforms and work trestles. For further discussion, refer to Section 3.14, Water Quality and Hydrology.

In the Columbia River, the Modified LPA with the double-deck fixed-span configuration would temporarily displace approximately 1.52 acres of in-water area, with about 86% of these effects resulting from the use of cofferdams during construction and demolition. Construction of either the single-level fixed-span (all bridge type options) or the single-level movable-span configuration would have similar temporary effects, with the

exception of slightly more in-water area temporarily displaced within cofferdams (an increase of approximately 0.42 acre compared to the double-deck fixed-span configuration).

In North Portland Harbor, approximately 0.40 acres of benthic habitat would be temporarily displaced, with approximately 60% of these effects resulting from drilled shaft isolation casings.

The Burnt Bridge Creek waterway may be temporarily affected from increased turbidity and loss of canopy cover related to construction of the Modified LPA, depending on the specific construction methods employed.

3.15.5 Indirect Effects

Indirect effects from the Modified LPA on wetlands and other waters of the state and U.S. could be caused by the following:

- As described in Section 3.4.4, the Modified LPA is likely to facilitate denser urban development in accordance with local and regional land use plans, particularly in areas with new light rail transit service. Such development could result in the loss of wetland buffers, along with increased public access to wetland areas resulting from increased multimodal access points to these areas. These indirect effects may introduce nuisance plant species and disrupt wildlife activity and other functions performed by existing wetlands.
- Changes could occur in runoff entering wetlands as a result of increases in impervious surfaces and requirements to capture and treat the resulting stormwater runoff. These changes may result in alterations in hydrologic inputs; however, stormwater treatment would have positive indirect effects on water quality in wetlands and other waters.

In addition, the No-Build Alternative would continue to discharge untreated stormwater within the study area into wetlands and other waters.

For further discussion of indirect effects on hydrologic, wildlife, or plant effects from the Modified LPA, refer to Section 3.14, Water Quality and Hydrology, and Section 3.16, Ecosystems.

3.15.6 Potential Avoidance, Minimization, and Compensatory Mitigation Measures

Long-Term Effects

Regulatory Requirements

- Develop the Modified LPA consistent with the applicable federal, state, and local agency regulatory mitigation related to filling or removing material in wetlands and other waters of the U.S. and state.
- Prepare a compensatory mitigation plan that satisfies applicable federal, state, and local regulatory requirements, and that demonstrates no net loss of function and values of wetland resources.

Program-Specific Mitigation

- Continue to evaluate mitigation to offset losses of wetland and waters functions and values, including wetland buffers, as the Modified LPA design progresses.
- In cooperation with federal, state, and local agencies, tribes, and conservation groups, identify agency-approved compensatory mitigation banks and potential permittee responsible mitigation (PRM) sites in both Oregon and Washington to fulfill the compensatory requirements for permanent, temporary, and indirect impacts.

- For unavoidable impacts to Vanport wetlands, increased mitigation ratios would be required because it is an existing wetland mitigation site.

Temporary Effects

Regulatory Requirements

- Implement appropriate high visibility/exclusionary fencing around avoided wetlands and other waters prior to the start of construction.
- Implement appropriate sediment and erosion control procedures during construction activities.
- Replace vegetation temporarily cleared for construction activity in accordance with local regulatory guidance.
- Avoid working outside of the in-water work window without first seeking an exception.
- Offset unavoidable temporary impacts that cannot be minimized through best management practices through the purchase of credits from a mitigation bank or PRM, similar to the mitigation used for certain long-term effects.

Program-Specific Mitigation

- Avoid and minimize short-term impacts to wetland resources in final design to the extent practicable.
- Restore temporarily disturbed wetland and wetland buffer habitats consistent with applicable regulatory requirements.

3.16 Ecosystems

Ecosystems comprise communities of organisms and the habitat that supports those communities. Ecosystems can exist at varying scales, including smaller systems within larger ones. Both natural and human factors can affect ecosystems, and ecosystem health can affect the quality of human life.

The information presented in this section is based on the Ecosystems Technical Report. A Biological Assessment has also been prepared for compliance with Section 7 of the Endangered Species Act. In addition, Section 3.14, Water Quality and Hydrology, and Section 3.15, Wetlands and Other Waters, provide more information on the Modified LPA's effects on the study area's environment.

3.16.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision, as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with ecosystems has been updated in this Draft SEIS to include:

- Species of interest (SOI[1]) lists have been updated with input from federal, state, and local resource management agencies and tribal resource staff.
- SOI life history and habitat requirements have been updated to reflect changes in best available science.
- Species' presence, associated habitat types, and baseline habitat conditions have been updated as applicable.
- Supplemental field surveys have been conducted to validate or update baseline assumptions.
- Federal, state, local, and tribal regulations and policies regarding ecosystem management, evaluation of effects, and compensatory mitigation have been updated.
- Effects analyses have been updated to reflect changes in scientific understanding of certain events and pollutants (such as emerging research related to 6PPD-quinone in stormwater).
- Changes in the project footprint necessitated by changed conditions.

Table 3.16-1 compares the impacts and benefits of the CRC LPA to those of the Modified LPA and identifies the reasons for the differences. Based on the analysis in this section, the effects of the Modified LPA would be similar to those of the CRC LPA.

[1] SOI is not a specific category of governmental or nongovernmental organization-designated species but refers to native species identified through tribal, local, state, and federal coordination as locally important due to their regulatory status, rarity, and/or special habitat considerations.

Table 3.16-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Permanent benthic habitat displacement (shallow and deep-water habitat)	• Approximately 0.21 acres of benthic habitat displacement from new bridges. • Approximately 0.64 acres of benthic habitat restoration from bridge removal (benefit). • Net restoration of approximately 0.43 acres of benthic habitat (benefit).	• Approximately 0.91 acres of benthic habitat displacement from new bridges. • Approximately 1.04 acres of benthic habitat restoration from bridge removal (benefit). • Net restoration of approximately 0.13 acres of benthic habitat (benefit).	• Bridge design updates and refined assumptions regarding construction impacts. • Proposed removal of existing North Portland Harbor bridge would result in a greater quantity of benthic habitat restoration.
Permanent water-surface level overwater shading	• Approximately 1.34 acres of new shading at the water surface. • Approximately 0.44 acre of surface-level shading removal (benefit). • Approximately 0.91 acre of net increase in surface-level shading removal (benefit).	• Approximately 1.04 acres of new shading at the water surface.	• Refined design of Columbia River bridges' foundations. • CRC LPA included removal of a portion of the existing dock at the Port of Vancouver's Terminal 1, which is not part of the Modified LPA.
Permanent elevated overwater shading	• Not quantified.	• Approximately 19.87 acres of elevated overwater shading from new bridges' decks. • Approximately 11.65 acres of elevated shading removal (benefit). • Net increase of approximately 8.22 acres of elevated overwater shading.	Elevated shading from bridges' decks was not quantified for the CRC LPA.
New Contributing Impervious Area (CIA)	• Approximately 41.5-acre increase in CIA compared to the No-Build Alternative. • Treatment would be provided for all post-project CIA, most of which is currently untreated (benefit).	• Approximately 29.6-acre increase in CIA compared to the No-Build Alternative. • Treatment would be provided for all post-project CIA (including adjacent non-project CIA that contributes stormwater to CIA associated with the project), most of which is currently untreated (benefit).	Changes in design.
Permanent and Temporary Impacts to Sensitive	• Permanent and temporary impacts to approximately: – 33.7 acres of Priority Habitats in Washington	• Permanent loss of terrestrial habitats and vegetation, including approximately: – 0.79 acres of riparian buffer in Washington	• Changes in design and changes in regulatory classifications for terrestrial habitats.

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
Terrestrial Habitats	– 117.7 acres of designated Critical Areas in the City of Vancouver – 52.6 acres of lands designated Habitat Conservation Areas by Title 13 of Metro's Urban Growth Management Functional Plan – 41.5 acres within City of Portland environmental zones (ezones)	– 0.15 acres of Biodiversity Area in Washington – Less than 0.01 acres of mapped oak woodland in Washington – 0.06 acres of wetland buffer in Washington – 0.58 acres of wetland in Oregon – 7.39 acres of wetland buffer in Oregon – 1.12 acres of area designated as "High" value riparian/wildlife habitat, and 6.20 acres of area designated as "Medium" value riparian/wildlife habitat in Oregon • Temporary disturbance of terrestrial habitats and vegetation, including approximately: – 1.15 acres of riparian buffer in Washington – 2.87 acres of Biodiversity Area in Washington – 0.03 acres of mapped oak woodland in Washington – 1.19 acres of wetland buffer in Washington – 2.56 acres of wetland in Oregon – 7.11 acres of wetland buffer in Oregon – 4.60 acres of area designated as "High" value riparian/wildlife habitat, and 5.70 acres of area designated as "Medium" value riparian/wildlife habitat in Oregon	• CRC evaluated impacts by Metro's Title 13, which has been replaced by habitat designations in the City of Portland's NRI. • CRC did not quantify areas of temporary disturbance separately from areas of permanent displacement.
Temporary Impacts to Aquatic Habitats during construction	• Approximately 1.81 acres temporary benthic habitat displacement.	• Approximately 2.06 acres temporary benthic habitat displacement.	Changes in design and refined assumptions regarding construction means and methods.

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in this Section	Explanation of Differences
	• Approximately 9.04 acres temporary overwater shading. • Handling and disturbance of fish during in-water work area isolation activities. • Temporarily elevated turbidity, and potential for accidental introduction of pollutants or debris. • Temporarily elevated underwater and terrestrial noise levels. • Overwater lighting. • Changes in avian predation pressure on juvenile salmonids.	• Approximately 15.61 acres temporary overwater shading. • Handling and disturbance of fish during in-water work area isolation activities. • Temporarily elevated turbidity, and potential for accidental introduction of pollutants or debris. • Temporarily elevated underwater and terrestrial noise levels. • Overwater lighting. • Changes in avian predation pressure on juvenile salmonids.	

Note: Data are approximate and rounded.
CIA = Contributing Impervious Area; CRC = Columbia River Crossing; EIS = Environmental Impact Statement; LPA = Locally Preferred Alternative; Metro = Oregon Metro; NRI = Natural Resource Inventory

3.16.2 Existing Conditions

This evaluation includes a primary and a secondary study area. Figure 3.16-1 shows the ecosystem's primary study area, and Figure 3.16-2 shows the secondary study area. The primary study area includes all areas that could experience direct long-term effects from the Modified LPA. The secondary study area is larger and includes all areas where construction-related (temporary) effects and indirect effects could occur. Where the more general term "study area" is used, it refers to both study areas.

The primary and secondary study areas include portions of the mainstem Columbia River, associated tributaries, and nearby terrestrial habitats on the Oregon and Washington sides of the Columbia River. The secondary study area extends to include downstream portions of the Columbia River mainstem to the mouth, and offshore coastal waters between Northern California and Alaska. This section describes the condition of the study area's aquatic, terrestrial, and botanical resource habitats and the species that use these habitats.

Aquatic Resources

This section describes aquatic resources (aquatic species and their habitat) in the primary and secondary study areas, which include the Columbia Slough, the Columbia River and North Portland Harbor, Burnt Bridge Creek, Fairview Creek, and Pacific Ocean coastal waters.

Aquatic Habitat

Columbia Slough

The Columbia Slough is a slow-moving, low-gradient drainage canal that flows from Fairview Lake (east) to the Willamette River (west) and consists of upper, middle, and lower reaches. The study area includes a portion of the lower reach. The lower Columbia Slough habitat supports a variety of aquatic species, including juvenile salmonids and other native and non-native fish species, freshwater shrimp, and crawfish.

Anadromous fish (those that migrate from salt water to fresh water to spawn) can access a portion of the lower Columbia Slough up to an impassable levee at river mile 8.3.

Figure 3.16-1. Ecosystems Primary Study Area

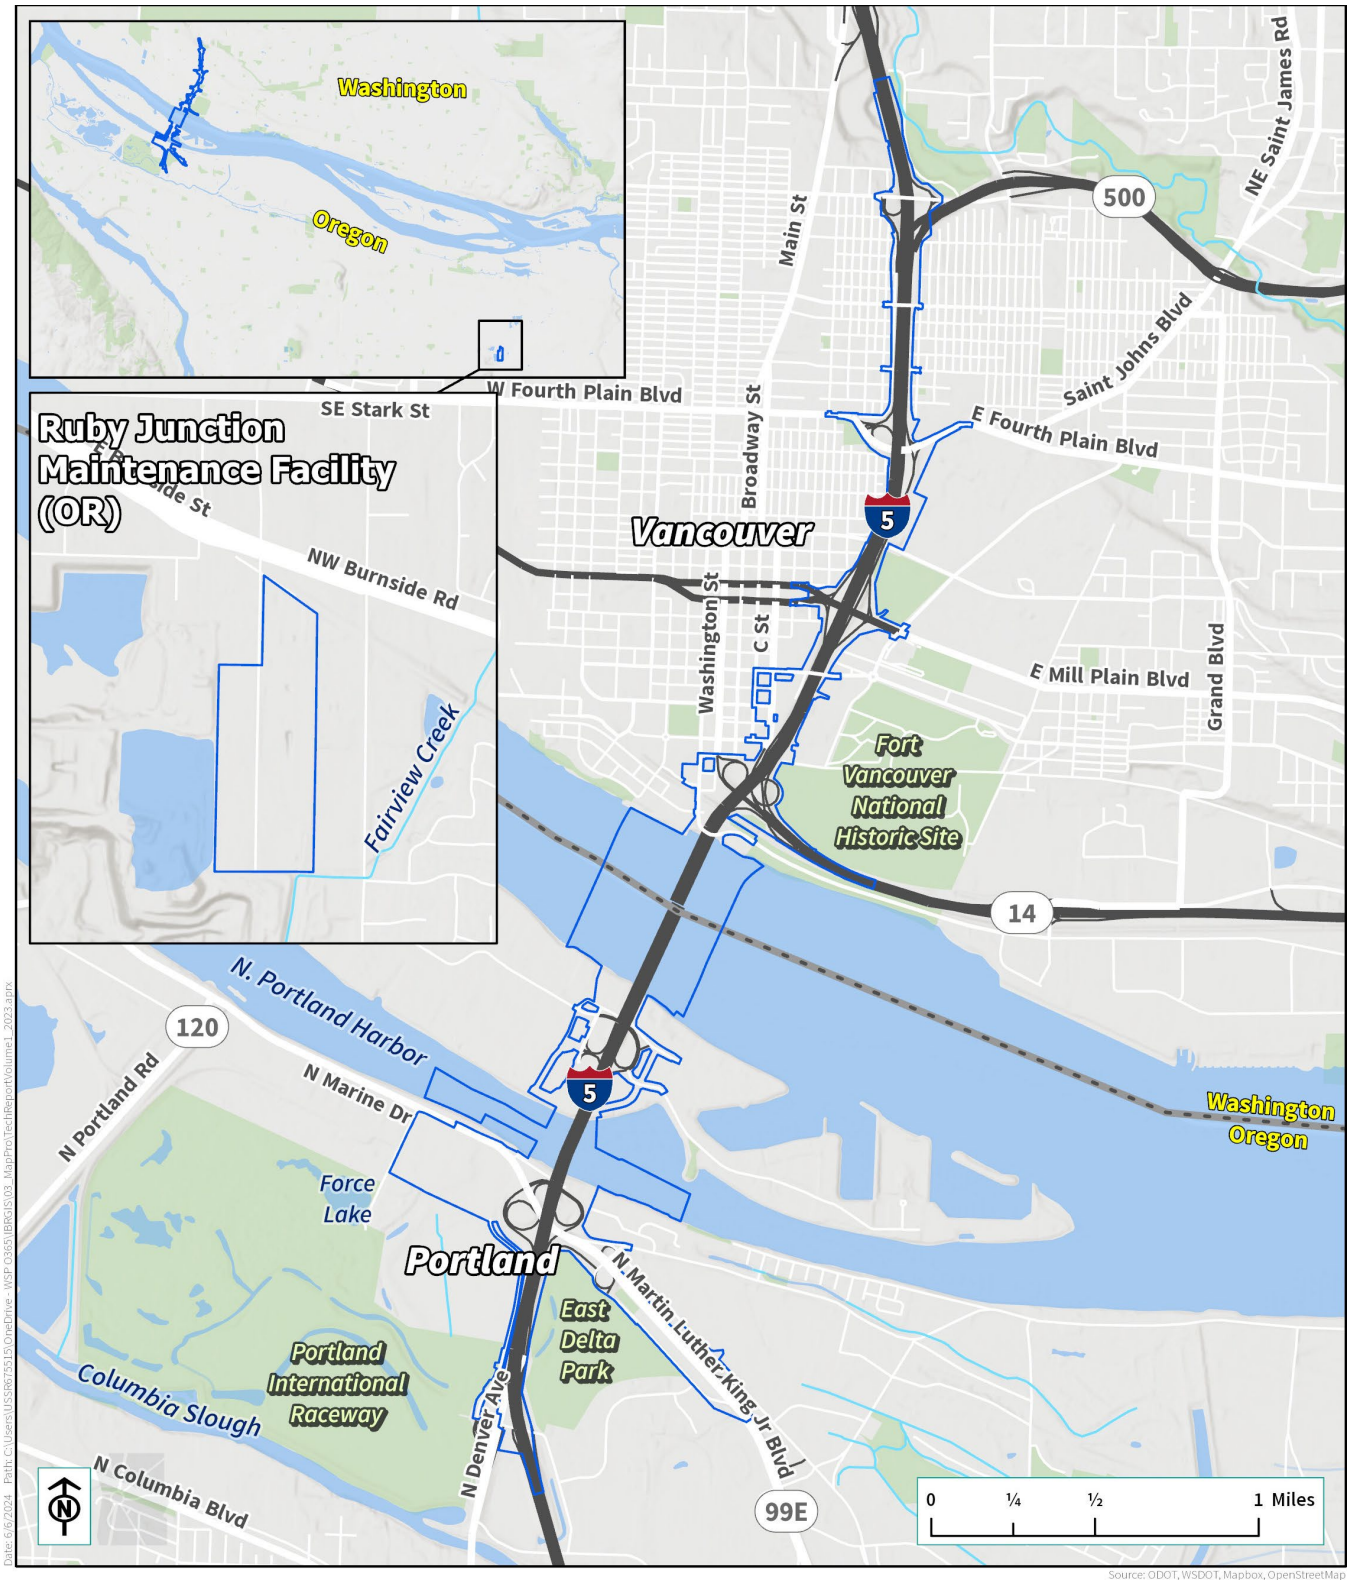


Figure 3.16-2. Ecosystems Secondary Study Area

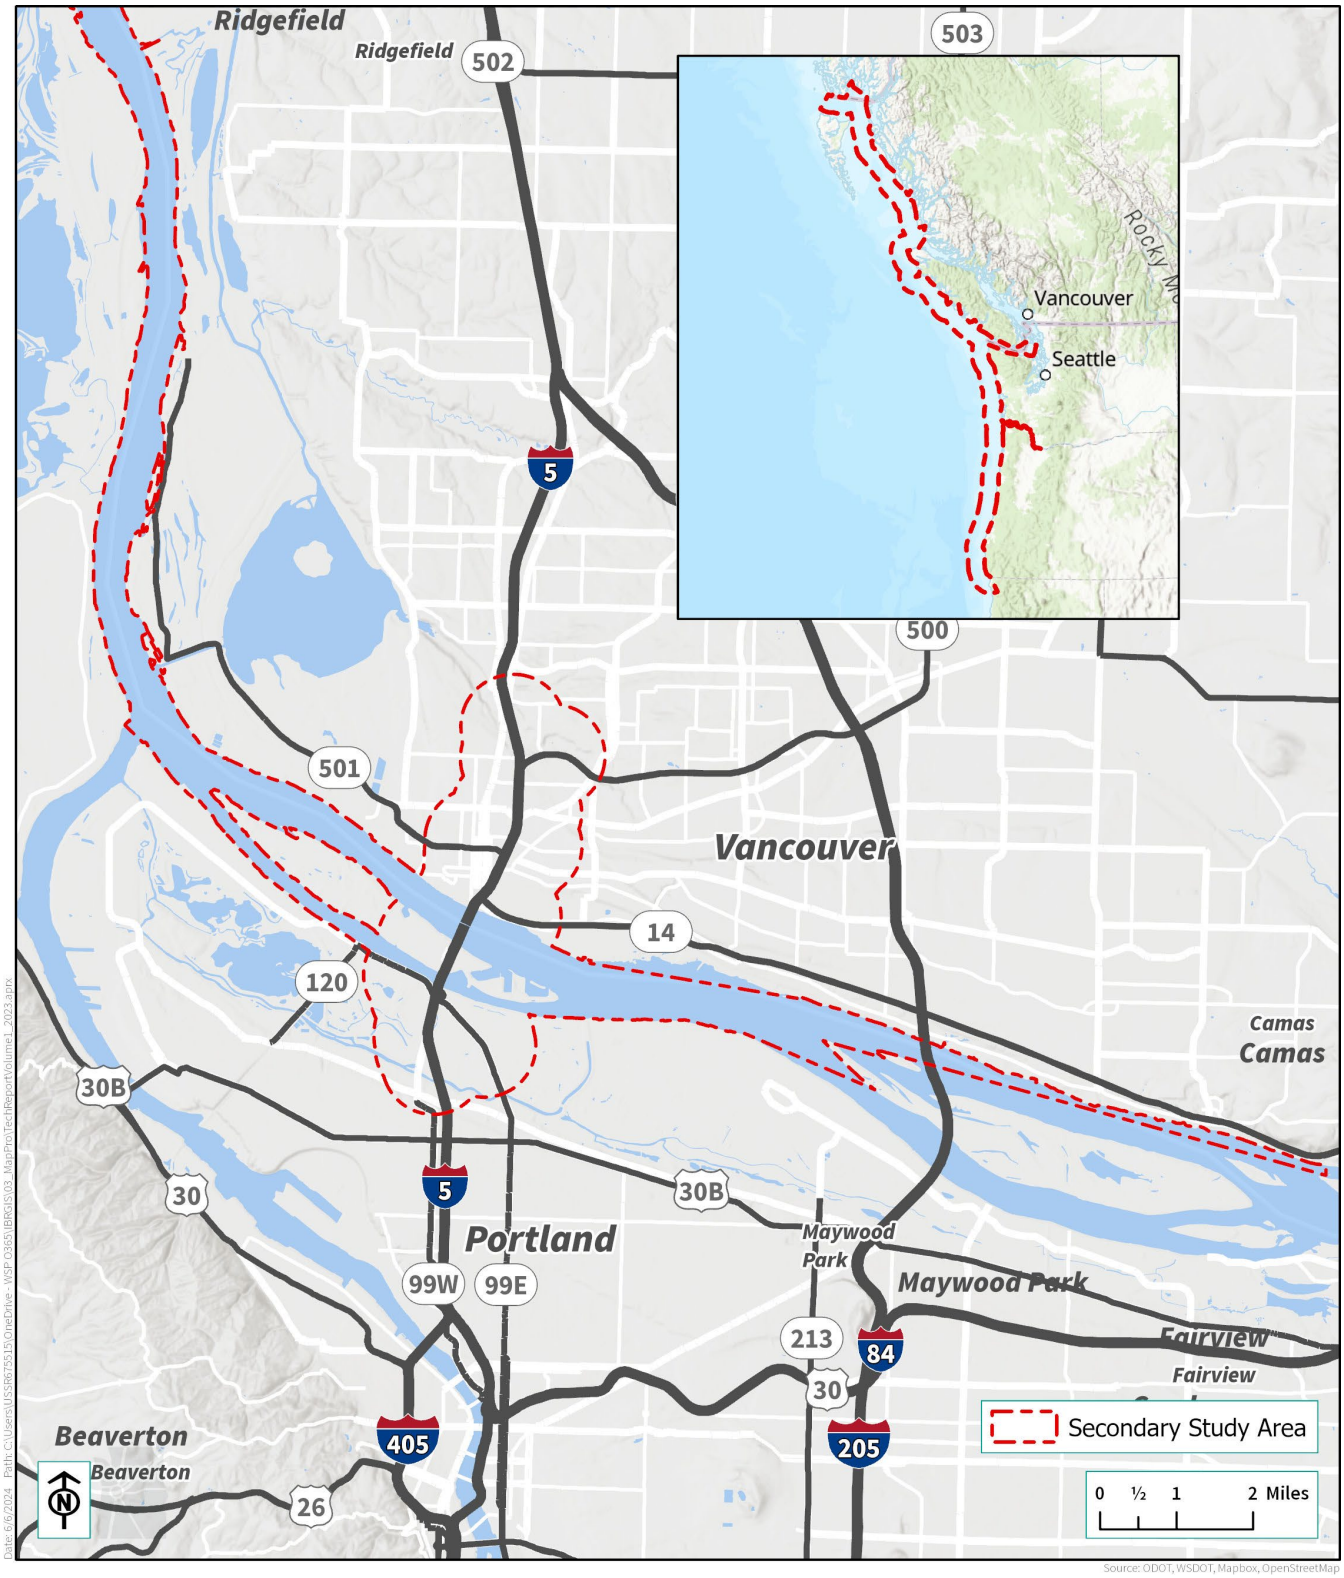

The Columbia Slough is listed under 303(d) of the Clean Water Act for failing to meet water quality standards for aquatic weeds, high levels of iron, and biocriteria. In addition, water temperatures often exceed levels considered suitable for juvenile salmonids, particularly in summer. Channel alterations, water diversions, and upstream dams on the Willamette and Columbia Rivers have reduced the flow rate, resulting in excess sedimentation and high levels of heavy metal contaminants. The contaminated sediments impact the health and habitat of the benthic organisms living in and along the waterway, resulting in low biodiversity. Development has contributed to industrial and stormwater discharges, increased pollutant and turbidity levels, and decreased the oxygen available for fish within the waterway.

What are benthic organisms?

In freshwater biology, benthic organisms are organisms living along a river, stream, or lakebed. Types of benthic organisms found in the study area include some species of snails, shrimp, and crayfish.

Columbia River and North Portland Harbor

The study area is located within the lower Columbia River subbasin. The Columbia River and its tributaries form the dominant aquatic system in the Pacific Northwest. The 1,214-mile-long Columbia River drains 259,000 square miles of the northwestern U.S. and southern British Columbia, Canada, into the Pacific Ocean. There are more than 250 reservoirs and around 150 hydroelectric projects in the Columbia River Basin, including 18 mainstem dams on the Columbia and its main tributary, the Snake River. Saltwater intrusion from the Pacific Ocean extends approximately 23 miles upstream from the Columbia River mouth at Astoria. Coastal tides influence the flow rate and river level up to Bonneville Dam at river mile 146.1.

Within the primary study area, the Columbia River is a highly managed waterbody whose flow is influenced primarily by upstream dams and also by Pacific Ocean tides. North Portland Harbor is a large side channel of the Columbia River located along the southern banks of Hayden Island. Developed uses of the river include commercial transport, power generation, irrigation, and recreation. The State of Washington, City of Vancouver, City of Portland, and Metro have designated the Columbia River and its shoreline as environmental zones subject to regulation.

Hydroelectric dams upstream impound water, raising the river's temperature and making fish passage more difficult by creating bottlenecks where predators have easy access to migrating salmon. Within the primary study area in Oregon, the Columbia River/North Portland Harbor waters are 303(d)-listed for toxic chemicals such as polycyclic aromatic hydrocarbons (PAHs); polychlorinated biphenyl (PCBs), dichlorodiphenyltrichloroethane (DDT) metabolites (DDE 4,4') and arsenic (DEQ 2020). Within the primary study area in Washington, the Columbia River is on the 303(d) list for temperature and PCBs (Ecology 2021). Within the primary study area, water depths in the Columbia River range between approximately 0 and 50 feet, with an average depth of approximately 27 feet. The Columbia River federally authorized navigation channel is dredged to an average depth of about 43 feet. Water depths in North Portland Harbor range between 0 and 20 feet, with an average water depth of approximately 14 feet.

Shallow-water habitat is present in the primary study area on both the Oregon and Washington sides of the river. It is influenced by flow and sediment input from tributaries and the mainstem river that eventually settles to form shoals and shallow flats. Juvenile salmonids in particular use this shallow-water habitat extensively for migrating, feeding, and holding. In general, rearing and outmigrating juveniles use shallow-water habitats more extensively, whereas adult fish rely on deeper-water habitats. The Columbia River also provides habitat for many non-anadromous native fish species, marine mammals, and benthic organisms, as well as substantial populations of non-native invasive species.

Burnt Bridge Creek

Burnt Bridge Creek flows through the city of Vancouver and is a direct tributary to Vancouver Lake, which drains into the lower Columbia River via Lake River. The creek drains one of the most heavily urbanized subbasins within Clark County and is 303(d)-listed within the study area for failing to meet water quality standards for temperatures, dissolved oxygen, fecal coliform bacteria, and pH (Ecology 2021). Physical habitat has been significantly modified throughout Burnt Bridge Creek, and habitat function has been diminished from historical conditions. The creek's upper reaches were historically a series of associated wetlands and marshes that have been filled, ditched, and drained. In addition, most of the tributary streams have been channelized or routed underground. However, the watershed has undergone significant restoration work in recent years to reconstruct side-channel wetland and floodplain areas and improve habitat. The creek provides suitable habitat for several salmonid species, as well as native resident fish species.

Fairview Creek

Fairview Creek is an urban creek that flows from spring-fed wetlands on the northeast side of Grant Butte in Gresham, Oregon, to Fairview Lake, a tributary to the eastern portion of the Columbia Slough. It passes close to the southeast corner of the Ruby Junction Maintenance Facility (Figure 3.16-1). The creek has been physically changed by the construction of dikes and levees, channelization, and historical gravel mining activity. These activities have altered the creek's hydrology, increased sedimentation, and reduced water quality. The waterway is 303(d)-listed for failing to meet water quality standards for biocriteria. In recent decades, some restoration of stream and riparian habitat has occurred through land acquisitions, conservation easements, riparian planting projects, and installation of large woody debris and boulders.

Anadromous salmonids are not currently present in Fairview Creek because there is an impassable barrier between the lower and middle sections of the Columbia Slough, approximately 10 miles downstream of Fairview Creek. In addition, high temperatures and other conditions within the creek limit habitat suitability for anadromous salmonids, although the creek likely provides suitable habitat for resident native and introduced fish.

Pacific Coastal Waters

The secondary study area includes marine waters off the Pacific coast where salmonid species from the Columbia River are available as prey for Southern Resident killer whales (SRKW), also known as orcas. This area encompasses the whale's entire coastal range from the mouth of the Columbia River and its plume, south as far as central California, and north as far as southeast Alaska. Effects on salmon and steelhead within the primary study area could in turn affect the SRKW prey base that occurs within these waters in the secondary study area. The diet of the SRKW is composed almost entirely of salmon, with adult male orcas needing approximately 325 pounds of salmon to meet their daily prey energy requirements. Although their diet tends to vary slightly throughout the year, including smaller amounts of salmon species such as coho, chum, and steelhead, about 80% of their total diet comes from Chinook salmon (SROTF 2018; Hanson et al. 2021).

The abundance of salmon has declined significantly since the late 1800s and early 1900s due to the compounded effects of harvest, habitat modifications, water-quality and water-quantity impacts, predation, and impacts to their own prey base (SROTF 2018). The Southern Resident Orca Task Force has identified impacts to prey availability—specifically, the availability of Chinook salmon—as a key threat to the recovery of the SRKW.

Aquatic Species of Interest

Approximately 20 aquatic SOI may be found within the primary and secondary study areas. The term "species of interest" is not a specific regulatory category; it refers to native species identified as locally important due

to their regulatory status, rarity, and/or special habitat considerations and coordinated with tribes and local, state, and federal agencies. This includes species listed under the federal Endangered Species Act (ESA), as well as other state and local designations. Table 3.16-2 presents a list of aquatic SOI that may occur within the primary and/or secondary study areas.

Table 3.16-2. Aquatic Species of Interest Potentially Occurring within the Study Area

Species Type	Species Common Name	Species Scientific Name	ESU or DPS [a]	Federal ESA Status [b]	State Status (OR) [c]	State Status (WA) [d]	Other Special Regulatory Status [e]
Fish	Chinook salmon	*Oncorhynchus tshawytscha*	Lower Columbia River (LCR) ESU	LT; Critical Habitat	SC	Not listed; PHS	EFH; SGCN-OR; SGCN-WA
			Upper Willamette River (UWR) ESU	LT; Critical Habitat	SC	Not listed; PHS	EFH; SGCN-OR; SGCN-WA

	California floater	*Anodonta californiensis*	N/A	Not listed	Not listed	C; PHS	SGCN-OR; SGCN-WA

a DPS = distinct population segment; ESU = evolutionarily significant unit; N/A = not applicable

b ESA = Endangered Species Act; Federal status: LT = Listed Threatened, LE = Listed Endangered, Not listed = No status designated; Critical Habitat = designated critical habitat (NOAA Fisheries n.d.; USFWS 2021a).

c Oregon State status: LT = Listed Threatened, S=Sensitive; SC = Sensitive Critical, Not listed = No status designated; (OCS 2016; ODFW 2021a; 2021b).

d Washington State status: C = Candidate, Not listed = No State Status; PHS = WDFW priority habitats and species (WDFW 2022, 2023).

e Other Special Regulatory Status: EFH = Essential Fish Habitat designated; SOC=Federal Species of Concern; MMPA = Marine Mammal Protection Act; SGCN-OR = Species of Greatest Conservation Need in Oregon (OCS 2016); SGCN-WA = Species of Greatest Conservation Need in Washington (WDFW 2015)

Terrestrial Resources

This section describes "terrestrial resources" in the study area, which includes non-aquatic habitats and wildlife species that these habitats support, including birds, mammals, amphibians, reptiles, and insects.

Terrestrial Habitat

Terrestrial habitats within the study areas are generally small and fragmented and have been modified from their historical conditions. Nevertheless, these areas provide habitat for various native mammals, birds, amphibians, and reptiles.

Table 3.16-3 lists approximate acreages of terrestrial habitat types within the study areas. Figure 3.16-3 shows the approximate extent and location of these habitat types. The predominant habitat type is the "Urban and Mixed Environs" classification, interspersed with small, isolated patches of wetland or forest habitats. The most intact terrestrial habitat areas adjoin the Vanport wetland in the south and the Burnt Bridge Creek Greenway in the north. The Ruby Junction Maintenance Facility is not shown on Figure 3.16-3 because the area is entirely developed and classified as "Urban and Mixed Environs."

Table 3.16-3. Acres of Terrestrial Habitat Classification within the Primary and Secondary Study Areas

Habitat Classification	Primary Study Area (acres)	Secondary Study Area (acres)	Total Area (acres)
Urban and Mixed Environs	396	4,518	4,914
Agriculture, Pasture, and Mixed Environs	0.3	141	141
Westside Riparian – Wetlands	17	608	625
Herbaceous Wetlands	0.3	74	74
Westside Lowlands Conifer – Hardwood Forest	1.3	122	123
Westside Oak and Dry Douglas Fir Forest and Woodlands	<0.1	53	53
Total	**415**	**5,516**	**5,930**

Urban and Mixed Environs

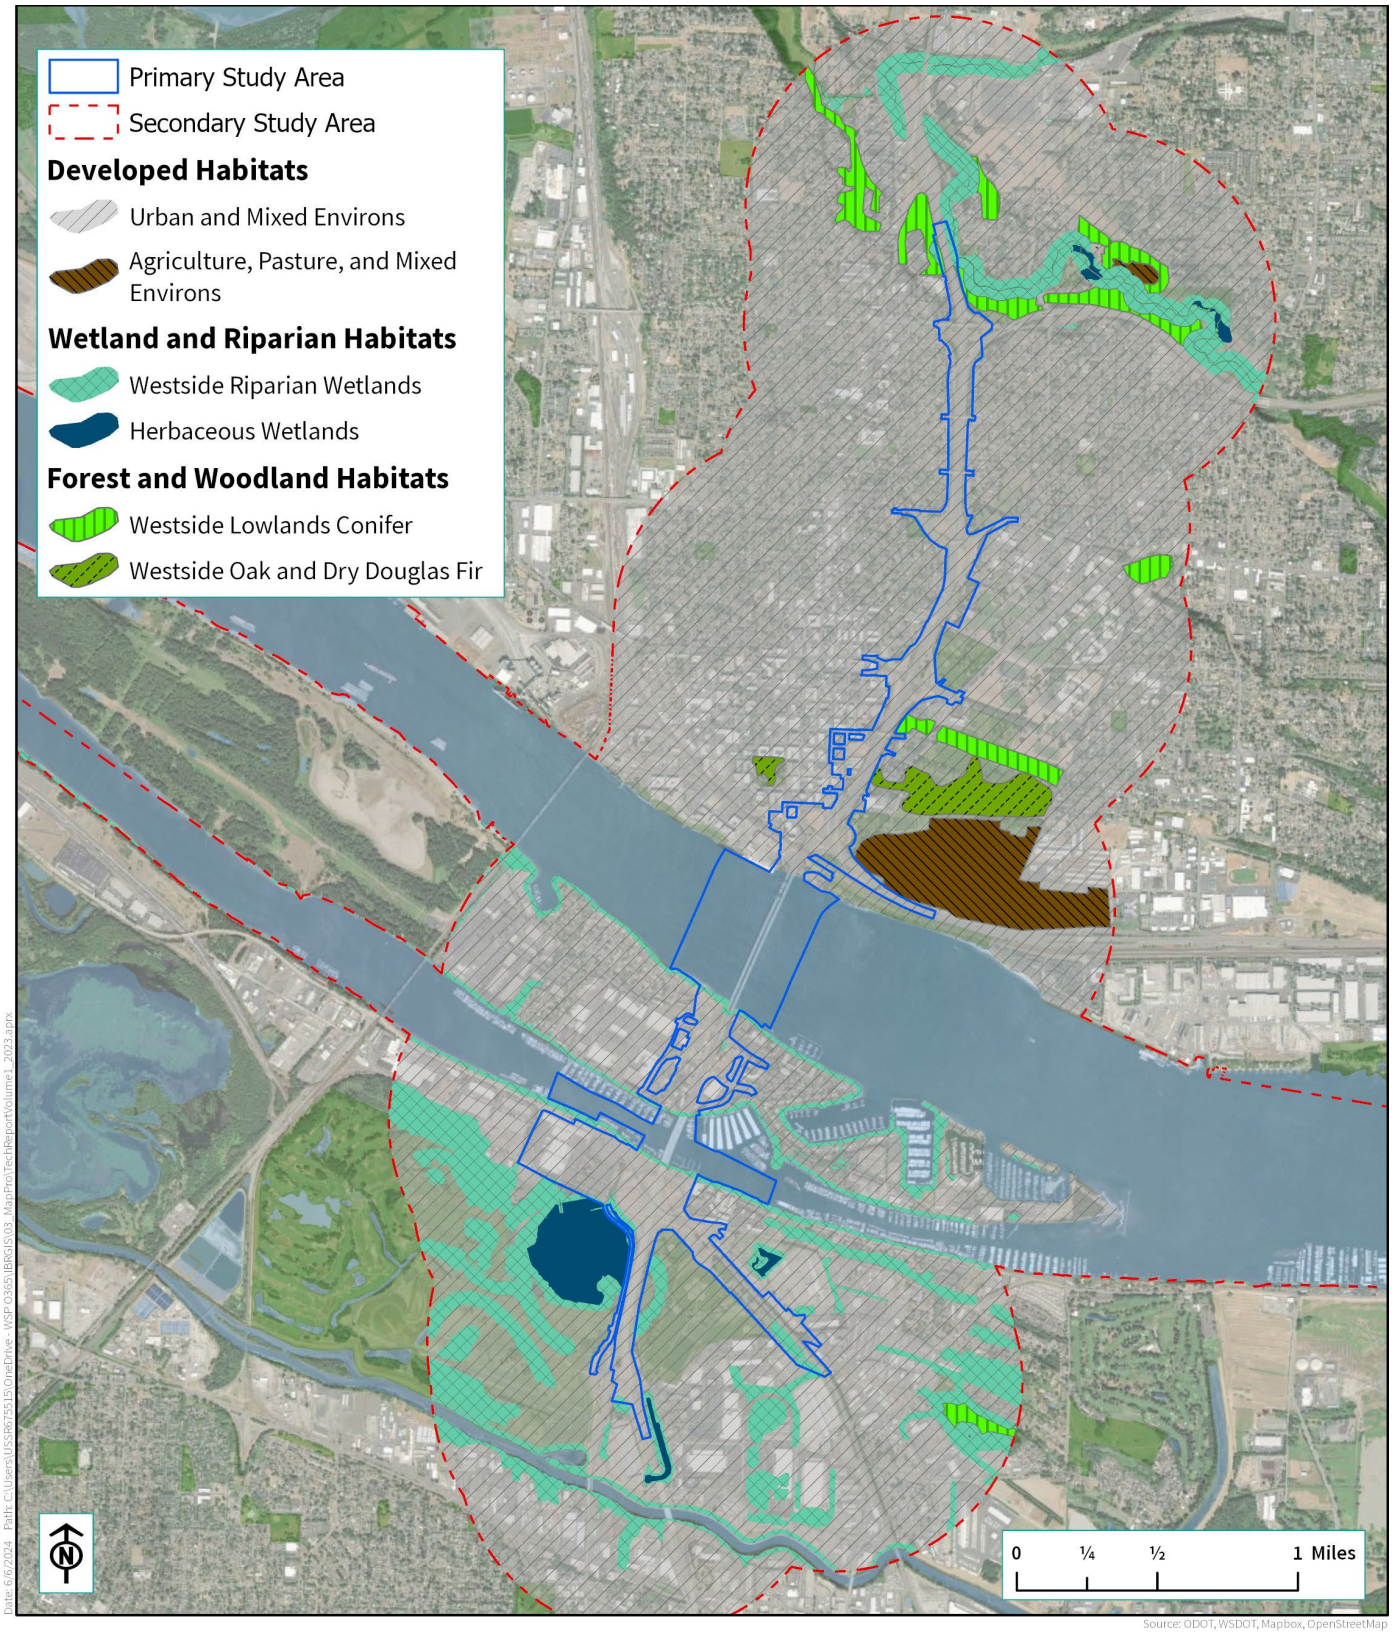
Although urban environments are usually considered to provide relatively low-quality habitat, some terrestrial wildlife species have adapted to these conditions. For example, bridges and other structures can provide nesting and perching habitat for certain migratory bird species. Examples of SOI associated with this habitat type include bald eagle, peregrine falcon, other migratory bird species, *Myotis* bats, Townsend's big-eared bat, and monarch butterfly. Because the study area is highly urbanized, suitable habitat for wildlife is fragmented, and passage is restricted. I-5 and other roads serve as barriers to passage and are unsuitable and dangerous corridors for most terrestrial wildlife.

Agriculture, Pasture, and Mixed Environs

The south end of the Fort Vancouver National Historic Site and the west end of the Pearson Field is a mowed/ maintained pasture that falls more closely within the "Agriculture, Pasture, and Mixed Environs" habitat type. This habitat type includes unimproved pastures, predominantly grassland sites and often abandoned fields that have little or no active management such as irrigation, fertilization, or herbicide applications (Johnson and O'Neil 2001). The "Agriculture, Pasture, and Mixed Environs" habitat type is used by a wide diversity of native species, particularly birds and small mammals. These areas also provide excellent foraging opportunities for raptors and other birds of prey. They are also prone to invasion by exotic species, due to their relatively high level of disturbance.

Examples of SOI associated with this habitat type include streaked horned lark, bald eagle, peregrine falcon, other migratory birds, *Myotis* bats, and Townsend's big-eared bat (Johnson and O'Neil 2001).

Figure 3.16-3. Habitat Classifications within the Primary and Secondary Study Areas



Wetland and Riparian Habitat

Wetland and riparian habitats within the study area are fragmented and disturbed from their natural condition, though they continue to provide habitat functions. There are narrow bands of riparian habitat adjacent to surface waters, including the Columbia River, North Portland Harbor, Columbia Slough, Burnt Bridge Creek, and Fairview Creek.

Herbaceous wetlands are present in the Vanport wetland system south of the Expo Center, immediately surrounding the open water pond/wetland system east of I-5 near Delta Park and east of I-5 along Whitaker Road. Herbaceous wetlands provide many habitat functions that are similar to forested and shrub-dominated wetlands. In general, they provide habitat for a variety of wildlife adapted to wetlands and riparian areas within an urban environment, including a variety of small mammals, amphibians, reptiles, migratory birds, waterfowl, and raptors. Examples of SOI associated with this habitat type include bald eagle, peregrine falcon, purple martin, other migratory birds, *Myotis* bats, Townsend's big-eared bat, pond turtles, painted turtles, and northern red-legged frog.

Forest and Woodland Habitat

Within the study area, the "Westside Lowlands Conifer – Hardwood Forest" habitat type is limited to small, isolated patches associated with Burnt Bridge Creek. These areas provide limited habitat function due to their isolated and fragmented nature. However, the habitat may provide for migratory birds' nests, and raptors may perch and use these areas for foraging in adjacent habitats. Examples of SOI associated with this habitat type include the bald eagle, peregrine falcon, other migratory birds, *Myotis* bats, and Townsend's big-eared bat.

The "Westside Oak and Dry Douglas Fir Forest and Woodlands" habitat type occurs in two small patches within the study area, one in the northern portion of Esther Short Park and one at the Fort Vancouver National Historic Site. These areas generally provide a similar suite of habitat functions as "Westside Lowlands Conifer – Hardwood Forest" habitats. However, oak woodlands can provide some unique functions due to their relative rarity in the landscape and their different structural composition.

Terrestrial Species of Interest

Table 3.16-4 presents a list of terrestrial SOI, including birds, mammals, amphibians/reptiles, and insects, that may occur within the study areas, along with their regulatory status.

Table 3.16-4. Terrestrial Species of Interest Potentially Occurring within the Study Area

	Species Common Name	Species Scientific Name	Federal Status [a]	State Status (OR) [b]	State Status (WA) [c]	Other Special Regulatory Status [d]
Birds	Streaked horned lark	*Eremophila alpestris strigata*	LT; Critical Habitat	SC	LE; PHS	MBTA; SGCN-OR; SGCN-WA
	Bald eagle	*Haliaeetus leucocephalus*	Not listed	Not listed	Not listed	BGEPA; MBTA; SGCN-WA
	Peregrine falcon	*Falco peregrinus anatum*	Not listed	S	Not listed	MBTA; SGCN-OR; SGCN-WA

	Species Common Name	Species Scientific Name	Federal Status [a]	State Status (OR) [b]	State Status (WA) [c]	Other Special Regulatory Status [d]
	Purple martin	*Progne subis*	Not listed	SC	Not listed	MBTA; SGCN-OR; SGCN-WA

	Other migratory birds	Multiple Species	N/A	N/A	N/A	MBTA
Mammals	Columbian white-tailed deer	*Odocoileus virginianus ssp. Leucurus*	LT	S	LT; PHS	SGCN-OR; SGCN-WA
	Long-legged myotis	*Myotis volans*	Not listed	S	Not listed; PHS [e]	SGCN-OR
	Fringed myotis	*Myotis thysanodes*	Not listed	S	Not listed; PHS [e]	SGCN-OR
	Long-eared myotis	*Myotis evotis*	Not listed	Not listed	Not listed; PHS [e]	SGCN-OR
	Townsend's big-eared bat	*Corynorhinus townsendii*	Not listed	SC	C; PHS	SGCN-OR; SGCN-WA
	Silver-haired bat	*Lasionycteris noctivagans*	Not listed	S	Not listed; Candidate	SGCN-OR; SGCN-WA
Reptiles and Amphibians	Western pond turtle	*Actinemys marmorata*	Not listed	S	LE; PHS	SGCN-OR; SGCN-WA
	Painted turtle	*Chrysemys picta*	Not listed	SC	Not listed	SGCN-OR; SGCN-WA
	Northern red-legged frog	*Rana aurora*	Not listed	S	Not listed	SGCN-OR; SGCN-WA

	Species Common Name	Species Scientific Name	Federal Status [a]	State Status (OR) [b]	State Status (WA) [c]	Other Special Regulatory Status [d]
Insects	Monarch butterfly	*Danaus plexippus*	C	Not listed	Not listed	N/A

a Federal ESA status: LT = Listed Threatened, LE = Listed Endangered, C = Candidate, Not listed = No status designated; Critical Habitat = designated critical habitat (NOAA Fisheries 2021; USFWS 2021a).
b Oregon State status: LT = Listed Threatened, LE = Listed Endangered, S=Sensitive, SC = Sensitive Critical, Not listed = No status designated (ODFW 2021a, 2021b).
c Washington State status: LT = Listed Threatened, LE = Listed Endangered, S=Sensitive, C=Candidate, PHS = WDFW priority habitat species; (WDFW 2022, 2023).
d Other Special Regulatory Status: SOC=Federal Species of Concern; PHS = Priority Habitats and Species; BGEPA = Bald and Golden Eagle Protection Act; MBTA = Migratory Bird Treaty Act; SGCN-OR = Species of Greatest Conservation Need in Oregon (OCS 2016); SGCN-WA = Species of Greatest Conservation Need in Washington (WDFW 2015); N/A = Not Applicable
e Roosting concentrations of *Myotis* bats are considered Priority Species by WDFW, where they occur.

Botanical Resources

Botanical Species of Interest

Table 3.16-5 lists the botanical SOI, their protection status, and suitable habitat that may occur in the primary study area. Most habitats within the study area have low suitability for these species, and they have not been documented in the primary study area.

Table 3.16-5. Botanical Species of Interest Potentially Occurring within the Primary Study Area

Species Common Name	Species Scientific Name	Federal Status [a]	State Status (OR) [b]	State Status (WA) [c]	Habitat Suitability in Primary Study Area	Typical Flowering Window
Golden paintbrush	*Castilleja levisecta*	T	E	T	Low – Agriculture, Pasture and Mixed Environs	April–June
Kincaid's lupine	*Lupinus oreganus*	T	T	T	Low – Agriculture, Pasture and Mixed Environs	April–June
Nelson's checkermallow	*Sidalcea nelsoniana*	T	T	E	Low – Agriculture, Pasture and Mixed Environs	Late May–July
Willamette Daisy	*Erigeron decumbens*	E	E	Not listed	Low – Agriculture, Pasture and Mixed Environs	June–July

Species Common Name	Species Scientific Name	Federal Status [a]	State Status (OR) [b]	State Status (WA) [c]	Habitat Suitability in Primary Study Area	Typical Flowering Window
Tall bugbane	*Actaea elata var. elata*	Not listed	Not listed	S	Low – Westside Riparian – Wetlands and Westside Lowlands Conifer – Hardwood Forest	May–August
Small-flowered trillium	*Trillium albidum ssp. Parviflorum*	Not listed	Not listed	S	Low – Westside Riparian – Wetlands and Westside Lowlands Conifer – Hardwood Forest	March–May
Western ladies-tresses	*Spiranthes porrifolia*	Not listed	Not listed	S	Low – Herbaceous Wetlands and Westside Riparian – Wetlands	May–August
Columbia cress	*Rorippa columbiae*	Not Listed	C	T	Low – Herbaceous Wetlands and Westside Riparian – Wetlands	April–October

a Federal Endangered Species Act status: C = Candidate; E = Endangered; Not listed = No status designated; P = Proposed; SOC = Species of Concern; T = Threatened (USFWS 2021b).

b Oregon State status: E = Endangered; Not listed = No status designated; T = Threatened, S=Sensitive; SC = Sensitive Critical (ORBIC 2021).

c Washington State status: C=Candidate; E = Endangered; PHS = Washington State priority species; S=Sensitive; T = Threatened, (WNHP 2021)

Noxious Weeds

Table 3.16-6 identifies 14 species of noxious weeds known or expected to occur within the primary study area. Noxious weeds are defined at the state level by the Oregon State Weed Board and the Washington State Noxious Weed Control Board. No noxious weeds designated under state law as requiring eradication are known or expected to occur within the primary study area.

Table 3.16-6. Noxious Weed Species Occurring within the Primary Study Area

Botanical Name	Common Name
Centaurea × gerstlaueri (*Centaurea pratensis)*	Meadow knapweed
Cirsium arvense	Canada thistle
Cirsium vulgare	Bull thistle
Clematis vitalba	Old man's beard
Conium maculatum	Poison hemlock
Convolvulus arvensis	Field bindweed
Cytisus scoparius	Scotch broom
Daucus carota	Wild carrot
Geranium robertianum	Herb-Robert's
Hedera helix	English ivy
Hypericum perforatum	St. John's wort
Phalaris arundinacea	Reed canarygrass or Ribbongrass
Fallopia japonica	Japanese knotweed
Rubus armeniacus	Himalayan blackberry

Federal, State, and Local Habitat Designations

Federal, state, and local regulatory frameworks designate important and/or protected habitat for ecosystem resources within the study areas. Table 3.16-7 summarizes these designations. Note that many of these designated areas overlap. For example, the open water habitat within the Columbia River is designated critical habitat for several species of ESA-listed fish, essential fish habitat for Pacific salmon, a Washington Department of Fish and Wildlife (WDFW) priority habitat, a designated Critical Area in the city of Vancouver, and a Portland environmental overlay zone (ezone).

Table 3.16-7. Federal, State, and Local Habitat Designations within the Study Areas

	Agency	Limits of Jurisdiction	Resource Designation	Description
Federal	NOAA Fisheries and USFWS	U.S.	Critical Habitat for ESA-listed species	Specific geographic areas contain features essential to the conservation of an endangered or threatened species and may require special management and protection.
	NOAA Fisheries	U.S.	Essential Fish Habitat	Waters and substrate that are necessary to fish for spawning, breeding, feeding, or growth to maturity. EFH has been designated for three categories of fish: Pacific salmon, groundfish, and coastal pelagic species.

	Agency	Limits of Jurisdiction	Resource Designation	Description
Oregon	Oregon DSL and ODFW	Oregon – Statewide	Habitats of Conservation Concern	Habitats of conservation concern within Oregon that provide important benefits to OCS Strategy Species. 11 Strategy Habitats have been designated.
	City of Portland	City of Portland	Environmental Overlay Zones	Establishes Environmental Protection zones and Environmental Conservation zones in Portland to protect important natural resource areas.
	Metro	Multnomah, Clackamas, and Washington Counties	Habitat Conservation Areas	Classifies regionally significant fish and wildlife habitat as Habitat Conservation Areas. Separate categories exist for Riparian and Upland Wildlife habitats.
Washington	WDFW	Washington – Statewide	Priority Habitats	Specifically designated habitat types that have been determined to have unique or significant value. WDFW has designated 20 priority habitats within the state.
	Ecology	Washington - Statewide	Shoreline Management Areas	The Shoreline Management Act defines certain waterbodies as "Shorelines of the State," and local jurisdictions establish shoreline management areas in which development activities are regulated.
	City of Vancouver	City of Vancouver	Critical Areas Ordinance	The Growth Management Act requires all cities and counties in Washington to adopt regulations protecting "critical areas" to preserve the natural environment, wildlife habitat, and sources of fresh drinking water. Five categories are defined, including fish and wildlife habitat conservation areas (FHWCAs). The City of Vancouver has a CAO that defines and regulates development activities within FHWCAs.

CAO = Critical Areas Ordinance; DSL = Department of State Lands; Ecology = Washington Department of Ecology; EFH = essential fish habitat; ESA = Endangered Species Act; Metro = Oregon Metro; NOAA Fisheries = North American Oceanic and Atmospheric Administration Fisheries Service; ODFW = Oregon Department of Fish and Wildlife; USFWS = U.S. Fish and Wildlife Service; WDFW = Washington Department of Fish and Wildlife

3.16.3 Long-Term Benefits and Effects

Table 3.16-8 summarizes the ecosystem effects of the Modified LPA, including design options, and the No-Build Alternative, followed by a discussion of the effects.

Table 3.16-8. Summary of Ecosystems Effects from the Modified LPA, Including Design Options, and No-Build Alternative

1	2	3	4	5	6	7
Effect Category	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Single-Level Fixed-Span Configuration, [a] One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5, all Park-and-Ride Site Options
Aquatic resources (total net change compared to the existing condition)	• Continued impacts from untreated stormwater from approximately 156.4 acres of existing CIA. • Potential for injury and habitat degradation in the case of a bridge failure.	• Benthic habitat impact: -0.13 acres (net restoration). • Overwater Shading (Water Surface): +1.04 acres. • Overwater Shading (Elevated Deck): +8.22 acres. • Beneficial effect of stormwater treatment for all post-project CIA, including approximately 156.4 acres of existing impervious area that is currently untreated.	• Similar to effects listed in Column 3, except would result in a greater amount of elevated overwater shading. • Overwater Shading (Elevated Deck): +13.02 acres.	• Benthic habitat impact: +0.03 acres. • Overwater Shading (Water Surface): +1.41 acres. • Overwater Shading (Elevated Deck): +10.78 acres.	• Benthic habitat impact: +0.07 acres of in-water area. • Overwater Shading (Water Surface): +1.58 acres. • Overwater Shading (Elevated Deck): +10.78 acres.	• Same as effects listed in Column 3.
Permanent impacts to terrestrial resources in Oregon (acres)	• Potential for injury and habitat degradation in the case of a bridge failure.	• “High” wildlife/riparian value habitats: 1.12. • “Medium” wildlife/riparian value habitats: 6.20. • Wetlands: 0.58. • Wetland Buffers: 7.39.	• Same as effects listed in Column 3.	• Same as effects listed in Column 3.	• Same as effects listed in Column 3.	• Similar to effects listed in Column 3, except would slightly reduce impervious surface.
Permanent impacts to terrestrial resources in Washington (acres)	• Potential for injury and habitat degradation in the case of a bridge failure.	• Riparian buffers: 0.79. • Biodiversity Areas: 0.15. • Oak Woodlands: <0.01. • Wetlands: 0. • Wetland Buffers: 0.06.	• Same as effects listed in Column 3.	• Same as effects listed in Column 3.	• Same as effects listed in Column 3.	• Same as effects listed in Column 3.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge types, unless otherwise specified.

No-Build Alternative

Under the No-Build Alternative, the existing Interstate Bridge, North Portland Harbor bridge, and I-5 interchanges would remain. Regular and intermittent maintenance activities would continue to be required, which have the potential to result in long-term impacts to aquatic and terrestrial species and habitats, including potential impacts to birds nesting on the existing Interstate Bridge. Stormwater from impervious surfaces within the primary study area would continue to enter aquatic habitat surface waters largely untreated. If a major earthquake event occurred that resulted in the existing Interstate Bridge over the Columbia River failing or collapsing, fish and wildlife species in the immediate vicinity and in aquatic habitats both upstream and downstream could be struck by falling debris and injured or killed. Fallen debris would also diminish habitat suitability and contribute chemical contaminants that could affect aquatic species and habitats upstream and downstream of the bridge.

Modified LPA

The subsections below describe the long-term impacts that would occur with the Modified LPA. As described in Chapter 2, several design options are being evaluated as part of the Modified LPA. Where impacts would differ associated with a design option, a comparison of the impacts associated with each design option is provided. The with or without C-Street ramp option, I-5 mainline westward shift or centered option, and the park and ride site options evaluated as part of the Modified LPA would not result in different levels or types of long-term effects to ecosystem resources and are, therefore, not specifically addressed further.

As described in Chapter 2, the construction activities associated with the Modified LPA would likely require both temporary and permanent modifications to portions of the Portland Metro Levee System, which is a system of federal flood control levees located along the south bank of the Columbia River within the primary study area. Such modifications may include activities to restore temporarily disturbed portions of the levees, or permanent modifications where proposed infrastructure would intersect with the existing levees, or where access to the levees would change as a result of reconfiguration of the roadways. Modifications may include improvements to existing levee function if such improvements are requested or required. Modifications or improvements would be coordinated for consistency with the planned future condition of the levees under the Levee Ready Columbia project. The assessment of long-term effects to ecosystem resources associated with the Modified LPA presented below includes those associated with potential reconstruction of, or modifications to, the federal levee system.

Aquatic Resources

Under the Modified LPA, bridge removal and replacement would result in direct permanent impacts to sensitive aquatic habitats in the Columbia River and North Portland Harbor. These impacts would include physical alteration of benthic habitat and changes in overwater shading. The Modified LPA would not directly impact or displace aquatic habitat in Burnt Bridge Creek, the Columbia Slough, or Fairview Creek. Table 3.16-9 summarizes the permanent aquatic habitat impacts associated with the Modified LPA.

Table 3.16-9. Permanent Benthic Habitat and Overwater Shading Aquatic Impacts Summary

Impact to Columbia River and North Portland Harbor	Double-Deck Fixed-Span Configuration (acres)	Single-Level Fixed-Span Configuration (acres) [a]	Single-Level Movable-Span Configuration (acres)	Restored Area from Removal of Existing Bridge (acres)	Total Net Change (acres)
Benthic Habitat Loss	0.91	1.07	1.11	-1.04	• Double-deck fixed-span: -0.13 • Single-level fixed-span: +0.03 • Single-level movable-span: +0.07
Overwater Shading (Water Surface)	1.04	1.41	1.58	0.00	• Double-deck fixed-span: +1.04 • Single-level fixed-span: +1.41 • Single-level movable-span: +1.58 acres.
Overwater Shading (Elevated Deck) [b]	19.87	24.13	24.13	-11.65	• Double-deck fixed-span: +8.22 • Single-level fixed-span: +10.78 • Single-level movable-span: +10.78

a The permanent benthic habitat and overwater shading impacts associated with the single-level fixed-span configuration would be the same for all bridge types.

b The addition of a second auxiliary lane in each direction would increase the amount of elevated overwater shading by approximately 4.8 acres compared to one auxiliary lane.

Benthic Habitat Impacts

For the Modified LPA with the double-deck fixed-span configuration, in-water piers to support the new Columbia River and North Portland Harbor bridges would displace approximately 0.91 acres of benthic habitat. Removal of the existing Interstate Bridge, including their underwater support structures, would result in the restoration of approximately 1.04 acre of benthic habitat. Thus, the Modified LPA with the double-deck fixed-span configuration would result in a net restoration of approximately 0.13 acres of benthic habitat. The Modified LPA with the single-level fixed-span configuration would require 24 more drilled shafts than the double-deck fixed-span configuration, which would result in a greater benthic impact of 1.07 acres and a 0.03-acre net reduction in benthic habitat. The Modified LPA with the single-level movable span configuration would require 36 more drilled shafts than the double-deck fixed-span configuration, resulting in a total benthic impact of 1.11 acres and a 0.07-acre net reduction in benthic habitat. It is important to note that the existing Interstate Bridge would remain in place during construction of the new Columbia River bridges; once the new bridges have been constructed the existing Interstate Bridge would be demolished.

Changes to benthic habitats could affect a variety of aquatic species, including:

- Adult and juvenile salmon, steelhead, and bull trout
- Adult green sturgeon, white sturgeon, Pacific eulachon, Pacific lamprey, and river lamprey

- Adult and juvenile native resident fish (e.g., sculpins, threespine sticklebacks, dace, and suckers)
- Freshwater invertebrates

However, the extent of the effect would be minor, given the relatively small area that would be affected and the net area that would be restored by the Modified LPA.

The addition of a second auxiliary lane in each direction would not change the amount benthic habitat impact compared to the one auxiliary lane option.

Overwater Shading Impacts

In addition to affecting benthic habitat, the Modified LPA's new bridges would increase the area of shading over the Columbia River and North Portland Harbor. Shading from overwater structures can affect the growth of aquatic vegetation, reduce habitat suitability for salmon and other native fish, and create habitat for species that prey on juvenile salmonids. The amount and duration of the effects can vary with the height of the overwater structures (increased structure height diminishes the intensity of shading by providing a greater distance for light to diffuse and refract around the bridges' decks); the orientation of the structure (a north–south-oriented structure creates a shadow that moves throughout the day); the density of piling or drilled shafts supporting the structure (an open structure supported by widely-spaced drilled shafts allows light to penetrate beneath the structure); and the material and reflectivity of the structure (concrete and steel are lighter and more reflective of ambient light than darker materials such as timber piles).

The structures with the greatest potential for overwater shading at the water's surface are the shaft caps for the new Columbia River bridges. The Modified LPA with the double-deck fixed-span configuration would result in a total of approximately 1.04 acres of shading at the Columbia River water surface. The Modified LPA with the single-level fixed-span configuration would require larger drilled shaft caps and would result in an increase of approximately 1.41 acres of shading at the Columbia River water surface. The Modified LPA with the single-level movable-span configuration would also require larger drilled shaft caps and would result in increased shading at the Columbia River water surface. The shaft caps for the movable spans would result in an increase of approximately 1.58 acres of shading at the Columbia River water surface. For all configurations, these shaded areas would be small relative to the amount of available habitat in the vicinity, and salmonids and other aquatic species would have access to suitable habitats outside the shaded areas. Therefore, the increased shading is not expected to have an appreciable effect on habitat function. The North Portland Harbor bridges would not have shaft caps at the water's surface and would therefore not result in overwater shading at the water's surface.

The replacement bridges would result in new elevated overwater shading from the bridges' decks and removal of elevated overwater shading from the existing bridge decks. However, with any of the bridge configurations, the height of the bridges' decks would minimize the potential for elevated overwater shading to result in reduced habitat function. The new Columbia River and North Portland Harbor bridges with the Modified LPA with the double-deck fixed-span configuration would have a total of approximately 19.87 acres of new elevated overwater shading, and the removal of the existing bridge would reduce elevated overwater coverage by approximately 11.65 acres, for a net increase of approximately 8.22 acres of elevated overwater coverage. Compared to the Modified LPA with the double-deck fixed-span configuration, the Modified LPA with the single-level fixed-span configuration would increase elevated overwater shading by 4 acres, and the Modified LPA with the single-level movable-span configuration would increase elevated overwater shading by approximately 5 acres.

The addition of a second auxiliary lane in each direction would not change the amount of surface-water shading, but would increase the amount of elevated overwater shading by approximately 4.8 acres compared to the one auxiliary lane option.

Floodplain Fill

Removal or placement of material within a floodplain can affect aquatic habitat by affecting peak and base flow conditions. While the Modified LPA would require both removal and placement of material below the 100-year floodplain elevation, its location on the Columbia River, where flows are regulated in part by upstream dams, makes the potential for changes in flow less pronounced. While specific volumes have not yet been calculated, it is anticipated that the net change in fill within the regulatory floodplain would be relatively small due to local code requirements. In 2024, the City of Portland updated its building code and zoning code that apply to development within floodplains. The updates are intended in part to bring the City's code into compliance with the recommendations of the 2016 Federal Emergency Management Agency (FEMA) National Flood Insurance Program BO that was issued by NOAA Fisheries in 2016. The cities of Fairview and Vancouver also regulate cut and fill activities within the floodplain through their environmental approval process. Pursuant to Executive Order 11988, a Location Hydraulic Study would be conducted to evaluate potential impacts to the floodplain, and to document the impacts, mitigation measures, alternatives, and findings following the provisions of 23 Code of Federal Regulations 650A.

The Modified LPA would also require both removal and placement of material within the functional floodplain, which is the portion of the regulatory floodplain that is below the ordinary high-water mark (OHWM). Specific quantities have only been estimated at this time and would depend substantially on final design and permitting details. It is estimated that the Modified LPA would install up to approximately 62,400 cubic yards of new material within the functional floodplain of the Columbia River and North Portland Harbor, and would remove approximately 13,250 cubic yards of existing material from within the functional floodplain. It is estimated, therefore, that the Modified LPA would result in a net increase of up to approximately 55,000 cubic yards of material within the functional floodplain. Most of this volume would be associated with the pile shaft caps for the Columbia River bridges, which are approximately 20 feet thick, and most of which would be below the OHWM elevation. Despite this increase, the Modified LPA would fully comply with applicable requirements to maintain floodplain function as described above, and would maintain floodplain function and hydrologic processes at the site.

Given the limited extent of functioning floodplain within the footprint of the Modified LPA, and the regulatory requirements to balance cut and fill within the floodplain and to maintain or improve floodplain function, the effects on floodplain function from construction of the Modified LPA are expected to be minimal.

Hydraulic Shadowing

Piers and other structures in the water can create areas of reduced water velocity immediately downstream of the structure. This phenomenon is referred to as a hydraulic shadow. Hydraulic shadowing may affect habitat suitability for native fish by creating low-velocity eddies that have the potential to increase exposure to predation, interfere with movement patterns, and alter sediment transport. Increased hydraulic shadowing may also benefit some fish by creating areas where they can rest during periods of high flow.

The Modified LPA, with any of the Columbia River bridge configurations, would create a hydraulic shadow extending up to approximately 1,600 feet downstream of each pier, with velocities in the range of 0 to 3 feet per second. The hydraulic shadow of the North Portland Harbor bridges would extend up to approximately 400 feet downstream of each pier, with velocities ranging from 0 to 2 feet per second. Although the length of the hydraulic shadow would increase compared to the existing conditions, the change to aquatic habitat suitability for native fish would be minor. In both cases, the area that would be affected by the hydraulic shadow is a relatively small area and the range of water velocities found in the hydraulic shadow are within the range fish encounter in the natural environment.

Stormwater Effects

The Modified LPA would install new impervious surfaces and rebuild existing impervious surfaces, which could contribute pollutants to stormwater and affect water quality and water quantity in the Columbia River, North Portland Harbor, Columbia Slough, Fairview Creek, and Burnt Bridge Creek. Stormwater runoff from roads and highways contains pollutants that can be toxic to aquatic life, even at very low concentrations. Pollutants commonly occurring in stormwater runoff include suspended solids, nutrients, oil and grease, agricultural chemicals, dissolved metals, and other organic chemicals. There is emerging research related to 6PPD-quinone, a chemical in tires, which has been linked to mortality of coho salmon under certain conditions (Tian et al. 2021), and may also be negatively affecting other aquatic species including Chinook salmon and steelhead (Brinkmann et al. 2022; Lo et al. 2023). However, among the Pacific salmonid species, coho salmon are the most sensitive to 6PPD-quinone and the most exposed to pollutants in urban stormwater runoff, given their habitat preference for small, lowland streams (Ecology 2022).

Table 3.16-10 compares the increase in contributing impervious area (CIA), which could potentially increase the amount of pollutants entering stormwater, for each configuration of the Modified LPA. The Modified LPA with the double-deck fixed-span configuration would add approximately 29.6 acres of CIA but would treat or infiltrate 207.2 acres of CIA. The Modified LPA with the single-level fixed-span and single-level movable-span configurations would increase the CIA by 32.9 acres (an increase of approximately 3.3 acres compared to the double-deck configuration). The addition of a second auxiliary lane in each direction would increase the amount of post-project CIA by approximately 3.9 acres under each configuration compared to the one auxiliary lane option.

Water quality treatment would be provided for all post-project CIA, including approximately 156.4 acres of existing impervious area that is currently untreated. This would represent treatment of over six times the area of net new CIA associated with the Modified LPA. The net effect on water quality and aquatic habitat would be a substantial net improvement for all design options compared to the No-Build Alternative. See Section 3.14, Water Quality and Hydrology, for additional information.

Table 3.16-10. Post-Project Increase in Contributing Impervious Area

	Double-Deck Fixed-Span Configuration	Single-Level Fixed-Span Configuration [a]	Single-Level Movable-Span Configuration
Increase in Contributing Impervious Area (acres) [b]	29.6	32.9	32.9

a The increase in contributing impervious area would be the same for all bridge types.
b The addition of a second auxiliary lane in each direction would increase the amount of post-project contributing impervious area by approximately 3.9 acres under each bridge design option compared to the one auxiliary lane option.

The Modified LPA with the single-level movable-span configuration would also require grease and other lubricants for the maintenance and operation of the lift span, which poses a potential risk that these substances could enter surface waters. However, the bridges would be operated in a manner that is compliant with applicable state water quality standards, and appropriate best management practices (BMPs) would be employed to maintain compliance with these requirements.

Overwater Lighting

Artificial light sources on overwater structures can affect fish and other aquatic species, including delayed migration and increased exposure to predation. The Modified LPA would install permanent lighting on the replacement bridges and would remove a source of overwater lighting on the existing bridge. The Modified LPA, with any of the configurations, is not expected to result in an increase in the amount of light on the water's surface. Permanent lighting for the bridges' decks would use directional, shielded lighting to control

glare and direct light onto the bridges' decks to the extent practicable. The bridges' decks with the Modified LPA would also be solid surfaces, which would reduce the amount of light illuminating the water's surface compared to the existing bridge.

Avian (Bird) Predation

Avian (bird) predation of juvenile salmonids is a limiting factor for salmon recovery in the Columbia River Basin. Other species subject to avian predation include adult and juvenile Pacific eulachon and lamprey. The existing Interstate Bridge and North Portland Harbor bridge provide perching opportunities for fish-eating birds such as Caspian terns, double-crested cormorants, and various gull species, though there is no evidence these species use the bridges extensively. The Modified LPA, with any of the configurations, may reduce the potential for avian predation. While the steel superstructure of the existing Interstate Bridge provide opportunities for birds to perch, the new Columbia River bridges would likely provide relatively fewer overhead perching opportunities. However, this would depend in part on the final design of the superstructure. Perching opportunity on the replacement North Portland Harbor bridges would be comparable to that on the existing North Portland Harbor bridge, though it could be slightly higher given the increase in the total number of structures.

Terrestrial Resources

As summarized in Table 3.16-11, the Modified LPA would result in the loss of small quantities of sensitive terrestrial habitats. The habitat designations shown in Table 3.16-11 overlap and are not cumulative. The amount of terrestrial habitat loss would be the same with one or two auxiliary lanes and all of the bridge design configurations.

The Modified LPA would also restore terrestrial areas that are currently displaced by existing infrastructure (the existing bridges and roadways). While a specific restoration plan has not yet been developed, these areas would be restored consistent with federal, state, and local regulatory requirements, and would provide new terrestrial habitat function.

Table 3.16-11. Permanent Loss of Sensitive Terrestrial Habitats

Sensitive Terrestrial Habitat (Oregon)	Permanent Loss of Sensitive Terrestrial Habitat (acres)
"High" wildlife/riparian value habitats	1.12
"Medium" wildlife/riparian value habitats	6.20
Wetlands	0.58
Wetland Buffers	7.39
Sensitive Terrestrial Habitat (Washington)	
Riparian Buffers	0.79
Biodiversity Areas	0.15
Oak Woodlands	<0.01
Wetlands	0
Wetland Buffers	0.06

Sensitive Terrestrial Habitats in Oregon

In Oregon, the Modified LPA would result in a permanent loss of approximately 7.32 acres of terrestrial habitats identified as having a "high" or "medium" combined wildlife/riparian value in Portland's Natural Resource Inventory (NRI). Most of the impacts would occur within disturbed terrestrial riparian habitats on the shorelines of Hayden Island, on the south shoreline of North Portland Harbor, near the Vanport wetland, and in a partially forested area south of Martin Luther King, Jr. Boulevard. The Modified LPA would also result in approximately 0.58 acre of permanent wetland fill, and approximately 7.39 acres of wetland buffer impact in Oregon, within areas designated as having "high" or "medium" wildlife/riparian value in Portland's NRI.

The Modified LPA would require the removal of trees. Tree removal reduces habitat complexity, can affect water temperature, and reduces the potential for large woody debris (an important component of fish habitat) to accumulate. Riparian areas adjacent to the Columbia River and North Portland Harbor in Oregon are armored with riprap and provide little riparian function. The Modified LPA would likely require removal of some trees that have established along the riprapped banks. Some tree removal would also be required in areas mapped as having "high" or "medium" combined wildlife/riparian value in Portland's NRI, primarily associated with wetlands and adjacent buffer areas. Tree removal would be conducted consistent with the City's Title 11 Tree Ordinance.

Sensitive Terrestrial Habitats in Washington

In Washington, permanent loss of sensitive terrestrial habitats would be minimal, as Modified LPA improvements would occur largely within a developed transportation corridor. In addition, the Modified LPA has been designed to avoid encroaching into sensitive resources, to the extent practicable.

The Modified LPA would result in a permanent loss of approximately 0.79 acres of riparian buffers, 0.15 acres of a designated biodiversity area, 0.01 acres of area mapped as oak woodland, and 0.06 acres of wetland buffer in Washington. Most of the loss would occur within terrestrial riparian habitat associated with Burnt Bridge Creek. While this riparian habitat is mostly disturbed vegetation on a sloping embankment between I-5 and NE Leverich Park Way some tree removal adjacent to Burnt Bridge Creek would be required. Some of this riparian buffer may be able to be restored and/or enhanced, and net unavoidable impact would be offset through compensatory mitigation.

Nesting Bird and Roosting Bat Habitat

The Modified LPA would require the removal of both natural features (trees and vegetation) and human-made structures (the existing bridges) that provide documented or potentially suitable habitat for nesting birds and roosting bats.

Activities with the potential to disturb nesting migratory birds, such as nest removal, would be conducted consistent with the provisions of the Migratory Bird Treaty Act (MBTA), which requires that nests of migratory birds be removed only when nests are inactive. However, the loss of a specific nesting structure could still be significant, particularly if similar replacement structures are not available.

The Modified LPA would require the removal of the existing Interstate Bridge, which has been a peregrine falcon nest site since 2001. Its removal would eliminate a suitable nesting structure and, while there are likely alternate nesting sites in the vicinity, could appreciably disrupt peregrine breeding, foraging, and/or nesting activity. Peregrines that use the existing Interstate Bridge would be forced either to find alternative nesting structures in the vicinity of the bridge or move outside of the study area. Providing an alternate nesting structure would greatly reduce the potential nesting impact.

Terrestrial Wildlife Passage

Terrestrial wildlife passage is severely limited in the primary study area due to the highly developed urban setting. The existing shoreline and riparian areas are narrow and provide limited suitable passage and habitat function for terrestrial species. Under the Modified LPA, landside piers for the Columbia River bridges may continue to obstruct wildlife movement along the shoreline, though this may be offset by the removal of the existing landside bridge piers. Options for improving wildlife passage are limited, given the developed nature of the corridor. Design efforts to avoid and minimize impacts to riparian habitat, would likely maintain or improve terrestrial wildlife passage in the long term.

Botanical Resources

The Modified LPA would have limited permanent vegetation removal, as construction activities would primarily occur within disturbed areas adjacent to existing roadway infrastructure. The Modified LPA would permanently remove native vegetation within a few relatively small areas of functioning riparian and wetland habitats. This removal would be avoided and minimized to the extent practicable through project design, and consistent with federal, state, and local regulations. Compensatory mitigation would offset the net loss in habitat function. The net result is expected to increase habitat quality for botanical resources.

No botanical SOI are known or expected to occur within the areas that would be permanently disturbed. Therefore, the Modified LPA would not impact botanical SOI species.

3.16.4 Temporary Effects

No-Build Alternative

The No-Build Alternative would not have construction-related temporary effects.

Under the No-Build Alternative, the existing Interstate Bridge and roadways would continue to require regular, intermittent maintenance activities, which have the potential to disturb aquatic and terrestrial species and habitats. Potential impacts from maintenance activities include temporarily impaired water quality, temporary underwater and/or terrestrial noise, and temporary vegetation impacts.

Maintenance activities could potentially impact birds nesting on the existing Interstate Bridge or within the vicinity. Activities with the potential to impact nesting migratory birds, such as nest removal, would be conducted consistent with the provisions of the MBTA which requires that nests of migratory birds be removed only at times when nests are inactive. Active nests (those with live eggs and/or viable chicks) are to be left undisturbed until they are no longer active.

Typical construction BMPs would likely be implemented during maintenance activities to minimize impacts to fish and wildlife species and habitats.

Modified LPA

The subsections below describe the short-term impacts that would occur associated with the Modified LPA, including potential modifications to the Portland Metro Levee System. As described in Chapter 2, several design options are being evaluated as part of the Modified LPA. Where impacts would differ associated with one or more of the design options, the subsections below provide a comparison of the impacts associated with each design option.

Certain design options that are being evaluated as part of the Modified LPA (the C-Street ramp options, I-5 mainline westward shift options, and the two park and ride site options) would not result in different levels or types of short-term effects to ecosystem resources, and these design options are not specifically addressed further in this section.

Aquatic Resources

In-water construction activities related to construction of the new bridges and demolition of the existing bridges within the Columbia River and North Portland Harbor could temporarily affect aquatic species and their habitats. This could include temporary disturbance of benthic habitat, overwater shading from work structures, work area isolation and fish salvage, water-quality impairment from turbidity or contaminants, overwater construction lighting, hydroacoustic events, and disturbance or displacement of individuals.

In-Water Work Timing

To minimize impacts to aquatic species and their habitats, certain work within the Columbia River and North Portland Harbor would have defined timing restrictions. Between 2005 and 2011, a set of project-specific in-water work timing restrictions were developed for the CRC LPA through extensive coordination with regulatory agencies, tribal partners, and other interested parties. These work timing restrictions were reviewed with agencies, tribes, and other interested parties in several meetings between 2022 and 2023 for the Modified LPA. Based on the outcome of these discussions, it was concluded that the timing restrictions that were developed for the CRC LPA were likely also the preferred windows to apply to construction of the Modified LPA. The following timing restrictions have therefore been proposed for the construction of the Modified LPA.

- Impact pile driving would be confined to September 15 through April 15 of each year.
- In-water debris removal with a bucket dredge would be confined to November 1 and February 28 of each year.

All other in-water and overwater construction activities would be conducted year-round and in compliance with permit conditions.

Temporary Benthic Habitat Impacts and Overwater Shading

In the Columbia River and North Portland Harbor, temporary impacts to benthic habitat and temporary overwater shading would result from the installation of temporary work platforms, bridges and piers, temporary isolation systems, cofferdams, casings, barges, and temporary piles associated with these structures. These temporary features are necessary to support construction and would be designed by a contractor after a contract is awarded. Table 3.16-12 provides a summary of these temporary aquatic habitat impacts.

In the Columbia River, the Modified LPA with the double-deck fixed-span configuration would temporarily displace approximately 1.52 acres of benthic habitat, with about 86% of these effects from cofferdams during construction and demolition. The Modified LPA with the single-level fixed-span configuration and the Modified LPA with the single-level movable-span configuration would have similar temporary effects, generally, however these two single-level design options would have approximately 0.42 acres more benthic in-water area temporarily displaced within cofferdams. This increase in acreage of temporary benthic habitat impact would not, however, result in a different net effect on ecosystems compared to the Modified LPA with the double-deck fixed-span bridge configuration. Overwater shading in the Columbia River is estimated to temporarily affect approximately 7.89 acres, with approximately half of these temporary effects resulting from temporary work platforms, bridges, and piers, and half resulting from barges.

In North Portland Harbor, approximately 0.40 acres of benthic habitat would be temporarily displaced, with approximately 60% of these effects resulting from drilled shaft isolation casings. Overwater shading in North Portland Harbor would temporarily affect approximately 7.72 acres, of which 62% would be due to temporary work platforms, bridges, and bents.

Table 3.16-12. Temporary Aquatic Habitat Impacts Summary

Temporary In-Water and Overwater Work Elements	Columbia River Temporary Benthic Impact (acres)	Columbia River Temporary Overwater Shading (acres)	North Portland Harbor Temporary Benthic Impact (acres)	North Portland Harbor Temporary Overwater Shading (acres)
Work Platforms/ Bridges/Piers and Associated Piles	0.18	4.23	0.13	4.78
Other Temporary Piles	0.01	0	0.01	0
Suspended Shaft Cap Isolation System	0	0.25	-	-
Sheet Pile Cofferdams (Construction)	0.44	0	-	-
Sheet Pile Cofferdams (Demolition)	0.86	0	-	-
Drilled Shaft Isolation Casings	-	-	0.24	0
Barges and Barge Mooring Piles (Construction)	0.01	2.75	0.02	2.41
Barges and Barge Mooring Piles (Demolition)	0.01	0.65	0.01	0.53
Total	**1.52**	**7.89**	**0.40**	**7.72**

Work Area Isolation and Fish Salvage

Certain in-water work activities would need to be isolated from the active flow of the Columbia River and North Portland Harbor, either for construction purposes or to reduce potential effects on fish and aquatic habitats. Areas that would be isolated in this manner include drilled shaft isolation casings and temporary sheet pile cofferdams. Sheet pile cofferdams for construction of Piers 2 and 7, and the drilled shaft isolation casings in North Portland Harbor, would be dewatered to provide a work area for construction. Sheet pile cofferdams for demolition of the existing Interstate Bridge (if used) would not be dewatered. Regardless of whether they are de-watered or not, isolation of in-water work areas would temporarily disturb benthic habitats and would temporarily limit access to these areas for fish.

Fish salvage would be conducted both during and after the installation of the sheet pile cofferdams (those for construction and for demolition) to remove fish from within the isolated work area. Since the drilled shaft isolation casings would be screened prior to installation, fish salvage would not be required within these structures prior to dewatering. These fish salvage operations would involve capture, direct handling, and transporting of fish, resulting in some risk that the process may harass, injure, or kill individual fish. Similarly, mortality is likely if a fish remains trapped in an isolated work area during construction.

Temporary Impacts to Water Quality

Water quality can be temporarily affected during both in-water and upland construction activities through the accidental release of construction materials or wastes to the water or through the disturbance of sediment

which generates turbidity. Upland ground-disturbing activities can also lead to erosion, causing turbidity in adjacent waterbodies.

Construction of the Modified LPA, with any of the configurations, would likely result in temporary, localized turbidity during in-water work in the Columbia River and North Portland Harbor from activities such as pile installation and removal, drilled shaft casing installation and removal, upland ground improvements, cofferdam installation and removal, and barge operations. Construction of the Modified LPA, with any of the configurations, has the potential to result in the release of chemical and/or debris into surface waters from sources such as overwater construction work, concrete installation, spills of fuels or other chemicals, upland ground improvements, and demolition of the existing bridge.

The Modified LPA would require avoidance and minimization measures, including a spill prevention, control, and countermeasures plan, pollution control plan, and an erosion and sediment control plan. A Water Quality Protection and Monitoring Plan would also be required to satisfy 401 Water Quality Certifications monitoring and reporting requirements. Construction of the Modified LPA would comply with permit requirements.

Temporary water quality impacts during construction could result in behavioral responses from fish or other aquatic species, including temporary avoidance and reduced foraging abilities. These types of responses have been documented in fish at very low turbidity levels. Since construction activities may occur year-round, all species and life stages of fish in the Columbia River and North Portland Harbor could be exposed to reduced water quality conditions. The extent and duration of exposure to elevated levels of turbidity are expected to be limited and short term, and the minimization measures identified in Section 3.16.5 that would be implemented would be sufficient to minimize effects.

Temporary Overwater Lighting

Temporary overwater lighting would be required throughout construction and demolition to provide adequate lighting for barges, work platforms/bridges, construction of the replacement bridges' decks, and demolition of the existing structures. Overwater lighting associated with temporary work structures may affect migratory movement and/or increase predation pressure within the study area for adult and outmigrating juvenile salmon, steelhead, and bull trout. Temporary lighting would not constitute a complete barrier to migrating juvenile fish; however, migrating juvenile salmonids, Pacific eulachon, Pacific lamprey, river lamprey, and other native resident fish that gather under light sources could be exposed to a higher risk of predation. Overwater lighting is not known to affect green or white sturgeon, given their preference for deep-water habitats. Similarly, seals and sea lions are not expected to significantly alter their behavior or movement in response to temporary overwater lighting.

Elevated Underwater Noise

Temporarily elevated underwater noise can alter behavior, physical injury or increase mortality in aquatic species, depending on the intensity and characteristics of the sound, the distance from the noise source, the location in the water column, and other factors. The primary sources of underwater noise associated with the Modified LPA are impact pile driving, vibratory pile driving, drilled shaft oscillation, and noise from vessels.

Impact Pile Driving

Impact pile driving is the loudest potential underwater noise source that would be required for construction of the Modified LPA. The Modified LPA has been designed to minimize the likelihood of impacts resulting from pile installation activities. Pile installation would be performed to the greatest extent possible using a vibratory hammer, though piles may need to be driven to final tip elevation or proofed, as necessary, with an impact hammer. Proofing is the process of striking piles with an impact hammer to verify their load-bearing capacity. A bubble curtain would be implemented during all in-water impact pile driving to reduce the extent of underwater noise generated.

NOAA Fisheries has established specific decibel level thresholds for injury and disturbance from underwater noise associated with impact pile driving. Injury thresholds have been established for noise from a single pile strike (peak thresholds) and for exposure to noise from multiple strikes over a period of time (cumulative thresholds). A disturbance threshold has also been established for levels of underwater noise during impact pile driving that could cause disturbance but would not result in injury.

Impact pile driving during construction of the Modified LPA would result in noise levels that would temporarily exceed these injury and disturbance thresholds within portions of the Columbia River and North Portland Harbor, and exposed fish may have an increase in lethal and sublethal injuries. The extent of the injury would depend on several factors, including the size of the fish, duration of exposure, proximity to the source (the pile being driven), and size of the pile.

All species and life stages of salmon, steelhead, eulachon, lamprey, green sturgeon, white sturgeon, and other resident fish would be subject to potential injury and disturbance if present during impact pile driving. Bull trout would not be affected by impact pile driving because they are not expected to be present in the area where construction-related underwater noise could occur.

Impact pile driving can also affect marine mammals. Steller and California sea lions and harbor seals could potentially be exposed to elevated noise levels during pile driving that could result in injury or harassment. Harassment of marine mammals is regulated under the Marine Mammal Protection Act, and appropriate authorization would be secured in the form of a Letter of Authorization. A marine mammal monitoring plan would also be developed and implemented to avoid and minimize the extent of any unavoidable harassment of marine mammals during impact pile driving.

Vibratory Pile Driving, Drilled Shaft Oscillation, and Wiresaw Operation

Noise generated during vibratory pile driving, drilled shaft oscillation, and operation of an underwater wiresaw does not generally result in injury to fish but can result in behavioral effects such as startling, momentary disruption in feeding, or avoidance of the area. Depending on site conditions, behavioral effects may be more significant with consequences for survival and reproduction. For example, avoidance of the study area could cause delays in feeding or migration that could in turn affect spawning or outmigration success.

All species and life stages of salmon, steelhead, eulachon, lamprey, green sturgeon, white sturgeon, and other resident fish that use aquatic habitats within the Columbia River and North Portland Harbor could be exposed to these effects when they are present in the portion of the primary and secondary study areas where underwater noise would be elevated during vibratory pile driving, drilled shaft oscillation, and operation of an underwater wiresaw. Bull trout would not be affected by noise from these activities, because they are not expected to be present in the area where construction-related underwater noise could occur.

Adult and/or juvenile fish present within the area where underwater noise would be temporarily elevated during vibratory pile driving, drilled shaft oscillation, and operation of an underwater wiresaw may be exposed to levels of underwater noise that could result in behavioral disturbance. This activity is unlikely to injure fish or significantly interfere with behaviors such as migration, rearing, or foraging. Thus, vibratory pile driving, drilled shaft oscillation, and operation of an underwater wiresaw are not likely to adversely affect these species.

Noise associated with vibratory pile driving, drilled shaft oscillation, and operation of an underwater wiresaw can also affect marine mammals. Steller and California sea lions and harbor seals could potentially be exposed to elevated noise levels during these activities that could result in harassment. Appropriate authorization under the Marine Mammal Protection Act would be secured in the form of a Letter of Authorization. A marine mammal monitoring plan would also be developed and implemented to avoid and

minimize the extent of any unavoidable harassment of marine mammals during impact vibratory pile driving, drilled shaft oscillation, and operation of an underwater wiresaw.

Vessel Noise

Various types of vessels, including barges, tugboats, and small craft, would be present during construction. These vessels would move and operate within the Columbia River and North Portland Harbor on a year-round basis. Such vessels already use this portion of the study area in relatively high numbers; therefore, the vessels to be used in the construction of the Modified LPA do not represent a new noise source, only a potential increase in the frequency and duration of this type of activity.

Avian Predation

Construction of the Modified LPA is not expected to have an appreciable effect on avian predation pressure on juvenile salmonids, Pacific eulachon, lamprey, or other native fish. Temporary overwater structures are not likely to attract large concentrations of avian predators, compared to such features as nesting islands, water impoundments, or dam tailraces. However, avian predators are known to congregate on overwater structures, and construction of the Modified LPA would temporarily increase the number of available perches. It is therefore possible that avian predation pressure could temporarily increase to some extent within the primary study area.

Terrestrial Resources

Construction activities associated with the Modified LPA would result in temporary disturbance of terrestrial habitats in Oregon and Washington. This could include vegetation removal, grading, or other forms of temporary access and construction activities. Table 3.16-13 summarizes the approximate area of each resource that may be temporarily disturbed. Note that the habitat designations differ by state as a result of differing regulatory frameworks and resource inventories. In some cases, the habitat designations also overlap, so the quantities are not cumulative.

Table 3.16-13. Temporary Disturbance of Sensitive Terrestrial Habitats

	Terrestrial Habitat	Temporary Disturbance of Sensitive Terrestrial Habitat (acres)
Oregon	“High” riparian/wildlife value habitats	4.6
	“Medium” riparian/wildlife value habitats	5.7
	Wetlands	2.56
	Wetland Buffers	7.11
Washington	Riparian Buffers	1.15
	Biodiversity Areas	2.87
	Oak Woodlands	0.03
	Wetlands	0
	Wetland Buffers	1.19

Sensitive Terrestrial Habitats in Oregon

In Oregon, construction of the Modified LPA would result in temporary disturbance of approximately 2.56 acres of wetland, 7.11 acres of wetland buffer, and approximately 10.3 acres of habitat identified as having a "high" or "medium" combined wildlife/riparian value in Portland's NRI. This would occur primarily within disturbed terrestrial riparian habitats on the shorelines of Hayden Island, on the south shoreline of North Portland Harbor, near the Vanport wetland, and in a partially forested area south of Martin Luther King Jr. Boulevard.

Construction of the Modified LPA would include revegetating temporarily disturbed riparian areas and other sensitive habitats in Oregon consistent with federal, state, and local regulations, for no net loss of habitat function.

Sensitive Terrestrial Habitats in Washington

In Washington construction of the Modified LPA would result in temporary disturbance of approximately 1.15 acres of riparian buffers, approximately 2.87 acres of a designated biodiversity area, approximately 0.03 acres of priority oak woodland habitat and approximately 1.19 acres of wetland buffer in Washington. This would primarily occur within terrestrial riparian habitat associated with Burnt Bridge Creek, which provides only moderate habitat function, as it is immediately adjacent to I-5. Construction of the Modified LPA would also disturb a small portion of an area designated as priority oak woodland habitat. However, the only area affected would be a grassy shoulder adjacent to I-5. No oak trees or vegetation would be removed within this location, and there would be no loss of oak woodland habitat function in this location.

Construction of the Modified LPA would include revegetating temporarily disturbed riparian areas and other sensitive habitats in Washington consistent with federal, state, and local regulations, for no net loss of habitat function.

Terrestrial Noise and Disturbance

Terrestrial noise, lights, vegetation removal, and other roadway and transit construction disturbances could negatively affect the breeding, foraging, and dispersal of terrestrial species such as raccoons, bats, reptiles, and other terrestrial wildlife. Temporarily elevated noise can result in a range of potential wildlife reactions, which can include altered vocal behavior, changes in vigilance and foraging behavior, and changes in body condition. These responses could in turn result in increased energy expenditure or movement into less desirable locations with potentially greater exposure to predation. Lights used for nighttime work could disturb nocturnal animals such as owls or bats or disrupt the flight patterns of night-migrating birds.

To minimize impacts to migratory birds, all activities would be conducted consistent with the MBTA. Although the existing Interstate Bridge does not provide ideal roosting habitat for bats, several bat species that may pass near and use them for temporary roosting could be affected by construction disturbance. Short-term effects on raccoons, bats, reptiles, and other terrestrial wildlife could also result from temporary vegetation clearing.

Terrestrial Wildlife Passage

Construction equipment mobilization, storage, and use on or near riverbanks may temporarily affect wildlife passage. Wildlife species could alter their behavior to avoid construction activities, which in turn could increase the risks of human-wildlife conflicts and wildlife mortality.

Botanical Resources

Temporary vegetation disturbance associated with the construction of the Modified LPA are expected to be relatively minor and to occur primarily within disturbed areas adjacent to existing roadway infrastructure. The Modified LPA would temporarily disturb native vegetation within a few relatively small areas of functioning

riparian and wetland habitats. Disturbance would be avoided and minimized to the extent practicable through project design and consistent with applicable federal, state, and local regulations. Compensatory mitigation would offset the net loss in habitat function.

No botanical SOI are known or expected to occur within the areas that would be temporarily disturbed. Therefore, botanical SOI are not expected to be impacted by the construction of the Modified LPA.

3.16.5 Indirect Effects

No-Build Alternative

No indirect effects are anticipated to result from the No-Build Alternative.

Modified LPA

Changes in Land Use and Traffic

Transportation system changes can have different types and degrees of effects on land use, including increased growth and changes in land use patterns. These effects can result in indirect effects on ecosystem resources by increasing the amount, rate, or location of development.

As described in Section 3.4.4, the Modified LPA is likely to facilitate denser urban development as provided in local and regional land use plans, particularly in areas with new light rail transit service. The proposed new station areas in downtown Vancouver and Hayden Island are within a highly developed corridor, where habitat for terrestrial species is of limited quantity and quality. Because the Modified LPA is expected to encourage more compact development and/or redevelopment within existing urban areas that have limited terrestrial resources and habitat, it is likely to reduce the potential loss of habitat and impervious surface throughout the region.

Applicable federal, state, and local environmental regulations would minimize impacts from any such development or redevelopment activities. Local regulations require the avoidance and minimization of impacts to sensitive resources, including shorelines, wetlands, and riparian habitats. As such, indirect changes in land use patterns are not expected to result in adverse effects to ecosystem resources.

The Modified LPA also has the potential to affect how traffic moves through the study area. The tolling program could cause some drivers to seek an alternate crossing at the I-205 bridge. If enough vehicles were to divert to an alternate route, this could result in effects such as changes in the distribution of stormwater pollutants. A regional travel demand model was run for both the No-Build Alternative and the Modified LPA, which indicates that the Modified LPA would result in an approximately 2% shift in the relative distribution of crossings at the I-205 bridge. The model also indicates that improvements in transit would likely result in an approximately 1% decrease in the total number of vehicle miles travelled per weekday in the Portland Metropolitan region. These relatively minor changes would not result in measurable indirect effects on ecosystem resources.

Prey Base for Southern Resident Killer Whales

Impacts on juvenile and adult salmon and steelhead and their habitat resulting from the Modified LPA could indirectly affect the food source for the ESA-listed SRKW. However, given the large numbers of fish in the Columbia River, the temporary nature of effects on individual fish, and the long-term beneficial effects on fish habitat that are anticipated because of mitigation and conservation measures, construction of the Modified LPA is not expected to have measurable effects on the distribution or abundance of potential food sources for the SRKW.

Federal Navigation Channel Dredging

Within the vicinity of the Interstate Bridge, there are four federally authorized navigation projects on the Columbia River: three federally authorized navigation channels that pass beneath the Interstate Bridge (the primary navigation channel, barge channel, and alternate barge channel) and the federally authorized Upper Vancouver Turning Basin located immediately downstream of the Interstate Bridge.

The federal navigation projects would be maintained with the Modified LPA. However, the primary navigation channel would be swapped with the existing barge channel, which would move the primary navigation channel closer to the center of the river than its current location. No changes are proposed to authorized or maintained channel depths, and no dredging is proposed or reasonably certain to occur as a result of the Modified LPA. The existing bathymetry at the locations of the proposed channels provide sufficient depth. Therefore, the reconfiguration of the navigation channels that would occur under the Modified LPA is not expected to result in adverse indirect effects to ecosystem resources.

3.16.6 Potential Avoidance, Minimization, and Mitigation Measures

The design of the proposed Columbia River bridges has been modified to avoid and minimize impacts. Examples of these modifications include reducing the number of in-water piers, timing restrictions on in-water work, enhancement of the proposed stormwater treatment to exceed regulatory minimums, and configuration changes to avoid and minimize impacts to sensitive aquatic and terrestrial habitats. It is anticipated that the Biological Opinion that will be issued by the National Marine Fisheries Service (NMFS) would include additional conservation measures (reasonable and prudent measures) and terms and conditions that are necessary and appropriate to minimize the effects from the incidental take of listed fish.

Construction methods have also been refined to avoid long-term impacts, such as developing an alternative shaft cap isolation system for four of the Columbia River bridges' piers, which would avoid the need for cofferdams and concrete seals in these locations.

Long-Term Effects

Regulatory Requirements

- Provide stormwater quality and quantity treatment that meets or exceeds applicable regulatory requirements for all post-project CIA.

Program-Specific Mitigation

- Avoid and minimize long-term impacts to ecosystem resources in final design to the extent practicable.
- Provide compensatory mitigation for unavoidable impacts to ecosystem resources, consistent with applicable federal, state, and local regulatory requirements.
- Prepare a compensatory mitigation plan that satisfies applicable federal, state, and local regulatory requirements, and that demonstrates no net loss of function of ecosystem resources.
- Provide an alternate nesting structure, either on the new Columbia River bridges or within the vicinity, to offset removal of an existing peregrine falcon nest from demolition of the existing Interstate Bridge.

Temporary Effects

Regulatory Requirements

The following impact avoidance and minimization measures would be implemented as regulatory requirements to avoid and minimize potential effects to ecosystem resources.

General Measures and Conditions

- Perform all work according to the requirements and conditions of the regulatory permits that are issued for the Modified LPA.
- Require contractor to prepare a Water Quality Protection and Monitoring Plan (WQPMP) to satisfy the monitoring and reporting requirements of the 401 Water Quality Certifications that are ultimately issued for the project. The WQPMP would be provided to NOAA Fisheries for review and approval prior to implementation. The WQPMP would identify the timing and methodology for water-quality sampling during construction of the Modified LPA, as well as methods of implementation and reporting. If, in the future, a standard water-quality monitoring plan is adopted by ODOT and/or WSDOT, this plan, with the agreement of NOAA Fisheries, may replace the contractor plan.
- In compliance with ODOT and WSDOT policy and construction administration practice in Oregon and Washington, have one or more Department of Transportation inspectors on site during construction. The role of the inspector(s) would be to monitor compliance with contract and permit requirements.
- If in-water dredging is required outside of a cofferdam, use a clamshell bucket. Dredging and handling and disposal of dredged materials shall be conducted consistent with the requirements and conditions of the regulatory permits issued for the Modified LPA.
- Prohibit work barges from grounding out.
- Dispose of excess or waste materials in an appropriate manner consistent with applicable local, state, and federal regulations; do not dispose of or abandon waste materials waterward of the OHWM or allow them to enter waters of the state.
- All pumps must employ a fish screen that meets the following specifications:
    - An automated cleaning device with a minimum effective surface area of 2.5 square feet per cubic foot per second and a nominal maximum approach velocity of 0.4 feet per second, or no automated cleaning device, a minimum effective surface area of 1 square foot per cubic foot per second and a nominal maximum approach rate of 0.2 feet per second; and
    - A round or square screen mesh that is no larger than 0.094 inches (2.38 millimeters [mm]) in the narrow dimension, or any other shape that is no larger than 0.069 inches (1.75 mm) in the narrow dimension; and
    - Each fish screen must be installed, operated, and maintained according to NOAA Fisheries fish screen criteria.

Spill Prevention/Pollution Control Measures

- Require contractor to prepare a spill prevention, control, and countermeasure (SPCC) plan and pollution control plan (PCP) prior to beginning construction. These plans would be provided to NOAA Fisheries for review and approval. The SPCC plan and PCP would identify the appropriate spill containment materials; as well as the means and methods of implementation, response, and reporting. All elements of the SPCC plan and PCP would be available at the project site at all times. For additional detail, consult ODOT Standard Specification 00290.00 to 00290.90.

- Require contractor to designate at least one employee as the erosion and spill control (ESC) lead. The ESC lead would be responsible for the implementation of the SPCC plan and PCP.
- Maintain applicable spill response equipment and material designated in the SPCC plan and PCP at the job site.
- With the exception of barges and stationary large equipment (cranes, oscillators) operating from barges or work platforms, fuel and maintain equipment at least 150 feet from the OHWM of any waterbody using secondary containment to minimize potential for spills or leaks entering the waterway.
- Clean and inspect all equipment to be used for construction activities prior to arriving at the project site, to ensure no potentially hazardous materials are exposed, no leaks are present, free of noxious weeds, and the equipment is functioning properly. Daily inspection and cleanup procedures would be identified.
- Should a leak be detected on heavy equipment used for the project, immediately remove the equipment from the area, and do not use again until adequately repaired. Where off-site repair is not practicable, the SPCC plan and PCP would document measures to be implemented to prevent and/or contain accidental spills in the work/repair area to ensure no contaminants escape containment to surface waters and cause a violation of applicable water-quality standards.
- Operate construction equipment from on top of floating barges, from the decks of temporary work bridges and platforms, the decks of the existing or replacement bridges, or from portions of the streambank above the OHWM. Barges and support vessels would be operated in the water.
- Provide suitable containment measures for all equipment (including barges, work decks, stationary power equipment, and storage facilities) in the SPCC plan and PCP to prevent and/or contain accidental spills to ensure that no contaminants escape containment to surface waters and cause a violation of applicable water-quality standards.
- Design and install temporary work bridges and platforms, cofferdams, and drilled shaft isolation casings consistent with the ODOT Hydraulics Manual, which establishes criteria to avoid these structures being overtopped during high water events.
- Process water generated on site from construction, demolition or washing activities would be contained and treated to meet applicable water-quality standards before entering or reentering surface waters.
- Do not conduct paving, chip sealing, or stripe painting activities during periods of rain or wet weather.
- In the SPCC plan and PCP, establish a concrete truck chute cleanout area to properly contain wet concrete as part of ODOT Standard Specification 00290.30(a).

Site Erosion/Sediment Control Measures

- Require contractor to prepare and implement a temporary erosion and sediment control plan (TESCP) to minimize impacts associated with clearing, vegetation removal, grading, filling, compaction, or excavation. The BMPs identified in the TESCP would be used to control sediments from all vegetation removal or ground-disturbing activities. Additional temporary control measures may be required beyond those described in the TESCP if it appears pollution or erosion may result from weather, nature of the materials or progress on the work. For additional detail, consult ODOT Standard Specifications 00280.00 to 00280.90.
- As part of the TESCP, delineate clearing limits with orange barrier fencing wherever clearing is proposed in or adjacent to a stream/wetland or its buffer and install perimeter protection/silt fence as

needed to protect surface waters and other critical areas. Location would be specified in the field, based upon site conditions and the TESCP. For additional silt fence detail, consult ODOT Standard Specification 00280.16(c).

- Require contractor to designate at least one employee as the ESC lead. The ESC lead would be responsible for the implementation of the SPCC plan and PCP and would also be responsible for ensuring compliance with all local, state, and federal erosion and sediment control requirements.
- All TESCP measures would be inspected and maintained as required by applicable permit requirements. Contractor would also conduct maintenance and repair of TESCP measures as described in ODOT Standard Specifications 00280.60 to 00280.70.
- For landward construction and demolition, locate project staging and material storage areas a minimum of 150 feet from surface waters, in currently developed areas such as parking lots or managed fields, unless a site visit by an ODOT/WSDOT biologist determines (and an ODOT/NOAA Fisheries liaison confirms) that the topographic features or other site characteristics allow for site use closer to the edge of surface waters.
- Complete excavation activities under dry or dewatered conditions where practicable. All surface water flowing toward the excavation would be diverted through utilization of cofferdams and/or berms. Cofferdams and berms must be constructed of sandbags, clean rock, steel sheeting, or other non-erodible material.
- Limit bank shaping to the extent as shown on the approved grading plans. Minor adjustments made in the field would occur only after engineer's review and approval.
- Install biodegradable erosion control blankets on areas of ground-disturbing activities on steep slopes (1V:3H or steeper) that are susceptible to erosion and within 150 feet of surface waters. Areas of ground-disturbing activities that do not fit the above criteria would implement erosion control measures as identified in the approved TESCP. For additional erosion control blanket detail, consult ODOT Standard Specification 00280.14I.
- Cover erodible materials (material capable of being displaced and transported by rain, wind or surface water runoff) temporarily stored or stockpiled for use in project activities to prevent sediments from being washed from the storage area to surface waters. Temporary storage or stockpiles must follow measures as described in ODOT Standard Specification 00280.42.
- Stabilize all exposed soils as directed in measures prescribed in the TESCP. Hydro-seed all bare soil areas following grading activities and revegetate all temporarily disturbed areas with native vegetation indigenous to the location. For additional details, consult ODOT Standard Specifications 01030.00 to 01030.90.
- Where site conditions support vegetative growth, plant native vegetation indigenous to the location in areas temporarily disturbed by construction activities. Revegetation of construction easements and other areas would occur after the project is completed. Trees would be planted when consistent with highway safety standards. Riparian vegetation would be replanted with species native to geographic region. Planted vegetation would be maintained and monitored to meet regulatory permit requirements. For additional detail, consult ODOT Standard Specifications 01040.00 to 01040.90.

Pile Installation and Removal Best Management Practices

- Use a vibratory hammer to drive steel piles to the maximum extent practicable, to minimize noise levels.

- Conduct impact pile driving below the OHWM between September 15 and April 15. Vibratory pile installation and removal (as well as certain other in-water construction activities) may occur on a year-round basis, provided they are conducted in compliance with all regulatory approvals.
- No more than two impact pile drivers would be operated simultaneously within the same waterbody channel.
- Employ a bubble curtain or other similarly effective noise attenuation device during all impact pile driving conducted in water depths greater than 2 feet (0.67 meters).
- Develop and implement a hydroacoustic monitoring plan, based on the template developed by the Fisheries Hydroacoustic Working Group, in coordination with FHWA and FTA to confirm the effectiveness of the noise attenuation devices and that predicted noise levels adequately capture the area of the potential onset of injury. The plan would be provided to NOAA Fisheries for review and approval prior to any impact pile-driving activity commencing.
- Prepare a marine mammal monitoring plan and establish injury protection zones for marine mammals.
- Install cones or other anti-perching devices on open-ended pipe piles to discourage perching by piscivorous birds.
- Remove temporary piles with a vibratory hammer, or by direct pulling, and prohibit intentionally breaking by twisting or bending.
- In the event that a temporary pile cannot be removed, cut or press the pile 3 feet below the mudline. At locations where hazardous materials are present or adjacent to utilities, temporary piles may be cut off at the mud line with underwater torches, if such activity would not conflict with navigation elements.

Work Area Isolation and Fish Salvage Best Management Practices

- Develop a Temporary Water Management Plan, consistent with the requirements of ODOT Special Provision Section 00245.03, and provide to NOAA Fisheries for review and approval prior to any work area isolation of fish salvage activities.
- Install cofferdams and isolation casings in a manner that minimizes fish entrapment. Sheet piles would be installed from upstream to downstream, lowered slowly until contact with the substrate.
- Screen drilled shaft isolation casings at the bottom, to minimize potential for fish entrapment during installation. Screen shall have maximum openings of approximately 3/32 inch (2.38 mm) measured on a diagonal (NOAA Fisheries 2022).
- Conduct fish salvage according to the best practices established in the biological opinion for ODOT's Federal Aid Highway Programmatic consultation.
- Have a qualified fishery biologist[2] conduct and supervise fish capture and release activity to minimize risk of injury to fish.
- Prepare a fish salvage report and submit to NOAA Fisheries, U.S. Fish and Wildlife Service (USFWS), Oregon Department of Fish and Wildlife (ODFW), and WDFW following project completion.

[2] The qualified biologist shall have a bachelor's degree in biology, fisheries, or equivalent and a minimum of 2 years of experience identifying northwest fish and aquatic species. If electrofishing is required, the lead biologist shall be competent with electrofishing procedures and have completed at least 100 hours of fish salvage following NOAA Fisheries, USFWS, ODFW, and/or WDFW fish salvage/fish removal protocols.

- Make a reasonable effort to capture ESA-listed fish known or likely to be present in an in- water isolated work area using methods that minimize the risk of injury. Attempts to seine and/or net fish would precede the use of electrofishing equipment.
- If electrofishing must be used, conduct consistent with NOAA Fisheries "Guidelines for Electrofishing Waters Containing Salmonids Listed under the Endangered Species Act" (NOAA Fisheries 2000), or most recent version.

Work Area Lighting BMPs

- Conduct construction activities consistent with local, state and federal permit restrictions for allowable work hours. If work occurs at night, temporary lighting may be required to provide better visibility for driver and worker safety. If temporary lighting is required, contractor would use directional lighting with shielded luminaries to control glare and direct light onto work area, not surface waters.

Program-Specific Mitigation

- Avoid and minimize short-term impacts to ecosystem resources in final design to the extent practicable.
- Restore temporarily disturbed terrestrial habitats consistent with applicable regulatory requirements.
- Provide compensatory mitigation for unavoidable impacts to ecosystem resources, consistent with applicable federal, state, and local regulatory requirements.
- Conduct activities with the potential to impact nesting migratory birds, such as nest removal, consistent with the provisions of the MBTA, which requires nests of migratory birds to be removed only at times when nests are inactive.

3.17 Geology and Groundwater

The Pacific Northwest is a complex, geologically active region. Bridges are vital links in the transportation system and are often especially vulnerable during seismic events. This section identifies, describes, and evaluates the long-term and temporary effects of geologic hazards, as well as geologic and hydrogeologic (groundwater) conditions. The information presented in this section is based on the Geology and Groundwater Technical Report.

3.17.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with geology and groundwater has been updated in this Draft SEIS to include:

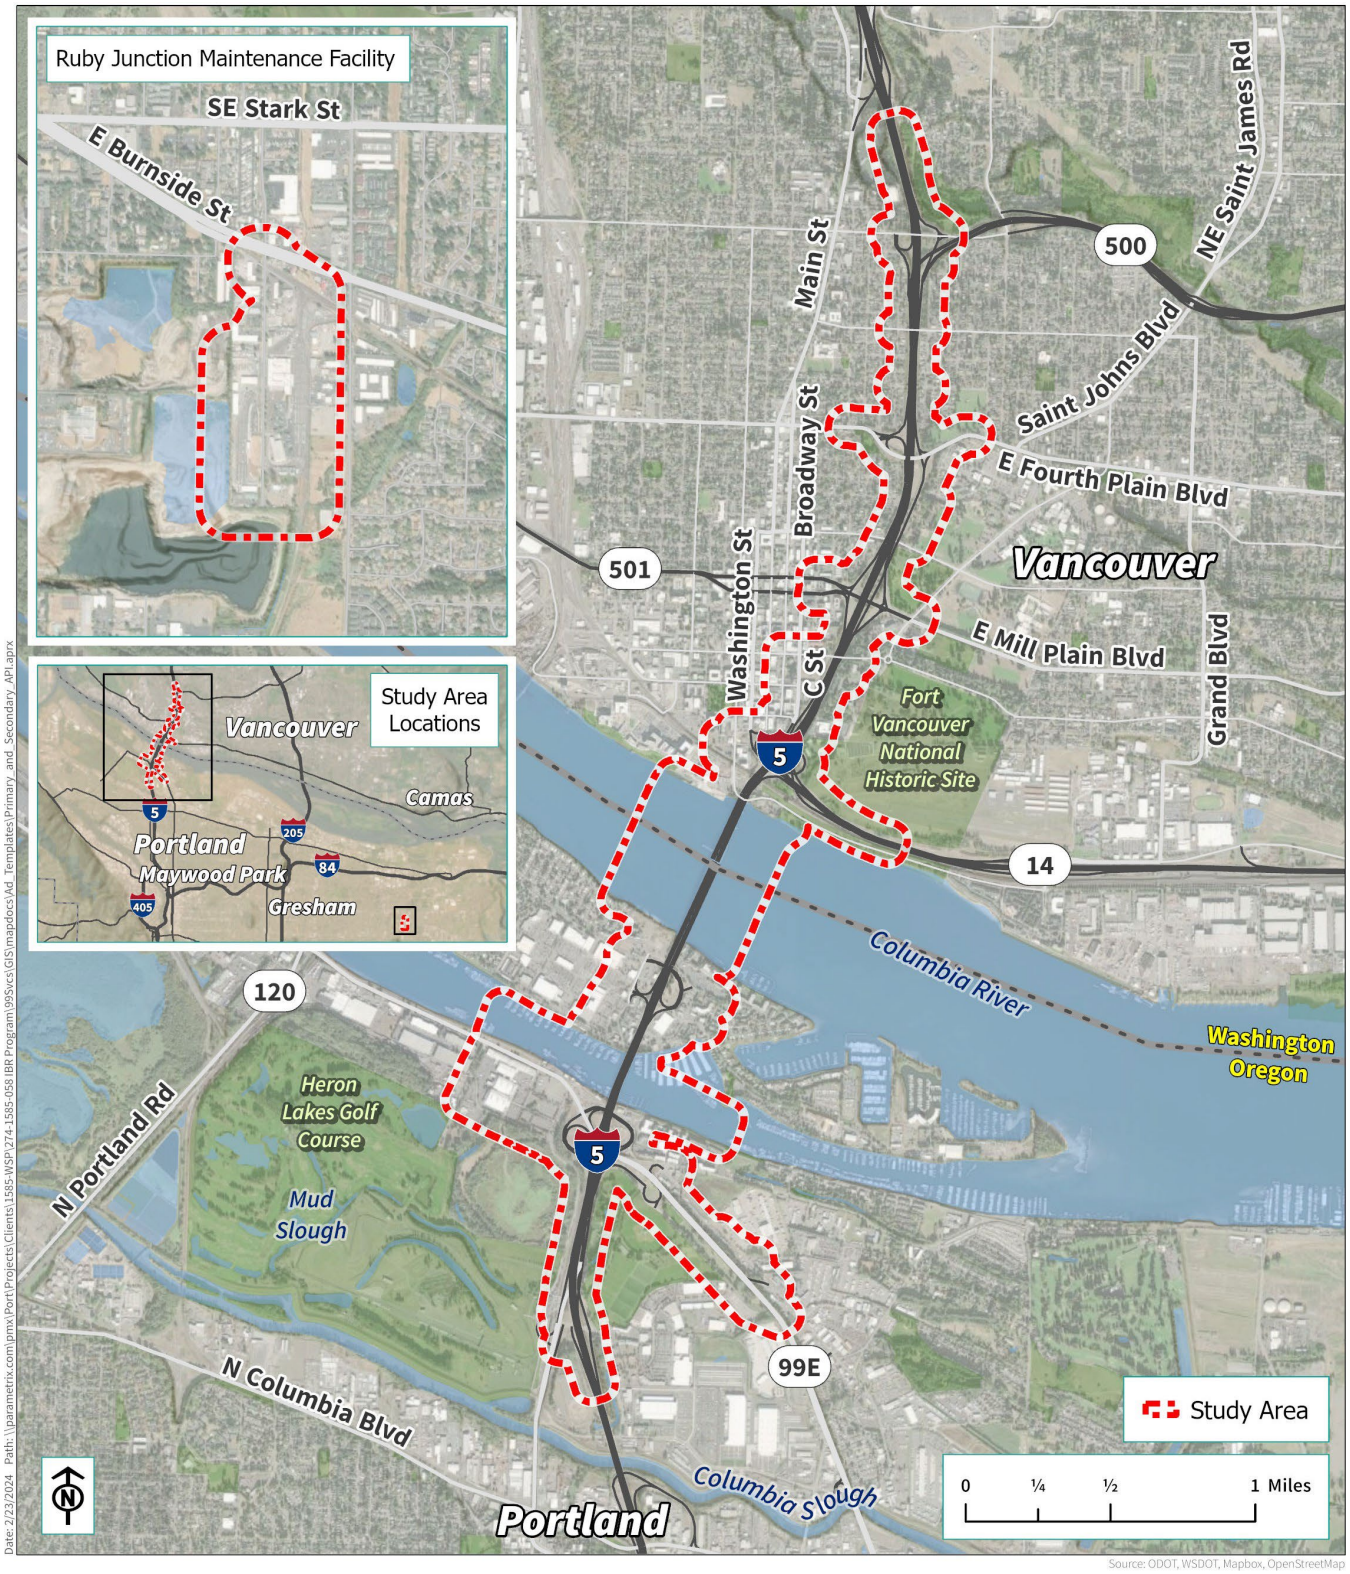
- Additional information about the increased risk for seismicity in the Cascadia Subduction Zone (CSZ).
- Additional consideration of geologic strata in the study area to accommodate new seismic standards.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the LRT alignment and modifying interchange designs.
- Updated assessments of the long-term and temporary effects of geologic hazards on the Modified LPA.
- Updated engineering to address geological and seismic conditions, including new design requirements established by WSDOT and ODOT in 2020.

Based on the analysis described in this section, geologic and groundwater resource impacts of the Modified LPA would be similar to the CRC LPA. Despite changes in seismic standards since 2013, both the Modified LPA and CRC LPA would improve seismic resiliency compared to the existing Interstate Bridge. The improved seismic resiliency would improve public safety and structural stability in the event of a seismic event, reduce the potential for soil erosion and slope failure, and decrease the risk of damage to the new Columbia River bridges due to scour from a lahar event.

3.17.2 Existing Conditions

The geology and groundwater study area (Figure 3.17-1) is within the CSZ, a convergent plate boundary system where the Pacific Ocean plate descends beneath the North American plate. The CSZ makes the region subject to serious geologic and seismic hazards such as earthquakes, tsunamis, and volcanic eruptions that can put people and infrastructure at risk. The study area contains specific geologic and groundwater conditions that influence the design, location, and construction techniques.

Figure 3.17-1. Geology and Groundwater Study Area



Geologic Resources

The study area is relatively flat, with steeper slopes in the northern portion near Burnt Bridge Creek. Unconsolidated deposits of granular material such as sand, gravel, cobbles, and boulders underlie the study area and surrounding areas. These deposits provide a valuable aggregate mineral resource in the region. In addition, volcanic bedrock occurs deep below the surface.

Geologic Hazards

Several types of earthquakes could occur in the study area. The most damaging potential earthquake would be caused by a shift in a large offshore fault located approximately 120 miles west of I-5. Such a shift could generate an earthquake with a moment magnitude (M_w) as high as M_w9.0. Effects from earthquakes result from ground motion amplification, soil instability, soil liquefaction, lateral spreading, seismic-generated water waves, and earthquake-induced landslides. Although moment magnitude is only one factor contributing to earthquake damage, earthquakes with high moment magnitudes can cause massive destruction.

Steep slopes, such as those in the Burnt Bridge Creek area, can be prone to erosion and landslides. However, there is no evidence of notable erosion or landslides in the study area.

Volcanic eruptions are not likely to occur within the study area. However, if Mt. Hood or another nearby Cascade volcano were to erupt, there is potential for some ashfall to accumulate in the study area and a large temporary increase in sediment load in the Columbia River. In the event of a Mt. Hood eruption, lahars (volcanic material flows) could carry sediment into the Sandy River, then into the Columbia River upstream of the study area.

What is moment magnitude (Mw)?

The moment magnitude scale, developed in the 1970s, is a method of measuring the strength of an earthquake. It has replaced the more familiar Richter scale because it can accurately measure a wider range of earthquake strengths. Like the Richter scale, the moment magnitude scale is *logarithmic*; an earthquake with M_w 6.0, for example, is about 32 times as strong as one with M_w 5.0. Moment magnitude scale measurements are similar to, but not precisely equal to, Richter scale measurements.

What is a lahar?

A lahar is a flow of volcanic material (such as rock debris and gases) and water that travels quickly and can cover great distances. Lahars typically flow downstream of a volcano within a river valley.

Groundwater Resources

The primary groundwater resource in the study area is the Troutdale Aquifer System in Clark County, Washington and Multnomah County, Oregon. Within Clark County, the aquifer is designated as a sole source aquifer (SSA). In addition, Vancouver has designated the entire area within the city boundaries as a Critical Aquifer Recharge Area. Groundwater from the SSA in Washington and in Oregon is used for industry, irrigation, heat exchange, and drinking water. Under Section 1424(e) of the Safe Drinking Water Act, projects that seek federal funding and have the potential to contaminate an SSA are subject to U.S. Environmental Protection Agency review and approval.

Within the study area, the Troutdale Aquifer System is composed of multiple unconsolidated sedimentary deposits in the Portland Basin and includes aquifer recharge areas and discharge areas. In aquifer recharge areas, groundwater is replenished through precipitation, infiltration from the Columbia River and streams, percolation of water through pervious surfaces, and contributions from drywells and underground sewage disposal. Discharge areas are where groundwater is withdrawn from wells or where it emerges from the subsurface in springs, streams, or underwater where it discharges to the Columbia River.

What is a sole source aquifer?

EPA defines a sole source aquifer as an aquifer or aquifer system that supplies at least 50% of the drinking water consumed in the area overlying the aquifer and one for which there is no alternative source or combination of drinking water sources that could physically, legally, and economically act to supply those dependent upon the aquifer.

No drinking water supply wells are currently used within the study area in Oregon. Within the study area in Washington, the city of Vancouver relies entirely on groundwater from the Troutdale Aquifer System. Within downtown Vancouver, groundwater flow is influenced by pumping from water supply wells. In accordance with federal and state regulations, Vancouver has established Special Wellhead Protection Areas around these wells, within which certain activities, such as hazardous material and municipal waste disposal, septic systems, and infiltration systems, are restricted to protect groundwater quality. A Special Wellhead Protection Area is located within the northern portion of the study area.

Groundwater Quality

Contaminants from commercial and industrial activities in Vancouver and Portland have resulted in areas of diminished groundwater quality. Information available from the Oregon Department of Environmental Quality and Washington Department of Ecology indicates that contaminants such as chlorinated solvents, petroleum products, and metals are found in groundwater at various locations in the study area.

As stipulated in the Safe Drinking Water Act and Washington Administrative Code Chapter 290, suppliers of drinking water must monitor for and meet primary and secondary drinking water standards. Beginning in approximately January 1979, the City of Vancouver has sampled and analyzed groundwater from its wells for the following classes of compounds: inorganics, volatile organic compounds, herbicides, pesticides, insecticides, radionuclides, fumigants, dioxins, and nitrate. A review of water quality data by the Washington State Department of Health indicates that none of these contaminants have been detected at or above their allowable limits in groundwater at any Vancouver water stations since the 1980s.

3.17.3 Long-Term Benefits and Effects

Table 3.17-1 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on geology and groundwater. Detailed analysis of the effects is provided in the following sections.

Table 3.17-1. Summary of No-Build Alternative and Modified LPA Effects on Geology and Groundwater

1	2	3
No-Build Alternative	Modified LPA with Double-Deck or Single-Level Fixed-Span Configuration,[a] One or Two Auxiliary Lanes, with or without C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options
• No change (seismic deficiencies remain, would not affect geologic resources, would sustain existing impacts to degradation of the groundwater quality).	• Improved public safety, minimizing damage to infrastructure, and limiting potential economic disruption due to seismic improvements. • Slight potential for increased use of materials that could spur expansion and/or opening of surface mines. • Benefits to groundwater as a result of stormwater management and treatment.	• Similar to effects listed in Column 2, but would require more substantial river piers and pier foundations to support the movable spans.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.

No-Build Alternative

Geologic Hazards

The No-Build Alternative would maintain the existing I-5 infrastructure in the study area and would not provide seismic improvements to the Interstate Bridge or other I-5 structures. The existing structures were built before modern seismic codes were developed and could be substantially damaged in an earthquake. The No-Build Alternative would also not address the risks of increased scour from potential flooding and sediment load due to upstream, seismic induced landslides or lahars resulting from regional volcanic activity.

Geologic Resources

The No-Build Alternative would have limited need for geologic resources for I-5 operation and maintenance. The No-Build Alternative would not affect local surface mining resources or expand local quarries.

Groundwater Resources

The No-Build Alternative would not provide stormwater management or treatment, and therefore existing impacts to degradation of the groundwater quality in the study area would continue.

Modified LPA

Geologic Hazards

Earthquakes

The Modified LPA would have the long-term benefit of improving public safety, minimizing damage to infrastructure, and limiting potential economic disruption in the event of an earthquake. The new Columbia River and North Portland Harbor bridges, as well as ramp and interchange structures and transit facilities, would be built to modern seismic safety standards. Design of the Modified LPA would apply advancements in

earthquake engineering, structural safety standards, and site-specific geological and seismic risk information in the study area, which would improve public safety and structural stability during an earthquake. To meet current design standards, the Columbia River bridges with the Modified LPA would include more substantial foundation elements than the existing Interstate Bridge. The single-level movable-span configuration may require more substantial foundation elements than the fixed-span configurations. This is because mechanical tolerances for this type of bridge may require additional support for a seismic event.

The Modified LPA would stabilize weak soils along the Columbia River, on Hayden Island, around Marine Drive, and at Burnt Bridge Creek that are susceptible to liquefaction during seismic events through ground improvements such as soil mixing or stone columns.

The Ruby Junction Maintenance Facility expansion area lies entirely within an area classified as Seismic Hazard Zone D – Least Hazard. Construction of the Modified LPA would not increase seismic effects hazards at the facility.

Soil Liquefaction

Soil liquefaction is a phenomenon associated with earthquakes in which sandy to silty, water-saturated soils behave like fluids. As seismic waves pass through saturated soil, the structure of the soil distorts, and spaces between soil particles collapse, causing ground failure. In general, young, loose sediment and areas with high water tables are the most vulnerable to liquefaction.

Non-Seismic Settling

In the Portland area, there are a number of flood control levees located within the study area. Additionally, enhancements to the levee system and some new structures that will be a part of the levee system are in the planning stages. The Modified LPA includes structures and significant fills placed in the vicinity of the existing or planned levee sections that could induce longer term settling of soils, which may cause a reduction in the overflow elevations for the levees. Structure foundation elements that penetrate the levees can compromise the ability of the levee to retain water and increase seepage.

In areas on both sides of the Columbia River, Hayden Island, and throughout the study area, the placement of construction fill, retaining walls, or other structures for the Modified LPA could result in non-seismic soil settling. The potential for non-seismic settling would be addressed as a part of the geotechnical design for the Modified LPA.

Steep Slopes, Soil Erosion, and Landslides

The Modified LPA would minimize construction on steep slopes. The roadway design would include retaining walls or other stabilization techniques to reduce the potential for soil erosion and slope failure hazards. In the Burnt Bridge Creek area, which has steep slopes, the design includes grading of slope angles, management of stormwater volume and flow to reduce erosion, and revegetation of disturbed areas.

As noted above, landslides are not known to occur within the study area. The Modified LPA would address the risks of increased scour that could result from potential landslides upstream caused by a major CSZ event. New bridge pier design would decrease the risk of bridge damage in the event of changes in river flow and/or sediment loads due to upstream landslides in the river.

The Ruby Junction Maintenance Facility expansion area is generally flat without steep slopes. No long-term effects on geologic hazards are anticipated in this area.

Volcanoes

The Modified LPA would include design measures to address the risks of increased scour from potential volcano-related impacts and decrease the risk of damage to the new Columbia River bridges due to lahar effects upstream of the study area.

In the event of a volcanic eruption within the Cascade region, the prevailing wind patterns would carry the majority of ash to the northeast, away from the study area. Therefore, ash accumulation is not anticipated to pose risks to the new bridges under the Modified LPA.

Groundwater Resources

The Modified LPA would provide long-term benefits to groundwater as a result of stormwater management and treatment throughout the study area. The associated reduction in pollutants from treatment of highway runoff would benefit the groundwater quality for the Troutdale SSA and groundwater flows that contribute to the Columbia River and Burnt Bridge Creek. There would be no adverse effects on groundwater resources.

3.17.4 Temporary Effects

No-Build Alternative

The No-Build Alternative would not have construction-related temporary effects on existing geologic hazards, geologic resources, or groundwater resources.

Modified LPA

The Modified LPA would require excavating filling, drilling, and grading activities during construction. Because the movable parts would be more sensitive to foundation settlement and movement during a seismic event, the single-level movable-span configuration may require slightly more construction effort and materials to construct the relatively larger river piers and pier foundations.

Geologic Hazards

Earthquakes

Construction of the Modified LPA, including construction of the new bridges and removal of the existing Interstate Bridge, would follow the American Association of State Highway and Transportation Officials standards. Temporary structures would incorporate appropriate seismic design. Although this would not provide the same level of resiliency as the completed infrastructure, it would minimize risks from earthquakes during construction.

Non-Seismic Settling

Although the design of the Modified LPA would address potential non-seismic settlement, if not correctly designed and constructed, new structures with the Modified LPA could experience settling during construction. Settling around structures occurs as soil conditions adjust to the weight of new structures. Settling can result in various adverse effects, such as roadway cracks and compromised foundations, which would require repair during construction. The greatest potential for settling is likely to occur on Hayden Island and along the shoreline of the Columbia River, where fill materials were previously used to extend shorelines and fill depressions.

In the Portland area, there are a number of flood control levees located within the study area. These levees could be impacted by the proposed construction and settlements could generate low spots in the levee system.

Potential non-seismic settlement could be present in areas of the Modified LPA where retaining walls and other structures are planned. Construction of retaining walls and backfilling could result in adverse effects from settling, if not properly engineered and compacted. In addition, ground improvement methods could be used during construction to provide beneficial structural performance in the Modified LPA. In areas where retaining walls are proposed at the edge of the project footprint, the Modified LPA would comply with current standards for geotechnical assessment, design, and construction to minimize the potential for settlement on adjacent properties. With the correct design and construction methods, the risks of settlement would be minimal.

Soil Erosion

Soil erosion could occur during construction if not controlled. Construction activities could expose erosive soils to wind and stormwater. Soil erosion has the potential to temporarily plug stormwater catch basins; deposit soil surface water on roadways; diminish surface water quality in the Columbia River, Vanport Wetland, and Burnt Bridge Creek; and undermine existing roadways and structures. The Modified LPA would expose approximately 415 acres of near-surface soils to potential erosion from excavation, fill, clearing, and grading during construction. Best management practices for erosion control, as described in Section 3.17.5, would be incorporated into construction specifications to minimize the potential for these hazards.

Geologic Resources

The Modified LPA would require large amounts of geologic resources during construction, including topsoil, fill, aggregate, and rock. Project-created demand could require existing aggregate mines to expand or new mine sites to be developed. Local geologic resources are not unique but are limited in number, material types, and volumes; approximately 33 mine sites are present within 10 miles of the study area.

Groundwater Resources

The Modified LPA is not expected to have substantial temporary effects on groundwater resources. Construction techniques for deep bridge foundations would be designed to minimize the need for groundwater dewatering. Dewatering may be necessary in areas where roadway sections are depressed and there is a shallow water table, but the volume of water produced is expected to be small and would come from shallow depths, not connected with groundwater resource production. Stormwater protection measures, including spill prevention plans, would be in place during construction to protect groundwater and surface water.

3.17.5 Indirect Effects

Geologic Hazards

The greatest risk from earthquakes under the Modified LPA occurs on Hayden Island and near the Columbia River and North Portland Harbor. Earthquake effects include ground motion amplification and soil liquefaction, which have a high potential to impact public safety, cause structural damage, and result in economic disruption. Compared to the No-Build Alternative, the Modified LPA may attract development near Vancouver's waterfront and Hayden Island, which is consistent with local land use plans (see Section 3.4.4). New and retrofitted buildings and structures would be built to current seismic safety standards, potentially enhancing public safety and decreasing the likelihood of structural and economic damage and disruption.

A flood protection system consisting of levees and flood walls is presently located on the southern edge of the Oregon Slough. The Modified LPA would necessarily cross these embankments and structures. Construction for the Modified LPA could introduce additional loads on the ground around these and cause some settlements, potentially generating low spots in the flood control system. Proper design and planning for the foundation elements would minimize these risks. In addition, the Program would carefully design foundation

elements that might be required to penetrate any levee elements or affect the stability of the levees in any way.

Groundwater Resources

Currently, stormwater in the study area is not treated. Over time, enhanced stormwater management requirements and treatment standards would likely improve local groundwater quality, particularly for the Troutdale Aquifer System.

Geologic Resources

Depending on the nature of long-term maintenance needs for the Modified LPA, there is the potential for increased use of materials such as aggregate and concrete for the project. This slight increase in demand for these materials could sustain mines or quarries over the long term. Mining operators would have to comply with federal, state, and local laws to minimize potential environmental damage.

3.17.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

- Design structures to comply with federal, state, and city building seismic codes and standards and apply advancements in earthquake science and construction materials and updates in the conceptual model.
- Design systems to minimize contamination of groundwater resources in compliance with Vancouver Municipal Code Chapter 14.26 Water and Sewers – Water Resources Protection and Portland City Code Title 21.35, Well Head Protection, and any applicable Washington and Oregon regulations.

Program-Specific Mitigation

- Design structures to consider stormwater infiltration or other changed conditions near shallow footings, retaining walls, and other structures that could increase the potential for soil liquefaction during a future seismic event.
- Design the Modified LPA to accommodate a range of future conditions resulting from climate change to provide resilience for geologic concerns, such as increased erosion and scour, as feasible.
- Conduct site-specific assessments of existing geologic hazards such as, but not limited to, faults, ancient landslides, steep cut slopes, non-seismic settlements, and soil liquefaction during design of the Modified LPA, as feasible. Site-specific assessments should include the use of geotechnical drilling, test pitting, material testing, geophysical techniques, subsurface displacement monitoring (inclinometers) and monitoring well installation, as feasible. Assessment would include recommended options for avoiding or mitigating geologic hazards.
- Consider the use of light weight fills or geoform in areas adjacent to existing flood control levees and structures to minimize the potential for settlements.
- Assess soil stabilization techniques to minimize the potential for soil liquefaction and non-seismic settlements during design of the Modified LPA. Stabilization techniques may include, but are not limited to, the use of soil mixing, compaction grouting, jet grouting, and stone columns.
- Locate stormwater treatment facilities, to the extent possible, away from City of Vancouver well head protection zones for WS-1 and WS-3, and the Cascade Expansion groundwater protection area in Gresham for the Ruby Junction location.

Temporary Effects

Regulatory Requirements

- Prepare and implement erosion control and stormwater pollution prevention plans and grading plans during construction. Plans would adhere to ODOT and WSDOT guidelines.
- Prepare and implement stormwater discharge permits for construction.
- Conduct inspection and observation monitoring of all Modified LPA elements during construction and long-term operations to ensure that appropriate construction and maintenance measures are being taken.

Program-Specific Mitigation

- Evaluate local geologic resources for future material needs.
- Recycle or reuse aggregate, quarry rock, asphalt, and concrete materials to the extent practical.

3.18 Hazardous Materials

This section identifies, describes, and evaluates potential temporary and long-term hazardous materials-related effects resulting from the No-Build Alternative and construction and operation of the Modified LPA. This section also describes measures to help avoid or mitigate adverse effects.

The information in this section is based on the Hazardous Materials Technical Report, which contains additional detail including analysis methods, an inventory and maps of recognized environmental conditions (RECs), and potential RECs identified through environmental data reports and desktop site assessment tools.

3.18.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with hazardous materials has been updated in this Draft SEIS to include:

- Updated assessment methodologies based on state and federal laws and requirements and lead agency environmental standard operating procedures.
- Updated datasets for hazardous material sites based on current database searches and the study area for the Modified LPA.
- Updated long-term and temporary property acquisitions for the Modified LPA.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the LRT alignment and modifying interchange designs.

Table 3.18-1 compares the impacts of the CRC LPA and the IBR Modified LPA as a result of the changes listed above. A detailed description of impacts and benefits to hazardous materials from the IBR Modified LPA and design options follows. Based on the analysis described in this section, the hazardous materials effects of the Modified LPA would be the same as or similar to the effects of the CRC LPA.

3.18.2 Existing Conditions

This section identifies existing hazardous materials sites within the study area, RECs on those sites, and other potential sources of pollutants in the study area, including stormwater runoff and spills.

Hazardous Materials Sites within the Study Area

The hazardous materials study area includes the limits of ground disturbance for the Modified LPA plus the maximum standard 1-mile database search radii established by ASTM E1527-21 for conducting environmental site assessments. A study area–level environmental database search identified 579 sites that could potentially contain hazardous materials. Of these, 358 were identified in Washington and 221 in Oregon.

The Ruby Junction Maintenance Facility is also identified as a small-quantity generator for hazardous wastes including solvents, batteries, and paints. Oregon Department of Environmental Quality (DEQ) files for the Ruby Junction property indicate that cleanup activities for leaking underground storage tanks (LUSTs) at the site were completed in 1994 and 1998. DEQ also identifies seven potentially contaminated sites within 500 feet of the proposed expanded facility boundaries.

Table 3.18-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects Identified in this Section	Explanation of Differences
Property acquisition	• Moderate potential for increased liability from the acquisition of contaminated sites. • Moderate potential for long-term beneficial effects on human health and safety from cleanup and remediation of contaminated areas on acquired sites.	• Similar potential to the CRC LPA for increased liability from the acquisition of contaminated sites. • Similar beneficial effects on human health and safety from cleanup and remediation of contaminated areas on acquired sites.	Approximate risk from property acquisition would be similar between the CRC LPA and the Modified LPA, as the overall number of sites affected by the two projects would be similar.
Surface water and groundwater quality	Beneficial effects from updates in stormwater conveyance and treatment, which would reduce pollutants in stormwater runoff and improve surface water and groundwater quality.	Same as the CRC LPA.	Risk to surface water and groundwater quality from the two projects would be similar, due largely to anticipated stormwater improvements providing beneficial effects.
Hazardous materials spill potential	Reduced spill risk due to reduced traffic congestion and collisions.	Same as the CRC LPA.	Risk due to hazardous material spill potential is similar for the two projects, as highway congestion and resultant collisions would be reduced under both the CRC LPA and the Modified LPA.

CRC = Columbia River Crossing; EIS = environmental impact statement; LPA = locally preferred alternative

The list of sites identified in the study area–level search was refined to focus on potential hazardous materials sites identified on properties proposed for acquisition by the IBR Program, or within sufficient proximity to potentially affect parcels proposed for acquisition. See the Hazardous Materials Technical Report for detailed discussion of the hazardous materials site identification and review process and methodology. In accordance with FTA Standard Operating Procedure (SOP) 19 (FTA 2016) and FHWA guidance, Phase I Environmental Site Assessments (Phase I ESAs) were completed for all properties proposed for acquisition. This included 137 total properties, consisting of 52 full parcels and 85 partial parcels. The purpose of the Phase I ESAs was to identify potential RECs, controlled RECs, (CRECs), or historical RECs (HRECs) on or near the properties proposed for acquisition.[1] Temporary construction easements were also identified and evaluated, as well as possible construction staging areas.

[1] ASTM Standard E1527-21 defines a Recognized Environmental Condition as, "…the presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: (1) due to any release to the environment; (2) under conditions indicative of a release to the environment; or (3) under conditions that pose a material threat of a future release to the environment. De minimis conditions are not recognized environmental conditions."

A total of 78 separate Phase I ESA reports were produced, encompassing 69 parcels in Washington and 68 parcels in Oregon. These reports cover all properties that would be acquired under any of the Modified LPA design options. Conclusions from the Phase I ESAs were used to determine the need for a Phase II ESA or other additional assessment on individual parcels. The findings of Phase II ESAs, as required, would be included in the Final SEIS and ROD.

Recognized Environmental Conditions

The RECs identified during the Phase I ESA process are related to historical and current land uses on the potentially acquired properties. Some of the land uses that resulted in the identification of RECs on potentially acquired properties include the following:

- Automobile maintenance and repair.
- Boat maintenance and repair.
- Vehicle fueling (gas stations).
- Waste disposal (landfills).
- Chemical or hazardous materials storage, including underground and aboveground storage tanks (UST/AST) and LUSTs.
- Military use.

Figure 3.18-1 through Figure 3.18-9 show the locations of Phase I ESAs and identified RECs in the study area.

Each Phase I ESA provides recommendations for additional study, if appropriate. Though individual Phase I ESAs recommend more specific actions, general categories that the recommendations fall into include:

- No Further Environmental Investigation.
- Hazardous building materials survey (HBMS) – recommended for sites with structures that may require demolition (it should be noted that a recommendation for a HBMS does not reflect the identification of a REC on the relevant property).
- Contaminated media management plan – recommended for sites with known but well-characterized contamination that could be managed during construction.
- Simple Phase II ESA – recommended for sites with known or suspected contamination that is not fully characterized but not expected to be significant based on the Phase I ESA.
- Complex Phase II ESA – recommended for sites with known contamination which is not completely characterized and has the potential to extend to additional media or adjacent parcels.

Additional recommendations may apply to some sites based on site-specific conditions.

An HREC is defined as, "…a past release of any hazardous substances or petroleum products that has occurred in connection with the property and has been addressed to the satisfaction of the applicable regulatory authority or meeting unrestricted use criteria established by a regulatory authority, without subjecting the property to any required controls."

A CREC is defined as, "…a REC resulting from a past release of hazardous substances or petroleum products that has been addressed to the satisfaction of the applicable regulatory authority, with hazardous substances or petroleum products allowed to remain in place subject to the implementation of required controls."

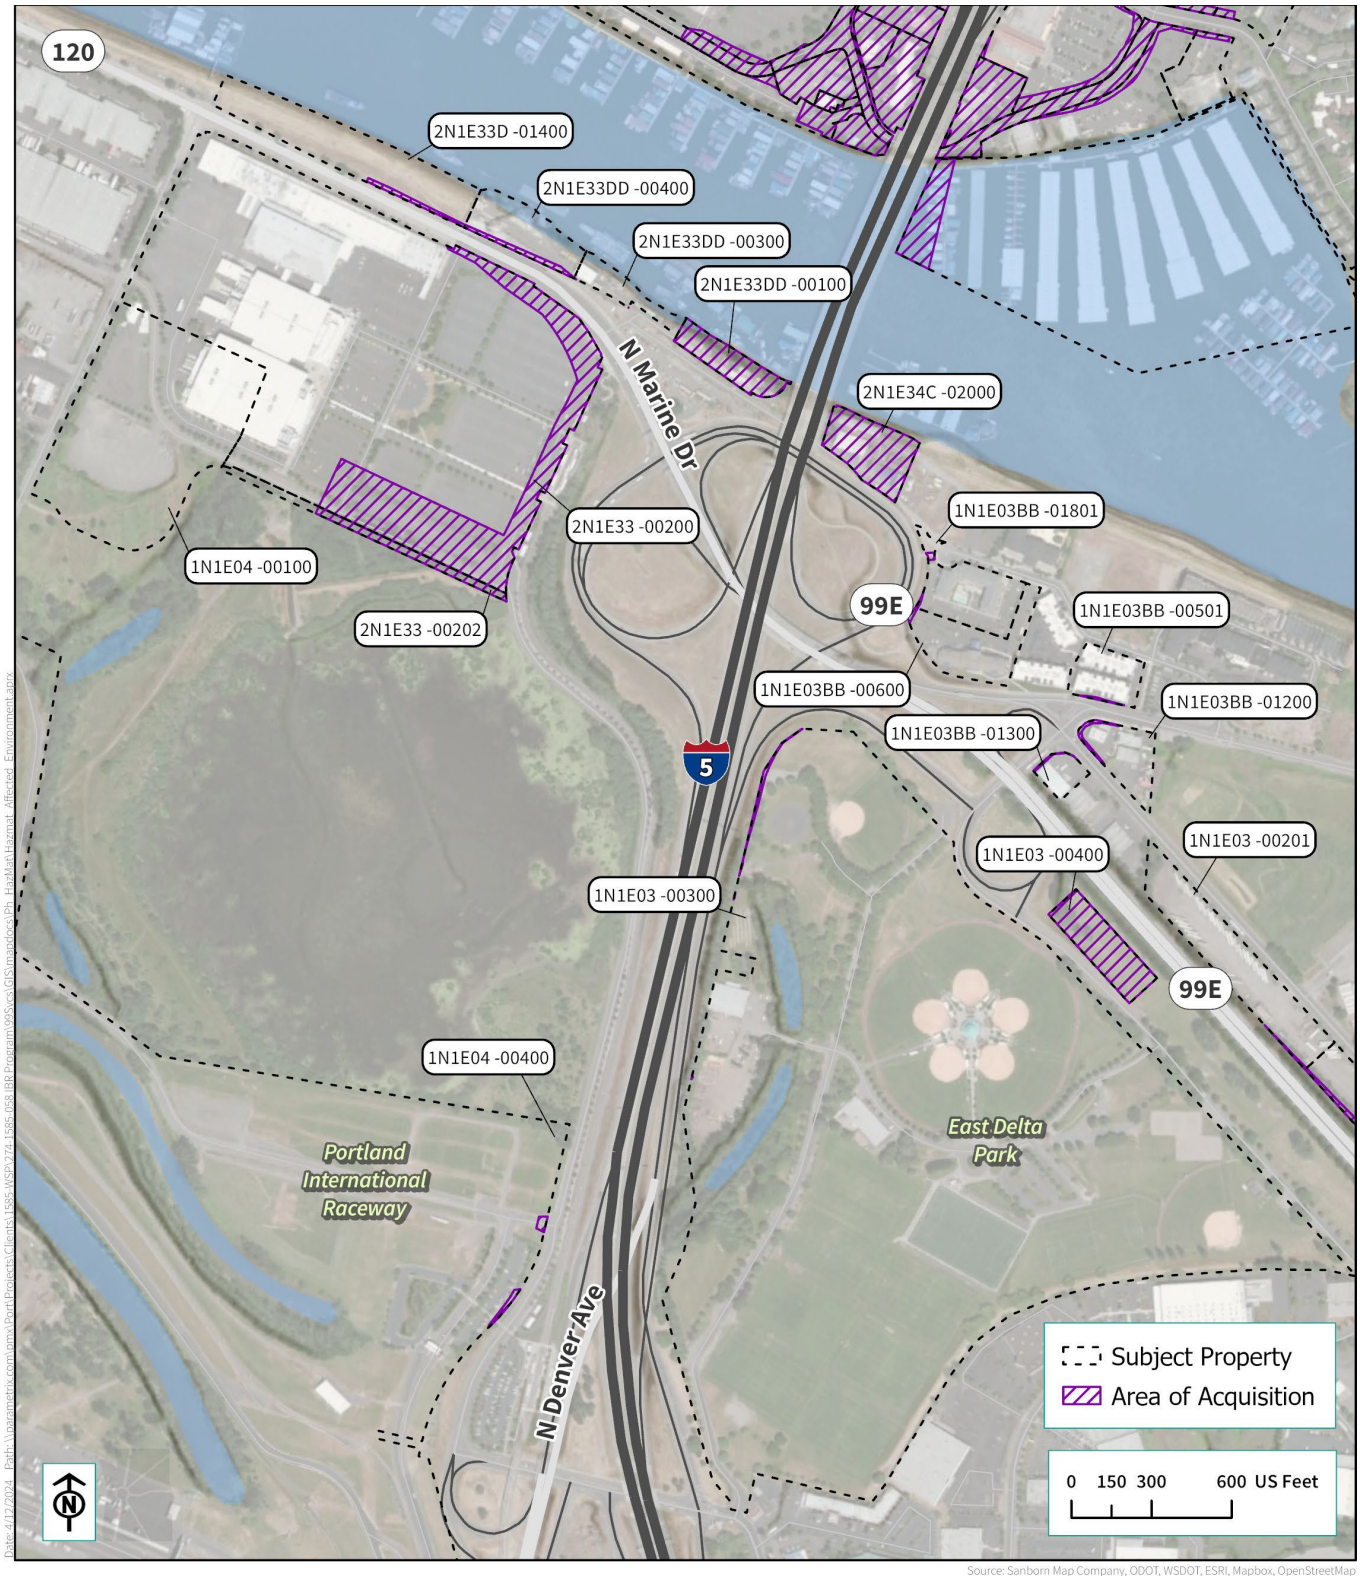

Figure 3.18-8. Phase I ESA Locations and RECs – Map 7

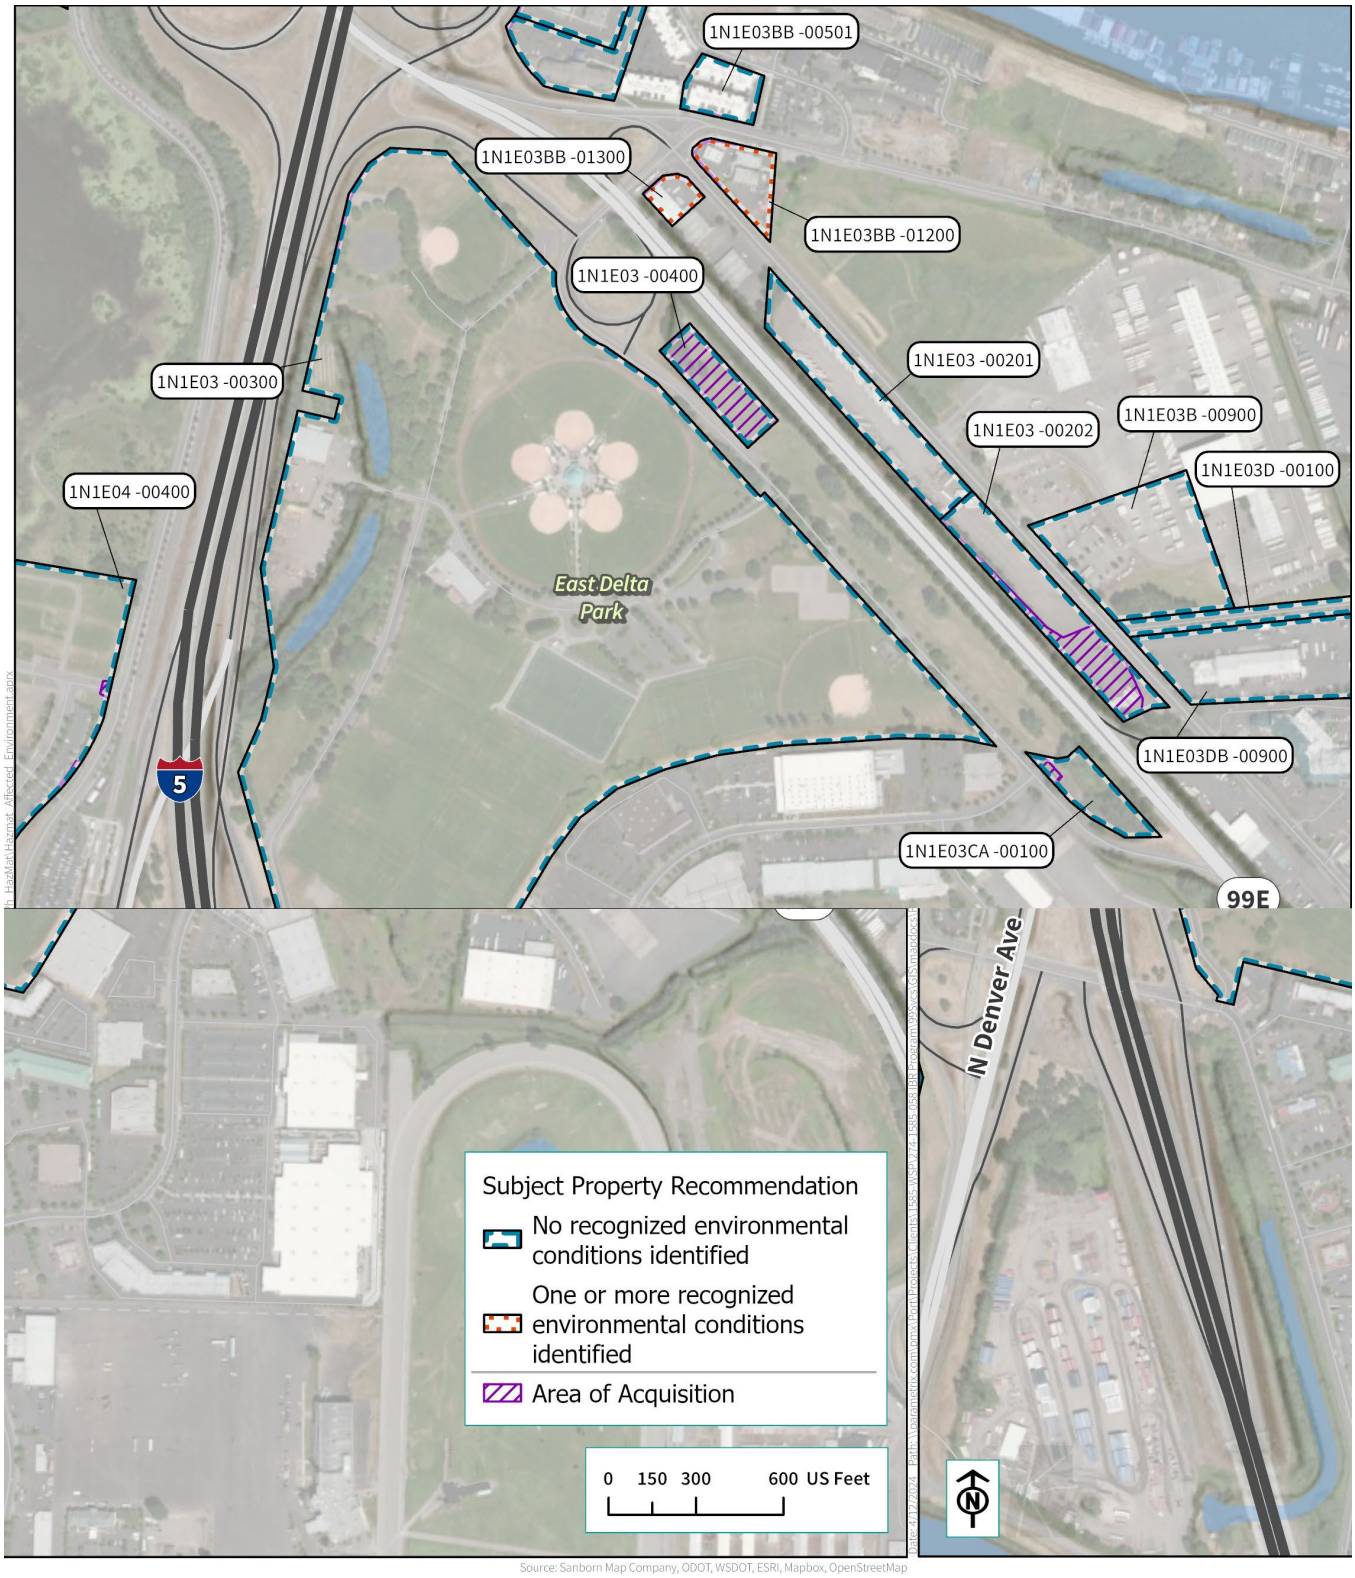

Figure 3.18-9. Phase I ESA Locations and RECs – Map 8

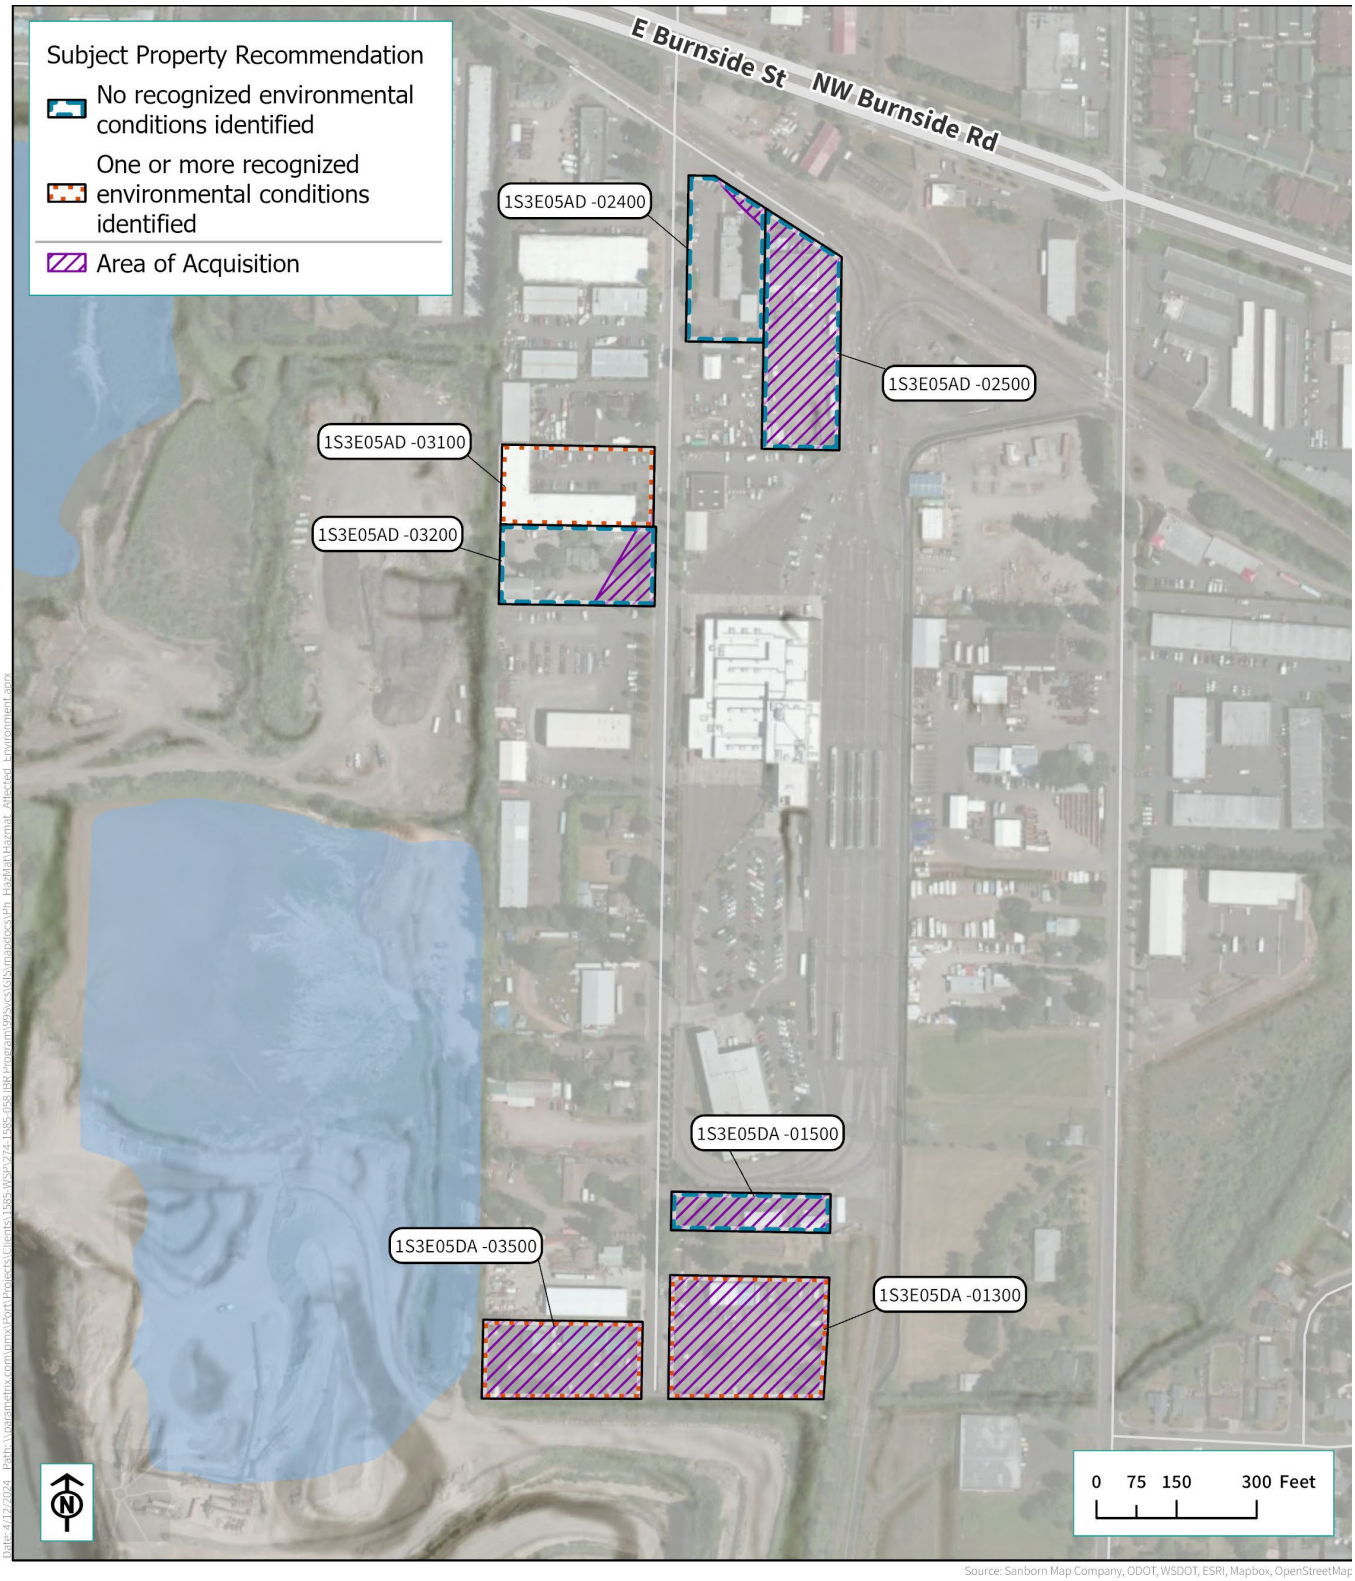

Of the 69 proposed acquisitions in Clark County, 59 received a recommendation of no further investigation (though five of those acquisitions have HBMS recommendations for impacted structures). Ten properties are recommended for further subsurface investigation (Phase II ESA) or contaminated media management plans; however, only 2 of these 10 properties are assumed to need more complex investigation.

Among 68 proposed acquisitions in Multnomah County, 35 received a recommendation of no further investigation (though 12 of those acquisitions have HBMS recommendations for impacted structures). Twenty-nine properties are recommended for further investigation, and 23 of the 29 are recommended for more complex investigation. In addition to these properties, some of these acquisitions are recommended for potential subsurface cleanup. The findings of the Phase II ESAs would inform mitigation and cleanup discussions in the Final SEIS.

Table 3.18-2 and Table 3.18-3 provide summaries of Phase I ESA recommendations for identified RECs in Washington and Oregon. Within Washington, the potential acquisitions requiring more complex investigation include the Clark Public Utilities property at 100 SE Columbia Way and a former industrial building at 215 W 4th Street. The potential acquisitions in Oregon that are likely to require more complex subsurface investigation and future cleanup are associated with the Pier 99 and Diversified Marine properties on North Portland Harbor, the Expo Center, the former Thunderbird Hotel and Hayden Island Landfill, and properties near former gas stations on Hayden Island east of I-5. Additional details on the conclusions of the Phase I ESAs, including those recommended for no further investigation, are provided in the Hazardous Materials Technical Report.

Stormwater Quality

The study area is located in the Columbia River watershed and the Burnt Bridge Creek watershed. These watersheds are highly urbanized within the study area. A substantial amount of the study area—including approximately 240 acres in the Columbia River watershed and 17 acres in the Burnt Bridge Creek watershed—is comprised of impervious surfaces that include highways, streets, parking lots, and alleys. Stormwater runoff from these surfaces—which contains pollutants such as automotive fluids, heavy metals, and small particles—flows into existing closed conveyance systems. These systems discharge runoff to either the Columbia River or Burnt Bridge Creek watersheds or to stormwater ponds and drywells that infiltrate into the subsurface soil.

In general, stormwater from the Columbia River watershed portion of the study area receives no water quality treatment prior to being released via several outfalls directly to the Columbia River. Runoff from the Interstate Bridge drains directly from the bridge decks through scuppers to the Columbia River or the ground below. In the smaller Burnt Bridge Creek watershed, most runoff is captured and treated by infiltration that removes pollutants as the stormwater percolates through the soil. Overall, approximately 21 acres within the study area receive some form of water quality treatment, while approximately 156 acres are untreated.

Additional discussion of stormwater quality and conveyance systems can be found in Section 3.14, Water Quality and Hydrology, and the Water Quality and Hydrology Technical Report.

Control Facilities for Spills and Releases

Roadway and transportation operations can result in the release of hazardous substances or petroleum products into the environment from accidental spills. These releases can migrate to surface water or groundwater and can affect properties outside of the right of way. Limited controls are currently in place within the study area to contain spills or releases of hazardous materials or petroleum products that could migrate to environmental media.

3.18.3 Long-Term Benefits and Effects

The long-term benefits and effects of the No-Build Alternative and the Modified LPA are summarized in Table 3.18-4 and detailed in the discussion below.

No-Build Alternative

Under the No-Build Alternative, I-5 and its interchanges and local street connections would remain as they are today. There would be no potential for encountering hazardous materials as a result of project development. The IBR Program would not assume liability for cleanup of contaminated sites. However, there would be no Program-related opportunities to improve existing contamination levels through the cleanup of acquired contaminated sites; existing contaminated sites would remain in their current conditions and pollutants may migrate off those sites.

The No-Build Alternative would include no improvements to roadways and bridges, which currently have limited controls in place to contain spills or releases that could migrate to environmental media. As such, the potential for adverse effects from spills or accidental releases is higher for the No-Build Alternative than it would be under the Modified LPA. Spills of hazardous materials from collisions as a result of traffic congestion would be assumed to continue at current levels or worsen as congestion increases over time. Stormwater would continue to be untreated on the existing Interstate Bridge and most other portions of I-5 within the study area; pollutants on roadways, such as oil from vehicles or heavy metals in brake dust, would continue to enter nearby surface water bodies and groundwater.

Modified LPA

The assessment of long-term effects from the construction, operation, and maintenance of the Modified LPA is based on information about the natural and built environments. The types of impacts evaluated include long-term liability from property acquisition, spills and releases of hazardous materials during project operation, contamination of groundwater and surface water by highway runoff, and the potential for legacy hazardous materials sites to affect operation and maintenance of Modified LPA facilities. Except where noted, effects would be similar for all Modified LPA design options.

Table 3.18-4. Comparison of Long-Term Benefits and Effects on and from Hazardous Materials

Type of Effect	No-Build Alternative	Modified LPA (all design options)
Property acquisition	Hazardous materials sites would not be acquired. No potential for adverse effects from acquisition of contaminated sites, such as increased liability and human health and safety if encountered during construction. No beneficial effects from the cleanup of contaminated sites.	• Moderate potential for increased liability for property owners (ODOT and WSDOT) from the acquisition of contaminated sites. • Beneficial effects on human health and safety and surface and groundwater quality from cleanup and remediation of contaminated areas on acquired sites and limiting the possible off-site migration of contamination. • If residual contamination remains on acquired hazardous materials sites after cleanup, moderate potential for adverse effects on human health and safety if encountered during construction or with the possible off-site migration of contamination.

Type of Effect	No-Build Alternative	Modified LPA (all design options)
Water quality	Stormwater that is untreated for the removal of pollutants would continue to enter surface waterbodies and groundwater.	Beneficial effects from improvements in stormwater conveyance and treatment, which would reduce pollutants in stormwater runoff and improve surface water and groundwater quality.
Hazardous materials spill potential	No improvement in existing spill risks from traffic congestion and collisions.	Reduction in spill risk due to reduced traffic congestion and collisions.
Legacy hazardous material sites	Future remediation activities at several sites have the potential to affect operation and maintenance of I-5.	Future remediation activities at several sites have the potential to affect operation and maintenance of the Modified LPA.

Source: Hazardous Materials Technical Report.
Note: The impacts for the Modified LPA are relative to No-Build and existing conditions.

Property Acquisition

Long-term liability can result when a project sponsor (in this case, ODOT or WSDOT) acquires a contaminated property. Liability can also result when a sponsor becomes legally or financially obligated to a property requiring investigation or remediation, or is subject to requirements associated with the long-term operation of a cleanup action. The Modified LPA would require the full or partial acquisition of properties that have been identified as hazardous materials sites, and therefore acquisition has the potential to result in long-term liability.

As an outcome of the Phase I ESAs described above, 36 of the properties identified for potential acquisition have been recommended for further subsurface investigation of potential or known contamination. Depending on the nature and extent of contamination encountered, long-term adverse effects from property acquisitions can be substantial. The need for cleanup can have the potential to affect the cost and schedule of project construction. For this reason, state and federal policies require due diligence (see sidebar) prior to property acquisition and construction.

To further assess the potential for liability related to cleanup requirements, following completion of the Draft SEIS, the IBR Program would prepare Phase II ESAs, consistent with ASTM E1527-21 or equivalent, for properties where identified RECs indicate that a subsurface investigation is needed to confirm the extent of contamination and to define specific measures and regulatory agency approvals needed to address the contamination. The findings of the Phase II ESA results would be incorporated into the Final SEIS to provide decision-makers with a more detailed understanding of cleanup obligations and costs associated with the Program. Properties with contamination in excess of regulatory standards would be subject to remediation and cleanup prior to construction. If residual contamination remained on acquired hazardous materials sites after cleanup, there would be moderate potential for adverse effects on human health and safety if contamination were encountered during construction or migrated off-site.

Due Diligence

Due diligence means taking appropriate precautions *before* a property is acquired to determine the presence, or potential presence, of environmental hazards. Due diligence provides the purchaser of a property with an understanding of the potential liability for environmental hazards and associated cleanup costs. The laws affecting legal liability for the purchasers of contaminated property differ between Oregon and Washington.

The two auxiliary lane design option and both of the single-level bridge configuration options would require the acquisition of a slightly larger area of property at the Fort Vancouver property (U.S. Army Vancouver Barracks) than the other design options. This site has a No Further Action determination for the possible presence of unexploded ordnance after a remedial investigation found no unexploded ordnance. Program activities on the site are therefore not expected to impact human health and safety. The site has been recommended for further hazardous materials investigations. Because ODOT and WSDOT would be required to clean up contaminated properties they acquired, the Modified LPA would result in long-term beneficial effects within the study area compared to the No-Build Alternative, which would not involve acquisition and cleanup of contaminated properties.

Stormwater Quality

Groundwater and surface water quality can be affected by pollutants contained in stormwater runoff from roadways and bridges and by erosion and runoff from contaminated soils exposed during excavation and grading activities. Compared to the No-Build Alternative, the Modified LPA would have a lower potential for adverse effects from contaminants in stormwater. The Modified LPA is anticipated to have substantial beneficial effects because it would treat all the stormwater runoff from existing, new, or reconstructed impervious surface area within the project footprint, including runoff from the Columbia River bridges. These improvements are anticipated to result in locally improved surface water, sediment, and groundwater quality. The Modified LPA stormwater conveyance system and treatment facilities would be monitored and maintained to ensure they perform as intended. Additional details regarding management and treatment of stormwater can be found in the Section 3.14 and the Water Quality and Hydrology Technical Report.

Spills and Releases

The Modified LPA also has the potential for adverse effects from spills or releases of hazardous substances or petroleum products during operation. However, these effects are anticipated to be less than under the No-Build Alternative. The Modified LPA would be constructed with updated road and bridge designs that would include controls within the stormwater system to contain or better manage releases on roadways and bridges. In addition, emergency response to such incidents would likely be quicker due to updates in roadway access and traffic safety. As such, the potential for adverse effects from spills or releases is lower for the Modified LPA compared to the No-Build Alternative.

The operation and maintenance of light-rail trains at the Ruby Junction Maintenance Facility requires the use of hazardous substances and the generation and disposal of hazardous waste. The facility currently has DEQ-approved plans and systems in place to control spills and manage hazardous materials. Operation of the expanded facility for light-rail maintenance would continue, and this existing use could create an incremental increase in existing risks; however, existing hazardous materials management plans and systems would be evaluated and adjusted as appropriate for the expanded scale of the facility. Therefore, expansion of the Ruby Junction Maintenance Facility would not be expected to result in substantial additional hazardous materials effects.

Legacy Hazardous Materials Sites

Legacy sites are hazardous materials sites that are or should be undergoing long-term cleanup actions by the owner, sites where additional investigation and cleanup may be required but where the responsible party has not yet complied, or orphan sites which are being managed by regulatory agencies. In special cases, site cleanup activities may coincide with the operation and maintenance of the Modified LPA. These activities could potentially interfere with the long-term operation and maintenance of components of the Modified LPA and result in financial liability or access restrictions.

The Modified LPA has a potential to experience adverse effects from legacy sites during operation. Hazardous materials sites of particular concern within the study area include former marine operations along North

Portland Harbor, the former Hayden Island Landfill (Thunderbird Hotel), and other former gas stations and industrial sites. These sites are identified above in Figure 3.18-1 through Figure 3.18-9 and listed in Table 3.18-2 and Table 3.18-3, and are discussed in further detail in the Hazardous Materials Technical Report.

A number of these sites have not been fully characterized, and cleanup actions have not been determined. Potential legacy issues associated with acquisitions along Marine Drive include cleanup actions for soil and sediment along the North Portland Harbor embankment or for in-water sediments. Potential future remedial activities that could affect the operation and maintenance of the Modified LPA include soil removal, sediment dredging, and capping. In addition, other potential legacy sites could be discovered during project construction activities. ODOT and WSDOT, as owners of the sites, would comply with all applicable federal, state, and local requirements for managing and mitigating contamination.

3.18.4 Temporary Effects

Temporary effects from hazardous materials include the risk of exacerbation of or exposure to existing contamination, accidental release of hazardous substances, and generation of hazardous waste during construction. The risk of these types of adverse effects has been evaluated for areas that would be disturbed during project construction and for staging and casting areas.

No-Build Alternative

Under the No-Build Alternative, there would be no Program-related construction or demolition, and therefore no construction-related disturbance of soils or sediments would occur that could potentially mobilize existing contamination into the environment. There would be no risk of accidental spills or releases of fuels, fluids, or other contaminants from construction vehicles, equipment, and materials.

Modified LPA

Property Acquisition (Temporary Construction Easements)

Some construction activities, such as construction of the new bridges and removal of the existing Interstate Bridge, would occur within temporary construction easements including subsurface and airspace easements. These would allow the state the right to use the property for short-term ground improvements or staging purposes. After fulfilling their intended purpose, temporary easements are typically returned to the landowner. Easements where RECs have been identified could result in potential liability. Liability issues can come in the form of incurred cleanup costs, schedule delays, and worker and public safety.

Prior to property acquisition and construction of the Modified LPA, the IBR Program would complete individual property evaluations and assessments (including the Phase I ESAs completed as part of this Draft SEIS and the recommended follow up actions from the Phase I ESAs). The nature and extent of soil, sediment, and groundwater contamination would be characterized, and specific measures and applicable regulatory agency approvals needed to address the contamination would be defined. Where contamination exists that may pose a risk to people or the environment if mobilized by construction activities, a remediation plan would be developed and executed for each property. The remediation or cleanup of hazardous material sites affected by the Modified LPA would occur prior to or during construction.

The properties requiring more complex investigation, as shown in Table 3.18-2 and Table 3.18-3, are mainly gas stations, automotive and marine repair and service facilities, landfills, and commercial or industrial operations with commercial LUSTs or other sources of hazardous releases. In accordance with FTA SOP 19 and applicable regulations for hazardous materials sites, actions to address this type of contamination would be defined in more detail at the individual property level. However, such sites would typically be addressed with soil excavation and disposal or the use of technologies such as in-situ chemical injection, bioremediation, or air sparge/soil vapor extraction. A period of groundwater monitoring during and after

remediation may also be required if groundwater is contaminated. Overall, the Modified LPA would include actions to identify and remediate contamination on temporary easements, resulting in long-term beneficial effects.

Accidental Release or Generation of Waste

Spills and Releases

Construction equipment can spill or release fuels or other vehicle fluids. Other pollutants such as paints, acids for cleaning masonry, solvents, and concrete-curing compounds are typically present at construction sites and have the potential to be released to the environment. Certain uses of construction materials, such as the subsurface pouring of wet cement, could also result in localized impacts to groundwater quality. Measures such as spill control and prevention plans, as described in Section 3.18.6, Potential Avoidance, Minimization, and Mitigation Measures, should render these risks negligible.

Lead- and Asbestos-Containing Materials

Buildings and structures that have lead or asbestos-containing materials (ACM) would require proper abatement procedures prior to demolition, renovation, or repair activities. At least 23 of the properties that would be acquired for the Modified LPA have structures built prior to 1980 that may contain asbestos and that are planned for demolition. Similarly, materials that contain lead (such as some types of paint) must be handled carefully during demolition and must be disposed of at an approved site.

Hazardous building material surveys would be conducted prior to demolition if properties are suspected of containing asbestos, lead, or PCBs.[2] Surveys would be consistent with OAR 248 and WAC 296-65, and would inventory lead-based paint, ACM, mercury and PCB-containing equipment, universal wastes, and/or abandoned waste. Based on survey results, abatement would be conducted prior to demolition, renovation and/or repair. The Washington State Department of Ecology or DEQ would be notified if unknown contamination is encountered during the assessments. Disposal of lead and ACM would be conducted at applicable Subtitle C or D solid waste facilities.

Asbestos

Asbestos was used extensively in building materials in the early and mid-twentieth century. Today, it is a known carcinogen, and is extremely *friable*; it crumbles easily. Demolition of buildings or other structures that contain asbestos can release small particles of asbestos into the air, and these particles can lodge in the lungs of people who breathe this air. Proper caution and *abatement procedures* can reduce or eliminate this hazard to human health.

Hazardous and Non-Hazardous Wastes

Hazardous and non-hazardous waste can be generated during construction activities. Waste can consist of contaminated soils; sediments; groundwater generated from excavation, drilling, and dewatering activities; and building materials containing lead or asbestos exposed by demolition activities. These wastes can be harmful to human health and the environment and would require management in accordance with applicable federal and state regulations if they are encountered during construction of the Modified LPA. The single-level movable-span bridge configuration would require an increased area of in-water work due to its larger bridge foundations, which could result in a comparatively greater potential risk of mobilizing hazardous materials in river sediments for this configuration as compared to others.

[2] polychlorinated biphenyls

Staging and Casting Areas

Potential off-site staging areas to support construction are currently being evaluated. Staging areas would be used for material laydown yards, equipment storage, and fabrication. The former Thunderbird Hotel site, identified as a potential staging area, is a REC. This location is the site of the former Hayden Island Landfill and a former automotive service station. Activities at this site may have resulted in contamination of subsurface soils and groundwater, which if disturbed during construction as a result of staging activities, could mobilize into the surrounding environment. However, most construction staging activities would occur on the ground surface, and excavation at this site is unlikely.

If the river crossing is built using precast concrete sections, an off-site casting yard would be required. One potentially available casting yard site has been identified to date: the former Thunderbird Hotel site on Hayden Island. Preliminary review of the site has identified existing RECs, as noted above.

3.18.5 Indirect Effects

In compliance with local land use plans, the Modified LPA could indirectly facilitate development and redevelopment of existing buildings and/or paved areas, as opposed to development in natural areas. As described in Section 3.4, local governments have adopted land use plans that support increased development densities in areas served by high-capacity transit, particularly in light-rail station areas. Redevelopment of properties in older urban areas, such as downtown Vancouver or Hayden Island, is more likely to encounter existing contamination. As a result, the Modified LPA, compared to the No-Build Alternative, has a somewhat greater potential for indirect adverse effects related to contaminated soils during construction. However, new development and redevelopment would be required to remediate known or discovered hazardous materials, including lead or ACM, in order to be in compliance with local land use plans; therefore, indirect land use changes resulting from the Modified LPA would be more likely to have long-term beneficial effects on hazardous materials than the No-Build Alternative.

Health effects have been documented from materials containing lead and asbestos. To the extent that land use changes involved the demolition, renovation, or repair of buildings and structures that have lead or ACM, proper abatement would be required. The risks are no greater for transit-oriented development than other residential and commercial construction, including potential release fuels or vehicle fluids from spills from construction equipment. Other pollutants such as paints, acids for cleaning masonry, solvents, and concrete curing compounds can be present at construction sites and have the potential to be released to the environment. These releases can migrate to soil, surface water, sediments, or groundwater. Developers would be required to comply with federal, state, and local requirements for managing hazardous materials and wastes, thereby minimizing the risks of releases to the environment.

3.18.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

In accordance with FTA and FHWA standard procedures, the IBR Program has prepared Phase I ESAs to identify existing environmental issues on properties to be acquired. The results and recommendations of the Phase I ESAs have been incorporated into this Draft SEIS.

- Prepare Phase II ESAs for properties where identified RECs indicate that a subsurface investigation is necessary to confirm the nature and extent of contamination and define the specific measures and applicable regulatory agency approvals needed to address the contamination. Incorporate the Phase II

ESA results into the Final SEIS and ROD to provide decision-makers with a more detailed understanding of cleanup obligations and associated costs.

- Develop detailed hazardous materials management plans during final design and as part of the property acquisition process. Obtain necessary regulatory approvals to address areas where cleanup and remediation are needed. The remediation or cleanup of hazardous material sites affected by the Modified LPA would be required prior to construction.
- In accordance with Safety Standards for Construction Work: Lead (WAC 296-155) and General Occupational Health Standards: Asbestos (WAC 296-62 Part I-1), conduct HBMSs on structures proposed for demolition, prior to demolition, to identify ACM, lead-based paint, and other hazardous materials. Based on the survey results, conduct necessary abatement prior to demolition. Dispose lead-based paint, ACM, and other hazardous materials at facilities permitted to receive these materials in accordance with federal, state, and local agency regulations.
- Prepare a Program-wide construction health and safety plan, as required by federal Occupational Safety and Health Act regulations and state regulations, to minimize the potential for exposure of construction workers to hazardous materials and the risk to human health and the environment.
- Prepare a site-specific contaminated media management plan to ensure proper characterization, management, storage, disposal, and reporting of contaminated materials encountered during construction activities. The plan would outline the roles and responsibilities of personnel; health and safety requirements; methods and procedures for characterizing, managing, storing, and disposing of waste; and reporting requirements.

Program-Specific Mitigation

No Program-specific mitigation measures are proposed for long-term effects related to hazardous materials.

Temporary Effects

Regulatory Requirements

To minimize temporary effects related to hazardous materials during construction, standard mitigation measures such as best management practices would be implemented. Construction best management practices applicable to the Modified LPA are discussed in Section 3.14, Water Quality and Hydrology. Other required measures to reduce the risk of spills, leaks, or other releases during construction activities include:

- Conduct fueling, maintenance, and cleaning in areas that are contained by berms or other containment.
- Minimize the production or generation of hazardous materials, both upland and during demolition and replacement of overwater spans.
- Label and store hazardous waste according to federal regulations.
- Locate hazardous waste (including contaminated spoils) storage away from storm drains or surface water.
- Recycle materials such as used motor oil and water-based paint as appropriate.
- Handle potential spills of hazardous materials in conformance with applicable regulatory requirements and adhere to the Program spill prevention, control, and countermeasure plan.

Program-Specific Mitigation

No Program-specific mitigation measures are proposed for temporary effects related to hazardous materials.

3.19 Climate Change

According to the U.S. Environmental Protection Agency (EPA), multiple lines of evidence show changes in weather, oceans, and ecosystems (EPA 2022b) across the world. Examples include:

- Changing temperature and precipitation patterns.
- Increases in ocean temperatures, sea level, and acidity.
- Melting of glaciers and sea ice.
- Changes in the frequency, intensity, and duration of extreme weather events.
- Shifts in ecosystem characteristics, like the length of the growing season, timing of flower and algal blooms, water temperatures for fish, and migration of birds.

These changes to the earth's climate are due to a recent buildup of greenhouse gases (GHGs) in the atmosphere, which has resulted in dangerous effects on human health and welfare and to ecosystems (EPA 2022a). Climate change may result in localized effects in the study area.

The developed world's transportation systems are reducing reliance on fossil fuels and increasing use of electric and renewable fuels energy production and vehicles. Along the I-5 corridor, California, Oregon, and Washington have regulations to reduce fossil fuel use over time. These regulations are expected to reduce GHG emissions associated with transportation sources.

This section identifies the climate conditions in the region, highlights federal and state policy and regulation on climate, identifies the potential long-term climate impacts from the Modified LPA, and provides potential mitigation measures for unavoidable effects. In addition to considering climate effects from the Modified LPA, this section considers the potential effects or influence of changing climate conditions on the Modified LPA. The information presented in this section is based on the technical reports for climate, transportation, and energy.

The IBR Program aims to accelerate the local reduction of GHG emissions by developing alternatives to driving, managing transportation demand, and minimizing emissions associated with construction. Through design, the IBR Program also intends to minimize the expected GHG associated with the long-term maintenance of the proposed new infrastructure.

Actions to reduce or reverse impacts associated with transportation emissions require a holistic approach that considers patterns in land use and regional travel flows, in addition to major infrastructure. Both Oregon and Washington have among the strongest land use laws in the nation, and both have recently passed statewide legislation to end single-family zoning to increase housing supply and limit sprawl. These laws will enable more diverse housing development, supporting compact growth and multimodal transportation that will further reduce transportation emissions.

3.19.1 Changes or New Information Since 2013

Although there have been changes in design and operations between the Modified LPA and the CRC LPA, the general location and scale of many components are similar. Since 2013, there have been regional and local changes in the built environment, population and employment, transportation, climate modeling, demographics, human health, and other aspects of the existing conditions, which are reflected in this analysis.

The CRC project's Cumulative Effects Technical Report included a chapter on climate change that used the best available science to evaluate project-level GHG emissions and assess the project's resiliency to the effects of climate change. This analysis builds on that work and is consistent with Presidential Executive Order

14008: Tackling the Climate Crisis at Home and Abroad, as outlined by the interim Council on Environmental Quality (CEQ) guidance on consideration of greenhouse gas emissions and climate change (CEQ 2023).

Important changes related to climate since 2013 include major policy actions to reduce emissions from all sectors and specifically from the transportation sector. Both Oregon and Washington have an array of climate policies, strategies, and executive orders that guide state agencies' efforts to reduce emissions and increase the resilience of the transportation system. Executive actions and legislation in both Washington and Oregon are now in place to manage the transition to clean fuels for transportation and vehicle electrification, as well as a transition to 100% clean energy generation. These policies and other state-level changes are described later in this section. Highlights include:

- Washington has established statewide GHG reduction targets with benchmarks at 2030 (45% below 1990 levels), 2040 (70% below 1990 levels), and 2050 (95% below 1990 levels).
- State agencies in Washington, particularly WSDOT, are charged with leading by example and reducing transportation emissions when making investments and spending decisions.
- The ODOT Climate Action Plan (2021) guides ODOT to reduce emissions from the transportation system and improve resilience to extreme weather events.
- Oregon has established statewide GHG reduction targets with benchmarks at 2035 (45% below 1990 levels) and 2050 (80% below 1990 levels).
- Oregon's updated statewide planning rules require metropolitan communities to take steps to reduce emissions, including to plan for increased transit service to the key corridors and centers, prioritize investments that make it easier to travel without reliance on a personal vehicle, plan and manage parking to avoid oversupply, plan for electric vehicle (EV) charging, and increase monitoring.

At the city level, both Portland and Vancouver have strong political support for climate action and have established citywide policies to address the impacts of climate change for their communities. Highlights include:

- Portland's Climate Emergency Workplan (City of Portland 2022) establishes emission reductions targets with benchmarks at 2030 (50% below 1990 levels) and 2050 (reach net zero).
- Portland's Transportation System Plan (City of Portland 2020) aims to implement projects that shift travel behavior to increase trips to active and low-carbon modes of travel and projects that reduce vehicle miles traveled (VMT) to meet emissions-reduction targets.
- Portland's Pricing Options for Equitable Mobility Strategy (City of Portland n.d.) provides specific guidance for making mobility in the city more equitable using community engagement, pricing strategies, and reinvestment of revenues generated toward equity and climate goals.
- The City of Vancouver's Climate Action Framework (City of Vancouver 2022) supports a just and equitable transition to communitywide carbon neutrality by 2040, with support for low-income residents and communities of color. It establishes four near-term next steps: (1) ongoing engagement, (2) climate risk assessment, (3) continued focus on high-priority areas, and (4) increasing capacity for implementation and evaluation.

The IBR Program has tracked all partner agency climate plans and policies and their alignment with the Modified LPA. A summary of the Modified LPA's consistency with these plans and policies is included in Section 3.19.7, and detailed information can be found in Appendix B to the Climate Change Technical Report.

Table 3.19-1 compares the impacts and benefits of the CRC LPA with those of the IBR Modified LPA. There are no impacts from the Modified LPA that would differ substantially from those of the CRC LPA. Based on the

analysis described in this section, the climate effects of the Modified LPA, such as GHG reduction and improved resiliency, would be the same as or similar to those of the CRC LPA.

Table 3.19-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA [a] Effects Identified in this Section	Explanation of Differences
Consistency with federal, state, and Local Goals, Policies, and Plans	Consistent with applicable policies.	Same as for CRC LPA (see analysis of consistency in Section 3.19.7).	N/A
VMT	• Less than 1% reduction in regional VMT. [b]	Similar to CRC LPA for regional VMT • Less than 1% reduction in VMT for traffic subarea. [b]	Although methods for estimating VMT have changed since 2011, both analyses show a predicted reduction of less than approximately 1%.
Transit trips in Design Year (2030 for CRC, 2045 for IBR)	• Increase in transit trips over No-Build Alternative.	• Increase in transit trips by approximately 1.75% over No-Build Alternative.	Both CRC LPA and Modified LPA would lead to an increase in transit trips. The CRC Final EIS did not quantify the LPA's effects on transit trips.
Pedestrian and bicycle trips in Design Year (2030 for CRC, 2045 for IBR)	• Increase in pedestrian and bicycle trips over No-Build Alternative.	• Increase in daily active transportation trips across the bridge from 400 under No Build to between 740 and 1,600 by 2045. [c]	Both CRC LPA and Modified LPA would lead to an increase in active transportation trips. The CRC Final EIS did not quantify the LPA's effects on active transportation trips.
Operational GHG Emissions in Design Year (2030 for CRC, 2045 for IBR)	Reduction in GHG emissions: • Regional emissions (macroscale): approximately 1% reduction from No Build in CO_2e emissions (MT) in 2030. [d] • Local emissions (microscale): approximately 5% reduction from No Build in CO_2e emissions (MT) in 2030. [e]	Reduction in GHG emissions: • Less than 1% reduction from No Build in total CO_2e emissions (MT CO_2e/day) in 2045.	The differences in the reported reduction metrics are due to changes in methodology. It is anticipated that both the CRC LPA and Modified LPA would reduce GHG emission compared to the No Build Alternative.

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA [a] Effects Identified in this Section	Explanation of Differences
Construction Energy and GHG Emissions	• 11,477,104 MMBtu total energy consumption. • 871,265 MT CO_2e emissions.	• 2,601,017 MMBtu total energy consumption. • 469,444 MT CO_2e emissions (MT).	The reductions in the estimated consumption and emissions are due to changes in methodology and assumptions. It is anticipated that actual energy use and emissions during construction would be similar between the CRC LPA and Modified LPA. [f]
Resiliency	Improved resiliency to Columbia River sea-level rise, greater variation in high- and low-water flow due to changes in snowpack, severe weather events, and other changes in the environment.	Same as CRC LPA.	N/A

a In this context, "Modified LPA" refers collectively to all design options evaluated in this Draft SEIS. Differences among the IBR design options are discussed in Section 3.19.8.

b The CRC Final EIS VMT estimates are from the transportation analysis, as they were not included in the energy section or the climate section under cumulative effects.

e.

c Estimate of daily active transportation crossings of the Columbia River bridge in 2045 using methods and range of conservative, moderate, and optimistic growth; methods are described in the Transportation Technical Report.

d Includes interstates, highways, and principal arterials within Washington, Clackamas, Multnomah, and Clark Counties as well as light--rail related emissions. Emissions are reported as daily estimates.

e Includes a 12.2-mile segment of I-5 between Portland and Vancouver. Emissions are reported for a 4-hour AM peak period and 4-hour PM peak period.

f The IBR Program method used updated tools available from FHWA and supplemental calculations for the estimate reported in this document; these estimates vary substantially from the cost-based estimate produced for the CRC LPA.

CO_2e = carbon dioxide equivalent; CRC = Columbia River Crossing; EIS = Environmental Impact Statement; GHG = greenhouse gas; I-5 = Interstate 5; LPA = locally preferred alternative; MMBtu = million British thermal units; MT = metric tons; N/A = not applicable; VMT = vehicle miles traveled

3.19.2 Expected Future Conditions Resulting from Climate Change

Designing infrastructure intended to be part of the transportation system for 100 or more years requires consideration of climate change. The following describes a range of possible climate conditions based on global actions to curb emissions. For more information on potential future conditions, see Chapter 4 of the Climate Change Technical Report.

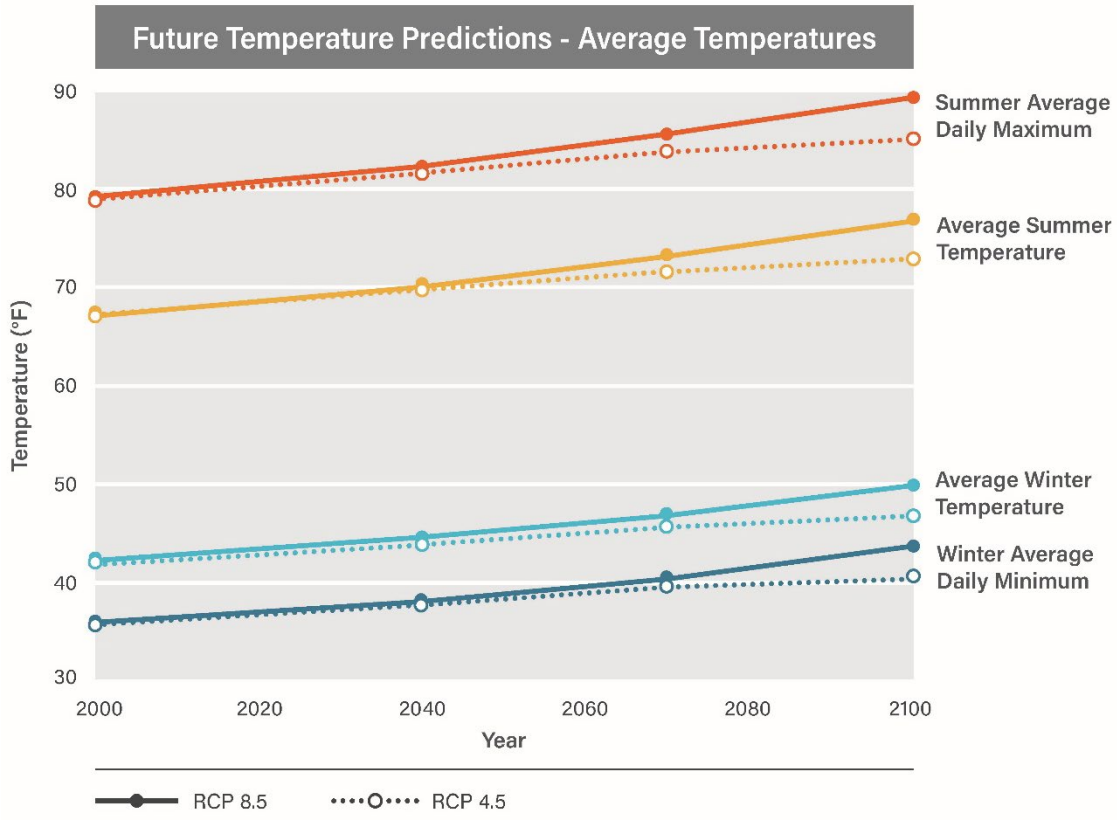
In the next century, the region is projected to experience an increase in average temperature (Figure 3.19-1) and in the number of extremely hot days. Additionally, changes to patterns of heavy precipitation are expected. While the region will experience roughly the same overall volume of rain, it is expected to come in more severe storm events (for example, atmospheric rivers). Increasing global temperatures may yield more precipitation falling as rain rather than snow, particularly in the Cascade Mountains and other areas of the lower Columbia River Basin. Rain falling on snow can further reduce accumulated snowpack, which would result in higher river flows during the rainy season and lower flows during the summer. Increased winter river flows and prevalence of severe storms result in a higher chance of flooding, which could impact low-lying land in the study area.

The expected future conditions in the study area were derived from two future scenarios representing a range of potential climate action between now and 2100. Climate change scenarios are often expressed as a Representative Concentration Pathway (RCP), which is a measure of the concentration of GHGs in the atmosphere, not the rate of emissions. Projections regarding precipitation and temperature are derived from the Climate Mapping for Resilience and Adaptation Assessment Tool, part of the U.S. Climate Resilience Toolkit (CMRA n.d.).

- **Strong Climate Action Scenario: RCP 4.5.** As shown in Figure 3.19-1, RCP 4.5 represents strong climate action to decrease atmospheric GHG concentrations, resulting in a leveling out of the warming effects by 2100 and a global average temperature increase of roughly 2 to 3 degrees Celsius (°C). This is commonly used as an optimistic scenario, although it still corresponds to significant climate disruption.
- **Weak Climate Action Scenario: RCP 8.5.** Also shown in Figure 3.19-1, RCP 8.5 represents the high end of plausible emissions through 2100 and a global average temperature increase of 4.3°C.

These expected future conditions have implications for design and operation of the Modified LPA.

Figure 3.19-1. Projected Average Temperature Changes over the Next 80 Years



Source: CMRA n.d.

3.19.3 Designing for Resilience in a Changing Climate

Temperature Changes

The average temperatures in the Program area are expected to increase between 5°F and 8°F by the end of the century. The increase in temperature is anticipated to be most evident in the summer months, where the average temperature is likely to climb between 5.5°F and 9.5°F, with an increase in average daily maximum temperatures between 6°F and 10°F. Extreme temperatures are expected to increase in the future. Currently,

the Portland-Vancouver metropolitan area experiences mild summer weather, where days with a heat index over 90°F happen only 5 to 6 days per year and where days with a heat index over 100 may happen once per year. In the future, the number of days over 90°F is predicted to occur between 30 and 60 days each year and days over 100°F are likely to become at least as common as days over 90°F are now. Finally, days with heat indices over 105°F are expected to occur from a once-in-a-decade phenomenon to up to 10 days every year (Merced n.d.).

To address long-term temperature increases, infrastructure designs should withstand regular air temperatures well over 100 degrees Fahrenheit during the summer months. Under excessive heat, the performance of light-rail transit rails and road surfaces are known to decrease. Active transportation commuters on the Columbia River bridges and users of public transit stations may need respite from the heat and sun in the summer.

Considerations for Climate Resilient Design

- Heat tolerance of materials
- Reflectivity and shading for active transportation and transit users
- Measures to minimize contribution to urban heat islands
- Designing stormwater systems with sensitivity to future storms
- Evaluating potential for sea level rise and saltwater intrusion at bridge site
- Worker safety during construction; air quality and heat effects

Precipitation Changes

Because the proportion of rain to snow precipitation is expected to increase, infrastructure design should plan for a wider range of water volumes and the possibility of higher and more frequent floods. Although the study area is not predicted to see a significant increase in overall precipitation, climate models predict an increase in the intensity of precipitation, specifically during the winter months. One-hour precipitation volumes are likely to increase, especially in the fall months.

Stormwater facilities should be sized to accommodate anticipated future storm frequencies and volumes. During construction, cut slopes should be protected from small landslides, especially during the winter months. Transit commuters may need additional shelter when waiting for trains, and active transportation commuters may need shelter on the bridge crossing. Infrastructure design should also consider the need for snow and ice removal, as increased winter storms may bring higher frequencies of freezing precipitation. Greater changes in river levels may also pose challenges to navigation, as there will likely be days when the Columbia River may be too high to accommodate vessels that might otherwise pass underneath fixed-span bridges; movable-span bridges may require more bridge openings if water levels are higher.

Other Climatic Factors

In addition to temperature and precipitation changes, climate change also has implications for wildfire risk and sea-level rise.

Wildfire Risk

While the wildfire risk is unlikely to damage infrastructure associated with the Modified LPA, because of its materials and location, landscape designs should consider the possibility of sparks from vehicles igniting plantings during dry, hot summer weather.

Exposure to wildfire smoke is a health threat, particularly to people directly exposed to the elements such as active transportation users, transit passengers, or construction workers (Grant and Runkle 2022).

Sea-Level Rise

Sea-level rise is a consideration on the coast, and the Columbia River is tidally influenced at the Interstate Bridge location. Sea-level rise at the mouth of the Columbia River is projected to range from 1.5 feet to 5 feet by 2150 (Miller 2018). The changes at the Interstate Bridge are expected to be much smaller and controlled by tides and precipitation. The resulting changes in water level are expected to be dwarfed by the seasonal changes from precipitation; the highest tidal swings are likely to occur when the Columbia River is relatively low (e.g., during the summer months) (USACE 2022). Saltwater intrusion is also not a cause for concern, as it is not expected to reach the Program area at river mile 106 according to the latest modeling from the Oregon Health and Science University Center for Coastal Margin Observation and Prediction, which estimates that saltwater will not be found upriver of approximately river mile 45 (Baptista 2018).

3.19.4 Federal Policy Context for Climate

Federal regulations and policies guide the development and evaluation of transportation projects and local communities' management of GHG emissions. The federal government has issued direction to address climate in NEPA documents. Consistent with Executive Order 13990, Protecting Public Health and the Environment and Restoring Science to Tackle the Climate Crisis and in recognition of NEPA's important role in providing critical information to decision-makers and the public, CEQ issued interim guidance to agencies involved in federal actions in January 2023. The CEQ guidance directs federal agencies to do the following:

- Consider GHG emissions in the identification of proposed actions and alternatives.
- Quantify a proposed action's projected GHG emissions or reductions for the expected lifetime of the action.
- Place GHG emissions in context and disclose relevant GHG emissions and climate impacts.
- Identify alternatives and mitigation measures to avoid or reduce GHG emissions.
- Provide additional context for GHG emissions to allow decision-makers and the public to understand tradeoffs associated with an action, including through the use of the best available social cost of GHG estimates.
- Incorporate environmental justice considerations into their analysis of climate-related effects.
- Use the information developed during the NEPA review to consider reasonable alternatives that would make the actions and affected communities more resilient to the effects of changing climate.

The IBR Program has followed the CEQ guidance and outlined a strategy for addressing climate change in the planning, design, construction, and operation of the Modified LPA. Data used to support the greenhouse gas emissions estimates were derived from the analysis in the Transportation Technical Report (for VMT and mode shift estimates) and the Energy Technical Report for estimates of GHG emissions associated with construction and operation of the Modified LPA.

3.19.5 Washington and Oregon Policy Context for Climate

Washington and Oregon, along with their local agency partners, have policy directives to reduce GHG emissions from transportation and other activities and have developed energy transition plans. Reducing emissions to the targets established by these entities will require aggressive action at all levels of government and by private industry.

Washington and Oregon have policies intended to promote a shift away from GHG emissions in the transportation sector. These transportation-related transition policies are summarized in Table 3.19-2.

Table 3.19-2. Washington and Oregon Transportation Transition Policies

Policy	Policy Directives
WSDOT Strategic Plan: Resilience Goal (WSDOT n.d.)	WSDOT will plan and/or invest resources to improve the ability to mitigate, prepare for, and respond to emergencies; combat climate change; and build a transportation system that provides equitable services, improves multimodal access, and supports Washington's long-term resilience.
Washington Governor's Executive Order 20-01: State Efficiency and Environmental Performance (2020)	When making purchasing, construction, leasing, and other decisions that affect state government's emissions of GHGs or other toxic substances, agencies shall explicitly consider the benefits and costs (including the social costs of carbon) of available options to avoid those emissions.
Climate Commitment Act – Washington State Department of Ecology (Ecology n.d.)	Directed by Washington State Legislature to design and implement a cap-and-invest program to reduce statewide GHG emissions. This program works by setting an emissions limit, or cap, and then lowering that cap over time to ensure Washington meets the GHG reduction commitments set in state law (95% reduction of GHGs by 2050).
Washington Clean Vehicles Program (Chapter 173-423 WAC)	Adopt California's Heavy-Duty Engine and Vehicle Omnibus rules. 100% of sales of light-duty vehicles sold in Washington will be electric by 2035. Requires increasing the number of new ZEVs sold in Washington until all new vehicles meet the ZEV standard starting in 2035.
Washington Clean Fuels Program (RCW 70A.535)	Requires fuel suppliers to reduce the carbon intensity of transportation fuels to 20% below 2017 levels by 2038.
Washington Clean Energy Transition Act (UTC n.d.)	100% of electricity sold in Washington will be renewable by 2045.
Oregon Climate Protection Program (DEQ 2021a)	50% reduction by 2035 and 90% reduction by 2050 in emissions for covered fossil fuel suppliers (from 2017–2019 average emissions).
Oregon Clean Fuels Program (DEQ 2022)	10% reduction in average carbon intensity for transportation fuels by 2025; 20% reduction by 2030; 37% reduction by 2035. In March 2020, Governor Brown issued Executive Order 20-04 to amend low-carbon fuel standards and schedule to phase in implementation with the goal of 20% below 2015 levels by 2030, 25% below 2015 levels by 2035. (The Oregon Clean Fuels Program Expansion was adopted by the Environmental Quality Commission in October 2022 and is effective as of January 1, 2023.)
Oregon Clean Energy Targets (DEQ n.d. d)	Targets for reducing GHG emission from electricity in Oregon from baseline (average annual emissions for 2010, 2011, and 2012): • 80% below baseline emissions by 2030. • 90% below baseline emissions by 2035. • 100% below baseline emissions by 2040.
Oregon Zero-Emission Vehicle (ZEV) (Senate Bill 1044) (ODOE n.d.)	At least 250,000 registered motor vehicles will be ZEV by 2025. At least 25% of registered motor vehicles, and at least 50% of new motor vehicles sold annually, will be ZEV by 2030. At least 90% of new motor vehicles sold annually will be ZEV by 2035.

Policy	Policy Directives
Oregon Clean Car Standards (DEQ n.d. c) and Advanced Clean Cars II (DEQ n.d. a)	The Oregon Department of Environmental Quality is beginning a rulemaking process to adopt California's Advanced Clean Cars II rule, which would require all light-duty vehicle sales in Oregon to be zero emission by 2035.
Oregon Clean Truck Rules 2021 (DEQ n.d. b) and Advanced Clean Trucks (DEQ 2021b)	Requires manufacturers of medium- and heavy-duty vehicles to sell a certain percentage of ZEVs beginning with 2024 vehicle model year: • 75% zero-emission sales for Class 4-8 rigid trucks by 2035. • 55% zero-emission sales for Class 2b-3 pickup trucks and vans by 2035. • 40% zero-emission sales for Class 7-8 tractor trucks by 2035.

GHG = greenhouse gas; WSDOT = Washington State Department of Transportation; ZEV = zero emissions vehicle

3.19.6 Existing Emissions Sources

User Emissions

Emissions from vehicles using transportation facilities comprise the transportation sector's majority of GHG emissions. In a case study of six state departments of transportation, the National Cooperative Highway Research Program found that user emissions by passenger and freight vehicles make up approximately 94% of transportation-related emissions, while 6%comes from construction and maintenance of the system. The remaining fraction (approximately 0.2%) results from administrative functions (e.g., operation of office buildings). Thus, reducing user emissions provides the greatest potential to make large reductions in total transportation-related emissions.

Across the U.S. transportation sector, roadway users account for over 80% of transportation emissions, with light-duty vehicles (passenger cars and trucks) producing the majority (57%) and medium- and heavy-duty trucks adding 26%. Of vehicle types, single-occupant light-duty trucks (which include the sport-utility vehicle class) are the least efficient mode, and they are a continuously growing share of the personal vehicle fleet.

Construction Emissions

Although construction emissions represent a smaller proportion of transportation sector GHG emissions, construction still produces substantial quantities. Figure 3.19-2 represents the average proportion of GHG emissions by category for the construction of transportation structures, highways, and streets per dollar spent.

The two largest categories of emissions are fuels used by construction equipment and production of construction materials (EPA 2023b). These categories provide the greatest opportunities for minimizing GHG emissions from construction activities. Construction material production includes concrete, asphalt, and steel products. The largest emissions in this category come from cement and concrete products and asphalt concrete pavement, including binders and aggregate. The remainder of construction-related GHG emissions come from fuel used in transporting materials and from other sources (e.g., engineering services, waste disposal).

Figure 3.19-2. Sources of Greenhouse Gas Emissions from Construction (EPA)

3.19.7 Summary of Climate Benefits

Modified LPA and GHG Emissions

The IBR Program proposes changes to the regional transportation system with the Modified LPA that would expand transit and institute tolling, which could encourage people to choose transportation modes other than driving alone (referred to as "mode shift"), and the Program would also reconfigure highway and local connections to improve the efficiency of the transportation network. Collectively, these changes could result in a decrease in regional GHG emissions. Compared to the No-Build Alternative, the Modified LPA is expected to reduce GHG emissions by affecting travel choices and traffic operations in the following ways:

- Encouraging mode shift to transit by providing an extension of TriMet's Metropolitan Area Express (MAX) light-rail between Portland and Vancouver and three new stations, expanded express bus service, and park and rides.
- Using demand management methods such as variable-rate tolling of the highway to reduce travel demand, promote mode shifts, and reduce travel during peak commuting periods.
- Improving traffic operations with ramp metering, auxiliary lanes, and roadway shoulders, which reduce idling by reducing congestion and disruptions due to vehicle crashes and other incidents.
- Encouraging mode shift from cars to active transportation (walking and bicycling) with facility

[1] Figure data notes: The values for this graphic are provided by the EPA U.S. Environmentally Extended Economic Input-Output Model. This model considers emissions for a wide variety of sectors in the U.S. economy, as categorized by the North American Industry Classification System (NAICS). The NAICS sector most closely aligned with Department of Transportation construction is 237310: Transportation Structures, Highways, and Streets. The model provides GHG emissions factors per U.S. dollar of purchase price (kilograms of CO_2e/$) and details about the largest sources of emissions for each industry.

improvements that provide a safe, comfortable, and direct path for walking, biking, and rolling.

IBR Program Climate Framework

The IBR Program has drafted a Climate Framework (see Appendix A of the Climate Change Technical Report) with two main objectives to guide processes and desired outcomes for climate: (1) reduce climate impacts and (2) improve climate adaptation and resilience through deliberate actions. The framework is intended to be applied during design, construction, and long-term operation and maintenance, with a goal of accounting for environmental impacts throughout the infrastructure life cycle. Evaluation of the IBR Program's performance related to climate objectives will be conducted at different stages. Table 3.19-3 provides an overview of the objectives for each stage.

Table 3.19-3. Climate-Related Objectives by IBR Program Phase

IBR Program Objective	Program Phase: Design/Refinement	Program Phase: Program Development and NEPA	Program Phase: Construction	Program Phase: Opening Day and Long-Term Operation
Design for resilience and adaptation	Avoid design choices that would restrict resilience to future climate conditions.	Assess future climate conditions, evaluate adaptability of design, develop climate-resilient design, and establish mitigation commitments.	Evaluate on-site needs regarding flooding, stormwater, heat tolerance, etc.; plan for and manage worker safety.	N/A; design and construction would be complete.
Reduce operational emissions	Design to support mode shift and VMT reduction. Develop high-capacity transit, improve active transportation, and implement roadway pricing.	Evaluate reasonable alternatives and design options in the NEPA process. Establish best management practices to reduce impacts.	N/A	Consider adaptive management and partner support. Consider air quality or temperature monitoring.
Reduce emissions during operations and maintenance activities	Design to support low or lower maintenance needs. Consider using on-site renewable energy for signage or other electricity needs.	Evaluate alternatives and design options in the NEPA process.	N/A	Consider adaptive management and requirements for lower GHG approaches to ongoing operations and maintenance. Optimize transit fuel use and equipment investments.
Minimize construction emissions and embodied carbon	Maintain options to use innovative approaches in construction	Evaluate and establish baseline.	Track equipment and materials.	N/A; construction would be complete.

IBR Program Objective	Program Phase: Design/Refinement	Program Phase: Program Development and NEPA	Program Phase: Construction	Program Phase: Opening Day and Long-Term Operation
	equipment and materials.			

N/A = not applicable; NEPA = National Environmental Policy Act; VMT = vehicle miles traveled.

Consistency with Goals, Policies, and Plans

ODOT, WSDOT, and the eight local agency partners have numerous climate-related goals, policies, and plans. Through an interagency working group, these agencies have been engaged with the IBR Program throughout the planning efforts to date. IBR Program staff and local agency partners developed a comprehensive database of local plans and climate initiatives, including specific climate commitments and emissions-reduction goals.

The IBR Program is consistently aligned with the climate aims of partner agencies. Important aspects of this alignment include:

- **Reducing emissions from the transportation system** – The Modified LPA would shift travel demand to lower GHG-emitting modes of travel and improve transportation efficiency. The Modified LPA would reduce vehicle-based GHG emissions by expanding transportation options for non-automobile trips, one of the most significant methods of reducing driving trips. New and improved transportation options include high-capacity transit and safe, comfortable bicycle and pedestrian infrastructure.
- **Reducing construction emissions and operations and maintenance emissions** – Construction goals for the IBR Program center on reducing construction-based emissions. The Program aims to reduce emissions associated with maintenance and operations by using an EV maintenance fleet.
- **Community resiliency** – The IBR Program includes climate resiliency goals such as designing for performance in a range of environmental conditions resulting from climate change. Equity in processes and outcomes for the community is prioritized by the IBR Program.

3.19.8 Long-Term Benefits and Effects

This section evaluates GHG emissions for the No-Build Alternative and the Modified LPA. Most of the Modified LPA design options would have similar emissions; those for which emissions may differ are discussed in the text. GHG emissions were estimated as a function of VMT, vehicle hours of travel (VHT), and vehicle hours of delay (VHD). Potential changes in travel behavior and VMT were estimated using the regional travel demand model that was jointly developed by Metro and Southwest Washington Regional Transportation Council (RTC) for use in the 2018 Regional Transportation Plan[2] (RTP), adopted by Metro in 2018 and RTC in 2019. The Transportation Technical Report, the Climate Change Technical Report, and the Energy Technical Report provide additional information on the modeling approach and the relationship between vehicle travel and GHG emissions.

[2] The transportation analysis for the No-Build Alternative and Modified LPA is based on the anticipated regional highway and transit networks and service levels for 2045 as informed by the regional transportation plans for both Metro (Metro 2018) and RTC (RTC 2019). The traffic model applied to this analysis reflects pre-COVID conditions. New surveys and model development efforts that include post-COVID travel behavior are planned to be incorporated in the 2028 RTP update.

Table 3.19-4 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on climate. Detailed analysis of the effects is provided in the following sections.

No-Build Alternative

Daily travel and delay information for the No-Build Alternative is shown in Table 3.19-5, and daily trips by mode in the region and the traffic subarea are shown in Table 3.19-6. These figures are shown alongside the Modified LPA results for comparison.

Roadway Operations, Transit, and Multimodal Trips

Table 3.19-5 presents modeled weekday results of VMT, VHT, and VHD. Together with vehicle types and fuel sources, these traffic measures are used to estimate GHG emissions from travel behavior. Results are presented for the Modified LPA with one auxiliary lane and with two auxiliary lanes. None of the other Modified LPA design options would result in a measurable difference in VMT, VHT, or VHD.

Table 3.19-6 presents data on daily trips through the I-5 corridor in the study area as estimated by the regional travel demand model. These trip estimates, in combination with information on vehicle fuel sources, are used to calculate transportation emissions. The regional model assumes the same number of person-trips in the No--Build and Modified LPA alternatives; however, the distribution of these trips varies based on proposed system changes. A more detailed analysis of trip generation and distribution is presented in the Transportation Technical Report.

Table 3.19-6 shows that, although the number of regional person-trips is held constant between the Modified LPA and the No-Build Alternative, the models predict the Modified LPA would lead to shifts between modes and destinations. Modeling results indicate that there would be a mode shift to transit and a decrease in the number of total trips across the Columbia River with the Modified LPA. The regional transit mode share would increase slightly, with the Modified LPA generating 12,500 daily new transit trips as a result of variable-rate tolling on the Columbia River bridges, the extension of light-rail transit between the Expo Center and near Evergreen Boulevard, new park and rides, and improvements to the speed and frequency of express buses.

Table 3.19-7 shows that, on a regional basis, the Modified LPA would result in small but measurable reductions in energy consumption and GHG emissions. This is the result of reductions in VMT, VHT, and VHD and a mode shift to transit under the Modified LPA.

Active Transportation

In addition to shifting trips to transit, the Modified LPA would include bicycle and pedestrian improvements on the Columbia River bridges, as well as facilities to access these bridges, which are expected to increase bicycle and pedestrian trips. In 2022, approximately 410 daily bicycle and pedestrian trips were estimated to use the existing path to cross the Columbia River; the Modified LPA is expected to increase this total to between 740 and 1,600 trips per day in 2045 (see the Transportation Technical Report for more information).

Considering the increasingly hot conditions expected in the future, active transportation users could experience discomfort (and potentially health risks), which could discourage the use of the facilities. The different design options for the main bridge crossing could produce different user experiences. If the active transportation path were on the lower deck of the double-deck bridge, that would provide cover for users, which would be beneficial for shading during summer heat events and providing protection from the rain in other months. Opportunities to provide shade or rain protection would not be exclusive to a double-deck option, as measures to provide shade (e.g., canopies, shade panels) could be incorporated on single-deck options.

Table 3.19-4. Summary of No-Build Alternative and Modified LPA Effects on Climate

1	2	3	4	5	6
No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5 or I-5 Westward Shift, all Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, Two Auxiliary Lanes, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Single-Level Fixed-Span Configuration,[a] One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	Modified LPA with Double-Deck Fixed-Span Configuration, One Auxiliary Lane, Without C Street Ramps, Centered I-5, all Park-and-Ride Site Options
• Substantially lower energy consumption and greenhouse gas (GHG) emissions in 2045 due to increased electric vehicles in fleet and decarbonized electricity sources.	• Lower energy consumption and GHG emissions in 2045, similar to No-Build Alternative. • Increased mode share of low and no emissions modes (transit, active transportation). • Improvements in climate resilience with materials and design.	• Similar to effects listed in Column 2, but would slightly reduce emissions due to improved congestion.	• Similar to effects listed in Column 2, but would slightly reduce operational emissions due to the reduced profile grade of the new Columbia River bridges.	• Similar to effects listed in Column 2, but would increase GHG due to the longer construction duration, additional materials required for the larger bridge foundations, and electricity required to raise and lower the bridge and as a result of idling during bridge closures.	• Similar to effects listed in Column 2, but would increase GHG due to increased congestion and volumes on the Mill Plain/15th Street couplet. Additionally, VMT and GHG would increase for trips with an origin or destination in downtown Vancouver south of Mill Plain Boulevard.

a The effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified. Differences in user emissions between the design options and the Modified LPA were not quantified because they are too small to be measurable at the scale of the region or the analysis area.

Table 3.19-5. 2045 Weekday Daily Vehicle Miles of Travel, Vehicle Hours of Travel, and Vehicle Hours of Delay

Alternative	Area	Vehicle Miles of Travel	Vehicle Hours of Travel	Vehicle Hours of Delay
No-Build Alternative	Portland Metropolitan Region	59,042,000	1,803,600	65,500
	Traffic Subarea [a]	14,349,500	439,600	24,900
Modified LPA with one auxiliary lane	Portland Metropolitan Region	58,950,700	1,792,300	58,300
	Traffic Subarea	14,270,500	428,000	17,400
Modified LPA with two auxiliary lanes	Portland Metropolitan Region	58,960,800	1,791,900	58,000
	Traffic Subarea	14,279,300	427,400	17,000
Change between No Build and Modified LPA with one auxiliary lane	Regional Difference	-91,300(<-1%)	-12,100 (<-1%)	-7,300 (-11%)
	Subarea Difference	-79,000 (<-1%)	-11,600 (-3%)	-7,500 (-30%)
Change between No Build and Modified LPA with two auxiliary lanes	Regional Difference	-83,300(<-1%)	-12,600 (-1%)	-7,600 (-11%)
	Subarea Difference	-70,900 (<-1%)	-12,200 (-3%)	-7,900 (-32%)
Change between Modified LPA with one auxiliary lane and two auxiliary lanes	Regional Difference	10,100 (<-1%)	-400 (<-1%)	-300 (<-1%)
	Subarea Difference	8,800 (<-1%)	-600 (<-1%)	-400 (-2%)

Source: Metro/RTC Travel Demand Model

a The traffic subarea is a subset of the region used to capture potential impacts and diversion of trips related to the IBR Program. This subarea includes an extent between the I-5 and I-205 split in Vancouver, south of I-84 in Portland, west of I-5 and east of I-205 in both Portland and Vancouver. See the Transportation Technical Report for more information.

Table 3.19-6. 2045 Weekday Daily Corridor Trips and Systemwide Transit Trips

Measure	No-Build Alternative	Modified LPA (One aux. lane)	Modified LPA (Two aux. lanes)
Regional Person-Trips (all modes)	11,905,000	Same as No Build	Same as No Build
Work Trips (all modes)	2,165,500	Same as No Build	Same as No Build
Non-Work Trips (all modes)	9,739,500	Same as No Build	Same as No Build
Total Regional Transit Trips [a]	626,300	638,800	638,700
Regional Transit Mode Share	5.26%	5.37%	5.36%
Regional New Transit Trips	N/A	12,500	12,400
Percentage Change from No Build	N/A	+2.00%	+1.98%

Source: 2022 Metro, RTC, C-TRAN, TriMet, and IBR Analysis

a Transit trips count each passenger only once between the origin and destination of their trip. Transit trips include all trips on any transit mode.

aux = auxiliary; LPA = locally preferred alternative; N/A = not applicable

Operational GHG Emissions

GHG emissions by gas- and diesel-powered passenger and freight vehicles are directly related to VMT, the age and type of vehicle, and the time spent traveling (e.g., travel efficiency, or speed, and congestion). Other factors, such as the amount of time vehicles idle in traffic congestion, also influence their GHG emissions. When people switch to more efficient modes of transportation—such as transit, carpooling, walking, or biking—GHG emissions are reduced. Depending in part on the composition of the electricity grid, GHG reductions will also occur as people switch to EVs.

Section 3.12, Energy, describes potential GHG emissions associated with VMT, transit trips, and emissions from routine maintenance. As shown in Table 3.19-7, energy consumption and GHG emissions in 2045 under the No-Build Alternative are expected to be substantially lower than existing values for the region due to requirements in existing regulations and voluntary low-emission vehicle commitments made by private sector automobile manufacturers. This means that even as the regional population grows, and VMT increases an expected 40% in the study area compared to existing conditions, the additional miles driven will generate substantially fewer GHG emissions over that same time period because of new regulations and a shift toward EVs.

Table 3.19-7. Daily Regional Energy Consumption and CO_2e Emissions (with Electric Vehicle Assumptions)

Parameter	Existing (2015)	No-Build Alternative (2045) (with EV Assumptions)	Modified LPA (2045) (with EV Assumptions)	Modified LPA Difference from No-Build (with EV Assumptions)
Total Energy Consumption (MMBtu/day)	290,732	190,771	190,302	-0.25%
CO_2e Exhaust Emissions (MT CO_2e/day)	22,273	11,440	11,409	-31 MT/day -0.26%
CO_2e Fuel Cycle Emissions (MT CO_2e/day)	6,014	6,668	6,653	-15 MT/day -0.22%
Total CO_2e Emissions (MT CO_2e/day)	28,286	18,108	18,063	-45 MT/day -0.25%

Notes: Table sourced from the Energy Technical Report; Emissions estimates produced using EPA MOVES model. Fleet assumptions listed in the Energy Technical Report.
CO_2e = carbon dioxide equivalent; EPA = U.S. Environmental Protection Agency; EV = electric vehicle; LPA = locally preferred alternative; MMBtu = million British thermal units; MT = metric tons

Modified LPA

As shown in Table 3.19-5, the Modified LPA would reduce regional VMT, VHT, and VHD compared to the No-Build Alternative. Daily VMT in the region would decrease by nearly 100,000 miles with the Modified LPA, which is due either to mode shift or to people choosing to make shorter trips or otherwise adjusting their travel patterns. Although the decreases for VMT and VHT are quite small at the regional scale, local reductions in the traffic study subarea represent a more substantial decrease. Total reductions in VHD compared to the No-Build Alternative are more significant both regionally and in the study area at 11% and 29%, respectively. This highlights the improvement in congestion reduction resulting from the Modified LPA and the influence of I-5 on overall delay in the region.

Analysis of the long-term effects of the two auxiliary lane design option using the regional travel demand model shows no statistically significant difference in GHG emissions compared to the single auxiliary lane option in the traffic assignment subarea, as shown in Table 3.19-8. However, an additional analysis using operational model outputs (modeling that provides more sensitivity to changes in speed and congestion) in the traffic subarea shows that GHG emissions associated with the Modified LPA could be approximately 2.5% lower those emission under the No-Build Alternative. In addition, the Modified LPA option with two auxiliary lanes could have approximately 2.9% lower emissions compared to emissions under the No-Build Alternative. This analysis shows that improving traffic speeds (i.e., reducing congestion) through the addition of a second auxiliary lane would have an effect on I-5 that translates into lower GHG in the whole study area.

The single-level fixed-span configuration would have slightly lower operational emissions than the double-deck configuration due to the reduced profile grade of the new Columbia River bridges (approximately 29 feet lower than the Modified LPA's double-deck configuration). The reduced profile grade is also characteristic of the single-level movable-span configuration, except that this option would increase energy consumption due to additional materials required for the larger bridge foundations, and electricity required to raise and lower the bridge, and as a result of idling by queued vehicles on the freeway during bridge closures. These emission differences were not quantified because they are too small to be measurable at the scale of the region or the traffic sub area, and as such, are unlikely to be useful in differentiating between alternatives.

The elimination of C Street ramps at the SR 14 interchange would result in additional congestion on local streets, which in turn would result in failing operations at 19 intersections, compared to 10 intersections for the Modified LPA with C Street ramps. This additional congestion and idling would decrease vehicle efficiency, resulting in increased GHG emissions compared to the Modified LPA with C Street ramps. As with the bridge design options, these emission differences were not quantified because they are too small to be measurable at the scale of the region or the analysis area, and as such, are unlikely to be useful in differentiating between alternatives.

Table 3.19-8. Comparison of Energy Consumption and GHG Emissions, Traffic Assignment Subarea

Parameter	Existing (2015)	No Build (2045)	Modified LPA with One Auxiliary Lane (2045)	Modified LPA with Two Auxiliary Lanes (2045)	One Auxiliary Lane Difference from No-Build	Two Auxiliary Lanes Difference from No-Build
Daily Vehicle Miles Traveled	11,267,296	14,349,500	14,270,500	14,279,300	-0.55%	-0.49%
Total Energy Consumption (MMBtu/day)	76,557	47,863	47,380	47,371	-1.01%	-1.03%
CO_2e Exhaust Emissions (MT CO_2e/day)	5,864	2,886	2,854	2,853	-1.01%	-1.14%
CO_2e Fuel Cycle Emissions (MT CO_2e/day)	1,583	1,644	1,630	1,630	-0.85%	-0.84%

Parameter	Existing (2015)	No Build (2045)	Modified LPA with One Auxiliary Lane (2045)	Modified LPA with Two Auxiliary Lanes (2045)	One Auxiliary Lane Difference from No-Build	Two Auxiliary Lanes Difference from No-Build
Total CO_2e Emissions (MT CO_2e/day)	7,447	4,530	4,484	4,483	-1.01%	-1.03%

Note: Values in this table represent emissions and energy consumption within the traffic assignment area. CO_2e emissions are calculated assuming an EV adoption rate consistent with Oregon and Washington state goals. If the adoption rates are less than the rates assumed in this analysis (52% EVs by 2045), GHG from both No-Build and the Modified LPA would be proportionately higher.
CO_2e = carbon dioxide equivalent; EV = electric vehicle; LPA = locally preferred alternative; MMBtu = million British thermal units; MT = metric tons

Emissions from Operations and Maintenance

GHG emissions from operations and maintenance activities include the emissions from vehicles performing routine maintenance activities to roadways, transit vehicles, and light-rail tracks, activities such as sweeping, restriping, and landscaping. Table 3.19-9 summarizes the energy and GHG emissions from maintenance activities under the Modified LPA. These would be similar to or lower than the annual maintenance activities with the No-Build Alternative because the facilities built for the Modified LPA would be new. There would also be several years where only light to minimal maintenance activity would be needed after construction is complete. Maintenance needs for a lift span would be higher than for the other bridge configurations because of the need for regular inspections and maintenance of the lift mechanism and other moving parts.

Table 3.19-9 Modified LPA Annualized CO_2e Emissions from Maintenance Activities

Project Element	Energy Consumption (mmBtu/year)	CO_2e Emissions (MT/year)
Annualized Value [a]	11,078	1,088

Source: ICE model output (available in Appendix A of the Energy Technical Report).
a Annualized value assumes a 30-year project life.
CO_2e = carbon dioxide equivalent; LPA = Locally Preferred Alternative; mmBtu = million British thermal units; MT = metric tons

3.19.9 Construction Effects

Modified LPA Components

Construction of the Modified LPA would include construction of the new bridges and removal of the existing Interstate Bridge. GHG emissions would be produced from construction equipment and the emissions embodied in construction materials. Construction impacts to energy consumption and GHG emissions from the Modified LPA are presented in Table 3.19-10. FHWA's Infrastructure Carbon Estimator (ICE) spreadsheet tool (ICF 2020) provided the basis for the calculation, which incorporates project features and construction traffic delays to calculate energy consumption from construction equipment, materials, and routine maintenance. The ICE tool was used for all elements of the Modified LPA except the main Columbia River bridges structure, which was evaluated using a material-based approach and is presented separately in Table 3.19-10. The Climate Change and Energy Technical Reports present a range of potential emissions to reflect the uncertainty associated with final

bridge design and specific construction materials. The high range of estimates for the Columbia River bridges is presented below.

These values represent the sum of the total impacts over the construction period. Emissions generated from the construction of any of the Modified LPA design options would be similar.

For more information, including a description of the methods used to develop this estimate, see the Energy Technical Report.

Table 3.19-10. Modified LPA Energy Consumption and GHG Emissions from Construction Activities

Construction Element	Modified LPA, Excluding Columbia River Bridge Structure [a] ($MT CO_2e$)	Columbia River Bridge Structure [b] ($MT CO_2e$)	Modified LPA Construction, Total Emissions ($MT CO_2e$)
Materials (e.g., embodied emissions in construction materials)	299,518	121,373	420,891
Transportation (e.g., transport of materials to the project site)	10,045	4,070	14,115
Construction (e.g., operation of equipment on site)	18,423	16,015	34,438
Total	**327,986**	**141,459**	**469,444**

Source: ICE model output (available in Appendix A of the Energy Technical Report)

a Values calculated from the Federal Highway Administration's Infrastructure Carbon Estimator Model.

B Values calculated using a material quantity-based estimate for materials using environmental product declarations and scaled factors for transportation and construction fuel usage.

CO_2e = carbon dioxide equivalent; LPA = Locally Preferred Alternative; MT = metric tons

Design Options

While it is expected that certain design options would require a greater volume of materials, and that a greater volume of materials would contribute more GHG emissions, design data to determine those volumes will not be available until the final design process. GHG emissions from construction of the Modified LPA were estimated as a range to reflect the uncertainty associated with construction material quantities for a single-level fixed-span configuration. The high value of the range is presented in Table 3.19-10.[3] The double-deck fixed-span or single-level movable-span configuration and the two auxiliary lane option would require a slightly greater volume of materials, which would contribute more GHG emissions compared to the same type of bridge in the single-span configuration with one auxiliary lane.

Emissions and energy consumption were estimated for the Modified LPA using the ICE planning-level model, which does not have the granularity to differentiate between the design options associated with roadway configurations. Estimates could be refined by using material quantity data similar to the bridge construction analysis, which would not be available until final design.

[3] For more information on the methods used to create this range, see the Energy Technical Report.

Traffic Delay Due to Construction

Construction of the Modified LPA is anticipated to last 9 to 15 years, impacting all modes of transportation within the study area as well as adjacent corridors. The Modified LPA could require nighttime closure of regional roadways, interchanges, and local roads during construction. Construction-related truck traffic for delivery of materials, equipment and for removal of materials/debris from demolition could also increase congestion and delays, particularly during periods of major construction. Closures during construction of the Modified LPA could temporarily affect transit operations and/or access to transit within the study area, sidewalks, bicycle facilities, and/or shared-use paths. Increased congestion due to temporary closures of roadways, transit facilities, and active transportation facilities could result in elevated vehicle emissions of CO_2e. Closures would be limited to off-peak hours to minimize impacts to regional travel during peak travel periods.

3.19.10 Indirect Effects

In the context of climate change, indirect impacts include potential growth-inducing effects and other effects related to project-induced changes in patterns of land use, population density, or population growth rate. As documented in Section 3.4, Land Use and Economic Activity, the Modified LPA is likely to facilitate growth within portions of the study area currently designated for denser development; however, it is not expected to result in unplanned growth or urban sprawl. This is because the transit improvements in the Modified LPA, in conjunction with tolling, will encourage growth and development along the new transit line while disincentivizing automobile trips.

Indirect impacts could also occur on the federal navigational channel of the Columbia River; climate change induced sea-level rise could have effects to the channel in two circumstances:

- Below Water – Increased water depth due to sea-level rise within the federal navigation channel could impose a residual future benefit for the federal navigation channel future operations and maintenance and utility (less dredging required).
- Above Water – Increased river stage along the federal navigation channel could reduce the vertical clearance available for vessels to transit under the new Columbia River bridges.

However, evaluation of the latest climate change data indicate that sea-level rise at the mouth of the Columbia River would likely have little effect on water surface elevations around the new Columbia River bridges. Based on the most likely future scenario, the 50% probability projection for 2150, a water surface elevation change of less than 8 inches could occur at the bridges, but this would only occur during high tide events that coincide with atmospheric river storm events in November, December, and January. Therefore, the risk to federal navigation channel operations and maintenance and navigation clearance as a result of climate induced sea-level rise is expected to be very low.

3.19.11 Cumulative Greenhouse Gas Changes and the Social Cost of Carbon

This section evaluates how the reduction in GHG emissions due to the Modified LPA's reduced VMT and improved traffic performance would be balanced by unavoidable new GHG emissions from project construction, operations and maintenance, and transit operations. These estimates reflect the difference between the Modified LPA and the No-Build Alternative. Table 3.19-11 summarizes the inputs used in the estimate of the social cost of carbon from the beginning of construction through 11 years of operation.

Table 3.19-11. Cumulative Emissions Estimates

Parameter	Annual Difference Between the Modified LPA and No Build (MT CO_2e)	Years	Total Over Evaluation Period (MT CO_2e)	Note
Construction Emissions	+46,944	2025–2034	469,444	A range of emissions was estimated; this value is the "high" estimate is 469,444 MT CO_2e over a 10-year construction period. [a]
Operations and Maintenance Emissions	0	2040–2045	0	Annual emissions of 1,088 MT CO_2e would be lower or similar to No-Build.
Transit Operational Emissions	+2,653	2035–2045	26,530	Emissions reflect expanded transit system.
Roadway User Emissions [b]	-15,802	2035–2045	- 158,017	Estimate based on daily reduction of 45 MT CO_2e/day in the region.

a A range of emissions was estimated and presented in Section 3.19.9. The value presented in this table is the "high" value, which assumes higher carbon intensity bridge design and materials for the main river crossing under the single-level bridge configuration with one auxiliary lane.

b Roadway user emissions were assumed to be constant over each year between 2035 and 2045. Due to shifts in the share of electric vehicles in the fleet over time, the 2035–2045 benefits may be underestimated (i.e., those years have more gasoline vehicles than expected in 2045). Changes to travel demand based on population, employment and land use after 2045 are not forecast at this time. Benefits from the Modified LPA would extend well beyond 2045.

MT = metric tons

The climate damages from the combination of construction emissions, transit operations, and benefits accruing from the decrease in roadway use compared to the No-Build Alternative were monetized using the updated SC-GHG values published by the EPA in the *Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances.*[4] Table 3.19-12 shows the present value in 2024 of the monetized climate costs for the 2025-2045 period under each discount rate. The present value of the monetized damages of the GHG emissions from the IBR Program range from $41 to $116 million in 2020 dollars.[5] The equivalent annualized costs of the emissions over the 20-year period range from $2.56 million to $6.46 million. The estimates presented in Table 3.19-12 reflect emissions reductions through 2045, the end of the traffic

[4] U.S. Environmental Protection Agency. (2023, November) Report on the Social Cost of Greenhouse Gases: Estimates Incorporating Recent Scientific Advances. https://www.epa.gov/system/files/documents/2023-12/epa_scghg_2023_report_final.pdf. All files related to EPA's updated estimates are available on EPA's webpage (https://www.epa.gov/environmental-economics/scghg), including the final technical report, all replication instructions and computer code for the estimates, a link to the public comments received and EPA's responses to the comments within the Oil and Gas rule docket, and all files related to the peer review process, including EPA's response to the peer reviewer recommendations. It also includes a link to a Microsoft Excel "Workbook for Applying SC-GHG Estimates" spreadsheet to assist analysts in applying the updated SC-GHG estimates in policy analysis, such as to monetize project SC-GHG emissions in an EIS.

[5] The EPA's social cost of carbon tool provides values for CO_2, CH_4 and N_2O. However, the construction, maintenance, and user emissions are presented in the body of this SEIS in CO_2e. Estimates of CO_2e were disaggregated into specific speciation of constituent chemicals (e.g., CO_2, CH_4 and N_2O) for vehicle operations, fuel cycle emissions, and fuel used during construction and transportation of construction materials. Data were not available to disaggregate embodied CO_2e from construction materials or transit operations, and CO_2e was input as CO_2. Using CO_2e in place of CO_2, CH_4 and N_2O to estimate the social cost of carbon for transit operations and construction materials may result in an overestimate of the social cost of the construction-related emissions.

forecast period. However, benefits from the Modified LPA would extend well beyond 2045 because the transit, active transportation, and roadway improvements are expected to last for many years.

Table 3.19-12. Social Cost of All Greenhouse Gas Emission Changes Associated with IBR Program Cumulative Emissions (2025–2045)

Value	Discount Rate 2.5%	Discount Rate 2.0%	Discount Rate 1.5%
Present Value in 2024 (millions 2020$)	$41.47	$67.67	$115.63
Annualized Value (20 years; millions 2020$)	$2.56	$3.98	$6.46

Source: EPA 2024. Additional detail on the methods and annual estimates of benefits are provided in the Climate Change Technical Report.

3.19.12 Potential Avoidance, Minimization, and Mitigation Measures

Regulatory Requirements

State-level legislation and policy in Oregon and Washington support reducing emissions from transportation to minimize contributions to climate change. There are no specific requirements for mitigation actions in federal, state, or local regulations.

Program-Specific Mitigation

As noted above, there are no specific requirements for mitigation actions in federal, state, or local regulations. However, the IBR Program supports state, regional, and local goals to reduce GHG emissions. The Program is improving and adding multimodal transportation options (to facilitate mode shift), including the extension of light-rail, and the expansion of active transportation facilities; implementing demand management (e.g., variable-rate tolling); and implementing operation and maintenance efficiencies (e.g., using renewable energy for bridge operation needs, using zero-emission transit vehicles). Best management practices and mitigation measures will be considered in coordination with IBR Program partners, subject to developing regulations and standards for transportation projects.

Long-Term Effects

The IBR Program would reduce GHG emissions in support of local, regional, and state goals. This section outlines concepts to further reduce or minimize GHG emissions associated with the construction or operations and maintenance of the Modified LPA. In developing these concepts, the IBR Program collaborated with ODOT, WSDOT, and the eight local agency partners. The IBR Program team will continue to consider and incorporate mitigation and minimization measures during the development of the EIS and through final design and construction.

User Emissions and User Experience: Design and Implementation Considerations

The following concepts address future climate conditions:

- To increase resiliency, the design will consider future conditions, including more frequent and severe winter storms, lower low-water conditions in the dry season, and an increase in the number and intensity of hot days during summer months.
- In consideration of the effects of changing future climate conditions on users of the transportation system, the design considers the provision of shade and other treatments, with a focus on active

transportation and transit users.

Operation and Maintenance

The GHG emissions anticipated as a result of the long-term operation and maintenance of the Modified LPA (as opposed to user emissions) are relatively minor. However, they represent an additional opportunity to improve climate outcomes and progress toward shared GHG reduction goals. As Program design and planning continue, ODOT and WSDOT will work together to develop plans for long-term operation and maintenance of the infrastructure.

Options for reducing GHGs through infrastructure maintenance include:

- Minimizing energy use (e.g., LED lights) and using green energy sources.
- Providing energy storage on the bridges for operations if power is interrupted.
- Maximizing the renewable electricity supply for operations (lights, signs, transit, toll collection) toward 100% as soon as practical.
- Exploring potential for wind generation, solar panels for energy needs, or piezoelectric energy harvesters to generate energy from traffic vibration.
- Using an all-electric or hydrogen maintenance fleet (anticipated by 2045).
- Establishing guidelines for replacement equipment, alternative fuel use, and materials standards.

Measures outlined in the Energy Technical Report are as follows:

- Applying best management practices for maintenance of the toll gantries and supporting infrastructure.
- Using energy-efficient electrical systems for toll gantries and technical shelters.

Construction Effects

Strategies to reduce the GHG emissions associated with the construction of the Modified LPA would include a range of options. Oregon and Washington have standard specifications that would reduce GHG emissions during construction, including:

- ODOT Standard Specifications Section 290, which has requirements for environmental protection, and include air pollution control measures. These control measures include vehicle and equipment idling limitations, which would also reduce energy usage and GHG emissions.
- Many of WSDOT's standards specifications to minimize air quality impacts would also reduce energy use and GHG emissions, including:
  - Minimizing delays to traffic during peak travel times.
  - Minimizing unnecessary idling of on-site diesel construction equipment.
  - Educating vehicle operators to shut off equipment when not in active use to reduce emissions from idling.
  - Preparing a traffic control plan with detours and strategic construction timing (such as night work) to continue moving traffic through the area and reduce backups and delays to the traveling public, to the extent possible.

As construction packages and plans are developed, the IBR Program will evaluate the potential to further reduce GHGs associated with construction. This could be implemented through construction bid document specifications or performance requirements, and could include:

- Construction materials.
  - Design specifications for materials to reduce embodied emissions; use Environmental Product Declarations to evaluate various material choices and options.
  - Minimize lengthy supply chains for materials by using local sources where possible while still maintaining acceptable quality levels for materials.
  - Use cleaner production methods for cement and concrete (e.g., consider different mixes, fuel specifications for kiln and manufacture), and if found viable, incorporate into material specifications.
  - Maximize inclusion of recycled material to reduce virgin material production and inclusion. This would include recycling existing concrete and asphalt pavements within Program limits to be used as aggregate base, subbase, backfill materials, etc.
  - Consider prioritizing suppliers that document accountability to their sustainable practices, such as by participating and reporting to EPA's Energy StarChallenge for Industry.
- Fuel and energy use.
  - Specify emissions targets for contractors and encourage use of renewable fuels and electric equipment.
  - Specify improved diesel emissions standards for construction and vehicles.
  - Use renewable diesel, renewable propane, or other lower-carbon fuels in construction equipment and transport of materials.
  - Select specified electrical equipment (e.g., lighting) to maximize for energy efficiency, as long as the equipment meets safety and other project needs and requirements.
  - Seek to prioritize the use of battery-powered equipment and limit the use of diesel equipment operating under less stringent emissions standards than EPA's Tier 4.[6]
- Waste reduction.
  - Minimize construction waste.
  - Consider adopting or establishing a zero-waste demolition plan, including a recycling plan, to maximize the recycling or reuse of old bridge components.
- Traffic management during construction.[7]
- Support and encourage alternative modes during construction, such as transit subsidies or elimination of fares during construction period.
- Other approaches as suggested by interested parties, agencies, and the public.

[6] EPA has adopted a comprehensive national program to reduce emissions from nonroad (construction equipment) diesel engines by integrating engine and fuel controls as a system to gain the greatest emission reductions. To meet these Tier 4 emission standards, engine manufacturers will produce new engines with advanced emission control technologies.

[7] Measures for minimizing the effects of construction-related traffic congestion (and thus emissions) are described in the Transportation Technical Report.

3.20 Environmental Justice

Executive Order (EO) 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations (February 11, 1994) reinforces the National Environmental Policy Act of 1969 (NEPA) by requiring federal agencies to analyze the "disproportionately high and adverse" environmental effects resulting from federal actions on minority and low-income populations. EO 12898 also calls for the fair treatment and meaningful involvement of all people, which refers to proactive efforts to increase low-income and minority participation.

On April 21, 2023, the Biden Administration signed EO 14096, Revitalizing Our Nation's Commitment to Environmental Justice for All. EO 14096 directs the federal government to build upon and strengthen its commitment to deliver environmental justice (EJ) through an updated definition of EJ, a change in the standard for what constitutes an EJ effect, and an expansion of EJ communities. Although formal guidance on how to apply EO 14096 to NEPA projects has yet to be published, the IBR Program has sought to meet the intent of the rule through a robust EJ analysis, coordinated with an equity analysis completed as part of the Equity Technical Report and summarized in Section 3.5, Neighborhoods and Equity.

Per U.S. Department of Transportation (USDOT) Order 5610.2C (May 14, 2021), determination of a "disproportionately high and adverse effect" depends on whether that effect is (1) predominantly borne by an EJ population, or (2) will be suffered by the EJ population and is appreciably more severe or greater in magnitude than the adverse effect that will be suffered by the non-EJ population. It is important to note that determination of disproportionately high and adverse effects takes into consideration the mitigation and enhancement measures that are planned for the proposed action.

The information in this section is based on the Environmental Justice Technical Report, which contains greater detail and analysis.

3.20.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with environmental justice has been updated in this Draft SEIS to include the following:

Legal/Regulatory Changes

- On April 21, 2023, EO 14096, Revitalizing Our Nation's Commitment to Environmental Justice for All, was signed by the Biden Administration, providing updates to the definition of EJ, a change in standard for what constitutes an EJ effect, and an expansion of EJ communities.
- On May 14, 2021, USDOT Order 5610.2C was authorized, providing an update to the legal standard for "disproportionately high and adverse effects" on EJ populations.

Methods and Analysis Changes

- Updated EJ analysis methodology to identify "meaningfully greater" and high-priority EJ areas. This methodology is described in more detail in Section 3.20.2, below.
- Updated demographic information to assess low-income and minority populations within the study area.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the light-rail transit alignment and stations.

- Design modifications that would reduce residential and commercial property acquisitions.
- Updated long-term, short-term, direct, indirect, and cumulative effects on low-income and minority populations resulting from the Modified LPA.
- Updated discussion of the effects on EJ populations that would result from a future IBR tolling program.

The IBR Program identified some impacts from the Modified LPA that would differ from those of the CRC LPA. Table 3.20-1 compares the key EJ-related impacts and benefits of the CRC LPA, as identified in the Final EIS (2011), and the IBR Modified LPA. Only the impact categories that would affect EJ populations are shown in the table. Key design changes that would affect EJ impacts include replacing the full interchange on Hayden Island that was part of the CRC LPA with a partial interchange and moving the proposed light-rail transit alignment closer to I-5 in downtown Vancouver. The changes proposed under the Modified LPA would require a smaller design footprint, reducing the number of residential and commercial displacements in meaningfully greater and high-priority EJ areas.

Table 3.20-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects

Type of Effect	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects Identified in This Section	Explanation of Differences
Residential Displacements	59 (approximately 18 in meaningfully greater and high-priority EJ areas)	43 for the Modified LPA, including all design options except the I-5 westward shift (none in meaningfully greater and high-priority EJ areas) The I-5 westward shift design option would shift I-5 west in downtown Vancouver, resulting in 33 residential units displaced in the Esther Short neighborhood (high-priority low-income neighborhood).	Modified LPA design changes would reduce residential property acquisition, including in meaningfully greater and high-priority EJ areas, for all design options except for the I-5 westward shift.
Business Displacements	69 (approximately 30 in meaningfully greater and high-priority EJ areas)	36 (13 in meaningfully greater and high-priority EJ areas) One design option would shift I-5 west in downtown Vancouver, resulting in 3 commercial displacements at the Regal City Center complex.	Commercial property acquisitions in meaningfully greater and high-priority EJ areas would also decrease due to the Modified LPA's smaller footprint.

Type of Effect	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects Identified in This Section	Explanation of Differences
Tolling	New toll would require a higher proportion of income for low-income drivers. Consideration of a variety of potential tolling schemes, including variable price tolls.	New toll would require a higher proportion of income for low-income drivers. Toll rates and policies, including a possible low-income toll program, would be jointly set by the OTC and WSTC. Both commissions have supported the study of a low-income toll program, including how such a program could be implemented in each state. They will work together to determine how to approach this for the IBR Program.	New analysis completed to understand the potential impacts of tolls on EJ populations under the Modified LPA.
High-Capacity Transit	The CRCLPA would bring new high-capacity transit to the I-5 corridor, including high-priority EJ neighborhoods such as Esther Short in Vancouver.	Same as CRC LPA.	None identified.
Social and Neighborhood Effects	Displacement of Hayden Island Safeway and bottle return.	None identified.	The Safeway grocery store (including a pharmacy and bottle return) closed after the CRC project was suspended. A new Target store, replacing some of these services, was constructed outside the Modified LPA footprint.

CRC = Columbia River Crossing; N/A = not applicable; OTC = Oregon Transportation Commission; WSTC = Washington State Transportation Commission

3.20.2 Affected Environment

Study Area

The IBR study area, also referred to as the primary study area, is a 5-mile segment of I-5 approximately between the SR 500 interchange in Washington and the I-5/Columbia Boulevard interchange in Oregon, as well as the Ruby Junction Maintenance Facility in Gresham, Oregon.

Impacts to EJ populations can extend beyond a project's limits. Therefore, the EJ analysis looked at a larger secondary study area, which extends over 15 miles from approximately 1 mile north of the I-5/I-205 interchange in Vancouver, south to the I-5/I-84 interchange, and 1 mile both east and west of I-5. The secondary study area captures the direct impacts as well as where the greatest potential for indirect impacts (e.g., traffic and development changes) could occur (Figure 3.20-1). The intent of using the secondary study area for the EJ analysis was to account for all EJ populations that could be directly and indirectly impacted by the Modified LPA. For the EJ analysis, references to the study area refer to this secondary study area unless noted otherwise.

Defining Environmental Justice Populations

EO 12898 instructs federal agencies and recipients of federal funds to integrate EJ into agency missions and to identify and address disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on low-income and minority populations. Hence, the EJ analysis considers all potential impacts of the Modified LPA to determine whether the IBR Program would result in disproportionately high and adverse effects on low-income and minority populations, which are defined as EJ populations.

The first step of the EJ analysis was to identify all EJ populations within the study area using best practices and methods consistent with FHWA guidance (FHWA 2011) and guidance sourced from the publication *Promising Practices for EJ Methodologies in NEPA* (EJ IWG2016), a compilation of agency approaches for incorporating EJ into environmental reviews published by the Environmental Justice Interagency Working Group. Per this guidance, a "no-threshold" analysis was conducted to identify all minority and low-income populations within the study area regardless of concentration relative to the general population. This analysis used 2016–2020 American Community Survey (ACS) data published by the U.S. Census Bureau, analyzed at the U.S. Census block group level. For the Final SEIS, the analysis will be updated with the most recent ACS data available.

Building from the no-threshold analysis described above, a "meaningfully greater" analysis was used to identify concentrations of EJ populations relative to the average for the Portland-Vancouver region. As with the no-threshold technique, this methodology is sourced from *Promising Practices for EJ Methodologies in NEPA Reviews* (EJ IWG 2016).

For the purposes of this project, low-income and minority populations 1.5 times greater than the corresponding average for the Portland-Vancouver region are considered "meaningfully greater." Low-income and minority populations that are 2 times greater than the average for the Portland-Vancouver Region are considered "high-priority" EJ areas.[1] Block groups where minority or low-income populations made up 50% or more of the population were also considered high-priority EJ areas. The purpose of identifying meaningfully greater and high-priority EJ areas is to provide a baseline reference for the relative concentration of where minority and low-income populations are present, and where disproportionately high and adverse effects could occur. Determining meaningfully greater and high-priority EJ areas also provides a reference for where there could be a need for additional outreach and analysis as part of the IBR Program.

The IBR Program acknowledges that demographic data providing population and household information are a valuable sampling tool and support analyses such as the EJ analysis. There are some limitations to the use of census data, however, and demographic data for a particular U.S. Census unit should not be the only factor used to determine disproportionality in EJ analysis. Consideration of the type, magnitude, severity, and distance of impacts in conjunction with demographic data forms a more complete understanding of potential impacts, including whether impacts would be disproportionately high and adverse to EJ populations.

Minority Populations

Minority populations are defined consistent with USDOT Order 5610.2C and FHWA's Guidance on Environmental Justice and NEPA (FHWA 2011):

- Black: A person having origins in any of the black racial groups of Africa.

[1] The meaningfully greater thresholds of 1.5 and 2 times the corresponding county or regional average were selected given the regional significance of the IBR Program, such that the determination of meaningfully greater and high-priority EJ areas was relative to the broader region. These specific thresholds were also used in the Southwest Corridor Light Rail Environmental Impact Statement, another regionally significant program (FTA 2022).

- Hispanic or Latino: A person of Mexican, Puerto Rican, Cuban, Central or South American, or other Spanish culture or origin, regardless of race.
- Asian American: A person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent.
- American Indian and Alaskan Native: A person having origins in any of the original people of North America or South America (including Central America).[2]
- Native Hawaiian and other Pacific Islander: People having origins in any of the original peoples of Hawaii, Guam, Samoa, or other Pacific Islands.

Tribal governments (federally recognized tribes) are sovereign nations as recognized by the U.S. Government, and consultation with federally recognized tribes occurs through a government-to-government consultation process separate and distinct from public and community outreach and comment.

Table 3.20-2 summarizes non-white, minority populations living in U.S. Census block groups within the study area for Portland and Vancouver (U.S. Census Bureau 2022). Minority populations account for 27.8% of this population, representing approximately 35,000 people, which is comparable to the percentage of minority populations in the Portland-Vancouver region (27.6%). Within the study area, block groups in Portland have a somewhat higher percentage of minority residents (31.0%) than in Vancouver (25.0%).

Table 3.20-2. Minority Populations in the Study Area (Portland and Vancouver)

Study Area	Minority Population	Percent Minority
Portland Block Groups	18,283	31.0%
Vancouver Block Groups	16,534	25.0%
Study Area Total	**34,817**	**27.8%**

Source: American Community Survey 5-Year Estimates, 2016–2020, Table B03002 (U.S. Census Bureau 2022).

Table 3.20-3 reports minority populations within the Rockwood neighborhood in Gresham. Demographics for Gresham are reported separately to account for its distance from the study area adjacent to the Interstate Bridge, distinct community characteristics, and separate but related set of improvements under the Modified LPA (Ruby Junction Operations and Maintenance Facility).

Table 3.20-3. Minority Populations in the Study Area (Gresham)

Study Area	Minority Population	Percent Minority
Gresham Block Groups (Rockwood)	8,227	60.0%
Study Area Total	**34,817**	**27.8%**

Source: ACS 5-Year Estimates, 2016–2020, Table B03002 (U.S. Census Bureau 2022).

[2] Not all American Indian and/or Native American populations are appropriately represented in U.S. Census data due to a history of termination, removal, and assimilation. Furthermore, tribal affiliation, citizenship, and/or sovereignty does not imply tribal ethnicity and cultural affiliation, and vice versa. The EJ analysis recognizes that the demographic analysis based on U.S. Census data is not fully representative of American Indian and/or Native American populations within the study area.

Figure 3.20-1. Environmental Justice Study Area

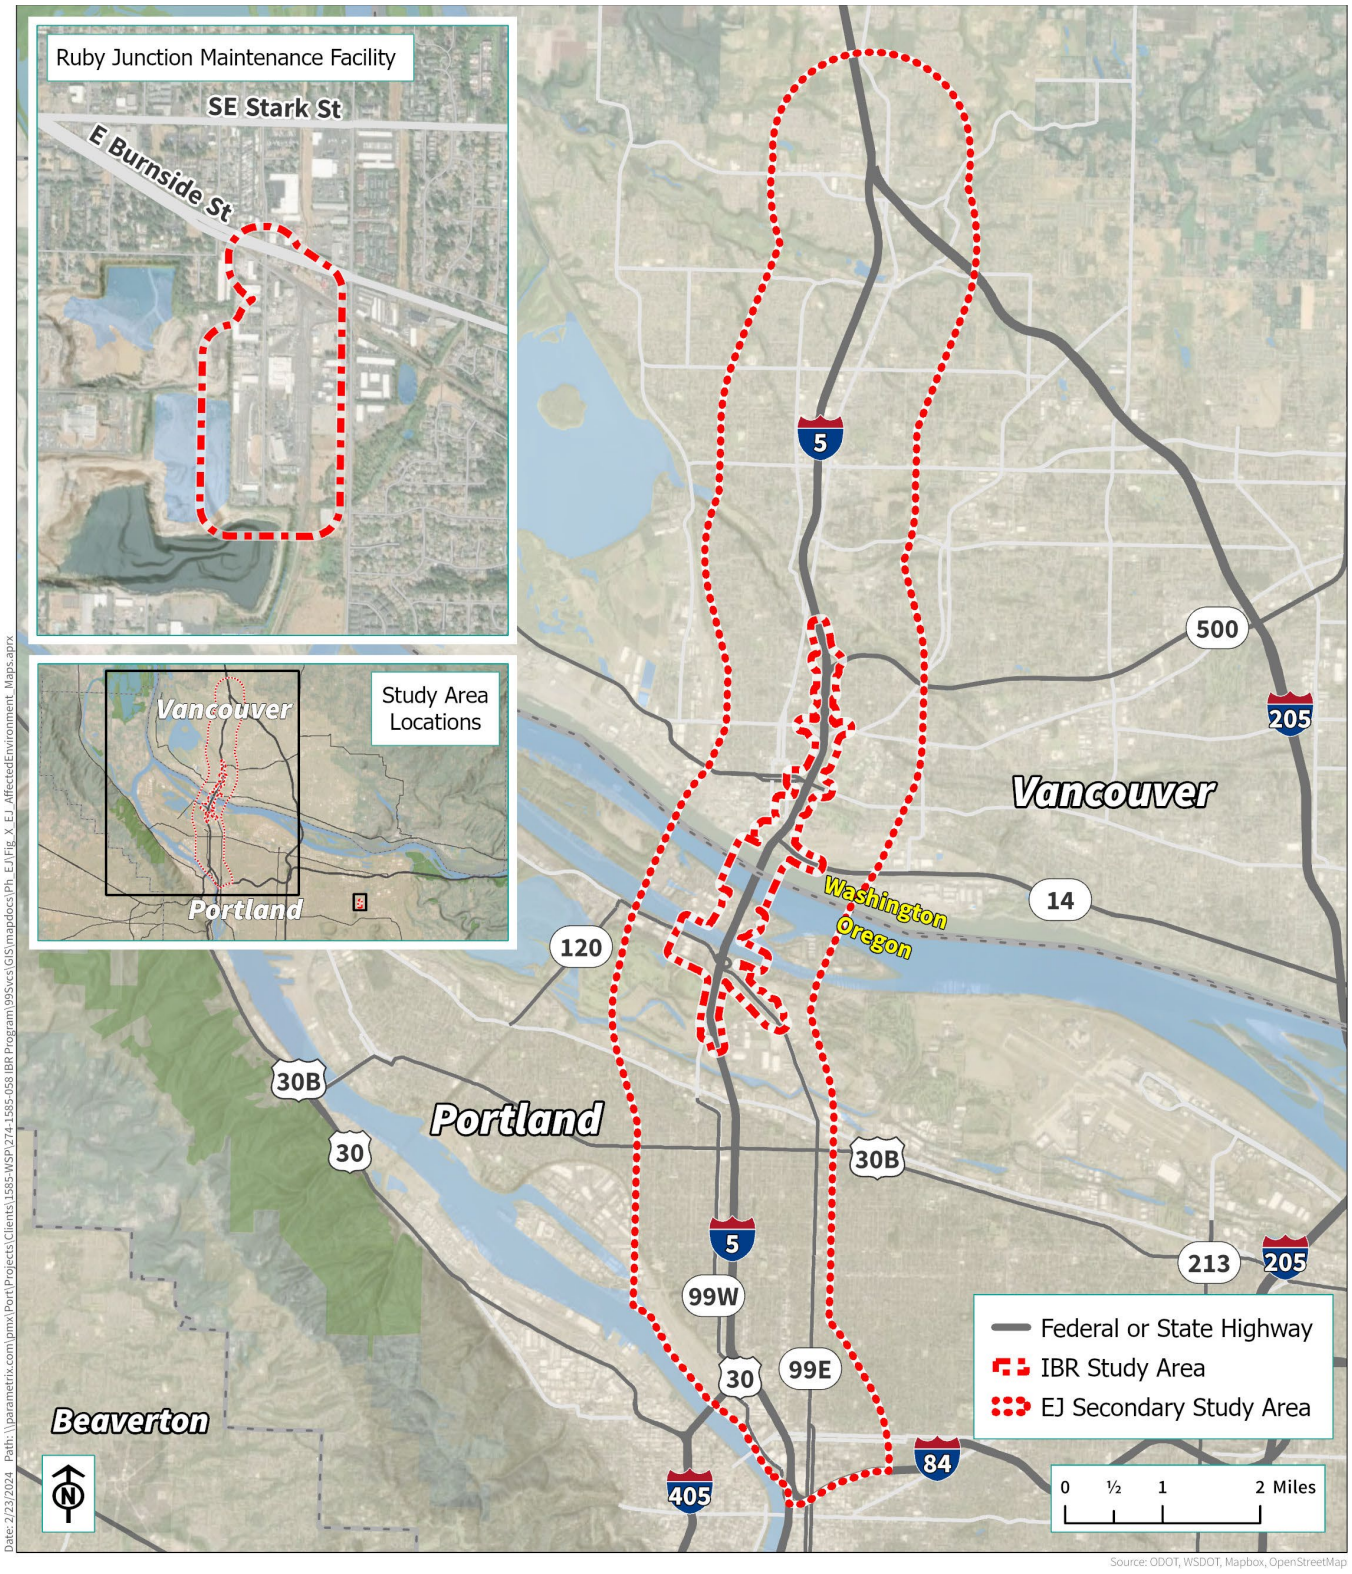

Table 3.20-4 summarizes minority populations in the study area by race and ethnicity (U.S. Census Bureau 2022). In the study area, white residents are the largest share of the total population (72.2%), followed by Hispanic or Latino (10.2%), Black or African American (6.7%), and two or more races (5.8%).

Within the study area, Portland's population is somewhat more racially diverse than Vancouver's. Compared to Vancouver, Portland study area block groups have a higher percentage of Black or African American, American Indian and Alaska Native, and Asian populations. However, Vancouver study area block groups have a higher percentage of Native Hawaiian and other Pacific Islander, two or more races, and Hispanic or Latino populations.

Table 3.20-4. Minority Populations in the Study Area by Race and Ethnicity (Portland and Vancouver)

Study Area	White Alone (Race)	Black or African American Alone (Race)	American Indian and Alaska Native Alone (Race)	Asian Alone (Race)	Native Hawaiian and Other Pacific Islander Alone (Race)	Some Other Race Alone (Race)	Two or More Races	Hispanic or Latino (Ethnicity)	Non-White Total
Portland Block Groups	69.0%	11.2%	0.8%	4.4%	0.3%	0.5%	5.7%	8.1%	31.0%
Vancouver Block Groups	75.0%	2.6%	0.5%	2.8%	0.6%	0.3%	5.9%	12.2%	25.0%
Study Area Total	**72.2%**	**6.7%**	**0.7%**	**3.6%**	**0.5%**	**0.4%**	**5.8%**	**10.2%**	**27.8%**

Low-Income Populations

EJ analysis conducted for the IBR Program defines low-income populations consistent with FHWA EJ guidance and the definition established in USDOT Order 5610.2C, which states that a low-income person is an individual whose median household income is at or below the U.S. Department of Health and Human Services poverty guidelines (USDOT 2021). As of 2022, the poverty guideline for a household of four persons is $27,750. The guidelines set by the U.S. Department of Health and Human Services are national and do not reflect distinct state and local economic realities; therefore, special attention must be paid to state and local thresholds.

FHWA allows localities to adapt poverty thresholds to local standards per the FHWA Environmental Justice Reference Guide (FHWA 2015). Regional agencies, such as TriMet and Metro, accept the regional poverty threshold to be 200% of the federal poverty level to reflect regional living costs and standards (Metro 2015; TriMet 2019). Under these regionally accepted standards, a household of four persons making $55,500 or less would be considered low-income in 2022, as shown in Table 3.20-6. Therefore, a four-person household was selected as the basis for determining the low-income poverty threshold, consistent with regional best practices.

Table 3.20-6. Low-Income Populations as Defined for the IBR Program Environmental Justice Analysis

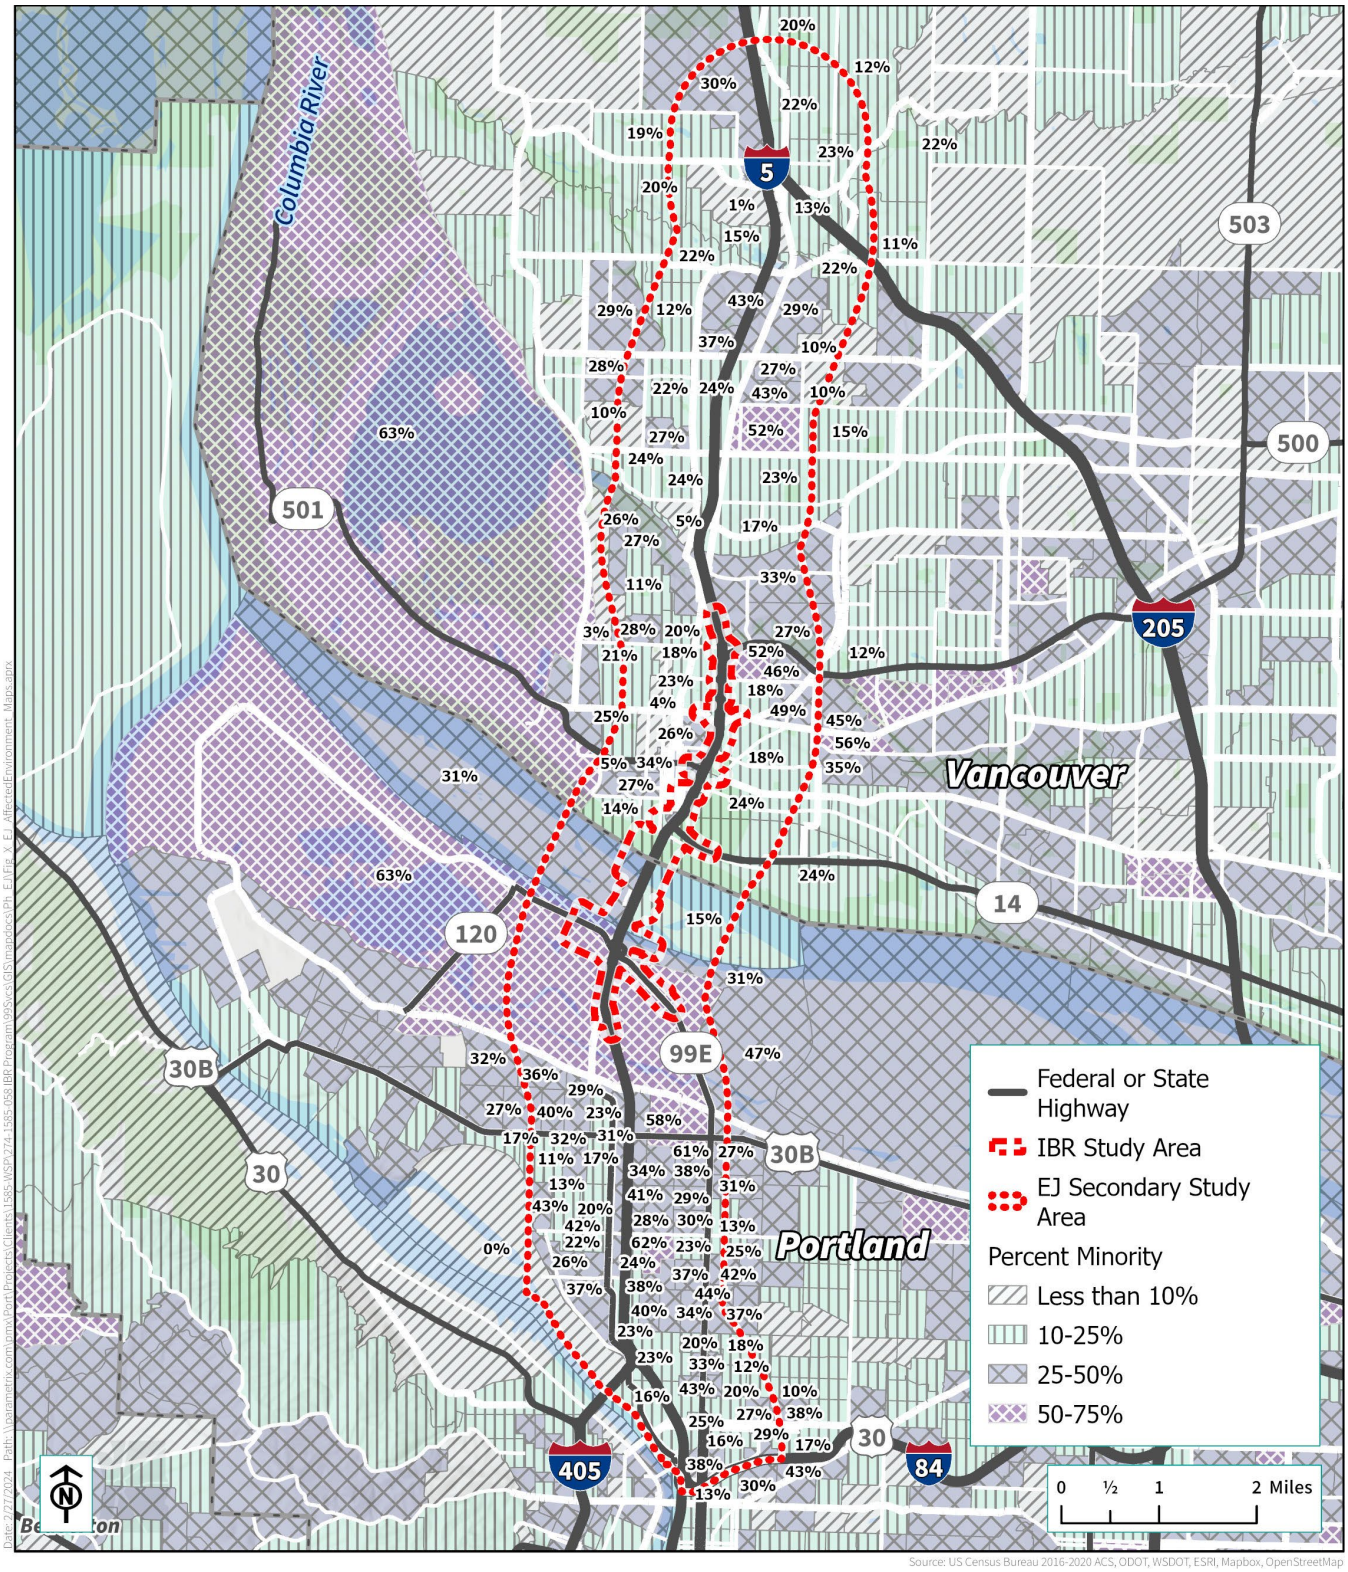
Low-Income Guideline	Household of Four	Individual
Federal Poverty Level	$27,750	$13,590
Low-Income (200% of Federal Poverty Level)	$55,500	$27,180

Source: U.S. Department of Health and Human Services Poverty Guidelines (HHS 2021).

Table 3.20-7 summarizes low-income populations in U.S. Census block groups within Portland and Vancouver (U.S. Census Bureau 2022). For the purposes of this EJ analysis, low-income populations also refer to an identifiable group of low-income persons, including houseless individuals and families in the study area.[3]

[3] The EJ analysis discusses low-income and minority populations and acknowledges that other communities, such as houseless populations or limited-English proficiency populations, may also belong to the EJ population. The equity analysis discusses populations not explicitly referenced in EO 12898; see Section 3.5 Neighborhoods and Equity, for additional analysis of equity populations.

Figure 3.20-2. Percent Minority by Block Group in the IBR Study Area



Within the study area, 25.8% of the population are low-income, approximately 32,000 people. Vancouver study area block groups have a higher percentage of low-income populations (27.1%) than Portland study area block groups (24.3%), which is comparable to the Portland-Vancouver region as a whole (23.7%).

Table 3.20-7. Low-Income Populations in the Study Area (Portland and Vancouver)

Study Area	Low-Income Population (200% of Federal Poverty Level)	Percent Low-Income
Portland Block Groups	14,269	24.3%
Vancouver Block Groups	17,592	27.1%
Study Area Total	**31,861**	**25.8%**

Source: ACS 5-Year Estimates, 2016–2020, Table C17002 (U.S. Census Bureau 2022).

Table 3.20-8 summarizes low-income populations in U.S. Census block groups within Gresham (U.S. Census Bureau 2022).

Table 3.20-8. Low-Income Populations in the Study Area (Gresham)

Study Area	Low-Income Population (200% of Federal Poverty Level)	Percent Low-Income
Gresham Block Groups (Rockwood)	14,269	49.6%

Source: American Community Survey 5-Year Estimates, 2016–2020, Table C17002(U.S. Census Bureau 2022).

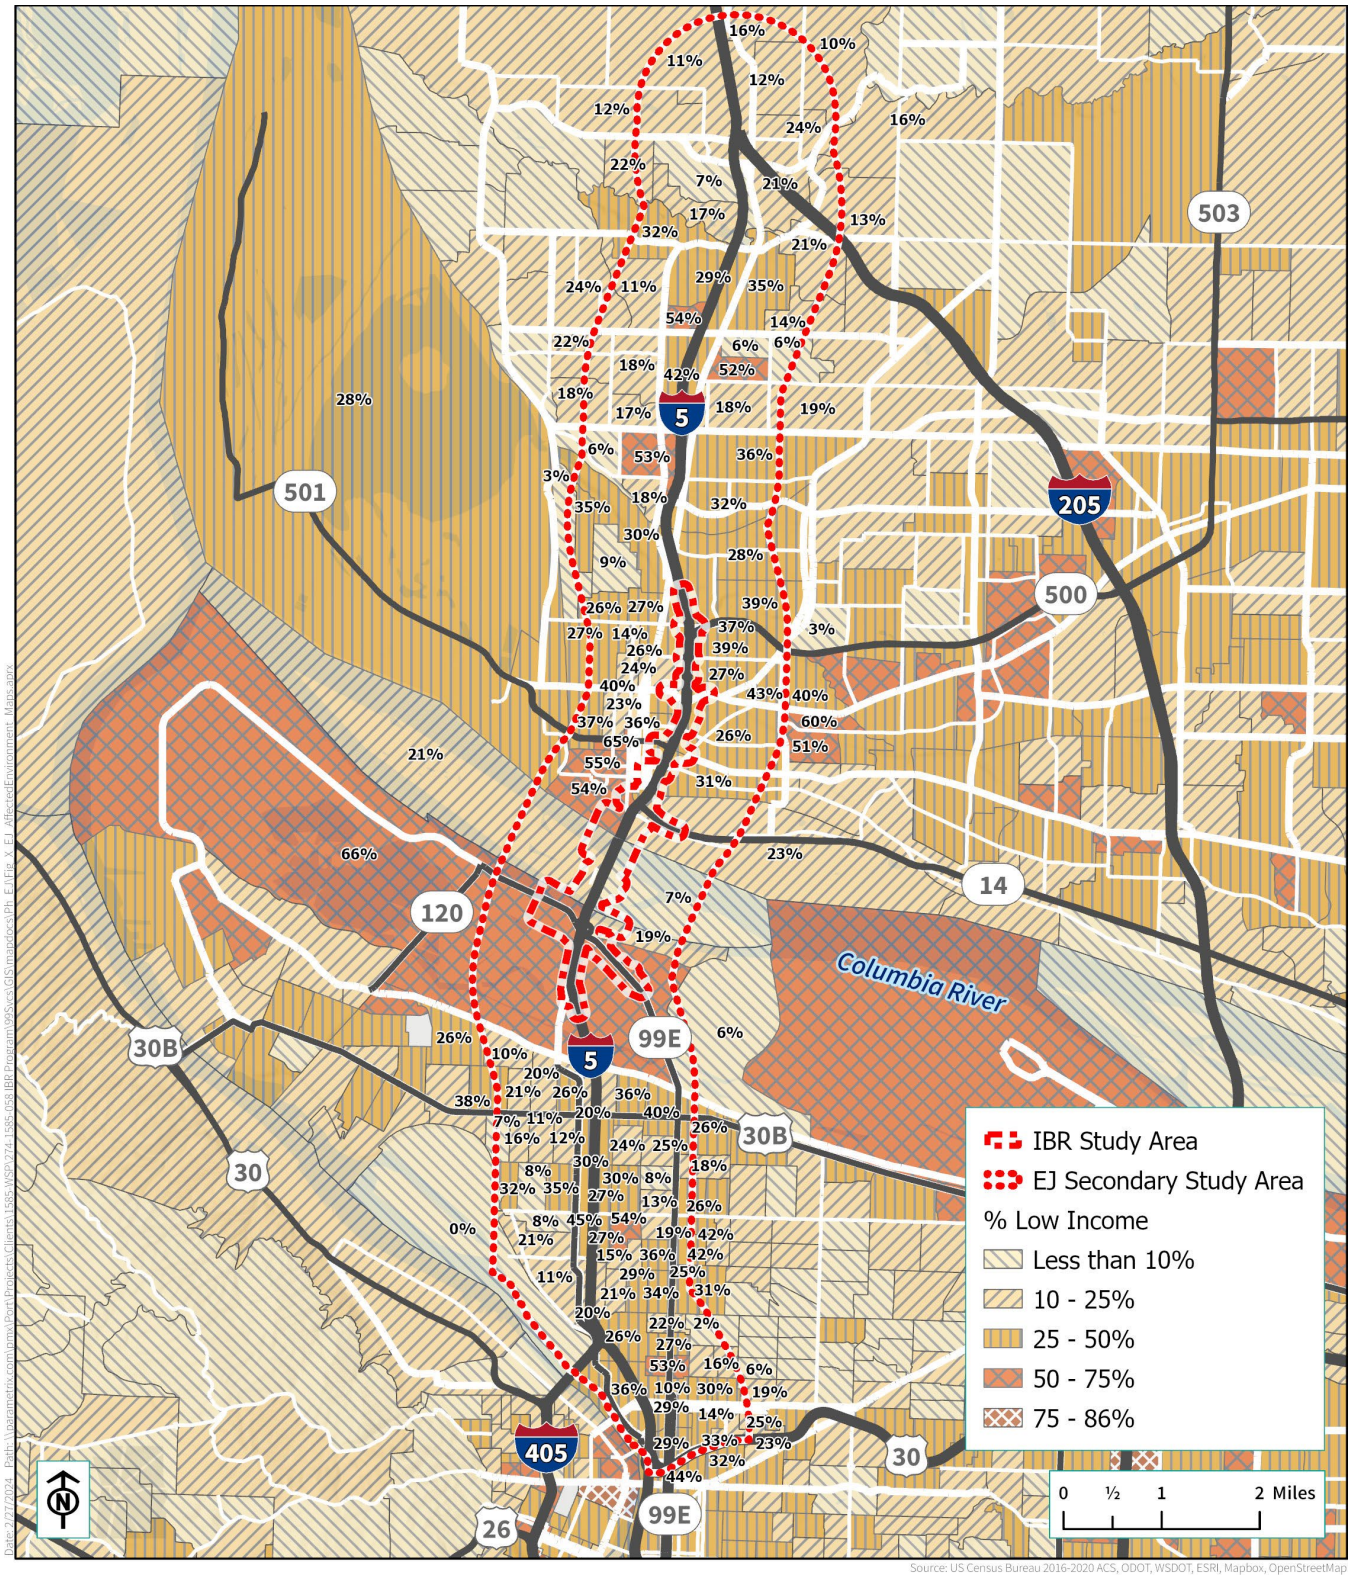
Figure 3.20-3 maps low-income populations within the study area by U.S. Census block group.

Meaningfully Greater and High-Priority EJ Areas

Building from the identification of all EJ populations based on the no-threshold analysis described above, additional analysis was conducted to identify concentrations of minority and low-income populations within the study area. Areas with higher concentrations of EJ populations provided a reference for where additional analysis and outreach may be needed as part of the IBR Program.

A "meaningfully greater" analysis methodology was used to identify higher concentrations of EJ populations relative to the general population. As with the no-threshold technique, this analysis technique is sourced from *Promising Practices for EJ Methodologies in NEPA Reviews* (EJ IWG 2016). The analysis considers EJ impacts in census block groups where levels of low-income or minority populations are meaningfully greater than corresponding county or regional averages—usually expressed in percentage ranges.

Figure 3.20-3. Percent Low-Income by Block Group in the IBR Study Area



Per the guidance set forth in the EJ methodology report, meaningfully greater analysis uses reasonable, subjective thresholds (e.g., 10% to 20% greater than the reference community) (EJ IWG 2016). For the purposes of this EJ analysis, low-income and minority populations 1.5 times greater than the corresponding average for the Portland-Vancouver region are considered meaningfully greater. Low-income and minority populations 2 times greater than the average for the Portland-Vancouver region are considered high-priority EJ areas[4] for the purposes of this project. Furthermore, block groups where minority or low-income populations made up 50% or more of the population were also considered high-priority EJ areas.[5]

Evaluating Effects on EJ Populations

It is important to note that, while meaningfully greater and high-priority EJ areas were used as tools to help identify higher concentrations of EJ populations relative to regional averages, these thresholds were not used as the analytical or legal basis for determining whether an environmental effect is disproportionately high and adverse. Per USDOT Order 5610.2c., determination of a "disproportionately high and adverse effect" depends on whether that effect is (1) predominantly borne by an EJ population, or (2) will be suffered by the EJ population and is appreciably more severe or greater in magnitude than the adverse effect that will be suffered by the non-EJ population.

EJ analysis conducted for the IBR Program defines low-income populations consistent with FHWA EJ guidance and the definition established in USDOT Order 5610.2C, which states that a low-income person is an individual whose median household income is at or below the U.S. Department of Health and Human Services (HHS) poverty guidelines (USDOT 2021). As of 2022, the poverty guideline for a household of four persons is $27,750. The guidelines set by HHS are national and do not reflect distinct state and local economic conditions; therefore, special attention must be paid to state and local thresholds.

The FHWA allows localities to adapt poverty thresholds to local standards per the FHWA Environmental Justice Reference Guide (FHWA 2015). Regional agencies, such as the Tri-County Metropolitan Transportation District (TriMet) and Metro, consider the regional poverty threshold to be 200% of the federal poverty level to reflect regional living costs and standards (Metro 2015; TriMet 2019). Under these regionally accepted standards, a household of four persons making $55,500 or less would be considered low-income in 2022, as shown in Table 3.20-6.[6]

The purpose of identifying meaningfully greater and high-priority EJ areas is to provide a baseline reference for the relative concentration of where minority and low-income populations exist, and where disproportionately high and adverse effects could exist. Determination of meaningfully greater and high-priority EJ areas also provides a reference for where there could be a need for additional outreach and

[4] The meaningfully greater thresholds of 1.5 and 2 times the corresponding county or regional average were selected given the regional significance of the IBR Program, such that the determination of meaningfully greater and high-priority EJ areas was relative to the broader region. These specific thresholds were also used in the Southwest Corridor Light Rail Environmental Impact Statement, another regionally significant program (FTA 2022).

[5] For the purposes of this project, the 1.5 and 2 times thresholds were developed based on an interpretation of the FHWA Environmental Justice Reference Guide that allows localities to adapt poverty thresholds to appropriate local standards (FHWA 2015). As described in the Defining Environmental Justice Populations section, TriMet and Metro accept the regional poverty threshold to be 200% of the federal poverty level to better reflect regional living costs and standards (Metro 2015; TriMet 2019). Meaningfully greater block groups indicate areas that are substantially impoverished relative to the Portland-Vancouver region—150%, or 1.5 times, below the "low-income" threshold established for the project. Block groups 200% or 2 times below are essentially the lowest-income block groups in the region. The same multipliers were applied to minority populations. Understanding these regional disparities served as one critical component for understanding the potential for disproportionately high and adverse impacts as part of the IBR Program.

[6] The average size of household in the Portland-Vancouver region is approximately 2.5 residents. Household sizes of one and four were reported based on other recently completed NEPA EJ analyses that have been performed in the region. For the purposes of this analysis, the federal poverty guideline for a four-person household is used.

analysis as part of the IBR Program. However, the determination of meaningfully greater and high-priority EJ areas was not used as the analytical or legal basis for determining disproportionately high and adverse effects on EJ populations (see *"Evaluating Effects on EJ Populations"* above).

As discussed above, low-income and minority populations 1.5 times greater than the corresponding regional average are considered meaningfully greater, and low-income and minority populations with 2 times the average are considered high-priority areas in the EJ analysis. Table 3.20-9 defines these values for the Portland-Vancouver-Hillsboro metropolitan area as defined by the U.S. Census.

Table 3.20-9. High-Priority and Meaningfully Greater Reference Values for EJ Areas

Reference Value	Low-Income (200% of Federal Poverty Level)	Minority
Portland-Vancouver-Hillsboro Metropolitan Average	23.7 %	27.6%
Meaningfully Greater (1.5 times)	41.4%	35.6%
High-Priority (2 times)	55.2%	47.4%

For the purposes of this discussion, meaningfully greater and high-priority EJ areas are described according to the neighborhoods within which they are located. The study area includes 43 neighborhoods, 19 of which are in Portland, 23 in Vancouver, and one in Gresham. Of these 43 neighborhoods, 10 contain meaningfully greater or high-priority percentages of EJ populations (either low-income or minority populations). Two of these neighborhoods are in Portland, one is in Gresham, and the remaining seven are in Vancouver.

The percentage of minority residents in the study area (27.8%) is higher than in the Portland-Vancouver region (23.7%). Both Portland and Vancouver neighborhoods in the study area have a higher percentage of low-income populations than the Portland-Vancouver region as a whole (23.7%).

Figure 3.20-4 displays neighborhood boundaries within the study area. Figure 3.20-5 shows meaningfully greater and high-priority low-income block groups in the context of neighborhood boundaries. Figure 3.20-6 shows meaningfully greater and high-priority minority block groups in the context of neighborhood boundaries.

3.20.3 Engagement Activities

23 CFR 771.111 requires the provision of public involvement opportunities and meaningful access to public information for minority populations and low-income households. Per FHWA and FTA guidance on Environmental Justice and NEPA, EJ documentation should include a discussion of major proactive efforts to ensure meaningful opportunities for public participation, including activities to increase low-income and minority participation. Public engagement information should also include affected populations' perception of the project and steps to resolve potential controversy. Additionally, EJ documentation should describe the degree to which affected minority and/or low-income populations have been involved in decision-making related to project alternatives, impacts, and mitigation.

The IBR Program team is engaged in an ongoing public outreach campaign that offers a wide range of opportunities for public involvement throughout the environmental review process. Meaningful public involvement in the IBR Program has included forming four advisory groups: the Community Advisory Group, Equity Advisory Group, Community Benefits Advisory Group, and Executive Steering Group. The advisory groups are composed of regional community members who were identified and appointed to represent a diverse range of perspectives, including EJ populations, as well as representatives from local agencies and

community-at-large members. The IBR Program has been engaging with partner agencies, tribal governments, and community-based organizations since late 2020 and has been conducting more formal intentional community engagement since January 2021. This process is documented in Section 2.5 of the Environmental Justice Technical Report, as well as in the IBR Community Engagement Report (IBR 2021) and Appendix B, Public Involvement, of this Draft SEIS.

The IBR Program is consulting with 10 federally recognized Indian tribes. Federally recognized tribes are sovereign nations as recognized by the U.S. Government, and consultation with federally recognized tribes occurs through a government-to-government consultation process separate and distinct from public and community outreach and comment. The government-to-government consultation goals and process are documented in Appendix A, Agency and Tribal Coordination. Additional discussion of federally recognized tribes is included in 3.5, Neighborhoods and Equity.

3.20.4 Long-Term Effects

In general, long-term impacts of the IBR Program were determined by evaluating the location and intensity of environmental impacts that would occur during operation of the Modified LPA in areas where EJ populations have been identified. In particular, the EJ analysis assessed whether impacts to EJ populations would be disproportionately high and adverse compared to the general population. The impact analysis included impacts derived from several IBR Program technical reports: Acquisitions and Displacements, Neighborhoods and Populations, Land Use, Economics, Visual Resources, Air Quality, Noise and Vibration, and Transportation.

All environmental resource topics were reviewed in coordination with subject matter experts to assess whether the effects identified for those resources under the Modified LPA had the potential to be predominantly borne by EJ populations or could be suffered by an EJ population in a manner appreciably more severe or greater in magnitude than the non-EJ population. Environmental resource topics with the potential to result in a disproportionately high and adverse effect on EJ populations under the Modified LPA became the focus of the EJ analysis and were studied further. Environmental resources that would not or were unlikely to result in disproportionately high and adverse effects under the Modified LPA were not studied further.

Table 3.20-10 summarizes all IBR environmental resource topics and indicates the relevant topics for the EJ analysis.

Figure 3.20-4. Neighborhoods in the IBR Study Area

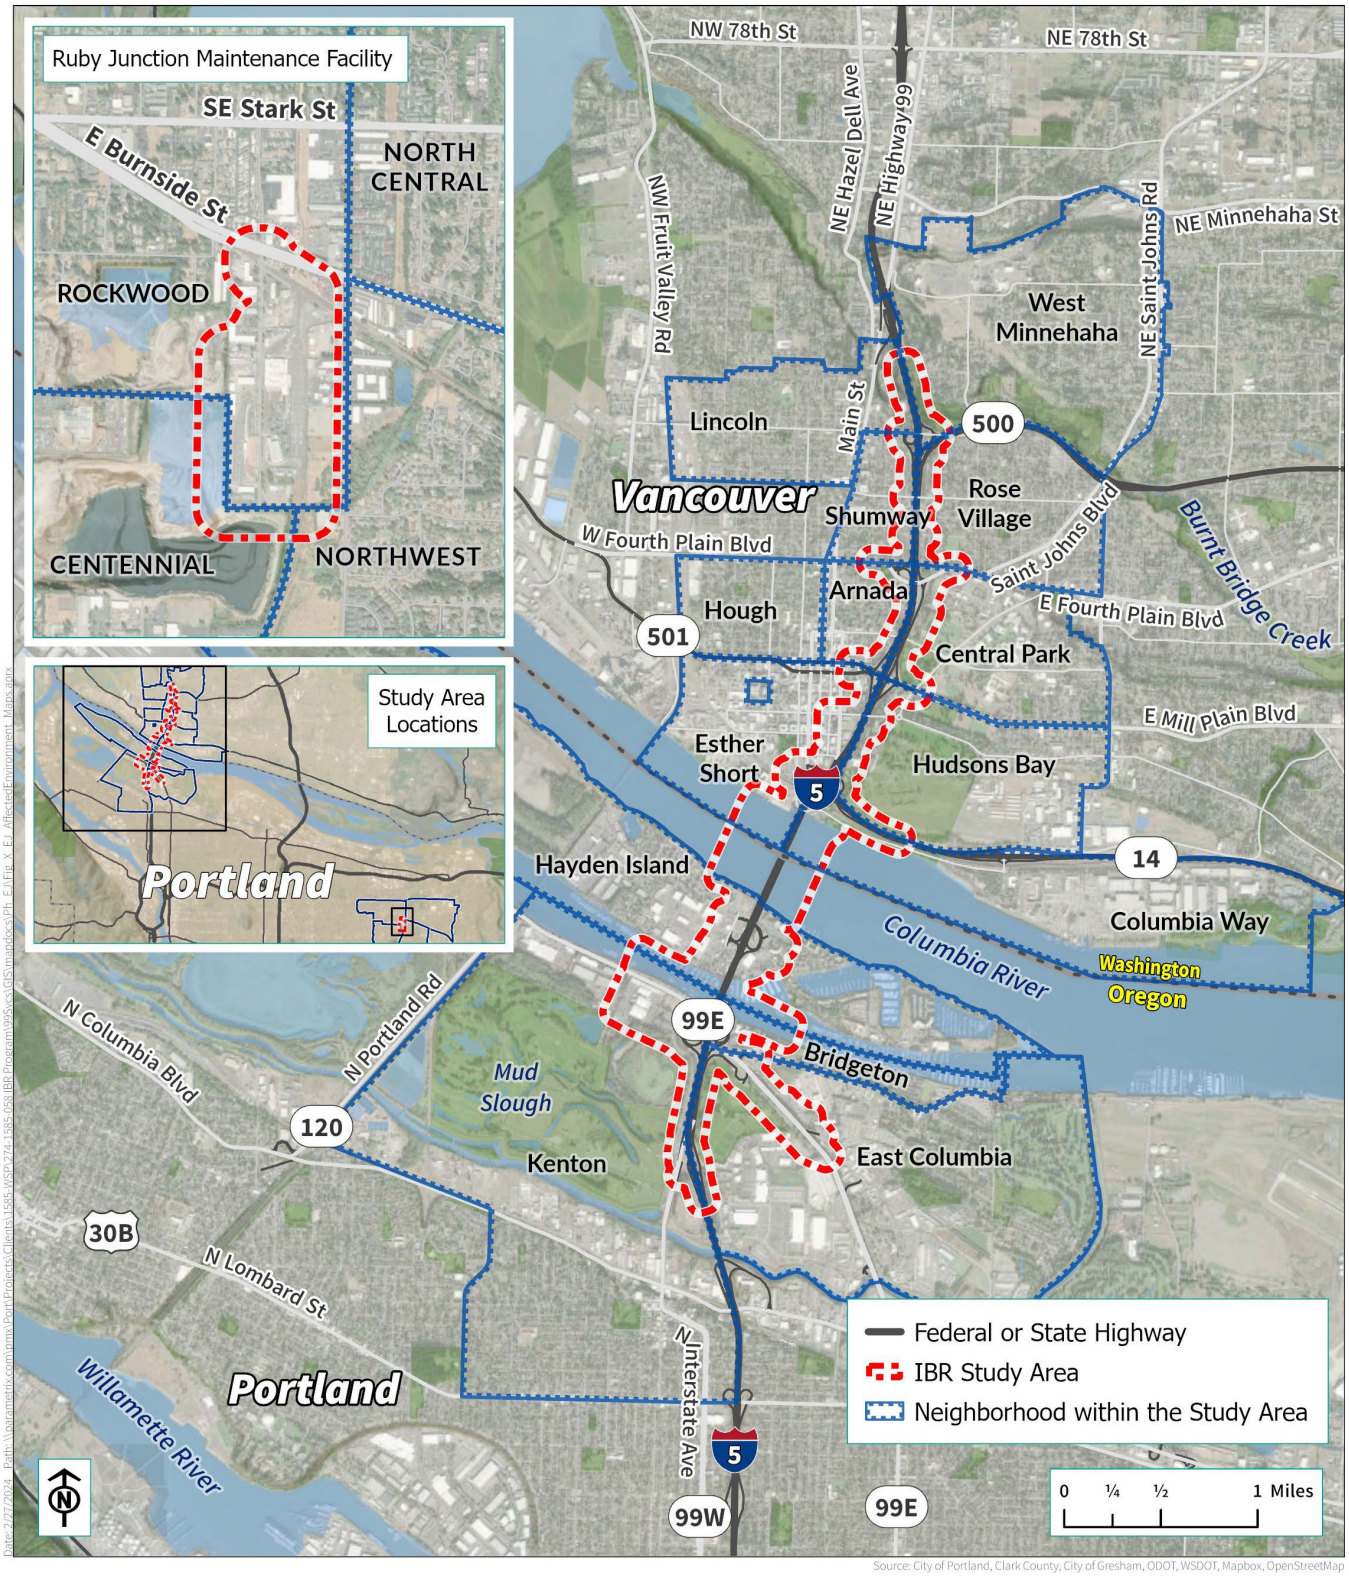


Figure 3.20-5. Meaningfully Greater and High-Priority Minority Block Groups and Study Area Neighborhoods

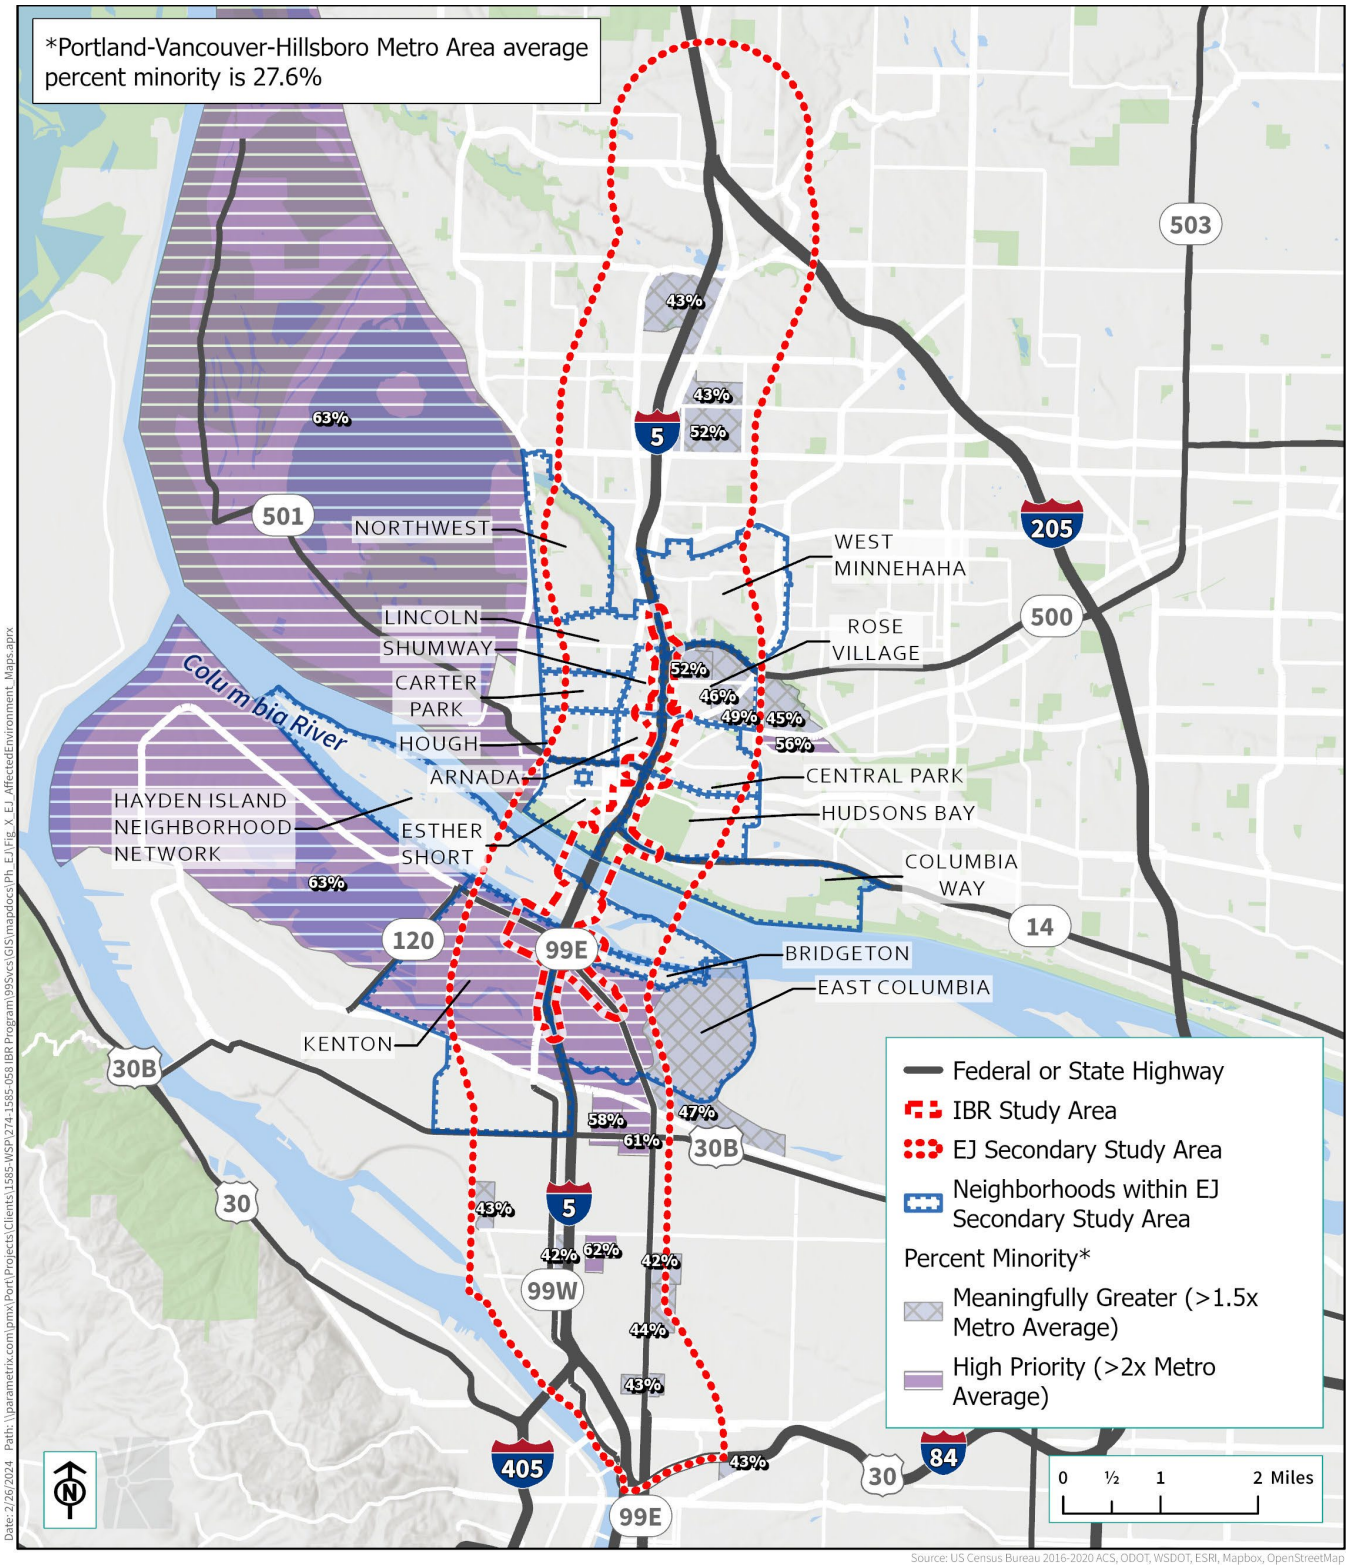

Figure 3.20-6. Meaningfully Greater and High-Priority Low-Income Block Groups and Study Area Neighborhoods

Table 3.20-10. IBR Environmental Resource Topics – Potential Impacts to Environmental Justice Populations

Environmental Resource Topic	IBR Reference	Potential Impact to EJ Populations?
Acquisitions, Displacements, and Relocations	Acquisitions Technical Report	Yes.
Air Quality	Air Quality Technical Report	Yes.
Archaeology	Archaeological Resources Technical Report	Yes.
Aviation	Aviation Technical Report	No; effects evaluated were limited to protected airspace and air navigation hazards.
Climate	Climate Technical Report	No; this is a larger-scale analysis of greenhouse gas emissions and climate resiliency that is not scalable to EJ population areas.
Economics	Economics Technical Report	Yes.
Ecosystems	Ecosystems Technical Report	No; this analysis evaluated effects to fish, wildlife and plants.
Energy	Energy Technical Report	No; this is a larger-scale analysis of energy usage that is not scalable to EJ population areas.
Electromagnetic Fields	Electromagnetic Fields Technical Report	No; this is a larger-scale analysis of EMF that is not scalable to EJ population areas.
Geologic Hazards	Geology and Groundwater Technical Report	No; this is a larger-scale analysis of geological hazards that is not scalable to EJ population areas.
Hazardous Materials	Hazardous Materials Technical Report	No; effects evaluated were site specific, whereas EJ population areas were evaluated at a neighborhood level.
Historic Resources	Historic Built Environment Technical Report	No; this analysis evaluated historic resources within the context of historical significance under the National Historic Preservation Act Section 106.
Land Use	Land Use Technical Report	Yes.
Noise and Vibration	Noise and Vibration Technical Report	Yes.
Social and Neighborhood Effects	Neighborhoods and Populations Technical Report	Yes.
Public Services	Public Services Technical Report	No; this analysis evaluated effects limited to public services without decreases in services to general and EJ populations.
Transportation	Transportation Technical Report	Yes.

Environmental Resource Topic	IBR Reference	Potential Impact to EJ Populations?
Tolling	Economics Technical Report	Yes.
Utilities	Utilities Technical Report	No; this analysis evaluated effects limited to utilities and potential utility relocations without impacts to service.
Visual Resources	Visual Quality Technical Report	Yes.
Water Quality and Hydrology	Water Quality and Hydrology Technical Report	No; this is a larger-scale analysis of water quality, and proposed changes would result in benefits to general and EJ populations.
Wetlands and Jurisdictional Waters	Wetlands and Other Waters Technical Report	No; this analysis evaluated wetlands and jurisdictional waters within the context of Clean Water Act Sections 401 and 404, as well as applicable state and local regulations.

EJ = environmental justice; EMF = electromagnetic field

The long-term impact assessment methods for each of the environmental topics relevant to the EJ analysis are summarized below.

- **Acquisitions and displacements.** The EJ analysis reviewed proposed property acquisitions and displacements within census block groups[7] and neighborhoods in the study area to determine impacts to EJ populations. The analysis reviewed the concentration of EJ populations compared with identified acquisitions and displacements to assess whether EJ populations within the study area would be disproportionately impacted by proposed acquisitions and displacements compared to the general population.
- **Air quality.** The EJ analysis reviewed changes to air quality resulting from the Modified LPA to determine whether EJ populations would be adversely and disproportionately impacted by airborne pollutants compared to the general population. The analysis was conducted for the study area and region and reviewed the six criteria pollutants regulated by the National Ambient Air Quality Standards, including carbon monoxide, lead (Pb), particulate matter (PM_{10} and $PM_{2.5}$), nitrogen dioxide (NO_2), ozone (O_3), and sulfur dioxide (SO_2).
- **Archaeology.** Investigations to determine the presence of archaeological resources within the study area are underway. If present, potential impacts to archaeological resources will be reviewed to determine if they would be culturally significant to EJ populations.
- **Land use and economics.** The EJ analysis evaluated the economic impact of the IBR Program to low-income and minority populations within the study area by reviewing several economic factors, such as the potential effects of business and employee displacements, changes to land uses in block groups with high concentrations of EJ populations, and the impact of tolling.
- **Noise and vibration.** Noise impacts were evaluated in block groups with high concentrations of EJ populations within the study area. The noise and vibration analysis used noise sample location data and noise modeling to compare existing and future noise and vibration levels. Adverse noise impacts were

[7] Block groups are statistical divisions of census tracts used by the U.S. Census Bureau, consisting of clusters of blocks within the same census tract. Block groups are generally defined to contain between 600 and 3,000 people and are used to present data and control block numbering.

evaluated to determine whether they would be predominantly borne by EJ populations within the study area as compared to the general population.

- **Social and neighborhood effects.** The EJ analysis evaluated community resource displacements and community cohesion impacts in block groups with high concentrations of EJ populations within the study area. The analysis evaluated whether adverse impacts to community resources or community cohesion caused by the IBR Program would be predominantly borne by EJ populations within the study area compared to the general population. The EJ analysis also considered potential impacts and access changes to facilities and services used by EJ populations, including healthcare centers, community facilities, and social service providers that serve low-income and minority populations.
- **Transportation.** The EJ analysis reviewed adverse transportation impacts resulting from implementation of the IBR Program. A range of impacts was considered, including construction-related and long-term changes to access, traffic impacts, public transportation impacts, and impacts to the nonmotorized transportation system. The analysis assessed whether these adverse transportation impacts would disproportionately burden block groups with high concentrations of EJ populations within the study area.
- **Tolling.** The EJ analysis assessed the potential impact of tolling on EJ populations. The analysis used two potential pricing scenarios currently being studied for the I-5 corridor—a typical commuter trip profile, and tolling prices as a percentage of median household income—to determine whether adverse tolling impacts would result in disproportionately high and adverse effects on EJ populations within the study area.
- **Visual resources**. The EJ analysis reviewed adverse impacts to views and visual resources to determine whether such impacts would disproportionately impact block groups with high concentrations of EJ populations.

The long-term impact assessment methods also accounted for potential benefits the IBR Program could bring to EJ communities, such as improved seismic resilience, multimodal access, and accessibility upgrades within the study area.

Table 3.20-11 summarizes the effects of the No-Build Alternative, Modified LPA, and design options on environmental justice. Detailed analysis of the effects is provided in the following sections.

No-Build Alternative

The No-Build Alternative would not displace residents, businesses, community resources, or jobs for any populations, including EJ populations. Travel times would increase by approximately 50% compared to existing times for drivers traveling within the I-5 corridor. This increase in travel times is not anticipated to impact EJ populations differently than the general population. The No-Build Alternative would not bring high-capacity transit to Hayden Island or downtown Vancouver, which would not be a benefit to EJ populations that may rely more on transit than the general population.

Modified LPA

Table 3.20-12 summarizes long-term impacts and benefits to EJ populations associated with the Modified LPA and all design options.

Table 3.20-11. Comparison of No-Build Alternative and Modified LPA Design Options

1 No-Build Alternative	2 Modified LPA With Double-Deck Fixed-Span Configuration, One or Two Auxiliary Lanes, with or without C Street Ramps, Centered I-5, all Park-and-Ride Site Options	3 Modified LPA Double-Deck Fixed-Span Configuration, One Auxiliary Lane, C Street Ramps, I-5 Westward Shift, all Park-and-Ride Site Options	4 Modified LPA Single-Level Fixed-Span Configuration, [a] One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options	5 Modified LPA Single-Level Movable-Span Configuration, One Auxiliary Lane, C Street Ramps, Centered I-5, all Park-and-Ride Site Options
• No displacement of residents, businesses, community resources, or jobs. • Travel times would increase by approximately 50% compared to existing times. Would not bring high-capacity transit to Hayden Island or downtown Vancouver. • Environmental conditions under the No-Build Alternative would affect EJ populations the same as the general population. Therefore, no disproportionately high and adverse effects have been identified.	• Increased access to high-capacity transit and active transportation, and reductions in vehicle travel time. Impacts to EJ populations would be the same as to the general public. • Increase in job access due to faster travel times. Because faster times would result from tolling, tolling would result in disproportionately high and adverse effects on EJ populations. • Residential and business displacements. Displacements in high-priority and meaningfully greater EJ areas such as the Esther Short neighborhood in Vancouver and the Rockwood neighborhood in Gresham would result in disproportionately high	• Similar to Column 2, but would increase residential and business displacements. Additional displacement of the Normandy Apartments in the Esther Short neighborhood as a result of the I-5 westward shift would result in disproportionately high and adverse effects on EJ populations.	• Similar to Column 2, except shared-use path users would have more exposure to noise, but would also have a shorter distance to climb and would be more visible and therefore feel safer. Noise and visual impacts to EJ populations would be the same as to the general population.	• Similar to Column 2, except bridge openings could delay transit and active transportation users. • Delays to transit and active transportation users as a result of bridge openings could also contribute to adverse effects on EJ populations. These effects would be the same for EJ populations as for the general population.

1	2	3	4	5
	and adverse effects on EJ populations. • Increased traffic and noise impacts from construction. Impacts to EJ populations would be the same as to the general public. • Improved air quality. Benefits to EJ populations would be the same as to the general public. • Some adverse impacts to community cohesion. Impacts to EJ populations would be the same as to the general public.			

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge types, unless otherwise specified.

A preliminary determination has been made based on the current assessment of environmental impacts, benefits, and mitigation strategies under the No-Build Alternative, as described in Table 3.20-11, above. Given that increased travel times under the No-Build Alternative would affect EJ populations the same as the general population, and given that all other environmental conditions would remain the same as of this writing, the No-Build Alternative would not result in a disproportionately high and adverse effect on EJ populations within the IBR study area. The remainder of this analysis, therefore, focuses on the effects of the Modified LPA on EJ populations, with a preliminary determination for the Modified LPA presented in Section 3.20.8.

Table 3.20-12. Summary of Potential Long-Term Effects from the Modified LPA on Environmental Justice Populations [a,b]

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
Acquisitions, Displacements, and Relocations	Full acquisition of 46 properties and partial acquisition of 132 properties, resulting in 43 residential displacements and 36 business displacements. **Oregon Neighborhoods**	The Modified LPA would acquire properties and displace residences and businesses in the identified high-priority and meaningfully greater EJ areas. **Oregon Neighborhoods** • East Columbia: 11 partial acquisitions of East Delta Park; no residential or business	None.

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	• 68 total acquisitions (25 full acquisitions, 43 partial acquisitions). • 36 residential displacements. • 26 business displacements. Residential displacements would occur in the Kenton and Hayden Island neighborhoods. Business displacements would occur in the Bridgeton, Kenton, Hayden Island, and Rockwood neighborhoods. Additional partial acquisitions from East Delta Park would occur in the East Columbia neighborhood. No residential or business displacements would occur in the East Columbia neighborhood. **Washington Neighborhoods** • 110 total acquisitions (21 full acquisitions, 89 partial acquisitions). • 7 residential displacements. • 10 business displacements. • I-5 westward shift design option: 33 additional residential displacements and 3 business displacements. Residential displacements would occur in the Esther Short and Shumway neighborhoods, and business displacements would occur in the Esther Short neighborhood, a high-priority EJ area. Additional acquisitions would occur at Marshall Park in the Central Park neighborhood (partial), Columbia Way (partial), Hudson's Bay (temporary), Lincoln (partial), and Rose Village (partial); none of these acquisitions would result in business or residential displacements. • **I-5 Westward Shift Design Option:** One design option would shift the I-5 mainline and ramps approximately 40 feet to the west between SR 14 and Mill Plain Boulevard. The impacts or	displacements; East Columbia is a meaningfully greater minority neighborhood. Partial acquisitions at East Delta Park within the East Columbia neighborhood would result in disproportionately high and adverse impacts to EJ populations. • Rockwood: 7 total acquisitions; 3 business displacements; Rockwood is a high-priority low-income and minority neighborhood. Rockwood acquisitions would result in disproportionately high and adverse impacts to EJ populations. **Washington Neighborhoods** • Esther Short: 27 total acquisitions; 10 business displacements; Esther Short is a high-priority low-income neighborhood. Esther Short acquisitions would result in disproportionately high and adverse impacts to EJ populations. • The design option that shifts I-5 westward would impact the Normandy Apartments, resulting in 33 additional residential displacements in Esther Short. Normandy Apartments displacements would result in disproportionately high and adverse impacts to EJ populations. • Rose Village: 8 total acquisitions; no displacements; Rose Village is a meaningfully greater low-income and minority neighborhood. Rose Village acquisitions would result in disproportionately high and adverse impacts to EJ populations. • **I-5 Westward Shift Design Option:** Although the Normandy Apartments are not identified by the U.S. Department of Housing and Urban Development as a low-income housing tax credit property (HUD n.d.), the 33 residential	

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	benefits to EJ populations associated with this design option would be similar to those described for the centered I-5 mainline, with two additional property acquisitions: – Normandy Apartments, where 33 residential units would be displaced. – Regal City Center complex, where 3 businesses would be displaced.	displacements would occur within the Esther Short neighborhood, a high-priority EJ area for low-income populations. As described above, Normandy Apartments and Esther Short acquisitions would result in disproportionately high and adverse impacts to EJ populations.	
Air Quality	Emissions for all Mobile Source Air Toxics and criteria pollutants are expected to be substantially lower than existing emissions, and the study area would remain in attainment for National Ambient Air Quality Standards.	No disproportionately high and adverse effects to EJ populations have been identified.	Improved air quality compared to existing conditions for all people, including EJ populations.
Land Use and Economics	• Permanent conversion of approximately 39 acres to transportation use (not inclusive of temporary construction staging). This land conversion would comprise a small portion of the total land in the Portland/Vancouver area and would not be substantial in a regional context. Converted land would be used for the extension of high-capacity transit, park-and-ride structures, and other transportation infrastructure, consistent with the goals and policies of adopted plans. • Business/employee displacements are anticipated to reduce tax revenues in Multnomah County and Clark County by approximately 0.2% and 0.3% to 0.4%, respectively. • The Modified LPA's direct impacts to Hayden Island, and, to a lesser extent, Vancouver, could have a substantial effect on wage earning opportunities for those seeking service industry employment. Some displaced businesses may	Although Hayden Island is not a meaningfully greater or high-priority EJ area, impacts to service industry workers and the conversion of property could impact low-income and minority workers in the study area. However, these land use and economic impacts would impact EJ populations the same as the general population, so no disproportionately high and adverse effects have been identified.	Increased jobs and economic development opportunities near the interstate and transit stations for all communities, including EJ populations.

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	choose to not relocate locally, and some employees would be displaced during construction.		
Noise and Vibration	**Oregon Neighborhoods** Increased noise levels (up to 10 dBA) at up to three sensitive receptors in Jantzen Beach RV Resort. This increase would remain below ODOT's Noise Abatement Criteria. No increase in vibration levels at Jantzen Beach RV Resort. **Washington Neighborhoods** Substantial noise impacts compared to No-Build are predicted to occur at up to six residences located between E 33rd Street and E 35th Street. No increase in vibration levels would occur at residences located between E 33rd Street and E 39th Street.	**Oregon Neighborhoods** None; Jantzen Beach RV Resort is not located in a meaningfully greater or high-priority EJ area, and impacts to EJ populations would be the same as to the general population. Therefore, no disproportionately high and adverse effects on EJ populations have been identified. **Washington Neighborhoods** The area between E 33rd Street and E 39th Street encompasses the Rose Village neighborhood—a meaningfully greater EJ area for both low-income and minority populations. The residences that would experience a substantial noise impact may include EJ populations. Therefore, noise impacts to the Rose Village neighborhood would result in a disproportionately high and adverse effect on EJ populations.	None.
Social and Neighborhood Effects	Impacts to cohesion could result from potential residential and business displacements and impacts to the visual landscape of neighborhoods. **Oregon Neighborhoods** • Displacements: Residential and/or business displacements would occur on Hayden Island, Bridgeton, Kenton, and Rockwood in Gresham. • No change to community resources. • Effects on cohesion: Adverse impacts to community cohesion have been identified on Hayden Island due to the high number of displacements within floating home communities.	**Oregon Neighborhoods** Social and neighborhood effects on EJ populations include displacements in the Rockwood neighborhood, a high-priority EJ area for both low-income and minority populations. These displacements would result in a disproportionately high and adverse effect on EJ populations. **Washington Neighborhoods** Social and neighborhood effects on EJ populations include displacements in the Esther Short neighborhood, a high-priority EJ area for low-income populations. These displacements would result in a disproportionately high and adverse effect on EJ populations.	Improved access, reliability, connectivity, and service frequency to transit for all communities, including EJ populations.

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	Washington Neighborhoods • Displacements: Residential and/or business displacements would occur in the Shumway and Esther Short neighborhoods. • Impacts to community resources: None identified. • Effects on cohesion: None identified.		
Tolling	Tolling on I-5, paired with other Program improvements such as increased transit and active transportation options, is expected to reduce travel times and improve travel reliability; however, tolls would result in higher transportation costs as a portion of household spending. Households in the region would expend an additional $1,600 per year on transportation, representing approximately 2% of median annual household income in the Portland-Vancouver metropolitan area. As described in this table under Transportation, the Modified LPA with all design options would not result in substantial diversion to I-205 as a result of tolling. Changes in vehicle volumes on I-205 on any of the studied screenline locations during the peak period range from -3% to +12% compared to the No-Build Alternative.	The cost of tolls on the Columbia River bridges would impact low-income populations disproportionately compared to the general population. Two of the toll price scenario schedules were used to study impacts to EJ populations, ranging from $2.15 to $3.55 (Scenario Schedule A) and $1.50 to $3.15 (Scenario Schedule B). For median-income households in Portland and Vancouver, the difference resulting from the new tolls would be relatively small for median-income households (a 2% increase from 14% to 16% of median annual household income in Portland and a 3% increase from 15% to 19% of annual household income in Vancouver). Four-member households at or below the federal poverty level would be the most significantly impacted by a future tolling program. Since these households already spend a relatively larger proportion of household income on transportation, the effect of tolling would increase household transportation costs from 29% of total household income under the No-Build Alternative to 35% under the Modified LPA. Tolling impacts to households at or below the federal poverty level constitute a disproportionately high and adverse effect on EJ populations.	Reduced travel times and improved travel reliability resulting, in part, from tolling would benefit all communities, including EJ populations.

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
		Low-income households would be impacted similarly to the general population and would experience an increase in household transportation cost of approximately 3%. Several tribes have preemptions[8] from tolling per treaties with the U.S. Government. For members of tribes with those preemptions, there would be no adverse effect from tolling. Several tribes consulting on IBR have requested exemption from tolling on the existing Interstate Bridge and future Columbia River bridges. The bi-state transportation committee made up of representatives of the Washington State and Oregon Transportation Commissions determines tolling exemptions or discounts and is considering a low-income toll program. In conclusion, tolling on the proposed Columbia River bridges would result in a disproportionately high and adverse effect on EJ populations.	
Transportation	The Modified LPA would reduce regional vehicle-miles traveled and provide the following changes by mode and facility type: • I-5 Highway: Key bottlenecks would be reduced along segments of I-5. The Oregon segment of I-5 northbound would meet ODOT's mobility performance standards during the AM peak. The Washington segment of I-5 southbound would meet WSDOT's mobility standards during the PM peak. • Diversion Impacts: AM and PM peak-hour screenline volumes within the study area were	Changes to local traffic circulation resulting from the Evergreen Station would occur in the Esther Short neighborhood, a high-priority EJ area. **Single-Level Movable-Span Configuration:** Disturbances to transit and active transportation resulting from bridge opening delays can negatively affect EJ populations. However, a disproportionately high and adverse effect on EJ populations is not anticipated (per FHWA and USDOT guidance), given that the impacts would be the same for all populations traveling through the study area.	The following would benefit all travelers, including EJ populations: • Reduction in bottleneck conditions for some I-5 segments during the AM and PM peaks. • Faster total travel time on I-5 between I-205 north of Vancouver and the Marquam Bridge in Portland.

[8] A preemption is an inherent right retained, while an exemption is granting freedom from an obligation.

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	analyzed using the regional travel demand model to determine the relative differences in traffic volumes between the No-Build Alternative and the Modified LPA. Generally, the Modified LPA would result in increased traffic on adjacent facilities compared to the No-Build Alternative. However, the increases would be relatively minor, ranging from approximately +4% to +12%. In Vancouver, most volume increases would divert to I-5 rather than to surrounding north-south facilities, reflecting greater capacity on I-5 during the peak period with the Modified LPA compared to the No-Build Alternative. In Portland, traffic diversion under the Modified LPA during both peak and off-peak times have differences of less than 50 vehicles compared to the No-Build Alternative. Compared to the No-Build Alternative, the Modified LPA with all design options would not see substantial changes in vehicle volumes on I-205 on any screenline location in the peak period (-3% to + 12%). Therefore, diversion impacts to I-205 are not anticipated to be substantial based on the analysis. • Freight Mobility and Access: Improved conditions on I-5 would similarly benefit freight and trucks. • Arterials and Local Streets Impacts would include changes to traffic circulation, property access, and traffic control, primarily around station areas. • Transit Impacts: Impacts would include extension of high-capacity transit and express bus across the Columbia River. Stations would accommodate connections with C-TRAN Vine, C-	**Design Option without C Street Ramps:** The removal of the C Street ramps would eliminate an access and egress point for downtown Vancouver and would shift between 300 and 600 vehicles per hour to the Mill Plain Boulevard ramps and roadways during the peak hours. This could cause additional traffic in Arnada, a neighborhood with a meaningfully greater concentration of low-income populations. However, impacts to EJ populations under this design option would be the same as for the general population. Therefore, no disproportionately high and adverse effect has been identified.	• Transit, active transportation, and safety enhancements associated with the Evergreen high-capacity transit station, and the Community Connector pedestrian bridge over I-5 near Evergreen Boulevard, would benefit EJ populations in Esther Short neighborhood. • More reliable transit service benefitting EJ populations that use transit to travel through the study area. • Improved bicycle level of traffic stress (BLTS) in Vancouver would improve the local network quality across and around the I-5 corridor for all users, including identified EJ populations in the East Columbia and Esther Short neighborhoods. • In Portland, the BLTS scores of nearly all affected streets would improve to a low stress standing for all travelers, including EJ populations. • **Single-Level Movable-Span Configuration:** Fewer

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	TRAN and TriMet local bus, other TriMet MAX lines, nonmotorized, and park-and-ride trips. • Active Transportation Impacts: New shared-use path facilities that would enhance safety and comfort of walking, biking, and rolling access across the Columbia River, along the rebuilt segments of highway and interchanges, and new station areas. • Safety Impacts: Forecast reduction of crashes by 15% to 30% and changes in crash types, severities, and locations due to modifications involving the Columbia River bridges, I-5 mainline, ramps, and ramp terminals. In Vancouver, bike level of traffic stress (BLTS) scores of nearly all affected streets would improve. • **Single-Level Movable-Span Configuration:** The Modified LPA with a single-level movable-span configuration would continue to subject transit and active transportation users to delays during bridge openings, even though there would be fewer openings overall compared to the No-Build Alternative. • **Design Option without C Street Ramps:** Under this design option, I-5 would be accessed from downtown Vancouver through the Mill Plain interchange rather than C Street. The removal of the C Street ramps could cause additional congestion at the Mill Plain Boulevard ramps.		bridge openings compared to the No-Build Alternative. • Design Option without C Street Ramps: None.
Visual Resources	The scale, form, and materials of the Columbia River bridges and structures would not contrast with the existing visual character. New transit, bicycle, and pedestrian structures would be new visual elements similar in visual character to other proposed elements. An increase in ambient light	The downtown Vancouver and Ruby Junction landscape units include neighborhoods identified as high-priority EJ areas (Esther Short and Rose Village in Vancouver and Rockwood in Gresham). Changes to visual quality in these areas are expected to be neutral overall, given that there is an	None.

Environmental Resource	Modified LPA Long-Term Impact Summary	Impact Specific to Minority and Low-Income Populations	Benefit Specific to Minority and Low-Income Populations
	levels may be perceptible; however, replacement lights would be designed to limit light and glare. New landscape views crossing the Columbia River bridges.	existing bridge structure with similar visual characteristics. Changes in Ruby Junction are expected to be low because the added structures and uses would be consistent with existing character and uses. Therefore, no disproportionately high and adverse effect has been identified.	

a All data and findings are based on the IBR technical reports for each environmental resource.
b The long-term effects associated with the Modified LPA would be the same for all design options, unless otherwise specified.

3.20.5 Temporary Effects

No-Build Alternative

There would be no temporary effects on EJ populations under the No-Build Alternative.

Modified LPA

Construction of the Modified LPA, which includes construction of the new bridges and removal of the existing bridge, is expected to last up to 15 years, affecting all modes of transportation within the study area and adjacent corridors. Temporary transportation effects, including road closures, detours, and construction-related delays, would occur to varying degrees. Table 3.20-13 summarizes temporary impacts to EJ populations associated with the Modified LPA, including all design options. The analysis identified a potential for disproportionately high and adverse effects on EJ populations with regard to noise (specifically in the East Columbia and Esther Short neighborhoods) and transportation (as a result of transit disruptions and temporary closures of cross-river bicycle and pedestrian facilities). Disproportionately high and adverse effects on EJ populations are not anticipated for the other impact categories evaluated.

Table 3.20-13. Summary of Potential Temporary Effects on EJ Populations from the Modified LPA [a]

Type of Impact	Temporary Impact Summary for the Modified LPA	Temporary Impacts Specific to EJ Populations
Acquisitions, Displacements, and Relocations	Temporary construction easements and staging areas for each project subarea are: • Oregon Mainland: 12 parcels; 45 acres. • Hayden Island: 3 parcels; 13.2 acres. • Downtown Vancouver: 51 parcels; 6.7 acres. • Upper Vancouver: 20 parcels; 4.8 acres. • Ruby Junction Maintenance Facility Expansion: None. Two sites have been identified as possible major construction staging areas that could be temporarily acquired or leased: • Vacant Thunderbird Hotel site (Hayden Island): 3.5 acres. The hotel site, in addition to 13.2 acres on Hayden Island, would constitute the largest staging area for the IBR Program. • Former WSDOT rest area along I-5 in Vancouver: 5 acres.	Temporary construction easements would occur at two properties in downtown Vancouver identified as providing low-income housing: Evergreen Inn and Lewis and Clark Plaza. Downtown Vancouver includes the Esther Short neighborhood, a high-priority EJ area. No residential or business displacements would occur as a result of these temporary construction easements. Activities at the sites would consist of temporary staging for construction and equipment and other construction support activities. These temporary construction easements would result in a disproportionately high and adverse effect on EJ populations.
Air Quality	Short-term impacts to air quality from construction activities would occur during the construction period. Construction-related activities would result in increased particulate matter in the form of fugitive dust (from demolition, ground clearing and preparation, grading, stockpiling of materials, on-site movement of equipment, and transportation of construction materials). Dust emissions typically occur during dry weather, ground-disturbing construction activities, or high wind conditions. Air quality may also be affected by exhaust emissions from material delivery trucks, construction equipment, and workers' private vehicles.	The anticipated temporary air quality impacts within the study area are not expected to result in a disproportionately high and adverse effect on EJ populations because construction-related air quality impacts would be the same for EJ populations as for the general population.

Type of Impact	Temporary Impact Summary for the Modified LPA	Temporary Impacts Specific to EJ Populations
Land Use and Economics	Construction has the potential to cause negative economic effects by blocking visibility and access to businesses, resulting in patrons choosing other locations for goods and services. Construction can also cause traffic delays and detours that increase travel times, increase the cost of deliveries, and make access to some locations difficult. Construction activities and temporary detours could extend the peak period traffic congestion, negatively impacting businesses whose employees commute using the I-5 corridor. Likewise, the movement of freight, goods, and services could be negatively affected if construction activities make travel times longer and/or less predictable due to increased traffic and congestion.	Adverse land use and economic impacts (excluding acquisitions and displacements) would not be experienced disproportionately by meaningfully greater and high-priority EJ neighborhoods within the study area compared to the general population. Similarly, freight impacts would impact EJ populations the same as the general population. Therefore, no disproportionately high and adverse temporary land use and economic impacts to low-income and minority populations have been identified.
Noise and Vibration	All neighborhoods in the study area could experience temporary noise and vibration increases from construction equipment and activities, particularly in areas adjacent to I-5.	Although the entire study area would be impacted by increased noise and vibration, some areas with higher concentrations of EJ populations could be impacted disproportionately. Particularly high levels of noise and vibration from pile-driving activities are anticipated near the Interstate Bridge span. However, additional noise and vibration impacts are also anticipated within the East Columbia and Esther Short neighborhoods, which are high-priority and meaningfully greater areas. Therefore, noise and vibration impacts would result in disproportionately high and adverse effects to EJ populations in these neighborhoods.
Social and Neighborhood Effects	Neighborhood quality and cohesion could be negatively affected throughout the construction period. All neighborhoods in the study area could experience temporary congestion, traffic detours, noise, air quality impacts, and increases in truck traffic during construction, particularly in the areas immediately adjacent to I-5. The use of temporary construction staging would minimize some of these negative impacts. The net impact of air, traffic, noise, and construction impacts would constitute social and neighborhood effects within the study area.	Neighborhood quality and cohesion impacts would be experienced throughout the study area, and impacts to EJ populations are anticipated to be the same as to the general population. Furthermore, the negative impacts that have been identified would be reduced through the use of construction best management practices. Therefore, disproportionately high and adverse effects on EJ populations have not been identified.

Type of Impact	Temporary Impact Summary for the Modified LPA	Temporary Impacts Specific to EJ Populations
Tolling	Pre-completion tolling would be implemented on the Interstate Bridge when construction begins. This tolling is expected to occur between 5 a.m. and 11 p.m.; overnight hours would not be tolled, as construction activities may reduce the number of lanes travelers could use. Pre-completion tolling would have similar impacts as long-term tolling for travelers except during the overnight hours.	I-5 is currently not tolled, and there are currently no plans to toll the bridge independently of the IBR Program. Pre-completion tolling would have similar impacts on EJ populations as long-term tolling. It is anticipated that pre-completion tolling would result in a slightly lesser impact than long-term tolls given that pre-completion tolling would only occur between 5 a.m. and 11 p.m. EJ populations crossing the Interstate Bridge during the overnight hours would not be tolled. However, although the impacts resulting from pre-completion tolling would be reduced compared to long-term tolls, any tolling of I-5 would still impact low-income populations disproportionately compared to the general public. Furthermore, it is uncertain whether a low-income or equitable tolling program would be operational during construction or if it would not be launched until post-construction. In the absence of tolling mitigation, there is a potential for pre-completion tolling to result in a greater impact to EJ populations than a long-term toll and associated low-income tolling program. Therefore, pre-completion tolling is anticipated to result in a disproportionately high and adverse effect on EJ populations traveling across I-5 during the construction period.
Transportation	Construction would result in temporary bridge closures, highway lane closures, bus stop relocations, light-rail station closures, partial or full temporary closures of park-and-ride facilities, and rerouting of sidewalks and bicycle lanes. Traffic diversion during construction would lead to higher traffic volumes on detour streets, which could lead to a temporary increase in collision frequency. To minimize disruptions to peak period and daytime transportation travel on I-5, some construction activities could occur during nighttime hours and on weekends with approval by ODOT and/or WSDOT. Additional impacts to transportation include: • Bus Service Impacts. Bus service could experience delays from increased congestion due to potential roadway or	Interruptions to bus and light-rail transit service in the study area could affect EJ populations more than the general population, as low-income populations are more likely to rely on transit to get to work, school, or other essential destinations. Transit interruptions would be likely to result in detours and out-of-direction travel, particularly for cross-river trips. Short-term closures of cross-river bicycle and pedestrian facilities could result in an adverse and disproportionate effect on EJ populations that rely on cycling or walking to cross the river. Bicycle and pedestrian facility closures on I-5 leave few options for crossing the river on foot or by bike, as the only other option would be to cross using the facilities on I-205. The

Type of Impact	Temporary Impact Summary for the Modified LPA	Temporary Impacts Specific to EJ Populations
	interchange closures. Buses that travel through downtown Vancouver could encounter temporary closures and reroutes as the transit guideway is installed at the north end of the light-rail transit alignment. • TriMet MAX Impacts. Construction along Expo Road and the Marine Drive interchange may require temporary relocation or closure of the TriMet MAX Yellow Line terminus station near Expo Center. These temporary relocations, closures, or schedule adjustments could occur for 4 years. • Pedestrian and Bicycle Impacts. Construction could temporarily and intermittently close or reroute sidewalks, bicycle facilities, and/or shared-use paths or reduce facility widths within construction areas. Limited opportunities would be available for active transportation crossings of I-5 and would therefore be maintained to the extent practical.	distance between I-5 and I-205 may not be a practical distance to travel for some pedestrians and bicyclists, which may fully prevent cross-river trips during certain periods. Furthermore, low-income populations that rely on walking and cycling as their primary mode of transportation may have fewer resources and access to alternative transportation modes than the general population. Therefore, interruptions to bus service, light-rail service, and cross-river bicycle and pedestrian facilities would result in a disproportionately high and adverse effect on EJ populations.
Visual Resources	Construction is expected to last up to 15 years, during which views to and from the area of visual effects would be altered. Temporary effects on visual quality would result from visual distractions, high-visibility signage, and additional lighting during nighttime construction. Vegetation may be removed from some areas to accommodate the construction of the new bridge structures, new ramps, transit guideways, staging areas, and casting yards. Each area would be revegetated upon completion.	None. Changes in views and visual effects are anticipated to be the same for EJ populations as the general population.

a The temporary effects associated with the Modified LPA would be the same for all design options, unless otherwise specified.

3.20.6 Indirect Effects

No-Build Alternative

As described in Table 3.20-11 above, the No-Build Alternative would not displace residents, businesses, community resources, or jobs. Environmental conditions would generally remain the same as they are the time of this writing. However, the No-Build Alternative would maintain worsening traffic growth and congestion pattens on I-5, with travel times anticipated to increase by 50% in the future compared to existing travel times. Increasing travel times and congestion on I-5 could negatively affect freight movement and the local and regional economy; increase vehicle idling and associated air emissions; and reduce access to key destinations and community resources in Vancouver and Portland. Furthermore, the No-Build Alternative would not bring high-capacity transit to Hayden Island or downtown Vancouver, forgoing potential benefits to EJ populations that may depend more on transit and active transportation as their primary mode of transport compared to the general population. However, most of these indirect effects would impact EJ populations the same as, or similarly to, the general population. Therefore, the indirect effects of the No-Build Alternative are not anticipated to result in disproportionately high and adverse effects to EJ populations.

Modified LPA

The areas with the highest likelihood of indirect effects from the Modified LPA are Hayden Island and downtown Vancouver, as the addition of high-capacity transit stations in these neighborhoods would have the potential to support transit-oriented development. Hayden Island has not been identified as a meaningfully greater or high-priority EJ area. The Esther Short neighborhood within downtown Vancouver has been identified as a high-priority EJ neighborhood due to its high concentration of low-income populations. It is important to note that transit-oriented development would not be undertaken by the IBR Program; rather, the addition of light-rail transit as part of the Program would facilitate redevelopment that is already provided for in community plans in anticipation of the high-capacity transit stations (see Section 3.4, Land Use and Economic Activity, for further discussion of this topic). Other indirect effects could include increased noise and pollution in neighborhoods directly adjacent to the corridor, including Arnada and Rose Village, which have been identified as high-priority and meaningfully greater EJ areas, respectively. Indirect effects on Esther Short, Arnada, and Rose Village have the potential to result in disproportionately high and adverse effects on EJ populations residing within these neighborhoods.

The analysis of indirect effects also considered the potential for gentrification, which refers to the causal relationship between investment and redevelopment and demographic changes. As rents and property taxes increase, properties can become unaffordable for low-income property owners and tenants, who move out and are replaced by higher-income populations. Increased property values and rents in downtown Vancouver could result in the types of demographic changes that are frequently characterized as gentrification; this could be considered an indirect effect of the IBR Program on EJ populations. Though the Modified LPA would not on its own cause gentrification, it could help accelerate it relative to the No-Build Alternative by increasing the value of property directly or indirectly affected by investments resulting from the IBR Program. If low-income renters were forced to move because rents and associated costs of living increased downtown, this could result in adverse effects. However, low-income homeowners could benefit from the same rise in property values and rents.

The City of Vancouver has adopted goals and policies that support affordable housing and a mix of housing types, and the Vancouver Housing Authority works to maintain affordable units in the city through voucher programs and the development of new affordable housing units. Even if low-income renters faced adverse effects, it is not clear that such effects would be disproportionate, as rising rent levels can also displace middle-income earners. Renters as a group typically move with some regularity, and the vast majority of affordable rental properties in Vancouver would not experience direct or indirect effects from the Modified LPA.

3.20.7 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Mitigation for long-term effects on EJ populations includes measures that would be used to avoid, minimize, and/or mitigate impacts from each of the impact categories evaluated for this analysis (acquisitions and displacements, traffic, noise, etc.). Some of these measures are required by existing regulations or design and construction standards, while others are Program-specific. The sections below describe both regulatory and Program-specific mitigation measures for each impact category analyzed for EJ. The following is a discussion of proposed mitigation to address impacts resulting from the Modified LPA. The IBR Program will continue to engage with EJ populations to identify impacts and benefits and to gather meaningful input on avoidance, minimization, and mitigation measures to address adverse effects.

Regulatory Requirements

The applicable regulatory requirements are listed below:

- Title 42 USC Section 4601, the Uniform Relocation Assistance and Real Property Policies Act (1970).
- Title 23 CFR Part 772, Procedures for Abatement of Highway Traffic Noise and Construction Noise.
- ORS 467.010, Chapter 340, Division 35, Noise Control Regulations.

The following subsections describe the effect of these regulatory requirements and related state policies in more detail as they relate to disproportionately high and adverse effects on EJ populations within the study area.

Acquisitions and Displacements

Title 42 USC Section 4601, the Uniform Relocation Assistance and Real Property Policies Act (1970), provides uniform and equitable treatment of persons displaced from their homes or businesses by federal and federally assisted programs and establishes uniform and equitable land acquisition policies for federal and federally assisted programs. These policies require that property be purchased at fair market value and that all residential displacements be provided with replacement housing and/or relocation assistance. Federal law requires replacement housing based on the characteristics of individual households. Relocation benefit packages for residents may include replacement housing for owners and renters, moving costs, and assistance in locating replacement housing. Relocation benefits for businesses can include moving costs, site search expenses, and business re-establishment expenses. Eligibility and terms of relocation assistance would be determined during future project planning. Discussion of the Uniform Relocation Assistance and Real Property Policies Act can also be found in Section 3.3, Property Acquisitions and Displacements.

For low-income populations or populations with special circumstances, a relocation program could include housing assistance. For example, the Washington State Department of Commerce participates in the U.S. Department of Housing and Urban Development's HOME Rental Development Program, a housing block grant program used to preserve and create affordable housing for low-income households. The extent to which similar housing programs could help offset displacement impacts resulting from the Modified LPA would depend on the availability of adequate housing stock to relocate EJ populations in the same general area.

Noise

FHWA requires consideration of noise abatement measures for highway projects where noise levels exceed certain thresholds. Long-term noise impacts to EJ populations were identified in the Rose Village neighborhood in Vancouver. After reviewing the locations of the predicted noise impacts, it was determined that noise walls are the only feasible form of noise abatement. The construction of noise walls is already considered a best management practice (BMP) for offsetting noise and vibration impacts.

The noise analysis completed for this Draft SEIS (see Section 3.11, Noise and Vibration) proposed 18 noise walls to mitigate traffic noise impacts predicted under the Modified LPA.[9] Noise impacts in the Rose Village neighborhood would be mitigated by Noise Wall 4, which would be located in the area east of I-5 between E 33rd Street and SR 500. Noise Wall 4 would replace an existing 4- to 8-foot-tall, approximately 200-foot-long wall located just north of the 33rd Street overcrossing and would continue along the WSDOT right of way until reaching the bridge over E 39th Street. The final decision and recommendation to include noise wall mitigation would be made during final design. As design advances, factors that affect the feasibility and cost-effectiveness of noise walls can change. In addition, should the noise-impacted residents oppose recommended noise mitigation, the mitigation measure may not be incorporated into the Modified LPA.

State requirements mandate noise and vibration monitoring. In addition to compliance with ODOT and WSDOT standard specifications for noise abatement that apply to highway construction activities, monitoring would include the following:

- Establish a complaint hotline to investigate noise complaints during construction. A construction monitoring and complaint program would help ensure that all equipment meets state, local, and manufacturer specifications for noise emissions. Equipment not meeting the standards would be removed from service until proper repairs were made and the equipment retested for compliance. This procedure would apply to all haul trucks, loaders, excavators, and other equipment that would be used extensively at the construction sites and that would contribute to potential noise effects.
- Conduct vibration monitoring of all activities that might produce vibration levels at or above 0.5 inches per second where structures are near the construction activity. This would include pile driving, vibratory sheet installation, soil compaction, and other construction activities with the potential to cause high levels of vibration. There is no effective method to completely eliminate vibration effects from construction; however, by restricting and monitoring vibration-producing activities, vibration effects from construction can be kept to a minimum.

Tolling

No regulations are currently in place to offset the impacts of IBR Program tolls on low-income populations, though such regulations may be implemented in the future in support of a low-income tolling program or equitable tolling policy that would reduce or offset the economic burden of tolling on low-income and minority populations. Toll rates and policies implemented on the existing Interstate Bridge (pre-completion tolling) and the replacement Columbia River bridges under the Modified LPA (long-term tolling) would be jointly set by the Oregon Transportation Commission (OTC) and the Washington State Transportation Commission (WSTC). The commissions would consider possible exemptions and discounts, which may include a low-income discount program. Both commissions would work together to determine how to apply such exemptions and discounts to the IBR Program.

Program-Specific Mitigation

Proposed Program-specific mitigation would include an attempt to minimize relocation impacts to residences, businesses, and public facilities as the project design is refined. The Modified LPA is currently at a conceptual level of design, and key features such as the number of auxiliary lanes, bridge type, and other design elements will not be determined until later stages of design. Furthermore, input from the IBR Executive Steering Group, Equity Advisory Group, Community Advisory Group, Community Benefits Advisory Group, and the public will support the refinement of the Modified LPA. The Program will attempt to minimize relocation impacts as these design and cost refinements occur.

[9] The final number of noise walls, considering feasibility and cost-effectiveness, will be determined as part of the Final SEIS.

Traffic Impacts

As described in Table 3.20-12, traffic impacts resulting from the Modified LPA are generally diffuse throughout the study area and would be experienced similarly by EJ populations and the general population. Under the Modified LPA, key bottlenecks would be reduced along segments of I-5 in both Oregon and Washington, high-capacity transit would be expanded in the region, new shared-use paths would be built, crashes would be reduced by 15% to 30%, and bicycle level of traffic stress (BLTS) would decrease to "low" stress, benefitting EJ populations and the general population alike.

Under the single-level movable-span configuration, the Modified LPA with a single-level movable-span configuration would continue to subject transit and active transportation users to delays during bridge openings, even though there would be fewer openings overall than under the No-Build Alternative. The single-level movable-span configuration would impact EJ populations the same as the general population, so no disproportionately high and adverse effects have been identified.

Under the design option without the C Street ramps, I-5 would be accessed from downtown Vancouver through the Mill Plain interchange rather than C Street. The removal of the C Street ramps could cause additional congestion at nearby collectors and ramps, shifting between 300 and 600 vehicles per hour to the Mill Plain Boulevard ramps during peak periods. However, the removal of the ramps would impact EJ populations the same as the general population, so no disproportionately high and adverse effects have been identified.

Because no disproportionately high and adverse effects have been identified, specific mitigation to offset, reduce, or minimize traffic impacts to EJ populations is not proposed. However, ODOT and WSDOT would monitor traffic operations and, as the need arises, pursue the following mitigation measures to benefit the general population, including EJ populations traveling through the study area.

- Monitor and adjust ramp meter rates to manage travel times, delay, and other operational performance measures consistent with ODOT and WSDOT highway procedures.
- Coordinate with local jurisdictions to adjust local street networks that could include the following actions:
  - Prohibit on-street parking during peak periods to improve vehicle flow and reduce travel delays associated with slowdowns to accommodate vehicles entering and exiting on-street parking spaces.
  - Add turn pockets at needed locations (e.g., a southbound right-turn lane at 15th and Columbia Streets in Vancouver) to improve vehicle flow and reduce travel delays associated with bottlenecking at intersections.
  - Alter traffic signal timing (e.g., for the Mill Plain Boulevard interchange signal) to maximize operational flow and reduce travel delays.

Air Quality

Air pollutant emissions are expected to be substantially lower in the future than under existing conditions. Regionally, future differences between the Modified LPA and the No-Build Alternative are small enough not to be meaningful within the accuracy of the estimation methods. Long-term air quality impacts are not expected to occur as a result of the IBR Program. Therefore, no disproportionately high and adverse air quality impacts would be expected on EJ populations as a result of the Modified LPA, and no specific mitigation is proposed.

Business Displacements and Loss of Service Industry Jobs

In addition to compliance with the Uniform Relocation Assistance and Real Property Policies Act, the IBR Program may provide mitigation for the loss of service industry jobs under a potential future workforce agreement and/or Project Labor Agreement. This agreement would be further defined as project design and planning progress, and would cover such topics as:

- Adopting goals for involvement of minority, women-owned, emerging, and disadvantaged businesses in Program construction contracting.
- Developing workforce practices to provide experience and business opportunities for disadvantaged workers and companies, such as requiring contractors to have apprentices perform a percentage of construction labor.
- Providing job training and establishing preferences in contracting for local services.
- Implementing a monitoring and evaluation program to track these measures through final project design, construction, and operation to help ensure that the benefits of promoting participation from minority-owned businesses are realized.

Tolling

Program-specific measures to minimize disproportionately high and adverse effects on EJ populations related to tolling are proposed as part of this SEIS. As described in Table 3.20-12 above, tolling new Columbia River bridges would result in higher transportation costs as a proportion of household spending for some EJ populations. Some of the project benefits—such as increased investments in the regional transit, walking, and bicycling network—may not be accessible or practical for EJ populations with fixed schedules and employment, school, and/or childcare commitments. Although the method of payment for a potential tolling program across the new Columbia River bridges has not been determined, a transponder model has the potential to present a burden to low-income and minority populations due to the up-front cost and technical requirements of purchasing and setting up a transponder.

Program-specific mitigation measures to address disproportionately high and adverse effects on EJ populations resulting from tolling may include:

- **A Low-Income and/or Equitable Tolling Program:** If the OTC and WSTC choose to implement a low-income toll program on the existing Interstate Bridge (pre-completion tolling) and the replacement Columbia River bridges under the Modified LPA (long-term tolling), it would play a role in mitigating disproportionately high and adverse effects of tolling on EJ populations. Additional mitigation may be needed if I-205 is tolled in the future or if a regional tolling system is implemented. Both transportation commissions are actively studying low-income tolling programs, including how such a program could be implemented in each state. The following key work has been done to date:
    - Oregon Tolling Program I-205 and I-5 Toll Projects' Equity Framework (2023). The OTC has advanced key elements of a low-income toll program—the first of its kind in the nation—that will serve low-income travelers who cannot change their travel schedules or who travel frequently on interstate facilities. The program will balance impacts to other travelers while still achieving overall program goals to reduce traffic congestion and raise revenue for transportation improvements. Key commitments include at least a 50% discount on tolls for customers in Oregon or Washington whose household income is up to 200% of the federal poverty level and exemptions for federally recognized tribes and tribal government vehicles.
    - WSDOT Low-Income Toll Program Study for I-405 & SR 167 Express Toll Lanes (2021). WSDOT has developed a range of program options and evaluation metrics to assess toll discount program options to benefit equity populations. Options include percentage-based and fixed-rate discounts per trip, time-based toll credits, free toll trips, and lowering the maximum toll rate. Although this study was for the I-405 and SR 167 Express Toll Lanes in Washington and would not directly apply to the IBR Program, the study and its findings may influence future discussions and coordination between the OTC and WSTC regarding the future of a regional toll program.

- **Equitable Access to Technology and Information**: ODOT, WSDOT, and regional partners will provide Program-specific information, such as how to obtain transponders and/or how to receive transportation assistance, particularly for low-income drivers.
    - Locate venues for acquiring transponders near lower-income neighborhoods. The IBR Program would partner with public agencies and public service providers to identify locations that are convenient for low- or lower-income neighborhoods and that are accessible by multiple modes of travel.
    - Enable populations without credit cards or checking accounts to obtain transponders by paying with cash or electronic bank transfer cards.
    - Share information with and through other public service providers, particularly those that provide direct service to EJ populations.
    - Share information about existing rideshare opportunities such as local carpool and vanpool providers or work with partners to develop new programs.
- **Early, Inclusive, and Equitable Public Engagement:** Public engagement and outreach is proposed as a critical step to ensure that transportation users can make informed travel choices when crossing the Columbia River. Public engagement should conduct specific outreach to potentially impacted EJ populations, connect these populations to assistance resources such as a future low-income and/or equitable tolling program and other travel options, and provide transparent information about the costs and impacts to their trips resulting from a future IBR tolling program.

Temporary Effects

Mitigation for temporary effects on some resources that would affect EJ populations would be provided through standard construction BMPs. BMPs applicable to the potential impacts described in Table 3.20-13 are discussed in Section 3.3, Property Acquisitions and Displacements; Section 3.10, Air Quality; and Section 3.9, Visual Quality. Mitigation for temporary effects on EJ populations is discussed below.

Acquisitions and Displacements

As described in Table 3.20-13, temporary construction easements would be acquired at two properties in downtown Vancouver identified as providing low-income housing: Evergreen Inn and Lewis and Clark Plaza. These properties are located in the Esther Short neighborhood, a high-priority EJ area. No residential or business displacements would occur as a result of these temporary construction easements. Activities at the sites would consist of temporary staging for construction and equipment and other construction support activities. Given their location within an identified EJ area and their provision of affordable housing, temporary construction easements at these two sites would result in a disproportionately high and adverse effect on EJ populations.

Temporary construction easements may also occur on Hayden Island to facilitate construction of both the transit and highway alignments. The census geography comprising Hayden Island is not a meaningfully greater or high-priority EJ area. However, the removal of the ramps would impact EJ populations the same as the general population, so no disproportionately high and adverse effects have been identified.

EJ-specific mitigation measures to offset temporary construction acquisitions and displacement impacts would be the same as those used to address impacts to the general population. These measures include increased coordination between the construction team and businesses, renters, and property owners who would be affected by temporary acquisitions to discuss details of the acquisition, such as the duration of the acquisition and the operating schedule for construction activities. The IBR Program would meet with property owners who would be affected by temporary acquisitions to discuss details of the acquisition, such as the

duration of the acquisition and the operating schedule for construction activities. Proposed mitigation measures are described in more detail in Section 3.3, Property Acquisitions and Displacements.

Transportation Impacts

As described in Table 3.20-13, construction activity for the highway and interchanges is anticipated to result in traffic delays on I-5 during construction. Depending on schedules and phasing, such delays could have greater impact to Hayden Island residents, as they have no other access to the island. The census geography comprising Hayden Island is not a meaningfully greater or high-priority EJ area. However, low-income and minority people living in the area may be affected and are considered as part of this analysis.

Temporary interruptions to bus and light-rail transit service in the study area could affect EJ populations more than the general population, as low-income populations are more likely to rely on transit to get to work, school, or other essential destinations. Transit interruptions would be likely to result in detours and out-of-direction travel, particularly for cross-river trips. These transit interruptions would result in a disproportionately high and adverse effect on EJ populations.

Short-term closures of cross-river bicycle and pedestrian facilities would also result in an adverse and disproportionate effect on EJ populations that rely on cycling or walking to cross the river. Bicycle and pedestrian facility closures on I-5 currently leave few options for crossing the river on foot or by bike, as the only other option would be to cross using the facilities on I-205. The distance between I-5 and I-205 (approximately 6 miles) is not practical for all pedestrians and bicyclists and may fully prevent cross-river trips during certain periods. Furthermore, low-income populations that rely on walking and cycling as their primary mode of transportation may have fewer resources and access to alternative transportation modes than the general population.

Therefore, interruptions to traffic, bus, light-rail service, and cross-river bicycle and pedestrian facilities would result in a disproportionately high and adverse effect on EJ populations.

Mitigation measures to address temporary transportation impacts to EJ populations would be similar to those used to address impacts to the general population. Disruptions to peak-period and daytime travel on I-5 are proposed to be mitigated through construction best practices, such as scheduling construction activities during nighttime hours and on weekends with approval by ODOT and/or WSDOT. Transit fare subsidies are proposed to offset impacts to transit riders, who may be more likely to belong to EJ populations; these subsidies would apply to all transit riders and not just to EJ populations. An emphasis would be placed on maintaining safe and accessible pathways during construction, especially near public housing, senior housing, and public services. The IBR Program would coordinate with TriMet to maintain paratransit service for qualifying mobility-impaired Hayden Island residents. Increased public outreach and construction-period communication are proposed to adequately inform travelers of delays and provide information about practicable detours throughout the construction period.

Mitigation measures for temporary transportation impacts are discussed in more detail in Section 3.1, Transportation.

Noise

As described in Table 3.20-13, the entire study area would be impacted by increased noise and vibration, though particularly high levels of noise and vibration from pile driving activities are anticipated near the Interstate Bridge span. Areas with higher concentrations of EJ populations could be impacted disproportionately compared to the general population. Temporary noise and vibration impacts have been identified within the East Columbia and Esther Short neighborhoods, which are high-priority and meaningfully greater areas. Therefore, noise and vibration impacts in these areas would result in disproportionately high and adverse effects on EJ populations.

Residents of Hayden Island are also likely to experience noise and vibration impacts due to construction equipment, vibratory compaction equipment, and pile driving during bridge construction. The census geography comprising Hayden Island is not a meaningfully greater or high-priority EJ area. However, low-income and minority people living in the area may be affected and are considered as part of this analysis. Residents living in floating homes may be particularly susceptible to noise and vibration impacts due to their close proximity to both the highway and transit alignments.

EJ-specific mitigation measures to address temporary noise and vibration impacts would be the same as the measures taken to address impacts to the general population. These measures would consist of compliance with existing federal and state noise abatement requirements[10] and monitoring, including the establishment of a complaint hotline to investigate noise complaints during construction, testing of construction equipment to ensure compliance with noise emission standards, and vibration monitoring of all activities that might produce vibration levels at or above 0.5 inches per second where structures are near the construction activity. There is no effective method to completely eliminate vibration effects from construction; however, by restricting and monitoring vibration-producing activities, vibration effects from construction can be kept to a minimum and reduce disproportionately high and adverse effects on EJ populations within the construction zone. Proposed mitigation measures for temporary noise and vibration impacts are described in more detail in Section 3.11, Noise and Vibration.

Air Quality

As described in Table 3.20-13, anticipated temporary air quality impacts within the study area are not expected to result in a disproportionately high and adverse impact to EJ populations because construction-related air quality impacts would be the same for EJ populations as for the general population. However, air quality may be affected on Hayden Island due to emissions from construction equipment. The census geography comprising Hayden Island is not a meaningfully greater or high-priority EJ area. However, low-income and minority people living in the area may be affected and are considered as part of this analysis. Residents living in floating homes and the mobile home park may be particularly susceptible to air quality impacts due to their close proximity to both the highway and transit alignments. Construction impacts to air quality could be minimized through measures discussed in more detail in Section 3.10, Air Quality.

3.20.8 Environmental Justice – Preliminary Determination Summary of Environmental Justice Impacts

EO 12898 directs federal agencies to make achieving EJ part of their respective missions by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations. For the IBR EJ analysis, the Modified LPA's impact to EJ populations was compared to the impact to the general population; in instances where disproportionately high and adverse impacts to EJ populations were identified, mitigation measures have been proposed to minimize, reduce, or offset those impacts.

Disproportionately high and adverse effects on EJ populations were evaluated using five questions based on FHWA guidance to support a preliminary determination as to whether the IBR Program would result in disproportionately high and adverse effects on EJ populations (FHWA 2011). These questions, and the Program's responses, are provided below.

[10] Title 23 CFR Part 772, Procedures for Abatement of Highway Traffic Noise and Construction Noise

ORS 467.010, Chapter 340, Division 35, Noise Control Regulations

Chapter 173-60 WAC, Maximum Environmental Noise Levels

Question 1: Would the Modified LPA result in disproportionately high and adverse impacts that would be predominantly borne by a minority or low-income population?

Yes.

- The Modified LPA would result in residential and business displacements in high-priority and meaningfully greater EJ areas such as the Esther Short neighborhood in Vancouver and the Rockwood neighborhood in Gresham. In Rockwood, EJ populations comprise more than 50% of the entire population, and displacement impacts would be disproportionately borne by minority and low-income populations.
- If the design option that shifts the I-5 mainline westward were chosen, the Modified LPA would also require full acquisition of the Normandy Apartments. This would result in an additional 33 residential displacements in the Esther Short neighborhood, a high-priority EJ area.
- As discussed in Table 3.20-11, the Modified LPA would result in temporary construction easements at the Evergreen Inn and the Lewis and Clark Plaza in Vancouver. These are two low-income apartment buildings that provide affordable housing within the Esther Short neighborhood. Given that these apartment buildings are located in an identified EJ area and that they specifically provide low-income housing to EJ populations within the study area, temporary construction easement impacts to these buildings would result in a disproportionately high and adverse effect. No residential displacements are anticipated from these temporary construction easements, so these impacts would be temporary in nature.
- The tolling program associated with the Modified LPA has the potential to result in adverse and disproportionate impacts to EJ populations. While tolls would be paid by all drivers using the new bridges, the tolls would represent a greater proportion of household income for low-income individuals than for higher-income individuals, resulting in a higher economic burden in some of the studied census block groups.

Question 2: Would the Modified LPA result in disproportionately high and adverse impacts on a minority or low-income population that would be appreciably more severe or greater in magnitude than the impact that would be suffered by the non-minority or non-low-income population?

Yes.

Residential displacements and implementation of the proposed tolling program have the potential to disproportionately burden EJ populations as compared to the general population, as described in the response to Question 1.

Question 3: Does the Modified LPA affect a resource that is especially important to a minority or low-income population? For instance, does the project affect a resource that serves an especially important social, religious, or cultural function for a minority or low-income population?

To be determined.

Adverse effects on culturally sensitive resources may be especially important to a minority population. In September 2020, FHWA and FTA contacted 21 tribes and Native Hawaiian organizations that were originally consulted regarding the CRC project and reinitiated government-to-government consultation. In February 2022, outreach was extended to an additional 17 tribes. Through that effort, 10 federally recognized tribes expressed an interest in consulting for the IBR program. Archaeological and ethnographic surveys are underway to determine the significance of resources present, make findings on level of effect from the Program, and identify possible strategies to avoid, minimize, or mitigate any adverse effects. If adverse effects on resources that serve especially important social, religious, or cultural functions for tribes are identified prior to completion of the Final SEIS, this analysis will be updated to reflect those effects. Any finding of adverse effect under Section 106 of the National Historic Preservation Act would be mitigated in accordance

with the terms of the Programmatic Agreement being developed for the IBR Program, as described in Section 3.8, Cultural Resources.

Question 4: Does the Modified LPA propose mitigation?

Yes.

Proposed mitigation is discussed in Section 3.20.8, Potential Avoidance, Minimization, and Mitigation Measures. Some of these mitigation strategies, such as those related to acquisition and displacement, noise and vibration, and transportation impacts are statutory requirements, BMPs, and obligations; others are Program-specific mitigation strategies to address disproportionately high and adverse effects on low-income and minority populations. Mitigation measures related to the future IBR tolling program, if advanced, will be important given the disproportionately high and adverse effect that tolling is anticipated to have on EJ populations, especially those for households living at or below the federal poverty level. A low-income toll program or equitable tolling policy would be an important mitigation strategy to offset disproportionately high and adverse effects on EJ populations resulting from future tolling on the new Columbia River bridges. Strategies to further reduce disproportionately high and adverse effects resulting from the potential use of tolling transponders could include public information campaigns to help EJ populations navigate and participate in the tolling system, the use of electronic benefits transfer cards, and financial assistance programs.

It is important to note that, although the IBR Program is committed to mitigation to address disproportionately high and adverse effects on EJ populations resulting from future tolling, tolling is still in a preliminary phase of planning and study. Once the structure of tolling has been determined, additional analysis, interagency coordination, and public involvement will be needed to define specific mitigation actions related to IBR Program tolling.

Question 5: Would EJ populations experience project benefits under the Modified LPA?

Yes.

- EJ populations would share benefits with the general population resulting from the construction of modern, seismically resilient, and multimodal bridges across the Columbia River.
- Under the Modified LPA, EJ populations would benefit from new and reliable high-capacity transit across the Columbia River. The decrease in transit travel time and increase in transit reliability would be a benefit for all populations but may benefit EJ populations differently to the extent that they ride transit at a higher rate than those with greater access to transportation options and/or higher incomes. [11]
- Under the Modified LPA, EJ populations would benefit from improved travel times and increased safety on I-5, as would the general population.
- Under the Modified LPA, EJ populations would benefit from improved bicycle and pedestrian travel across the Columbia River and from bicycle and pedestrian improvements to the local street system within the study area. Improved bicycle and pedestrian travel will benefit all populations but may benefit EJ populations differently to the extent that they rely on walking or bicycling as a primary mode of transportation at a higher rate than those with greater access to multiple transportation options and/or higher incomes.

[11] While it is important to note that many low-income populations would benefit greatly from a faster, more reliable trip, EJ principles hold that to offset a disproportionate adverse effect on low-income populations, the benefit also needs to disproportionately affect low-income populations. In this case, the benefits of a faster, more reliable trip apply to all populations and not just low-income populations.

Preliminary Determination

The FHWA Guidance on Environmental Justice and NEPA (FHWA 2011) provides the following direction for determining disproportionately high and adverse effects on EJ populations:

> *As per FHWA Order 6640.23A, a disproportionately high and adverse effect on a minority or low-income population means the adverse effect is predominantly borne by such population or is appreciably more severe or greater in magnitude on the minority or low-income population than the adverse effect suffered by the non-minority or non-low-income population.*
>
> *1) EJ considerations should be summarized in the appropriate section of the NEPA document; such as the social-economic section of the environmental consequences chapter. References to other sections in the NEPA document can be cited, as appropriate. The beneficial and adverse effects on the overall population and on minority and low-income populations, in particular, need to be addressed under the applicable topics such as: air, noise, water pollution, hazardous waste, aesthetic values, community cohesion, economic vitality, employment effects, displacement of persons or businesses, farms, accessibility, traffic congestion, relocation impacts, safety, and construction/temporary impacts, etc.*
>
> *2) Compare the impacts on the minority and/or low-income populations with respect to the impacts on the overall population within the project area. Fair distribution of the beneficial and adverse effects of the proposed action is the desired outcome. If the effects remain adverse after mitigation is considered, then a determination must be made whether those effects are disproportionately high and adverse with respect to minority and/or low-income populations. If the effects on minority and/or low-income populations are disproportionately high and adverse even with mitigation and benefits to those populations taken into account, the NEPA document must evaluate whether there is a further practicable mitigation measure or practicable alternative that would avoid or reduce the disproportionately high and adverse effect(s).*
>
> *3) Under NEPA, consideration must be given to mitigation (as defined in 40 CFR 1508.20) for all adverse effects regardless of the type of population affected. Discuss what measures are being considered for alternatives to avoid or mitigate the adverse effects. Follow the protocol of avoidance first, then minimization, and finally measures to offset or rectify the adverse effects. Using opportunities to enhance and increase sustainability in communities and neighborhoods is desirable. Any activity that demonstrates sensitivity to special needs should be highlighted, such as accommodations for transit dependency and/or addressing the need for translators.*
>
> *4) If the effects remain adverse after mitigation is considered, then a determination must be made whether those effects are disproportionately high and adverse with respect to minority and/or low-income populations. If the effects on minority and/or low-income populations are disproportionately high and adverse even with mitigation and benefits to those populations taken into account, the next section must be followed.*
>
> *5) If there are no disproportionately high and adverse effects on minority and/or low-income populations once mitigation and benefits are considered, that determination should be stated in the document and the EJ evaluation is complete. (An example of a statement of a determination of no disproportionately high and adverse effects: "Based on the above discussion and analysis, the XYZ alternative(s) will not cause disproportionately high and adverse effects on any minority or low-income populations in accordance with the provisions of E.O. 12898 and FHWA Order 6640.23A. No further EJ analysis is required.".)*

A preliminary determination has been made based on the current assessment of environmental impacts, benefits, and mitigation strategies under the Modified LPA as described in this section. A final determination will be made in the Final SEIS subject to future refinements to the Modified LPA design options, input obtained through public involvement, and refined mitigation measures.

The preliminary determination finds that minority or low-income populations have been identified that would experience disproportionately high and adverse effects from the Modified LPA, even after mitigation. Therefore, in accordance with the provisions of EO 12898 and FHWA Order 6640.23A, further EJ analysis is required, as well as additional public engagement to refine potential impacts and gather public input on mitigation measures, in order to evaluate whether there is a further practicable mitigation measure or practicable alternative that would avoid or reduce the disproportionately high and adverse effect. This determination is based on the following:

- As of this writing, a number of design options under the Modified LPA are still being actively studied. The selection of preferred design options may impact the extent and magnitude of impacts, benefits, and mitigation strategies related to low-income and minority populations.
- As noted in Question 4 above, tolling on the Interstate Bridge is currently in a preliminary planning stage, and more analysis is required to understand the extent of impacts to EJ populations under the Modified LPA. Therefore, mitigation to avoid, minimize, reduce, or offset disproportionately high and adverse effects on low-income and minority populations has not been fully developed. More analysis and public involvement is required to gain a more complete understanding of impacts to low-income and minority populations from potential future tolls. Updated findings related to tolling will be documented in the Final SEIS.
- Some transportation impacts, such as temporary diversion impacts during the construction period or longer-term diversion impacts resulting from the proposed future tolling on the Interstate Bridge and new Columbia River bridges, require further analysis to understand EJ-specific impacts. As of this writing, the AM and PM peak-hour screenline analysis indicates that diversion impacts under the Modified LPA would range between +4% to +11%, representing a relatively minor change compared to the No-Build Alternative. Furthermore, the analysis has not found that EJ high-priority or meaningfully greater areas would experience diversion impacts disproportionately or in a greater magnitude than the general population. However, this analysis will be updated as part of the Final SEIS process to continue to identify potential disproportionately high and adverse effects on EJ populations.
- The IBR Program will hold a public comment period after the Draft SEIS and associated IBR technical reports are published. This will be the first time the general public will have the opportunity to review the identified impacts, benefits, and proposed mitigation actions for EJ populations. This period will also include a robust process to engage EJ populations specifically, which will provide critical feedback on the Draft SEIS and Environmental Justice Technical Report. The IBR Equity Advisory Committee, Community Advisory Committee, and Community Benefits Advisory Group will also provide feedback on the Draft SEIS and the draft reports. All public and advisory committee feedback will be incorporated to develop the Final SEIS.

FHWA guidance provides steps on how to proceed when disproportionately high and adverse effects have been identified after project benefits and mitigation have been taken into account (FHWA 2011). Following the additional analysis and community input described in the bullets above, the Final SEIS must evaluate whether there are further practicable mitigation measures or practicable alternatives that would avoid or reduce the disproportionately high effect(s). FHWA and FTA will approve the proposed action only if it determines that no such practicable measures exist, and FHWA and FTA's determination must be stated in the document. The Final SEIS must also describe how the impacted populations were involved in the decision-making process.

The document also needs to identify what practicable mitigation commitments have been made at the time of Final SEIS completion.

In addition, if the affected population is a minority population protected under Title VI, FHWA will not approve the proposed action unless FHWA and FTA determine that:

1. There is a substantial need for the project, based on the overall public interest; and
2. Alternatives that would have less adverse effects on protected populations have either:
    a. Adverse social, economic, environmental, or human health impacts that are more severe; or
    b. Would involve increased costs of an extraordinary magnitude.

Where appropriate, the Final SEIS document must include both of these evaluations and contain the FHWA and FTA determination on the explicit issues required within these evaluations.

3.21 Section 6(f) and Federal Lands to Parks

Analyses of impacts to park and recreation resources protected under Section 6(f) of the federal Land and Water Conservation Fund (LWCF) Act of 1965 (Section 6(f)) (16 U.S. Code [USC] 4601-4 et seq. and Public Law 88-578, 78 Stat. 897) and the Federal Lands to Parks (FLP) program are included in this section.

3.21.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with Section 6(f) and FLP has been updated in this Draft SEIS to include:

- Updates to information on Section 6(f) and FLP resources.
- Changes in land uses such as development at the Vancouver Waterfront, planned uses on Hayden Island, and recently constructed, altered, or removed buildings.
- Changes in the project footprint necessitated by changed conditions resulted in shifting the LRT alignment and modifying interchange designs.
- Updates to long-term and temporary effects of the Modified LPA.
- Updates to mitigation, in consultation with the agencies with jurisdiction, for the long-term and temporary effects of the Modified LPA.

The Parks and Recreation Technical Report for the CRC Final EIS identified the following four resources in the study area that are protected by either Section 6(f) and/or the FLP program. The CRC Final EIS discussed potential FLP replacement property related to Marshall Park but did not conclude the FLP or 6(f) processes. The same four facilities are identified in this Draft SEIS.

- East Delta Park and Strasser Field (Oregon) – Section 6(f) (south of North Union Court) and FLP program (north of North Union Court)
- Burnt Bridge Creek Trail (Washington) – Section 6(f)
- Old Apple Tree Park (Washington) – FLP program
- Marshall Community Center and Park (Washington) – FLP program

What is Section 6(f)?

Section 6(f) of the Land and Water Conservation Fund Act protects parks and recreational facilities that have received funding through this act. Converting protected properties to non-recreational use requires replacement land of at least equal fair market value and reasonably equivalent recreational utility and location.

3.21.2 Relevant Laws and Regulations

The following provides a description of the Section 6(f) and FLP program regulations and requirements.

Section 6(f)

Section 6(f) of the LWCF Act requires that an area funded with LWCF assistance be "continually maintained in public outdoor recreation use" unless the Secretary of the Interior, via the National Park Service (NPS), approves substitution per the conversion requirements. Environmental review of affected properties must include the entire LWCF-assisted park proposed for conversion even if only a partial conversion is proposed (54 U.S.C. § 200305(f)(3)).

The purpose of the LWCF Act is to assist in preserving, developing, and ensuring accessibility to outdoor recreation resources and to strengthen the health and vitality of the citizens of the United States by providing funds, planning, acquisition, and development of recreational facilities.

A partial acquisition of Section 6(f) property cannot affect the recreational function of the parklands. A temporary use of the land for more than six months may be considered a permanent conversion and acquisition of replacement land may be required.

Section 6(f)(3) requires that conversion of these lands or facilities be coordinated with NPS via the appropriate state liaison officer(s), which, for the IBR Program, are the Oregon Parks and Recreation Department (OPRD) and the Washington State Recreation and Conservation Office (RCO), and that all practical alternatives to the conversion of a 6(f) property must be evaluated as a prerequisite for conversion approval. If conversion is approved, other recreation properties of at least equal fair market value and of reasonably equivalent usefulness and location must be substituted.

FLP Program

The FLP program, administered by NPS in compliance with Section 203 (k)(2) of Public Law 91-485, as amended (40 USC 484 (k)(2)), helps communities to acquire, reuse, and protect federal properties for local parks and recreation. States, counties, and communities may (at no cost) acquire federal land and buildings that are no longer needed by the federal government with the condition that they are protected as public parks and recreation. FLP program lands or facilities have similar restrictions as Section 6(f) properties in that their conversion requires replacing with land of comparable or greater value and recreational utility, with another federal public-benefit conveyance program (such as for education, public health, or law enforcement) or purchased at fair market value (NPS 2022). If property conveyed under this program is acquired for a nonpark or recreation use, this conversion must be approved by NPS, and replacement property of equal market value and reasonable equivalent recreational utility must be identified and acquired. Additionally, the General Services Administration (GSA) must concur on a conveyance and exchange of property rights.

What is Federal Lands to Parks?

The FLP program helps communities to acquire, reuse, and protect federal properties for local parks and recreation. Similar to Section 6(f), converting FLP properties to a non-recreational use requires replacement land of comparable or greater value and recreational utility.

3.21.3 Existing Conditions

As described in Section 3.7, Parks and Recreation, parks and recreation facilities were identified within the study area, which extends from approximately the SR 500 interchange in Washington and the I-5/Columbia Boulevard interchange in Oregon and includes the potential construction staging sites, identified in Chapter 2, and the Ruby Junction Maintenance Facility in Gresham, Oregon. Both East Delta Park and the Burnt Bridge Creek Trail have received LWCF grant funds (OPRD 2023; RCO 2023). Portions of Marshall Park, Old Apple Tree Park, the Burnt Bridge Creek Trail, and a portion of East Delta Park that is not currently in use are protected by the FLP program. Parks within the study area that are protected by Section 6(f) and the FLP program are shown on Figure 3.21-1.

Figure 3.21-1. Section 6(f) and FLP Program Resources in the Study Area

Note: This figure does not include resources protected under Section 4(f) of the U.S. Department of Transportation Act, which are described in Chapter 4 of this Draft SEIS.

East Delta Park (Oregon)

Protected by Section 6(f) of the LWCF Act and FLP Program

East Delta Park is an 87.5-acre neighborhood/regional park located adjacent to I-5 between NE Martin Luther King Jr. Boulevard and N Denver Avenue.

East Delta Park is open to the public from 6:00 a.m. to 10:00 p.m. and is managed by Portland Parks and Recreation (PP&R). Facilities at East Delta Park include a sports complex with seven lighted softball fields, four synthetic soccer fields, five grass soccer fields, six sand volleyball courts, a playground, picnic tables, restrooms, a parking lot, support buildings, and nature trails. An off-leash dog area was located in ODOT right of way across Union Court; the dog park is currently closed. East Delta Park is also home to the PP&R Urban Forestry Division Headquarters, located between I-5 and Walker Slough. The area of East Delta Park protected with LWCF federal assistance is only the area within the official Section 6(f) boundary identified by NPS and shown in OPRD's geographic information system (GIS) data layer. No official boundary determination has been requested at this point; however, a boundary determination would be requested before conclusion of the NEPA process.

The FLP program–protected land is limited to an approximately 1-acre area north of North Union Court. This portion of East Delta Park is separate from the land protected by Section 6(f).

Old Apple Tree Park (Washington)

Protected by FLP Program

Old Apple Tree Park is a 1.3-acre community park located north of the Columbia River and BNSF Railway and south of SR 14 in the Vancouver National Historic Reserve (VNHR). Old Apple Tree Park can be accessed from Waterfront Park via a pedestrian underpass beneath the railroad or from the VNHR using the Confluence Land Bridge over SR 14. It is owned and maintained by the City of Vancouver and is open to the public from 5:00 a.m. to 10:00 p.m. The Old Apple Tree died in 2020 at the age of 194. Its history lives on through saplings that share its genetic makeup. Interpretive signs, fencing, and the stump of the original tree remain. Old Apple Tree Park still provides passive recreational space, viewing, and bike parking for the Confluence Land Bridge.

Marshall Community Center, Luepke Senior Center, and Marshall Park (Washington)

Protected by FLP Program

The Marshall Community Center and Park is a 19-acre community park located on the east side of I-5 south of McLoughlin Boulevard. Marshall Park, which was renovated in 2006, is owned and maintained by the City of Vancouver and is open from 5:00 a.m. to 10:00 p.m. The site facilities include large fully accessible playground with multiple features, community gardens, a loop trail, picnic tables, horseshoe pits, ball fields, and the Marshall Community Center and Luepke Senior Center. The Marshall Community Center, open weekdays from 6:00 a.m. to 8:00 p.m., with shortened hours on Fridays and weekends, has a swimming pool, a fitness center, two basketball courts, a commercial kitchen, meeting rooms, administrative offices, an aerobics dance studio, and an arts and craft studio. In 2022, the City of Vancouver completed a playground renovation at Marshall Park. The parking lot contains 272 parking spaces, including 26 spaces that are accessible per requirements of the Americans with Disabilities Act. The Luepke Senior Center is a full-service senior center with a multi-purpose room and meeting rooms. In 2010, a large group picnic shelter was added to Marshall Park.

The property was originally transferred to the City of Vancouver in 1986 through the FLP program, as administered by NPS. The FLP parcel is described in the original Application for Federal Surplus Property as a grassy area that is used by the public. It is adjacent to a horseshoe pit area and is gently sloping from south to

north. The existing parcel also contains a few medium-sized trees and provides a partial vegetative buffer between Marshall Park and I-5.

Burnt Bridge Creek Trail (Washington)

Protected by Section 6(f) of the LWCF Act

The Burnt Bridge Creek Trail is an 8-mile paved multiuse trail that travels through the Burnt Bridge Creek Greenway located on the east and west sides of I-5, north of the I-5/SR 500 interchange. The trail is owned and maintained by Vancouver Parks, Recreation and Cultural Services and travels over I-5 on a pedestrian and bicycle-only overcrossing south of the I-5/Main Street interchange.

3.21.4 Long-Term Benefits and Effects

East Delta Park and Strasser Field (Oregon)

Protected by Section 6(f) of the LWCF Act and FLP Program

Under all current design options, the Modified LPA would require the permanent acquisition of a sliver of park land (approximately 0.1 acres) to construct a wall supporting the I-5 northbound to Marine Drive interchange ramp along the western edge of East Delta Park (see Figure 3.21-2). This acquisition is being evaluated as a potential conversion of a Section 6(f)-protected resource. The IBR Program is coordinating with the Portland Parks and Recreation Department and OPRD on how to avoid, minimize, and/or mitigate potential impacts to East Delta Park—most recently in October 2023. As the coordination proceeds, OPRD will coordinate with NPS. Final approvals would occur after completion of the Draft SEIS process as project design is further developed and right of way is acquired.

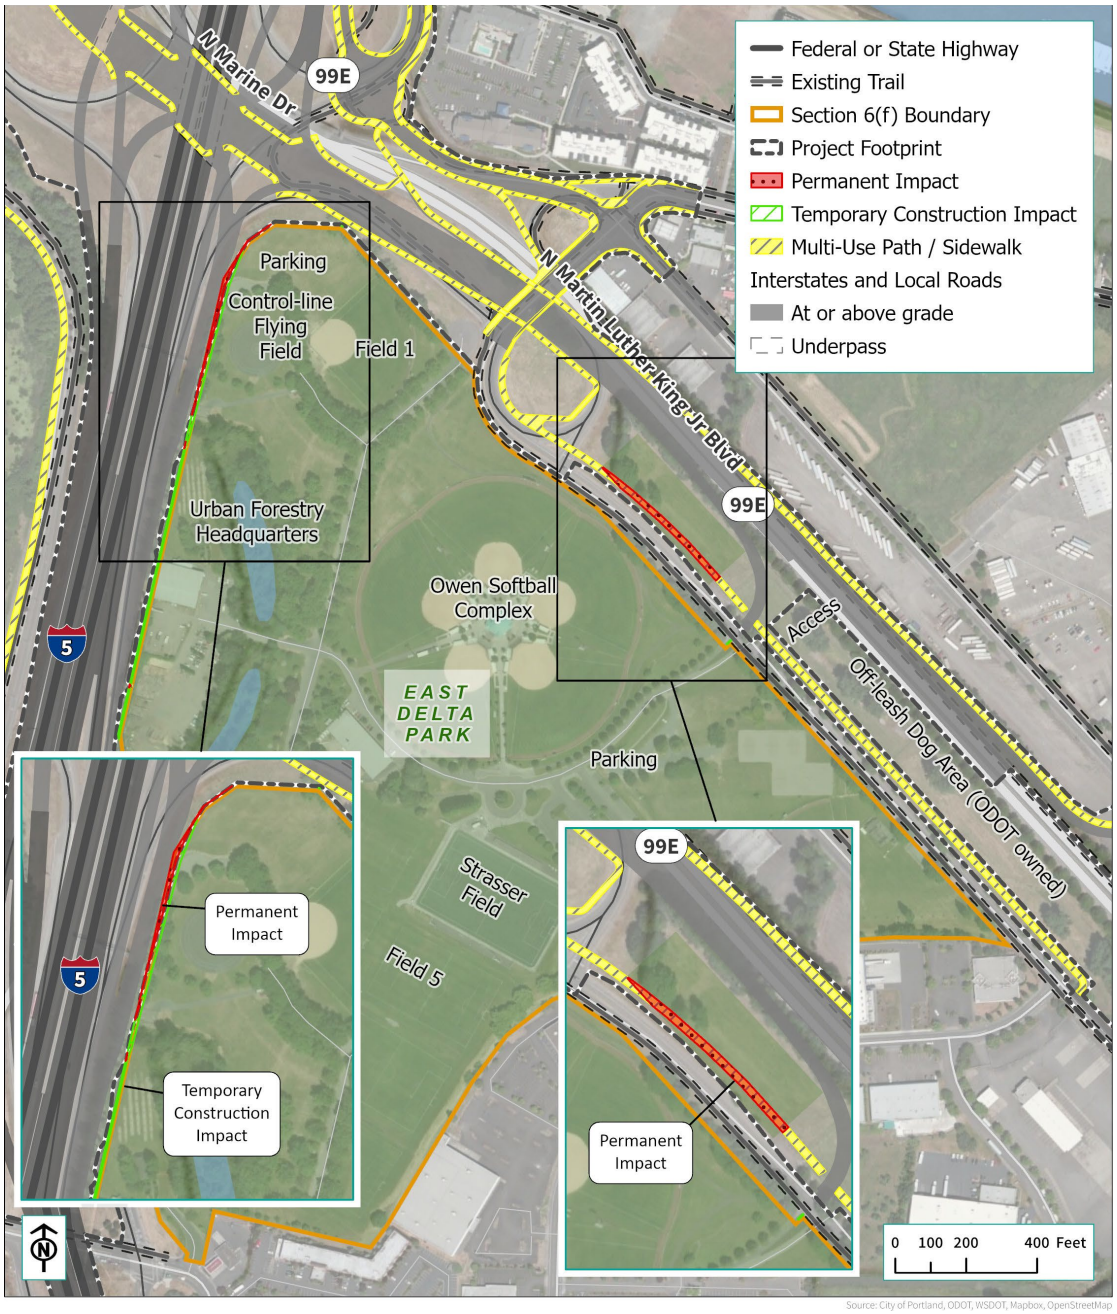
Approximately 0.1 acres of additional PP&R-owned park land would be acquired to construct the roadway connection between Martin Luther King Jr. Boulevard and N Union Court. This portion of East Delta Park is protected by the FLP program. This area is a small parcel located northeast of the main park and is not used by PP&R. Because the Modified LPA would affect FLP program–protected lands, it would require identifying replacement recreational land. Coordination and consultation will occur during the NEPA process, but final approvals of replacement land would occur after completion of the Draft SEIS process, as project design is further developed and right of way is acquired. These approvals by OPRD and NPS of the replacement land would be documented in a signed and executed LWCF conversion amendment.

Old Apple Tree Park (Washington)

Protected by the FLP Program

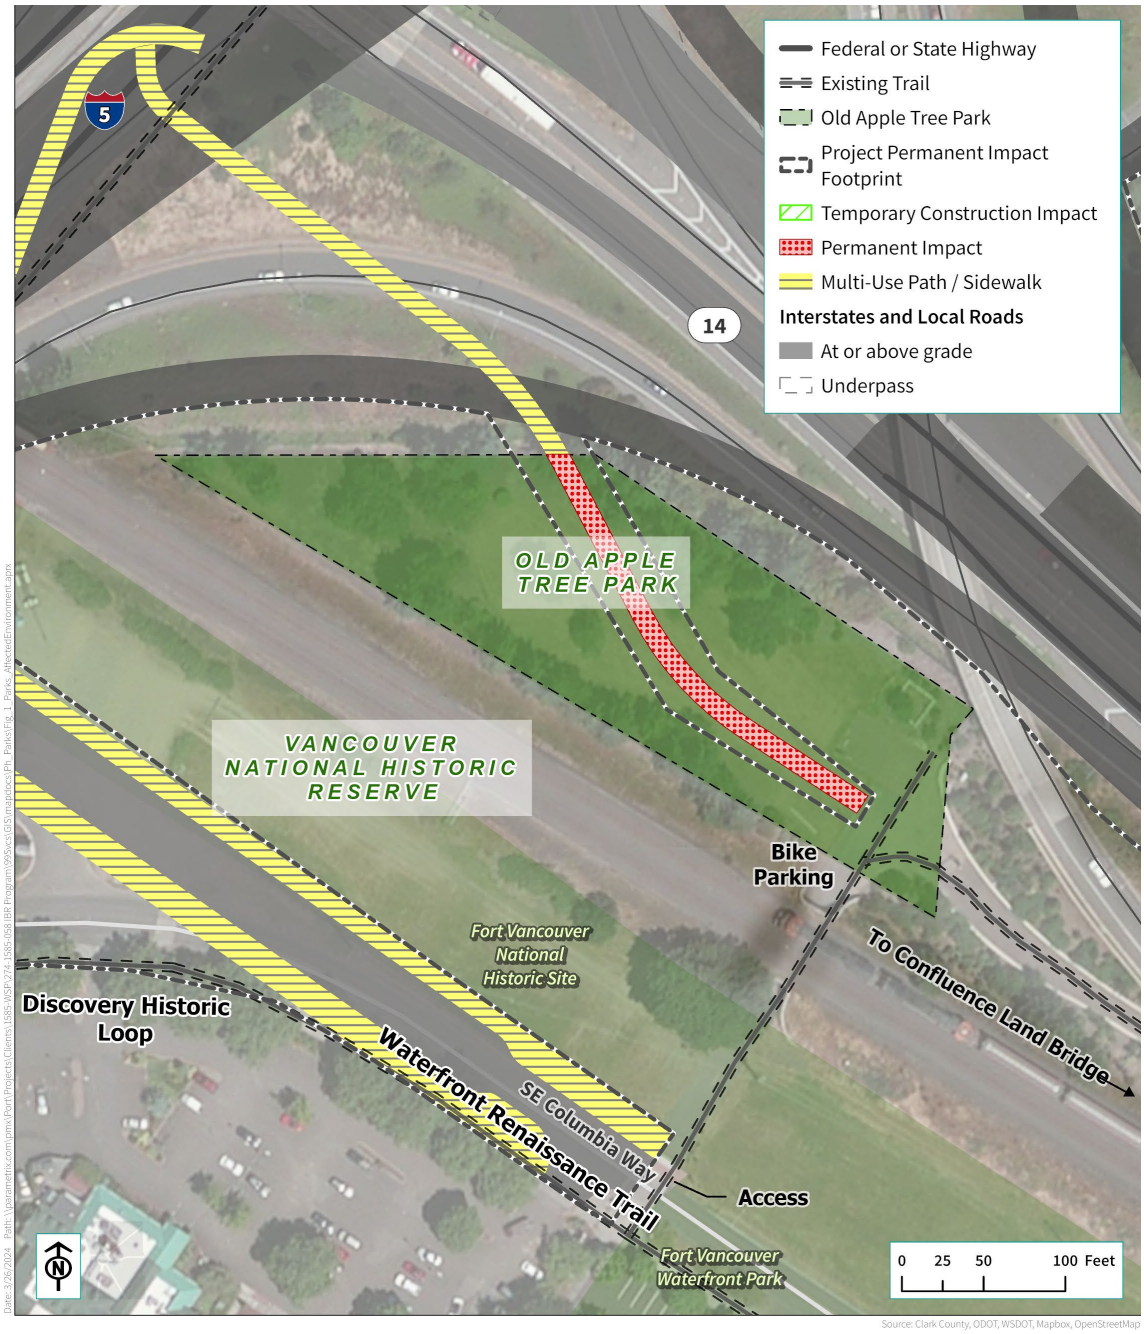
Under all design options, the Modified LPA would permanently acquire approximately 0.08 acres from Old Apple Tree Park for a new shared-use path that would link Main Street and downtown Vancouver (Figure 3.21-3). Users of the Confluence Land Bridge, which extends over SR 14 and connects the Vancouver waterfront with the VNHR, would benefit from this new path as they travel through Old Apple Tree Park. This acquisition may require providing replacement parkland, pending coordination among the IBR Program, RCO, and NPS. The IBR Program is coordinating with the City of Vancouver and NPS on how to avoid, minimize, and mitigate potential impacts to Old Apple Tree Park—most recently in October 2023.. Final approvals of replacement land would occur after completion of the Draft SEIS process, as the project design is further developed and right of way is acquired.

Figure 3.21-2. East Delta Park Section 6(f) and FLP Program Boundaries



All design options would also require a permanent airspace easement (less than 0.1 acres) over the northwest corner of Old Apple Tree Park for maintenance of the I-5 northbound to SR 14 elevated ramp. This easement would provide WSDOT with the right to enter Old Apple Tree Park with equipment to perform routine inspections of the ramp structure. This easement would not change the recreational use of the park, affect landscaping on the park property, or convert the land to a nonpark use.

Figure 3.21-3. Old Apple Tree Park FLP Program Boundaries



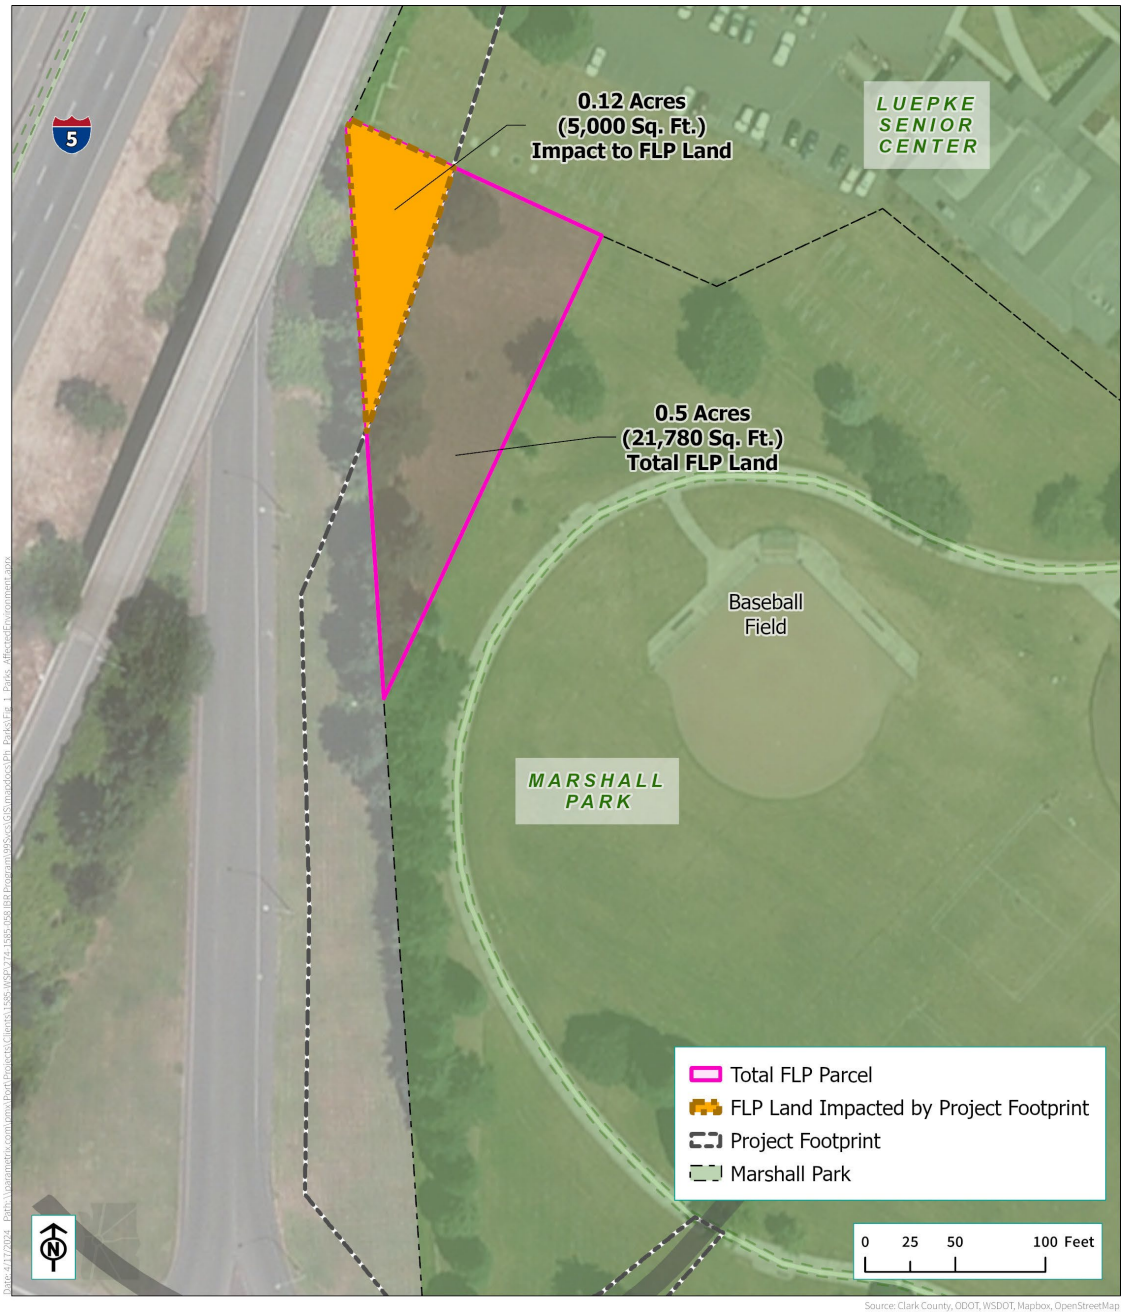
Marshall Community Center, Luepke Senior Center, and Marshall Park (Washington)

Protected by the FLP Program

The total area of FLP program–protected land at Marshall Park is approximately 0.5 acres. All design options for the Modified LPA would require approximately 5,096 square feet (0.12 acres) of the 0.5 acres of FLP program–protected land. Figure 3.21-4 shows this permanent property acquisition occurring along the western edge of the park parcel. These 5,096 square feet of land represent a small portion of the park's overall recreational utility and do not include recreational attributes that are unique to Marshall Park. The IBR Program is coordinating with the City of Vancouver and NPS on how to avoid, minimize, and mitigate potential impacts to Marshall Park—most recently in October 2023.. Final approvals of replacement land

would occur after completion of the Draft SEIS process as the project design is further developed and right of way is acquired.

Figure 3.21-4. Marshall Community Center, Luepke Senior Center, and Marshall Park FLP Program Boundaries

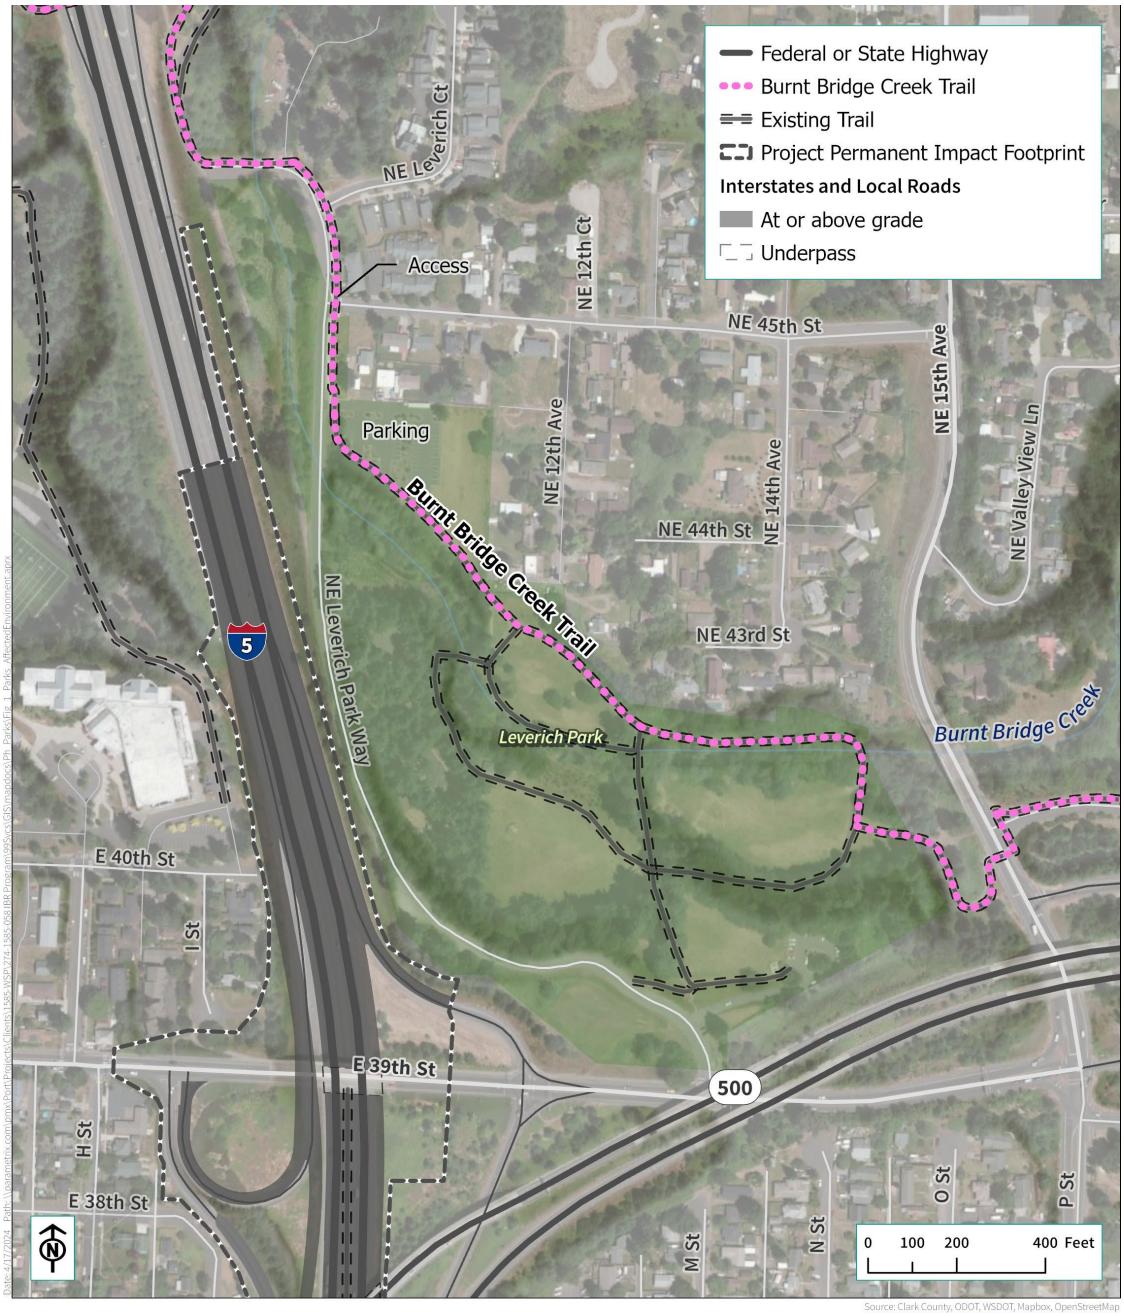


Burnt Bridge Creek Trail (Washington)

Protected by Section 6(f) of the LWCF Act

No design option under the Modified LPA would result in a conversion of the Burnt Bridge Creek Trail that is protected by Section 6(f) of the LWCF Act. The Burnt Bridge Creek Trail travels through Leverich Community Park (Figure 3.21-5) but would not be affected by the ramp from 39th Street to I-5 northbound that would tie into mainline I-5 south of the trail overpass. No adverse impacts to the trail are expected and no conversion would occur.

Figure 3.21-5. Burnt Bridge Creek Trail



3.21.5 Temporary Effects

No parklands protected by FLP would be subject to conversion during the construction of the Modified LPA, including construction of the new bridges and removal of the existing Interstate Bridge.

A temporary occupancy of approximately 0.2 acres and lasting less than 180 days at East Delta Park would be required during nearby construction activities. Because East Delta Park has been granted funds through the LWCF State Assistance Program, a request for the temporary non-conforming use within the LWCF boundary area must be submitted to OPRD, under the guidelines of the LWCF Federal Financial Assistance Manual. Later in the NEPA process, this would require state approval from OPRD and ultimately approval from NPS. Because the use would be temporary and would not exceed beyond 180 days, there would be no requirements for the provision of substitution property; however, mitigation will require bringing this area back to its original state,

including reseeding the lawn in this area and replanting any landscape that would require removal during construction. Criteria for OPRD and NPS approval of a temporary non-conforming use within an LWCF boundary area may include some or all of the following, depending on further consultation with and direction provided by OPRD and/or NPS:

- Size of the parkland area affected by the temporary non-recreation use, and its lack of significant impact to the other areas of the fund-assisted park.
- Temporary use does not result in permanent damage to the park and mitigation ensures there are no residual impacts on the site after the temporary use is concluded.
- No practical alternatives to the proposed temporary use exist.
- All applicable federal requirements for approval are met.

The application for approval from OPRD and NPS for temporary use requires the following documentation:

- OPRD recommendation.
- Complete description of the proposed temporary use, including the following:
  - Start and completion dates.
  - Identification of the portion of the site affected, including a map.
  - Justification of why the area needed is the minimum necessary for the proposed use.
  - Analysis of alternatives considered.
  - Description of impacts.
  - Mitigation and schedule.
- An acknowledgement from local agencies with jurisdiction over LWCF resources and OPRD stating that a full conversion will result if the temporary use extends beyond the maximum six-month (180-day) period.

3.21.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

This Draft SEIS identifies potentially affected Section 6(f)- and FLP-protected parkland resources, potential avoidance alternatives, and agency process requirements, which are early steps in a much longer process required to convert Section 6(f)- and FLP-protected properties to nonpark uses. The IBR Program has initiated consultation with OPRD and the City of Portland to discuss potential 6(f) impacts at East Delta Park. The IBR Program has initiated consultation with NPS, the City of Vancouver, and the City of Portland to discuss potential FLP impacts at Marshall Park, Old Apple Tree Park, and East Delta Park.

Looking forward, the conversion process will generally include replacement property proposal and consultation.

This process will consider public comment on potential conversion of LWCF and FLP lands identified in the Draft SEIS. The IBR Program will continue to look for ways to first avoid and then minimize effects on LWCF and FLP resources. If all practical alternatives to conversion of LWCF and FLP resources have been ruled out, the IBR Program will coordinate with the local agencies with jurisdiction over the LWCF and FLP resources, as well as a broader coordination process with OPRD NPS, and the GSA.

Avoidance

Alternatives to avoid 6(f) properties including reducing the right-of-way width of I-5 or realigning the Modified LPA farther west were evaluated.

Reducing the Right-of-Way Width of I-5 under the Modified LPA and Design Options

Measures to reduce the right of way of I-5 near East Delta Park could include reducing project elements such as shoulders, travel lanes, or light-rail transit (LRT) tracks. The Modified LPA and design options must meet federal and state highway design requirements for safety, to avoid substandard roadway design, and maintain or improve traffic operations. The project could potentially reduce the number of through travel lanes or eliminate the wider shoulders or auxiliary lanes. These measures would not meet the Program's Purpose and Need. The purpose of the Modified LPA is "to improve I-5 corridor mobility by addressing present and future travel demand and mobility needs in the IBR study area." Specific objectives include: "a) improve travel safety and traffic operations on the Interstate Bridge and associated interchanges; b) improve connectivity, reliability, travel times, and operations of public transportation modal alternatives in the study area; c) improve highway freight mobility and address interstate travel and commerce needs in the study area; and d) improve the Interstate Bridge's structural integrity (seismic stability)." Eliminating project elements including travel lanes, auxiliary lanes, shoulders, or LRT tracks would not improve traffic operations; connectivity, reliability, travel times, and operations of public transportation modes; nor would it improve highway freight mobility.

Reducing the width of project elements such as shoulders, and travel lanes would not meet federal and state highway design requirements, could compromise safety and would not meet the Program's Purpose and Need. For these reasons, reducing the width of the project is not a practical alternative to conversion of land from Delta Park.

Realigning Program Elements West

IBR Program Modified LPA and design options were designed to minimize impacts to existing businesses, residences, and natural resources in North Portland by using the existing I-5 alignment and right of way to the maximum degree possible. Shifting the Modified LPA or design options alignments to the west would incur large-scale impacts to businesses and residents in North Portland and also to natural resources. For example, immediately to the west of the proposed alignment near East Delta Park are the Vanport Wetlands.

For this reason, a westward alignment shift is not a practical alternative.

Program-Specific Mitigation

Program-specific mitigation measures for long-term effects related to LWCF resources will be developed in coordination with mitigation proposed for parks and recreation (see Section 3.7), and will be based on further consultations with the local, state, and national parks agencies throughout and beyond the NEPA process.

Temporary Effects

Mitigation measures for temporary effects related to LWCF resources will be developed in coordination with mitigation proposed for parks and recreation (see Section 3.7) and will be based on further consultations with the local, state, and national parks agencies throughout and beyond the NEPA process.

3.22 Aviation

An important goal of the IBR Program is to avoid or minimize hazards to aircraft navigation at nearby airports and associated airspaces. This section discusses existing aircraft navigation conditions and evaluates the associated beneficial and adverse effects of the Modified LPA and the No-Build Alternative.

There are two airports near the study area: Pearson Field in Washington and Portland International Airport (PDX) in Oregon. Each of these airports has federally protected airspace regulated by the Federal Aviation Administration (FAA). Long-term effects to aviation were evaluated using federal aviation regulations, which are the FAA rules that govern all U.S. aviation activities. Federal aviation regulations relevant to the IBR Program include regulating air navigation systems, lights or glare that may affect visibility, and management of wildlife hazards that may increase the probability of aircraft strikes.

The information presented in this section is based on analyses found in the Aviation Technical Report.

3.22.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with aviation has been updated in this Draft SEIS to include:

- Changes to aviation conditions and needs.
- Changes to federal, state, and local aviation regulations.
- New bridge configurations added for evaluation due to changed conditions that would each have varying heights with respect to proximity to protected airspace.

The main IBR Program component relevant to aviation is the replacement bridges over the Columbia River. The CRC LPA and IBR Modified LPA would both include a pair of double-deck fixed-span bridge configurations with 193 feet maximum height of the bridge with signage and luminaires. The Modified LPA also includes two additional configuration options: a single-level fixed-span configuration and a single-level movable-span configuration.

Table 3.22-1 compares the impacts and benefits between the CRC LPA and the IBR Modified LPA from the changes listed above. Based on this analysis, the Modified LPA would have the same or similar effects as the CRC LPA on aviation. A detailed description of impacts and benefits to aviation from the Modified LPA and associated design options follows.

Table 3.22-1. Comparison of CRC LPA Effects and IBR Modified LPA Effects to Aviation

Technical Considerations	CRC LPA Effects as Identified in the 2011 Final EIS	Modified LPA Effects as Identified in the Draft SEIS	Explanation of Differences
Aviation Safety	Less intrusion into Pearson Field protected airspace compared to the existing Interstate Bridge. Reduced potential for bird nesting or roosting.	Same as CRC for all configuration options.	N/A

Note: The CRC LPA and Modified LPA effects are as compared to a No-Build Alternative, unless otherwise noted.
CRC = Columbia River Crossing; LPA = Locally Preferred Alternative; N/A = not applicable; SEIS = Supplemental Environmental Impact Statement

3.22.2 Existing Conditions

Protected airspace is regulated by FAA per 14 Code of Federal Regulations (CFR) Part 77, including several imaginary[1] surfaces, in space and on the ground, established in relation to an airport and its runways. Figure 3.22-1 illustrates the following protected surfaces for civil (commercial) airports, such as Pearson Field and PDX, as defined in 14 CFR § 77.19:

Approach, departure, and other protected air navigation surfaces represent imaginary lines extending upward and outward from the center of the runway that define the area for evaluation of potential obstructions to safe takeoffs and landings.

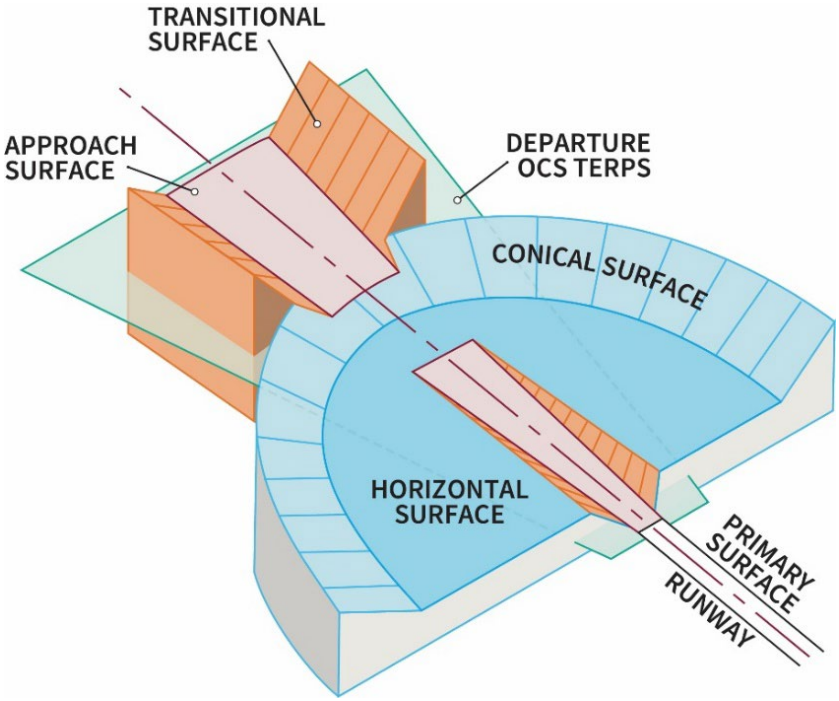
- **Horizontal surface**. A horizontal plane 150 feet above the established airport elevation.
- **Conical surface**. A surface extending outward and upward from the periphery of the horizontal surface at a slope of 20 feet of run to 1 foot of rise for a horizontal distance of 4,000 feet.
- **Primary surface**. A surface longitudinally centered on a runway.
- **Approach surface**. A surface longitudinally centered on the extended runway centerline and extending outward and upward from each end of the primary surface. The approach surface protects the airspace for aircraft on approach to land, ensuring that there are no obstacles or structures that could pose a hazard to aircraft during their approach and landing phases.

Transitional surfaces. These surfaces extend outward and upward at right angles to the runway centerline and the runway centerline extended at a slope of 7 to 1 from the sides of the primary surface and from the sides of the approach surfaces. Transitional surfaces ensure obstacle clearance for aircraft during the initial phases of their approach and departure.

In addition, aircraft departures from airports are managed by procedures developed under FAA Order 8260.3E U.S. Standard for Terminal Instrument Procedures (TERPS) as established in 14 CFR Part 95 and Part 97. Departure procedures must evaluate obstacles that penetrate a 40 feet of run to 1 foot of rise slope beginning at the end of a runway, which is called the "obstacle clearance surface" (OCS). If obstacles penetrate the OCS, then the airport is required to establish obstacle departure procedures for aircraft pilots.

[1] Surfaces are called imaginary because a person cannot see them; however, they define volumes of airspace to protect air navigation.

Figure 3.22-1. Typical Civil Airport Protected Airspaces



Portland International Airport

PDX is located about 3 miles southeast of the Interstate Bridge on the Oregon side of the Columbia River. It is the Portland area's major regional and international airport and serves large commercial passenger and freight service, private aircraft, and the Oregon Air National Guard. Potential future expansions include runway extensions and the addition of a new runway; however, the most recent Airport Master Plan update determined that these facilities would not be required through the 2035 planning horizon (Portland Bureau of Planning and Port of Portland 2008). Protected Part 77 airspace for PDX in the vicinity of the Interstate Bridge is approximately 130 feet above the top of the lift-span towers, and the Interstate Bridge is outside the OCS for PDX. As a result, the existing Interstate Bridge creates no intrusion or hazard for aircraft navigation at PDX.

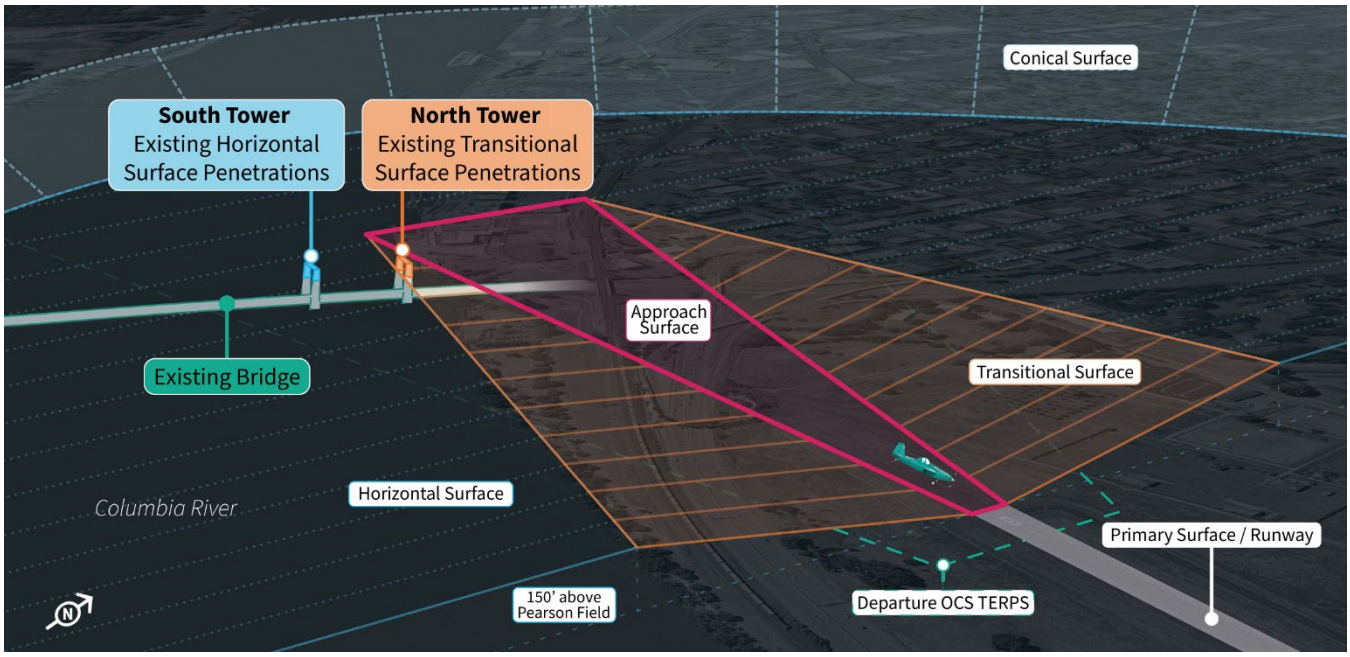
Pearson Field

Pearson Field, on the Washington side of the Columbia River, serves primarily small, piston-engine aircraft weighing 10,000 pounds or less. Because it is surrounded by developed urban uses and the Vancouver National Historic Reserve, there are no plans to expand facilities or operations at this airfield.

The existing Interstate Bridge and Pearson Field both predate current 14 CFR Part 77, Part 95, and Part 97 regulations. Currently, the Interstate Bridge lift-span towers intrude into Part 77–protected airspace (70 feet into the horizontal surface and 98 feet into the transitional surface) and the OCS for Pearson Field (see Figure 3.22-2). To mitigate these conditions, the existing lift-span towers are marked with lights, and the FAA issues obstacle departure procedures to avoid the Interstate Bridge lift towers.

Furthermore, the existing Interstate Bridge's open-truss framing unintentionally provides bird roosting and nesting areas, which in turn can contribute to potential wildlife strike hazards for aircraft. Wildlife strikes can cause damage to aircraft and potential loss of life; thus, birds and their habitat are an important concern at Pearson Field. To date, ODOT has used deterrents such as sound cannons to discourage birds from using the existing bridges.

Figure 3.22-2. Pearson Field Protected Airspace – Existing Bridge Penetrations



3.22.3 Long-Term Effects

No-Build Alternative

Under the No-Build Alternative, the Interstate Bridge lift-span towers would continue to intrude on Pearson Field's protected airspace. Existing obstacle departure procedures would remain in place for pilots. The open-truss structure of the existing bridge would continue to provide bird roosting and nesting habitat, functioning as a potential source of aircraft wildlife strike hazards. Hazards to aviation would remain because the Interstate Bridge lift-span towers have historically been an aviation hazard, and aircraft wildlife strike hazards from birds using the structure are documented and subject to mitigation measures.

Modified LPA

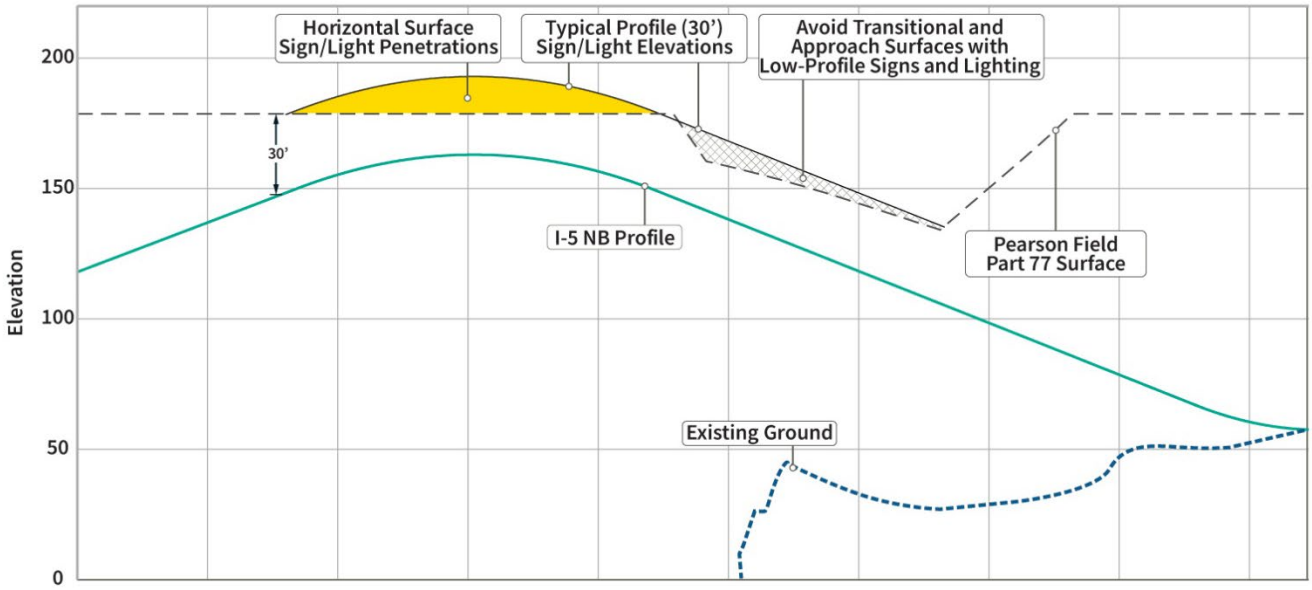
The Modified LPA, including all design options, would benefit aviation safety and efficiency. The new Columbia River bridges would be located slightly farther downstream and thus slightly farther from Pearson Field compared to the existing Interstate Bridge. The IBR Program has assumed a 17-foot vertical clearance envelope above the roadway surface to account for the height of vehicles operating on the highway. Above this envelope, the IBR Program assumes an additional 13-foot envelope to accommodate signs and lighting. The FAA provided feedback on potential penetrations, noting penetrations in the horizontal and transitional surfaces could be mitigated with low-profile signs and lighting, but penetrations in the approach surface could not be mitigated. Therefore, as bridge design progresses, the IBR Program will pursue designs that avoid penetrating the approach surface at Pearson Field. Effects to protected airspaces by bridge configuration include the following, summarized in Table 3.22-2:

- The roadway deck for the Modified LPA with a double-deck fixed-span configuration would have an approximate maximum height of 160 feet and would be outside protected airspace for Pearson Field. The 17-foot envelope above the deck for vehicle traffic would also avoid penetration of all protected airspace. The current design assumes a 13-foot envelope for signs and lighting above the vehicle envelope. If designed to the extent of this envelope, some signs and lighting would penetrate the horizontal surface to a maximum depth of

12.5 feet. Where needed, low-profile signs and lighting would be used to avoid intrusions into the approach and transitional surfaces (Figure 3.22-3 and Figure 3.22-4).

- The single-level fixed-span configuration (with the girder, extradosed, and finback bridge types)[2] would avoid intrusions to protected airspace.
- The lift-span towers for the Modified LPA with the single-level movable span configuration would penetrate the Pearson Field protected airspace, specifically the horizontal surface. The penetration would be located south of the existing tower locations, such that the new obstructions would not penetrate the Pearson Field transitional or approach surfaces (Figure 3.22-5). Therefore, although the single-level movable-span configuration would penetrate Pearson Field horizontal surface, it would not likely be a hazard to aviation.

Figure 3.22-3. Locations for Low-Profile Signs and Lights on Modified LPA with Double-Deck Fixed-Span Configuration (Profile View)



[2] See Chapter 2, Description of Alternatives, for more information on the girder, extradosed, and finback bridge types.

Figure 3.22-4. Locations for Low-Profile Signs and Lights on Modified LPA with Double-Deck Fixed-Span Configuration (Plan View)

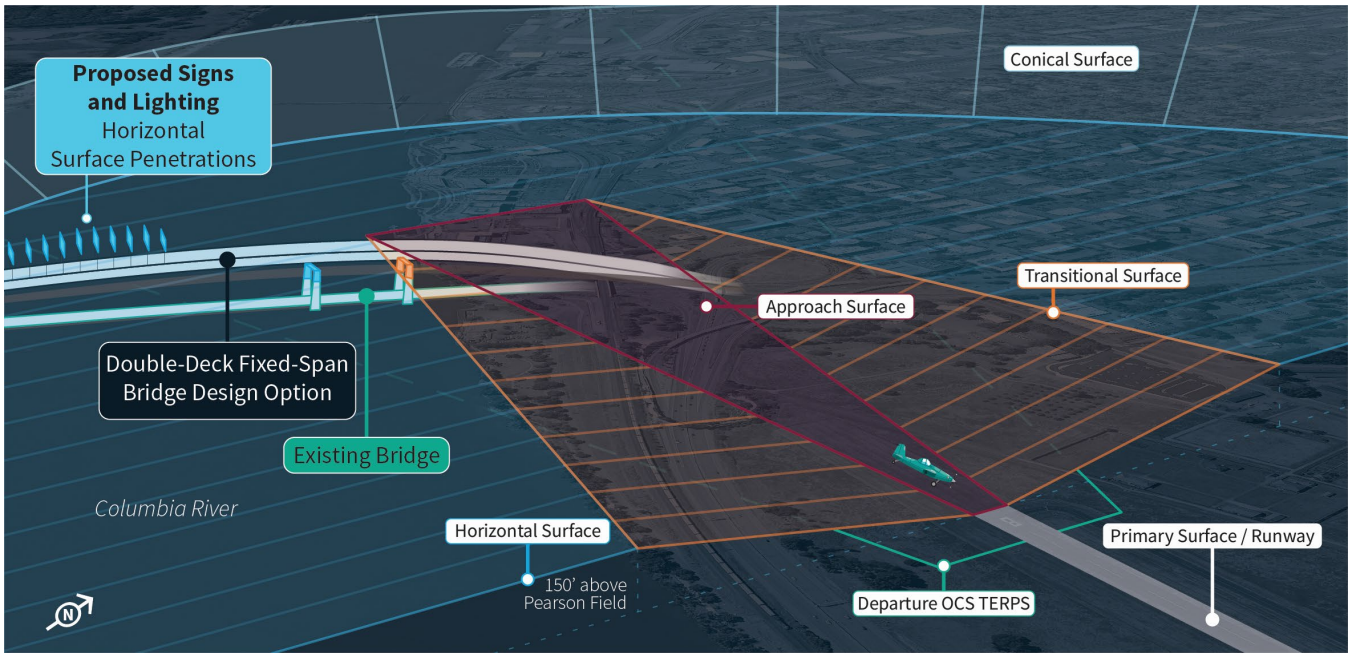


Figure 3.22-5. Pearson Field Protected Airspace – Modified LPA with Single-Level Movable-Span Configuration Intrusion

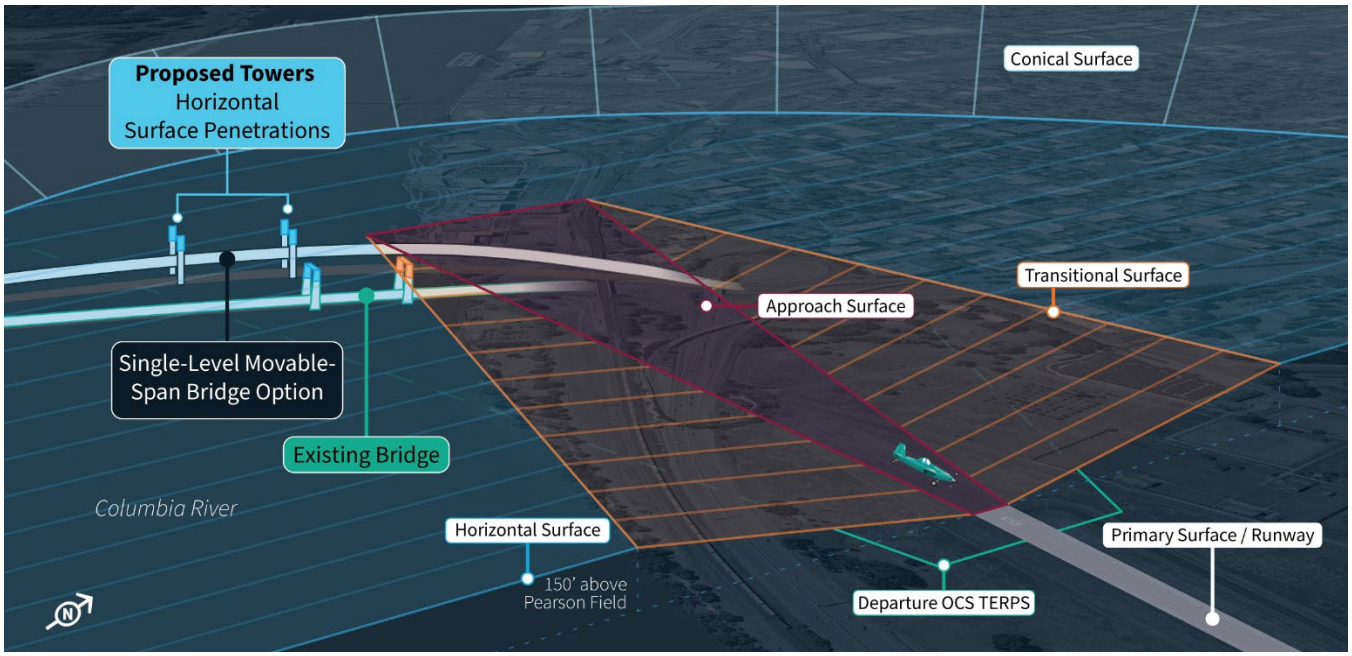

The goal of the new Columbia River bridges configuration and alignment is to minimize effects on both Columbia River marine navigation and Pearson Field air navigation. However, the vertical navigation clearance for marine vessels/cargo and the westbound departure OCS for Pearson Field overlap. Therefore, obstruction of the westbound departure OCS is unavoidable by any configuration or alignment. Under all the design options and configurations for the Modified LPA, westbound departure procedures would be required,

though these departure procedures would be to a lesser degree than the No-Build Alternative (Table 3.22-2). The effects of the Modified LPA on westbound departure procedures include:

- The Modified LPA with either the double-deck fixed-span configuration or the single-level fixed-span configuration (all bridge type options), including with the C Street ramps design option, would decrease the No-Build Alternative westbound departure procedures climb gradient from 650 feet per nautical mile (ft/NM) to approximately 427 ft/NM (double-deck) and 474 ft/NM (single-level), as the existing lift towers would no longer be an obstacle.
- The single-level fixed-span configuration (all bridge type options) without the C Street ramps at the SR 14 interchange would further reduce the westbound departure procedures climb gradient to approximately 401 ft/NM (double-deck) and 357 ft/NM (single-level).
- The Modified LPA with the single-level movable-span configuration would decrease the westbound departure procedures climb gradient from 650 feet per nautical mile (ft/NM) to approximately 544 ft/NM and 612 ft/NM respectively. There is no difference associated with or without C Street ramps, as the movable-span configuration would constrain the climb gradient.

The Modified LPA would be designed with consolidated structural elements that reduce the areas on which birds can land, roost, and potentially nest. Fewer birds would be attracted to the new Columbia River bridges as a result, and continued incorporation of bird deterrent measures into the bridge maintenance program would further reduce the potential for wildlife strike hazards at Pearson Field. Stormwater ponds constructed as part of the Modified LPA would include deterrent features commonly used at other airports, such as nets, to discourage birds from using the ponds.

No long-term effects on aviation activities at PDX would result from the Modified LPA because the new Columbia River bridges would remain outside its protected airspace. Protected airspace for PDX in the vicinity of the Interstate Bridge lift-span towers is approximately 130 feet above the top of the existing lift-span towers. Because the current preliminary movable-span configuration design proposes new lift towers at an elevation similar to the existing lift towers, the single-level movable-span configuration would not penetrate or create a hazard for aircraft navigation at PDX.

Table 3.22-2. Long-Term Effects on Pearson Field Aviation Surfaces and Departure Procedures

Aviation Component	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration	Modified LPA with Single-Level Fixed-Span Configuration [a]	Modified LPA with Single-Level Movable-Span Configuration
Horizontal Surface	98 vertical feet penetration by south lift tower, illuminated to increase visibility.	Up to 12.5 vertical feet penetration by signs and lighting, illuminated to increase visibility.	No penetration.	64 vertical feet penetration by lift towers; illuminate to increase visibility
Approach Surface	No penetration.	Use low-profile signs and lighting on north ends of upper decks to avoid penetration.	No penetration.	No penetration.
Transitional Surfaces	Penetration by existing Interstate Bridge north lift tower; illuminated.	Use low-profile signs and lighting on north ends of upper decks to avoid penetration.	No penetration.	No penetration.

Aviation Component	No-Build Alternative	Modified LPA with Double-Deck Fixed-Span Configuration	Modified LPA with Single-Level Fixed-Span Configuration [a]	Modified LPA with Single-Level Movable-Span Configuration
Westbound Departure OCS	Obstacle departure procedures required to avoid existing Interstate Bridge lift towers; climb gradient is 650 ft/NM.	Obstacle departure procedures required to avoid new bridges; climb gradient reduced to 427 ft/NM. Without C Street ramps, climb gradient further reduced to 401 ft/NM.	Obstacle departure procedures required to avoid new bridges; climb gradient reduced to 474 ft/NM. [b] Without C Street ramps, climb gradient further reduced to 357 ft/NM.	Obstacle departure procedures required to avoid new bridges; climb gradient reduced to 544ft/NM for vertical lift span, with and without C Street ramps.
Wildlife strike risk	Existing open-truss framing continues to provide bird roosting and nesting areas, existing ODOT deterrence measures continue; aircraft wildlife strike risk continues at existing level.	Design bridge features to reduce potential for bird nesting and roosting combined with continued deterrence measures would reduce potential for aircraft wildlife strikes from existing level.	Design bridge features to reduce potential for bird nesting and roosting combined with continued deterrence measures would reduce potential for aircraft wildlife strikes from existing level.	Design bridge features to reduce potential for bird nesting and roosting combined with continued deterrence measures would reduce potential for aircraft wildlife strikes from existing level.

a The long-term effects associated with the single-level fixed-span configuration would be the same for all bridge type options, unless otherwise specified.

b The climb gradient is steeper for the single-level fixed-span configuration with C Street ramps compared to the double-deck fixed-span configuration because of the single-level fixed-span configuration's increased width and the reduced distance between the C Street off-ramp and the Pearson Field runway.

ft/NM = feet per nautical mile; LPA = Locally Preferred Alternative; NB = northbound; OCS = Obstacle Clearance Surface; ODOT = Oregon Department of Transportation; Part 77 = CFR Part 77; TERPS = Terminal Instrument Procedures

3.22.4 Temporary Effects

No-Build Alternative

No Program-related construction activities would take place under the No-Build Alternative that would have temporary benefits or effects to aviation.

Modified LPA

Tall cranes used during construction of the Columbia River bridges and the SR 14 interchange and demolition of the Interstate Bridge may be hazards to aviation at Pearson Field. Equipment used to remove the existing lift-span towers would likely be the tallest construction equipment on site and therefore the most likely to present a hazard to aviation. The degree to which aviation would be affected depends on the construction methods employed. FAA would review construction plans to determine potential effects and associated mitigation before construction could begin.

Construction activities are not anticipated to affect aircraft navigation to and from PDX because construction equipment is not anticipated to exceed a height of 375 feet, the point at which it would begin to penetrate the PDX protected airspace.

Construction of the SR 14 interchange would penetrate the restricted airspace for Pearson Field. Temporary storage of fill, cranes, or other construction-related materials and equipment could also temporarily intrude into the aviation surfaces. As with the construction of the Columbia River bridges, the actual intensity of effects would depend on the equipment and construction methods proposed by the contractor. Following FAA's review of the equipment locations and heights proposed by the contractor, the FAA may issue temporary flight procedures during construction to aircraft operating at Pearson Field.

Construction dust or emissions from construction equipment in the SR 14 area could pose a short-term hazard to aviation from Pearson Field by reducing visibility. Wind could cause dust by disturbing uncovered fill or open excavations. Trucks and equipment traveling on unimproved construction roads could also stir up dust, impairing visibility.

Activities at the staging and casting yards would not be expected to have temporary effects on aviation.

Temporary aviation effects under the single-level movable-span configuration would be similar in character to those described above but would be longer in duration than for fixed-span configurations—potentially up to an additional two years. Effects would be prolonged because tall cranes would be required to construct the new lift towers associated with the movable-span configuration.

3.22.5 Indirect Effects

No anticipated indirect effects to aviation have been identified for the Modified LPA, including all design options.

3.22.6 Potential Avoidance, Minimization, and Mitigation Measures

Long-Term Effects

Regulatory Requirements

Standards and regulatory measures to avoid or minimize long-term effects on aviation have been evaluated and screened. These measures have been incorporated during the development of the Modified LPA to the extent possible and will continue to be refined as the design progresses.

During final design, the IBR Program would comply with the FAA's findings in response to the Program's Form 7460-1. The FAA would issue a finding of "hazard to aviation" or "no hazard to aviation" upon completion of the aeronautical review. In addition, the FAA would have requirements for marking obstacles; this would likely include marking according to FAA AC 70/7460-1M "Obstruction Marking and Lighting" using equipment specified in AC 150/5345-43J "Specification for Obstruction Lighting Equipment."

Program-Specific Mitigation

In addition to regulatory requirements, potential Program-specific mitigation measures have been identified and will be developed with the Modified LPA design.

Specific mitigation for aviation includes:

- Provide obstruction marking and lighting to make the river crossing structures visible to aircraft. Design roadway or accent lighting on the bridges and surrounding interchanges to limit light or glare that could affect aviation at Pearson Field or PDX.
- Place wire mesh or other deterrents over the top of stormwater detention ponds to conceal open water when they are full to prevent birds from landing or using selective plantings within ponds.

- Incorporate designs of proposed structures and features of the Program that minimize locations for birds to roost or nest.

Temporary Effects

Regulatory Requirements

To protect and minimize temporary effects on aviation during construction, standard and regulatory mitigation measures such as best management practices (BMPs) would be implemented. Construction BMPs applicable to the Modified LPA are discussed in Section 3.14, Water Quality and Hydrology.

Standard and regulatory mitigation measures for aviation include:

- In the area of demolition of the Interstate Bridge and construction activities for the Columbia River bridges and the SR 14 interchange, FAA would review and approve the location and height of tall construction equipment proposed by the contractor. Equipment would be marked following the FAA's Obstruction Marking and Lighting Standards described in Advisory Circular 70/460-1M.
- Apply dust control measures, such as watering exposed soil and using gravel surfacing on temporary construction roads, to mitigate potential reduction in visibility to aviation from construction activities in the SR 14 area. Section 3.10.6, Air Quality, lists dust control requirements in both Oregon and Washington. Manage construction materials and activities to minimize glare and smoke.

Program-Specific Mitigation

- Construction specifications for contractors working near Pearson Field would include a condition that any electronic devices used for communication or other purposes cannot interfere with equipment required for air navigation and communication.
- Place wire mesh or other deterrents over the top of temporary stormwater ponds to prevent birds from landing on open water.
- Provide public involvement throughout construction to provide information to pilots and the public.

3.23 Cumulative Effects

Cumulative effects result from the incremental effect of a proposed action when added to those of other past, present, and reasonably foreseeable future actions, regardless of the agency (federal or nonfederal) or person that undertakes such other actions. Cumulative effects can result from individually minor but collectively substantial actions that take place over a period of time (definition paraphrased from 40 CFR 1508.7).

The cumulative effects timeframes considered in this analysis are as follows:

- "Past" actions vary by component of the environment.
  - Natural environment analysis considers broad changes beginning in the 1800s.
  - Cultural environment analysis begins 15,000 years before present.
  - Built environment analysis starts in the early 1950s, with the construction of I-5. Additional historical context prior to the 1950s is described given the lifespan of the Interstate Bridge.
- "Present" actions are those ongoing in nature, such as maintenance of the existing transportation system.
- "Future" actions are those that will occur between the present (2024) and 2045, the design year of the IBR Program.

This analysis considers past major actions; planned transportation projects; population, employment, and land use forecasts; comprehensive land use plans; and other major public and private projects that are under development or reasonably expected to occur. Because the geographic scale of analysis varies by discipline, the cumulative effects analysis uses the study area identified in each technical report when evaluating cumulative effects on a particular resource.

The information presented in this section is based on the Cumulative Effects Technical Report, which contains greater detail and additional analysis.

3.23.1 Changes or New Information Since 2013

The Columbia River Crossing (CRC) Selected Alternative identified in the 2011 Record of Decision (ROD), as revised by the 2012 and 2013 re-evaluations, is referred to as the CRC Locally Preferred Alternative (CRC LPA). Over the past 10+ years since the CRC LPA was identified, the physical environment in the study area, community priorities, and regulations have changed, which necessitated design revisions and resulted in the IBR Modified LPA (see Section 2.5.2). Evaluation of potential impacts associated with cumulative effects has been updated in this Draft SEIS to include:

- Updates to past, present, and reasonably foreseeable future actions, or projects, in the study areas that have affected or could affect environmental and community resources.
- Changes in land uses such as development at the Vancouver waterfront, planned uses on Hayden Island, and recently constructed, altered, or removed buildings.
- Changes in the project footprint necessitated by changed conditions resulting in shifting the light-rail transit alignment, modifying interchange designs, and adding bridge configuration options.
- Change in transportation modeling and analysis.
- Changes in the direct and indirect effects on specific resources (as documented in each resource section).

Based on the analysis described in sections of Chapter 3, the effects of the Modified LPA would be similar to the CRC LPA. As such, the Modified LPA would have a similar contribution to effects caused by past, present, and reasonably foreseeable future actions and would have cumulative effects similar to those of the CRC LPA.

3.23.2 Past, Present, and Reasonably Foreseeable Future Actions

Past Actions

Past transportation projects, urbanization, housing, and other developments have influenced the social, economic, and natural environment reflected in the existing conditions of the region and study area. Past projects were not always planned and implemented with meaningful public input and communication.

Native Americans have occupied and traveled through the study area for thousands of years. Traces of their past activities are no longer easily identifiable in the study area's current natural and built environment; however, there are numerous cultural resources in the study area associated with these activities. In the 1800s, Euro-American settlement began and expanded with the Hudson Bay Company's post in Vancouver, and the Portland and Vancouver area population began to dramatically increase.

In the 1890s early urbanization in Portland and Vancouver was greatly influenced by the trolley line system, followed by the introduction of the automobile in the early 1900s. Construction of the Interstate Bridge occurred in two stages: the original bridge was built in 1917, followed in 1958 by construction of a parallel bridge and conversion of the 1917 bridge to northbound traffic only. Prior to 1917, unlimited vertical navigation (VNC) clearance at the Interstate Bridge location was available; however, the bridge limited this clearance to 178 feet when the bridge lift was fully opened. At that time, it was not expected that any navigation would have been reduced as larger vessels and cargo shipments began to transit the Columbia River in the 1930s to support building hydroelectric dams and the 1940s to support World War II shipbuilding activities.

Other past actions that influenced the built, social, and natural environment in the study area, include the removal of Indigenous peoples to reservations; authorization and maintenance of the federal navigation system on the lower Columbia River; airplane manufacturing at Pearson Field during World War I and shipyard manufacturing during World War II; urban renewal and large-scale transportation projects such as the construction of I-5; and greater concentration of development in urban centers under growth-management policies in Oregon and Washington.

Recently Completed Transportation Projects

Recent projects in or near the study area that give a sense of current development trends include:

- Port of Vancouver's West Vancouver Freight Access Project (Vancouver, west of I-5).
- Waterfront Renaissance Trail (Vancouver, east of I-5).
- Interstate Bridge northbound trunnion replacement (Vancouver/Portland).
- Interstate Bridge northbound active traffic management (Vancouver).
- Clark County Public Transit Benefit Area Authority (C-TRAN) bus-on-shoulder service (Vancouver, I-5, and Interstate 205 [I-205]).
- New metering on southbound I-5 at the 39th Street/SR 500 off-ramp (Vancouver).
- The C-TRAN The Vine on Mill Plain and Fourth Plain (bus rapid transit) (Vancouver).

Recently Constructed Development

- Multifamily residential buildings along N Marine Drive and N Anchor Way (Portland, east of I-5).
- Vanport wetlands restoration (Portland, west of I-5).
- Jantzen Beach Center redevelopment (outdoor mall) (Portland, Hayden Island, west of I-5).

- Floor and Décor (commercial store) (Portland, Hayden Island, east of I-5).
- Vancouver Waterfront (mixed-use development) (Vancouver, west of I-5).
- Hurley Building condominiums (Vancouver, west of I-5).
- New Seasons (grocery store) (Vancouver, west of I-5).
- West Barracks renovation (commercial properties) (Vancouver, east of I-5).
- Vancouver Community Library (Vancouver, west of I-5).
- Aegis/Providence Academy redevelopment (mixed-use development) (Vancouver, west of I-5).
- Block 10 (mixed-use development) (Vancouver, west of I-5).
- Office buildings at 210 W 4th Street and 1010 E 6th Street (Vancouver, west of I-5).
- Vancouver Center Condos (Vancouver, west of I-5).
- Vancouver Innovation, Technology and Arts Elementary School (Vancouver, east of I-5).

Present Actions

Present actions are those that are ongoing in nature, such as regional population growth and maintenance of the existing transportation system and ongoing transportation safety improvements. These include maintenance of the Interstate Bridge, the City of Vancouver's Pavement Management program, and the City of Portland's Fixing Our Streets program.

Reasonably Foreseeable Future Actions

For many resources, anticipated changes in conditions over time are linked to future changes in population, employment, traveler behavior, and transportation system performance, and land use patterns. Regional transportation forecast modeling is built upon the best available projections of 2045 population, employment, and land use changes and includes the transportation improvements that are reasonably expected to occur by 2045. Therefore, the analyses based on regional traffic forecast modeling are already cumulative. This includes the analysis of air quality, climate, energy (fuel and greenhouse gas [GHG] emissions), noise and vibration, and transportation.

The list of reasonably foreseeable future actions included in the cumulative effects analysis has been organized into three categories:

1. Future transportation projects.
2. Other future projects (non-transportation).
3. Future growth and regional changes identified in adopted state, regional, and local plans.

Future Transportation Projects

The list of reasonably foreseeable future transportation projects is based primarily on the transportation modeling conducted for the IBR Program, which is detailed in Appendix A of the Transportation Technical Report.[1] The list includes a variety of projects that are assumed to be built and in operation before 2045.

[1] ODOT's Regional Mobility Pricing Project was not included in the modeling or cumulative effects analysis as that project was not included in the 2018 RTP. Additionally, all work on the Regional Mobility Pricing Project was halted in March 2024 at the direction of the Oregon governor, and the project is not anticipated to be reinitiated at this time.

Sources for this future transportation project list include the financially constrained project list in the 2018 Regional Transportation Plan (RTP) . [2]

The list of future transportation projects considered for the No-Build Alternative cumulative effects analysis includes the projects noted above but does not include the improvements proposed under the Modified LPA and assumes that the Interstate Bridge would not be tolled. The Modified LPA assumes the same future transportation projects as the No-Build Alternative, with the addition of the Program components, including additional auxiliary lanes on I-5, light-rail transit extension from the Expo Center Station in Portland to Evergreen Boulevard in Vancouver, active transportation improvements, and variable-rate tolling on the Columbia River bridges.

The RTP transit projects and the service levels they include reflect regional growth priorities and policies emphasizing lower reliance on driving and more transit and active transportation to meet future regional mobility needs. The Transportation Technical Report provides further detail on the other transportation projects included in the 2018 RTP, but the primary transit projects in the 2018 RTP to improve regional transit and meet the demands of future growth are listed below.

- Five high-capacity transit projects: Division Transit, Southwest Corridor, Red Line extension, the Central City Capacity Analysis, and Steel Bridge Improvements.
- Nineteen enhanced transit projects and two streetcar extensions, involving capacity, speed and reliability improvements throughout the region.
- Investments in the vehicle fleet, maintenance facility expansions, and technology to improve operations.

Other Reasonably Foreseeable Future Projects

Other reasonably foreseeable future projects considered in the cumulative effects analysis were identified based on proximity to the area where most physical changes associated with the Program would occur (see Figure 2-1 in the Cumulative Effects Technical Report). This list of projects, described below, was confirmed with local and regional partner agencies.

- **Vancouver Waterfront.** This ongoing project is a large-scale mixed-use development led by a public/ private collaborative partnership between the City of Vancouver and private development interests. A master plan was approved for the 20-block, 32-acre site, which included new office and residential space in addition to a public park and multiuse trail. While the improvements are largely complete, private properties at the waterfront continue to be developed. No timeline is currently available for when the remaining blocks would be developed, but construction could overlap with construction of the Modified LPA.
- **Terminal 1.** The Port of Vancouver USA is developing a 10-acre property known as Terminal 1, which is located between the Vancouver waterfront (described above) and the existing Interstate Bridge. Terminal 1 would be a mixed-use development with a hotel, office and retail space, outdoor gathering areas, and a public marketplace. Terminal 1 would also complete a missing segment of the Vancouver Waterfront Renaissance Trail, connecting the existing trail at the Vancouver waterfront to the existing Columbia River Renaissance Trail east of Terminal 1. Some elements have been constructed, including an outdoor amphitheater. Construction of other features is underway, with an anticipated completion date of 2027.

[2] Federal regulations require that an RTP be financially constrained. This means that total transportation expenditure levels identified within the RTP must not exceed the total revenue level reasonably expected to be available for the metropolitan region over the life of the plan; this includes existing revenues and new revenues that may be reasonably anticipated. Transportation modeling typically includes only projects in the fiscally constrained RTP. However, one transportation project, the Fourth Plain Safety and Mobility project, is not listed on the financially constrained list in the RTC's regional transportation plan (RTP) but was incorporated into the modeling at the request of partner agencies.

- **Renaissance Boardwalk.** The Renaissance Boardwalk project is a public-private partnership between Kirkland Development and the City of Vancouver to develop a 2.3-acre plot of land directly to the east of the Interstate Bridge. The development plans include two new buildings and underground parking, with 230 apartments and retail space for 30 tenants. A public walkway along the water's edge would be included in the development and would connect to existing trails. Construction is planned to begin in spring 2024; an anticipated end date has not been published.
- **Waterfront Gateway.** This project, run by the Vancouver City Center Redevelopment Authority, would redevelop a 6.4-acre site in downtown Vancouver near City Hall. The City Center Redevelopment Authority has selected a development team to move forward with efforts to turn the site into a mixed-use destination space that includes office, retail, and residential uses. The City has identified this project as a major opportunity for housing and economic growth, given the site's position between the waterfront and downtown Vancouver. While some project details are available (including a high-level site plan and potential residential units), environmental studies are not currently available for the project. The project is currently in the design phase, with construction projected to begin in early 2025 and end in 2027.
- **Levee System Improvements.** There are two concurrent efforts underway to improve the existing levee system along the Columbia River near the Interstate Bridge: the U.S. Army Corps of Engineers (USACE) and Urban Flood Safety & Water Quality District (UFSWQD) Portland Metro Levee System project and Flood Safe Columbia River. Proposed improvements include raising the elevation of the levees. Anticipated environmental impacts for this project are documented in the Final Integrated Feasibility Report and Environmental Assessment (USACE and CCDD 2021), with a Finding of No Significant Impact signed in April 2022. The IBR Program is coordinating with the agencies involved to ensure the design efforts consider the timing and scope of the proposed modifications to the levees.
- **Restoration and Habitat Projects.** There are several planned restoration projects within and near the Program footprint and along habitat corridors or waterways that pass through the footprint. Restoration activities are planned along Burnt Bridge Creek in Vancouver and the Columbia Slough in Portland (Ecology n.d.; Lee and Stamberger 2018, respectively). These projects are led by various agencies and organizations including the Cities of Vancouver and Portland and the Columbia Slough Watershed Council. Restoration actions are likely to occur as funding becomes available, and no specific timeline is available.
- **Portland Expo Center Redevelopment (Expo Future).** Metro owns the Portland Expo Center, which is a 53-acre employment and exhibition site located west of I-5. Following a development opportunity study, Metro recommended redevelopment of the Expo Center into a sports and cultural complex. While a general future use has been recommended, project details are still to be determined, and therefore many potential effects (and contribution to cumulative effects) cannot be described quantitatively at this time. No schedule or timeline is currently available for this project. The IBR Program will continue to coordinate with Metro as the Expo Center project progresses.
- **Cascade Renewable Transmission Project.** Installation of a new high-voltage transmission cable buried in the bed of the Columbia River through the study area will transfer energy from utility-scale wind, solar, and other renewables to help meet renewable energy demand in Oregon and Washington. The transmission cable will extend from The Dalles to Portland, traveling approximately 100 miles beneath the Columbia River. Some general environmental information is available about the project and the proposed technology; however, no detailed studies are available and it is anticipated this project will require an EIS. No schedule or timeline is currently available for this project. The IBR Program will coordinate with the utilities involved to consider the timing and location of the proposed facility.

Future Growth and Regional Changes Identified in Adopted State, Regional, and Local Plans

Adopted state, regional, and local plans include visions of growth or change in the region over the next 20 years. These visions are reflected in this analysis, as the plans' assumptions regarding growth were inputs into the regional modeling conducted for air quality (including GHG emissions), energy, noise and vibration, and transportation. Details on how projected changes in population, land use, employment, and other factors are reflected in the regional modeling are provided in Appendix A of the Transportation Technical Report.

3.23.3 Cumulative Effects

Please see the resource technical reports for additional information on anticipated Modified LPA effects on a particular resource (e.g., air quality, wetlands). Although there are some differences in direct and indirect impacts and benefits associated with the various design options, these differences generally do not change the conclusions regarding the Program's contribution to cumulative effects for each resource.

Transportation

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Past and present actions affecting transportation in the study area (and region) include population growth and accompanying development, which subsequently led to an increase in single-occupancy and freight vehicles on roads, and the expansion of public transit and active transportation networks. Past actions that have supported the growth and reliance on single-occupancy vehicles include the construction of I-5 and the Interstate Bridge. Past public transportation improvements in the area include expansion and increase in service of the Tri-County Metropolitan Transportation District of Oregon (TriMet) bus and light-rail system (including the extension of light-rail to the Expo Center in 2004), as well as the C-TRAN bus service (including the recent introduction of bus rapid transit along Fourth Plain Boulevard and Mill Plain Boulevard in 2017 and 2023).

Many of the reasonably foreseeable future actions, primarily those identified in the 2018 RTP, are transportation projects that address the anticipated needs of the community for travel by vehicles, freight, public transit, and active transportation. The non-transportation future actions reflect the ongoing growth and development in the region that will rely on the existing and planned transportation networks, including new commercial and residential units at Waterfront Gateway, Renaissance Boardwalk, and Terminal 1.

Primary transportation trends in the study area include the growing number of vehicles on the roads (with increasing congestion and crash rates) and a growing demand for more public transit and active transportation options.

No-Build Alternative

Under the No-Build Alternative, congestion would continue to increase and the active transportation and transit improvements proposed under the Modified LPA would not be constructed. Congestion at the bridge would continue to be caused by overall high traffic volumes, the structure's limited capacity, limited sight distance, substandard shoulders, short merge and diverge locations north and south of the bridge, high-volume on- and off-ramp flows north of the river, and high truck volumes.

Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on transportation (identified above) would continue under the No-Build Alternative. Future growth and development would continue to increase transportation demand. Although other transit projects may be implemented in the region, their benefits would be reduced if the Modified LPA is not included as anticipated in adopted regional plans. Active transportation systems would be expanded but not between Portland and Vancouver. Tolling of I-205 (Abernethy Bridge), which is currently on hold, but if advanced in Oregon would

likely contribute to the beneficial cumulative effects of several future projects that would reduce regional congestion and increase the use of public transit and active transportation.

Modified LPA

The Modified LPA would reduce freight and vehicle congestion, improve safety, and improve the connectivity, capacity and reliability of active transportation and transit networks. Future travel demand would be more efficiently served by the multimodal transportation improvements included in the Modified LPA as well as other improvements in the region, consistent with adopted regional transportation plans. The region's goals for higher levels of transit and active transportation use would be better supported by the completed transit and trail connections between Portland and Vancouver, in combination with other regional projects. The key drivers of transportation demand—other future population growth and accompanying developments—will continue to affect conditions for all transportation modes and facilities in the study area and region.

Cumulative Effects Conclusion – Transportation

Past actions affecting transportation in the study area include the construction of I-5 and the Interstate Bridge, construction of state and local transportation networks, implementation of public transit service, and the establishment of local transit agencies (TriMet, C-TRAN) and regional metropolitan planning organizations (Metro, RTC). These actions, taken in response to rapid regional growth, have had a cumulative effect of providing additional transportation capacity, safety improvements, transportation demand management and transportation systems management enhancements on highways, public transit systems, and active transportation networks. Some areas continue to experience congestion where the demand for transportation exceeds capacity, and safety challenges are still present. Recent projects, such as development in downtown Vancouver, along with population growth have continued the trend of more vehicles on the road and exacerbated congestion, while other projects, such as The Vine, have improved access to alternative transportation options. Planned reasonably foreseeable future actions included in the 2018 RTP will contribute to managing congestion, improving safety, and expanding the transit and active transportation networks; however, under the No-Build Alternative (including the effects of past, present, and future actions), congestion would continue to grow and safety would continue to worsen. As compared to the No-Build Alternative with past, present, and reasonably foreseeable future actions, the cumulative effect of the Modified LPA (including the effects of past, present, and reasonably foreseeable future actions) would be an improvement to congestion and safety (see Table 3.1-10 and 3.1-12).

When combined with past, present, and reasonably foreseeable future actions, the No-Build Alternative would have adverse cumulative effects because of growing congestion and crashes. The cumulative effects on transportation from the Modified LPA combined with past, present, and reasonably foreseeable future actions, when compared to the No-Build Alternative, would be beneficial with fewer vehicle hours of delay and lower crash frequency on I-5.

Navigation

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Past actions affecting river navigation include authorization and construction of the Columbia River federal navigation channel, construction of upstream dams and navigation locks, construction of the existing Interstate Bridge and North Portland Harbor bridge, and other bridges constructed downriver and upriver of the study area, such as the BNSF Railway Bridge (which has 79 feet of vertical clearance when in the closed position and unlimited vertical clearance when in the open position) and the I-205 Glenn L. Jackson Memorial Bridge (which has a fixed vertical clearance of 136 feet). The location of the existing navigation channels in the river requires vessels to make an S-curve maneuver between the Interstate Bridge and the BNSF Railway Bridge opening when transiting the barge or alternate barge channels.

The federal navigation channel at and upstream of the Interstate Bridge was established as a deep-draft (27 feet) channel to accommodate ocean-going ships upstream to The Dalles. This shipping traffic never materialized, and the USACE currently maintains the channel to a depth of 17 feet, reflecting current river traffic. If the USACE were to deepen the channel from Vancouver to The Dalles to 27 feet as authorized, it would allow deeper-draft vessels to traverse the study area, which could contribute to a change in waterway use. Few properties exist within this reach of the river (BNSF Railway Bridge in Vancouver to Celilo Falls BNSF bridge) that have current commercial/industrial facilities using waterborne shipping or the potential for future such facilities. The primary factors affecting commercial/industrial development along the Columbia River are political and geographic constraints, including the Columbia River Gorge National Scenic Area, transportation routes paralleling the river, steep topography, and existing recreational and open space uses. Industrial uses generating marine vessel traffic are typically located within industrial parks in urban areas.

Several ongoing and planned navigation maintenance projects downriver and upriver of the Interstate Bridge could contribute to long-term beneficial cumulative effects on navigation in the study area. The USACE maintains the federal navigation channels to the authorized and/or maintained depths by conducting maintenance dredging on a yearly basis for the federal navigation channel along the Columbia River. The USACE is developing an updated Channel Maintenance Plan with lower Columbia River ports to ensure that the federal navigation channel downstream is maintained and operational for another 20 years. Dredging is also conducted by ports and private entities in the area to maintain adequate waterway depth at marinas and marine terminals.

No reasonably foreseeable future actions were identified that would contribute to a long-term adverse cumulative effect by restricting reasonable navigation. Upriver navigation and marine commerce development would continue to be restricted by existing political and geographic constraints, such as the National Scenic Area and the navigation clearance under the I-205 bridge and other upriver governing structures (e.g., bridges, utility lines).

Temporary cumulative effects on navigation would occur during construction of other reasonably foreseeable future actions, as addressed in Section 3.23.4.

No-Build Alternative

Columbia River navigation conditions would not be changed by the No-Build Alternative; navigation would continue to be affected by the existing piers and bridge opening restrictions. Under the No-Build Alternative, the primary navigation channel under the Interstate Bridge would remain in its current position, which generally lines up with the opening in the BNSF Railway Bridge. The alternate channels under the Interstate Bridge are located toward the center and south bank of the river, thus requiring vessels to make an S-curve maneuver between the Interstate Bridge and the BNSF Railway Bridge opening.

Routine maintenance dredging performed by the USACE's dredge *Yaquina* would continue to maintain the federal navigation channel to an adequate depth to support current navigation needs. Without seismic upgrades to the Interstate Bridge, a major earthquake could collapse or seriously damage one or both bridges, temporarily restricting or preventing navigation.

Modified LPA

Under the Modified LPA (including all bridge configurations), river navigation safety in the main channel of the Columbia River would be improved by (1) reducing the need for an "S" curve maneuver (to align with the BNSF Railway Bridge opening) for many vessels that currently use the barge and alternate barge channels and could use the northern channel under the Modified LPA, which would provide a straighter route between the two bridges, (2) increasing horizontal navigation clearance by reducing the number of piers, and (3) improving

seismic resiliency.[3] In addition to the main channel, the Modified LPA would improve navigation safety on North Portland Harbor through improved seismic resiliency and wider pier spacing, which would allow more room for smaller vessels to pass under the new bridges.

There would be some differences in impacts to navigation from a fixed-span configuration (either double-deck or single-level) compared to a single-level movable-span configuration, specifically associated with the VNC. The movable-span configuration would provide a VNC of 178 feet in the open position for a vertical lift span bridge and be consistent with the U.S. Coast Guard's Preliminary Navigation Clearance Determination (issued in May 2022). The two fixed-span configurations would provide 116 feet VNC, which would prohibit some existing vessels from transiting unless modifications or other accommodations were made to those vessels or cargo. A fixed-span configuration would permanently prevent vessels with VNC requirements of greater than 116 feet (and unable to modify the vessel) to transit under the bridge for its 100+ year service life.

Under a movable-span configuration, vessels requiring a bridge opening would be restricted to specified time periods to transit the new Columbia River bridges; timing restrictions would be updated and formalized during a federal rulemaking process. Under the single-level or double-deck fixed-span configuration, all vessels would pass under the bridges without timing restrictions.

Dredging activities performed by the USACE's dredge *Yaquina* would not be affected by the Modified LPA; however, during construction of the Modified LPA, there would be occasions when the dredge *Yaquina* would not be able to transit the bridge unless the dredge was modified, or alternate measures of dredging would be implemented.

Cumulative Effects Conclusion – Navigation

Past actions have both improved and limited navigation conditions in the study area. The establishment of federal navigation channels and associated dredging improved navigation and allowed for deeper draft vessels to transit the Columbia River from the Pacific Ocean to the BNSF Railway bridge in Vancouver, while the construction of bridges, dams, and overhead utilities across the river, as well as land use restrictions, have limited navigation along the full length of the Columbia River. Past, present, and reasonably foreseeable future actions along with the No-Build Alternative would retain the existing Interstate Bridge with nine in-water pier sets and narrow horizontal navigation clearances. Vessels that do not require a bridge opening, including most tugboats with barges, would continue to use the barge and alternate barge channels requiring S-curve maneuvers, which can be hazardous to navigation in inclement weather and high-water conditions, to align with the nearby BNSF Railway bridge. Ongoing and planned maintenance of the navigation channels by USACE and others would continue under the No-Build Alternative.

Along with maintenance of the navigation channels, the Modified LPA would improve navigation by providing a straighter route for many vessels to transit through the new Columbia River bridges and the BNSF Railway Bridge via the relocated barge channel (north) and a reduction in the number of in-water piers, as well as improved seismic resiliency. Vessels using the primary navigation channel (center) and alternate barge channel (south) would need to make an S-curve maneuver; however, the wider horizontal navigation clearance would enable vessels to begin this maneuver earlier in downbound transits and providing greater distance before needing to transit the BNSF Railway Bridge resulting in improved navigation safety. Under the Modified LPA with a fixed-span configuration, navigation for some vessels would be prohibited.

It is difficult to predict Maritime Transportation System demands and associated need for bridge openings for the 100+ year service life of the bridge since vessel traffic and river-level conditions vary from year to year and

[3] All vessels that can transit with 100-feet of vertical clearance (for fixed-span configurations) or 89-feet of vertical clearance (for movable-span configuration) could use the relocated north barge channel, which would provide the straightest route between the new Columbia River Bridges and the BNSF Railway Bridge. Only those vessels or cargo requiring a higher vertical clearance would need to use the relocated primary navigation channel and make an "S" curve maneuver.

economic trends for maritime commerce may change over time. If a fixed-span configuration is selected, the Modified LPA would contribute to a cumulative adverse effect on navigation by further limiting navigation upstream on the Columbia River, which has been limited by past and present actions, such as construction of roads and rail lines, creation of the National Scenic Area, and construction of bridges with less than 178 feet of vertical clearance.

Under the No-Build Alternative, the cumulative effects on navigation from past, present, and reasonably foreseeable future actions would remain unchanged. Compared to the No-Build Alternative, the cumulative effects on navigation from the Modified LPA with a double-deck or single-level fixed-span configuration would be adverse for some vessels or fabricators shipping large cargo due to the reduction in VNC. Cumulative effects on navigation from the Modified LPA with a single-level movable span would retain the existing VNC so all vessels and cargo that currently transit the bridge would continue. Beneficial cumulative effects on navigation from the Modified LPA, under all bridge configurations, would occur as a result of increased horizonal navigation clearance and increased use of the northern channel for many vessels, thereby, improving navigation safety as vessels transit through both the new Columbia River Bridges and the BNSF Railway Bridge.

Property Acquisitions and Displacements

Effects from Past, Present, and Reasonably Foreseeable Future Actions

The original construction of I-5 during the late 1950s and early 1960s required substantial property acquisitions and displacements in the study area. According to historic aerial photos, the floating home moorages were developed following the original construction of I-5, and therefore no floating homes were displaced by I-5. Most of the area (approximately 84%) that would be directly affected by the Modified LPA is already public right of way from previous transportation projects or other infrastructure projects.

No known reasonably foreseeable future projects would require displacements on the Hayden Island floating home community along North Portland Harbor. Existing state and federal regulations have made it difficult to permit new moorages for floating homes, making it unlikely that new slips would be available in the future. In addition to the existing floating home sites along North Portland Harbor, there are slips along the Multnomah Channel in northwest Portland, St. Helens, and Scappoose and in Washington near Caterpillar Island on the Columbia River. In June 2023, 76 floating homes were available for purchase in the Portland metro area, with 30 located on owned slips (versus rented from the moorage) (Portland Floating Homes 2023). A review of publicly available information did not identify any information suggesting that moorages have been declining.

Most of the reasonably foreseeable future projects would not result in the displacement of existing residential or commercial properties, although one (Renaissance Boardwalk) may require one business displacement. Based on recent and proposed developments in Vancouver, ongoing infill development may displace additional businesses (see the Land Use Technical Report for additional details).

While redevelopment of the Expo Center would change the underlying use of the site to a sports and cultural complex, the property would remain under the control of Oregon Metro and does not constitute a displacement.

No-Build Alternative

Under the No-Build Alternative, no Program-related acquisitions would occur. Other reasonably foreseeable future actions in the study area would continue under the No-Build Alternative; however, most reasonably foreseeable future actions are not currently anticipated to result in acquisitions or displacements.

Modified LPA

In Oregon, most of the acquisitions and displacements resulting from the Modified LPA would be commercial properties and floating homes on Hayden Island. As noted above, current regulations and a lack of other moorage spaces limits opportunities for relocating displaced floating homes.

In Washington, most acquisitions and displacements would be commercial properties and multifamily dwellings in downtown Vancouver. Some single-family residences would be acquired and displaced along I Street in Vancouver's Shumway neighborhood. The Modified LPA would displace up to 13 businesses in downtown Vancouver.

Cumulative Effects Conclusion – Property Acquisitions and Displacements

Past actions, including the construction of I-5 and other major roadways, have required substantial acquisitions and displacements in the study area. Most of the present and reasonably foreseeable future actions are not anticipated to acquire or displace businesses or residences (with the exception of one potential business displacement). Reasonably foreseeable future transportation actions would follow federal and state guidelines, such as the Uniform Relocation and Real Property Acquisitions Policies Act of 1970, as amended, to provide replacement housing and relocation benefit packages.

The No-Build Alternative, combined with past, present, and reasonably foreseeable future actions, would not contribute to cumulative acquisitions and displacements. The acquisition of property for the Modified LPA would be substantially smaller than the acquisitions associated with the original construction of I-5 in the corridor but would make a small cumulative contribution to the conversion of residential and commercial land to transportation use, and to the total number of acquisitions and displacements that have occurred within the study area.

Under the No-Build Alternative, the cumulative effects on acquisition from past, present, and reasonably foreseeable future actions, would continue to be adverse through conversion of private property to public infrastructure. The cumulative effects on acquisition from the Modified LPA would have an incremental adverse effect with additional property acquired for public right-of-way.

Land Use and Economic Activity

Land Use

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Past development in the Portland-Vancouver region transformed land use over time from wilderness to urbanization. Since the 1950s, actions affecting land use have included the construction of I-5 and other transportation projects, increased urbanization, and new growth-management regulations. Land use on Hayden Island has changed from recreational to residential and commercial development, including the Jantzen Beach Center (a regional large-format retail shopping center) and surrounding retailers. Residential uses in the area include manufactured homes and floating homes associated with small marinas, as well as other low- to medium-density developments.

Vancouver's downtown has changed greatly over the past decade, broadening from mainly professional offices to tourism and recreation, retail shopping, meeting and convention activities, housing, and entertainment. Revitalization of the retail core and central waterfront has included new office, mixed-use, and residential development including projects such as the Vancouver Waterfront. New and growing land uses include retail, office/commercial, and multifamily residential.

Identified reasonably foreseeable future actions in the study area that could contribute to cumulative effects on land use include:

- Improvements to public transit, state highways, local road networks, and active transportation facilities, as identified in the 2018 RTP. Land use cumulative effects from reasonably foreseeable future transportation-related improvements have been evaluated by using results of the transportation analysis.
- Metro's future redevelopment of the Expo Center could replace or expand the exhibition hall use that currently occurs at this location. Future plans may include a sports and cultural complex.
- The redevelopment of Hayden Island's commercial core from the current large-scale retail land use pattern to a more urban form with more mixed uses, pedestrian-scale design, and transit orientation. The City of Portland's 2009 plan also identifies a replacement bridge over the Columbia River and the addition of high-capacity transit—both of which the IBR Program would provide—as important elements of future development on the island.
- Several developments for the Vancouver Waterfront. These redevelopments include (1) the Port of Vancouver's Terminal 1 mixed use (i.e., hotel, office and retail space, outdoor gathering areas, and a public marketplace) project, which also includes trail connection to the Vancouver Waterfront Renaissance Trail; (2) Renaissance Boardwalk, which is public-private partnership for a mix of apartments, retail and underground parking: and, (3) the Waterfront Gateway Project, run by the Vancouver City Center Redevelopment Authority, to redevelop an area between the waterfront and downtown Vancouver with mixed-use office, retail, and residential uses. These future Vancouver Waterfront developments would continue to expand the present and recent past developments to create more commercial-residential uses compared to past industrial uses along the waterfront.
- Adopted state, regional, and local agency and port plans that identify future visions for growth and land use planning to accommodate that growth. Population is projected to increase and result in needs to expand employment opportunities, which also necessitate adequate levels of housing, utilities, recreation facilities, schools, and other services.

No-Build Alternative

The No-Build Alternative would not address current deficiencies in the Interstate Bridge structure, design, or capacity. Other reasonably foreseeable future actions would be expected to proceed and would address some elements of state, regional, and local agency visions; however, without improvements associated with the Modified LPA, the existing and future land uses that rely on I-5 to travel within the region could be affected by high levels of congestion, unsafe conditions, and potential earthquake-induced failure. There would also be no high-capacity transit service to connect the regional centers of downtown Vancouver and downtown Portland, which would be inconsistent with the stated policies and goals of applicable regional transportation and land use plans. In addition, the No-Build Alternative would not meet certain goals in the Hayden Island Neighborhood Plan or the Vancouver City Center Vision & Subarea Plan, such as providing light-rail transit service or improving connectivity within the neighborhoods.

Other reasonably foreseeable future actions would contribute to cumulative impacts to land use as new development and redevelopment would continue to change the landscape of existing and future land use.

Modified LPA

The Modified LPA is consistent with and would support land use policies, transportation system plans, and development trends in Oregon and Washington, which encourage investment in urban infrastructure, multimodal transportation, freight mobility, economic development, and compact urban development. It would also support statewide policies and goals directing high-density growth to urbanized locations and integrating planned transportation facilities. These anticipated land use changes could accelerate development (e.g., residential, commercial, office) focused near new light-rail facilities, but land use would remain consistent with adopted plans. Land use and development in Oregon and Washington is governed by

state and growth-management laws, local land use plans, zoning regulations, and other controls. These land use controls require all development to be consistent with existing zoning and comprehensive planning in order to be permitted.

The Modified LPA would convert approximately 47 acres of land, currently zoned as commercial, industrial, residential, mixed-use, and open space, into transportation use (see Section 3.3, Acquisitions). The Community Connector near Evergreen Boulevard in downtown Vancouver would address existing gaps in active transportation connectivity between residential and commercial land uses created by the past construction and presence of I-5.

Variable-rate tolling as part of the Modified LPA would support regional and local policies for managing traffic congestion. Tolling is not expected to change land use patterns because land use and development in the study area are governed by state land use and growth-management laws, local land use plans, zoning regulations, and other controls. However, the combination of improved transit service and the introduction of tolling would shift some trips from vehicle to transit and reduce overall vehicle travel miles traveled across the Columbia River on an average weekday by approximately 1% compared to the No-Build Alternative.

Cumulative Effects Conclusion – Land Use

Past actions have changed land use throughout the study area, typically increasing the density of development and converting undeveloped or residential areas to commercial or transportation uses. None of the present actions are anticipated to convert land uses or alter land use patterns. Reasonably foreseeable future actions include planned transportation projects, which would include the conversion of land currently in non-transportation uses to transportation use, and development and redevelopment that would create additional residential, commercial, industrial and recreational land uses in the study area. All present and reasonably foreseeable future actions would be required to comply with the applicable adopted land use plans.

The No-Build Alternative, combined with past, present, and reasonably foreseeable future actions, would not convert existing land uses to a transportation use; however, it would be inconsistent with adopted land use plans, such as the Hayden Island Neighborhood Plan and the Vancouver City Center Vision & Subarea Plan that included goals of providing light-rail transit service. Although the Modified LPA would include right of way acquisitions that would convert existing land uses to a transportation use, it would be consistent with the goals of local land use plans to provide light-rail transit service and providing transit stations near planned land use development.

Under the No-Build Alternative, the cumulative effects on land use from past, present, and reasonably foreseeable future actions would be negligible because land use from reasonably foreseeable future actions would continue to comply with local land use plans. Compared to the No-Build Alternative, the cumulative effects on land use from the Modified LPA would be beneficial as it would provide light-rail transit service to Hayden Island and downtown Vancouver and may facilitate planned growth and development in station areas consistent with local land use plans.

Economic Activity

Effects from Past, Present, and Reasonably Foreseeable Future Actions

I-5 runs continuously from Mexico, through the United States, and into Canada and is used for freight, business, and personal travel. In the Portland-Vancouver region I-5 is the central component of the transportation infrastructure. Freight needs are a major driver for future improvements along the I-5 corridor.

The Columbia River is the regional backbone of marine commerce. Commercial vessels on the Columbia River include cruise vessels, tugs, tows, barges, and marine contractors' vessels. Commercial tugs and barges have

the highest share of river usage and transit year-round and accounted for approximately 54% of the bridge opening events across a 35-year study period.

The Ports of Portland and Vancouver are critical to the region's economic growth and prosperity. The total annual tonnage moving through the two ports is expected to double from approximately 300 million tons in 2007 to almost 600 million tons in 2040 (Cambridge Systematics 2015). Both ports connect to the surface transportation network within the study area, as well as the Columbia River, to move products to, from, and within the region. To remain competitive with other West Coast ports, efficient and cost-effective multimodal transportation systems must be available. Increases in regional traffic congestion could severely hinder the ports' ability to move goods and impact their competitiveness. Similarly, economic growth in the region would increase demands along the I-5 corridor, as Metro forecasts that the number of jobs in the Portland-Vancouver Standard Metropolitan Statistical Area would increase by approximately 1.6% per year. This is slightly higher than the Oregon-area growth rate of 1.1% per year and the Washington-area growth rate of 1.0% per year.

Identified reasonably foreseeable future actions in the study area that could contribute to cumulative effects on economic activity include:

- Continued development of Terminal 1 by the Port of Vancouver, which will expand the mixed-use Vancouver Waterfront area nearer to the I-5 corridor and is anticipated to enhance the waterfront as a regional attraction for commercial and retail jobs.
- A stated goal of the Waterfront Gateway development is to strengthen the economy by creating a "bustling center with high-quality jobs." While no job estimate is available at this time, the development will include new office and retail uses, which will support job creation in the study area.
- Portland Expo Center is a 53-acre redevelopment site that has been recommended by Metro to be redeveloped into a sports and cultural complex. The redevelopment could be a local and regional attraction drawing visitors to the I-5 corridor and surrounding businesses and lodging. This project is still in the early stages but would likely contribute commercial and retail jobs to the study area.
- The 2018 RTP includes short- and long-term strategies and transportation projects. These strategies and projects are integral to the local and regional economy, addressing economic growth, environmental health, and equitable mobility.
- The Cascade Renewable Transmission Project is estimated to support 300 to 400 jobs and apprenticeship programs during construction and generate revenues that will strengthen local tax bases. The cables will also add east-to-west energy transfer capability in the region and assist in the distribution of increased power flows, especially during extreme heat events, which would help maintain power supply for commercial activities.

No-Build Alternative

Under the No-Build Alternative, increasing congestion and unreliable travel times on I-5 could result in negative economic effects, as planned economic development may occur more slowly with business owners reluctant to locate in an area with poor access and mobility for employees and customers. Freight reliability would decrease as congestion continues to spread throughout the day and customers could elect to shop in areas with better access and mobility. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects with an increase in jobs and commerce (identified above) would continue under the No-Build Alternative.

Modified LPA

The Modified LPA would have both adverse and beneficial impacts on economic activity, with the overall long-term economic effects after construction expected to be positive (short-term cumulative effects during

construction are addressed in Section 3.23.4). The Modified LPA's highway, transit, and active transportation components would move people and commerce more effectively and efficiently through the I-5 corridor. The Modified LPA, along with other projects aimed at reducing congestion and enhancing freight mobility, would support an improvement in economic activity. Congestion relief in the study area would benefit freight traffic generated by Swan Island, the Rivergate area, the Port of Portland, and the Port of Vancouver. Incremental benefits would include decreased travel times, increased mobility, and increased reliability for freight vehicles. The Modified LPA would provide a slight improvement to marine commerce for many vessels as most vessels would be able to pass under the bridges without timing restrictions, providing more flexibility in operating schedules and reducing wait times. With the fixed-span configurations, some larger vessels and future freight shipments would not be able to pass under the bridges; the IBR Program is coordinating with these river users to develop measures to avoid economic impacts through vessel or cargo modifications and other accommodations.

The Modified LPA would acquire additional rights of way from taxable property with the potential for decreasing property tax revenues. However, the reduction in sales tax is not anticipated to have a substantial economic impact, given that most of the affected businesses would be commercial offices.

Cumulative Effects Conclusion – Economic Activity

The Portland-Vancouver region and economy is largely dependent on its role as a gateway and distribution center for domestic and international markets. The development of corridors along the Columbia and Willamette rivers, the BNSF Railway and Union Pacific Railroad transcontinental rail lines, Portland International Airport, and marine terminals of Portland and Vancouver are all integral components to the region's ability to transport goods, with the I-5 corridor serving as the backbone of the region's transportation network. Many past projects have worked to solidify I-5 as the central component of regional infrastructure (including construction of the Interstate Bridge and development of the ports). Freight needs are an important driver for future improvements along the I-5 corridor, and economic growth in the region would increase demands along the I-5 corridor.

Several reasonably foreseeable future projects will support job creation and improve freight mobility and connectivity in the area, thereby benefiting economic activity. The 2018 RTP includes several capacity and safety projects west of I-5 that are designed to improve safety and flow for commercial trucks traveling between I-5 and industrial areas to the west. Additionally, plans for the area would generally improve travel conditions for commercial trucks, but those improvements could be offset by congestion resulting from projected growth in population and employment.

Increased congestion, decreased freight reliability, and unreliable travel times on I-5 associated with the No-Build Alternative, as well as past, present, and reasonably foreseeable future actions, would contribute to adverse cumulative effects on economic activity by slowing planned economic development. Economic activity requires reliable transportation; therefore, the improvements in capacity, safety, and reliability provided by the Modified LPA, in combination with past, present, and reasonably foreseeable future actions, would cumulatively benefit economic activity by allowing commercial and industrial activity that is constrained by existing transportation conditions to improve.

With the No-Build Alternative, reasonably foreseeable future economic activity could be limited by increased congestion and decreased freight reliability that would occur as future travel demand would not be met by the available transportation infrastructure provided by past, present, and reasonably foreseeable future actions. The Modified LPA, in combination with these other actions, would cumulatively benefit employers, businesses, marine commerce, and economic activity through job creation, reduced congestion, enhanced marine operating schedules, freight mobility, transit access, and vehicular circulation when compared to the No Build Alternative.

Neighborhoods and Equity

Effects from Past, Present, and Reasonably Foreseeable Future Actions

Past projects adversely affected neighborhoods in the I-5 corridor, while more recent transportation projects have generally provided net benefits through improved access, pedestrian-oriented development, mitigation, and other amenities. Past highway development had significant effects on neighborhoods and communities along the I-5 corridor, including equity priority communities.[4] The development of I-5 required the acquisition of right of way and the relocation of many businesses and homes and contributed to a loss of community cohesion. Local planning efforts serve to strategically place and design current and future transportation to maximize benefits and minimize negative impacts. Neighborhoods within Portland and Vancouver formally adopt neighborhood plans as part of their respective comprehensive plans and typically include goals, objectives, proposed comprehensive plan and zoning changes, and an implementation strategy. Neighborhood plans and comprehensive plans for each respective city will contribute to the current trend of improving neighborhood access and mobility.

Reasonably foreseeable future actions in the study area that could contribute to cumulative effects on neighborhoods and equity include transportation and development projects with the potential for displacement or relocation of businesses and homes or actions that affect connectivity and cohesion. Many of the reasonably foreseeable future projects have yet to complete environmental assessments, but at this time none have been identified that would require the displacement or relocation of homes. Renaissance Boardwalk may result in one business displacement, although it would also improve connectivity along the waterfront. There are no known encampments of houseless populations at the sites of the reasonably foreseeable future actions; however, encampments are typically transient and the potential for displacement would need to be evaluated for each project prior to construction.

The Main Street Promise project will improve safety and connectivity in downtown Vancouver through improvements to vehicle and active transportation infrastructure. Other transportation improvements in the adopted RTPs would contribute to the cumulative effect of improving connectivity in neighborhoods in the study area.

No-Build Alternative

The No-Build Alternative would not displace residences or businesses and would not directly change community cohesion. Neighborhoods in the study area would continue to develop according to local and regional plans, though their development might not be fully consistent with goals that assume improved mobility in the I-5 corridor and expanded transit access. Neighborhoods and equity priority communities would experience increased traffic congestion, decreased safety, and no benefits from increased mobility and accessibility from construction highway improvements, light-rail, and active transportation facilities. Other reasonably foreseeable future actions in the study area that could contribute to cumulative effects on neighborhoods and equity would continue under the No-Build Alternative.

Modified LPA

The Modified LPA would have both beneficial and adverse effects on neighborhoods and equity. The Modified LPA is not anticipated to adversely affect community cohesion in most neighborhoods, except for Hayden Island. Benefits from the Modified LPA to equity priority communities include increased access to high-
